How Much to Give and How to Frame It?
Donation Size and Donation Framing in Cause-Related Marketing

Sarah S. Müller, University of Hamburg, Germany
Anne Fries, University of Hamburg, Germany
Karen Gedenk, University of Hamburg, Germany

ABSTRACT

In cause-related marketing (CM) companies promise a donation to a cause every time a consumer makes a purchase. In this research, we analyze the impact of the size and framing of these donation promises on a CM campaign's effects on brand choice and brand image. Framing can be monetary or nonmonetary, or consist of a combination of both types of information. Furthermore, this study considers nonlinear effects of donation size and potential moderating effects of donation frames as well as a financial trade-off for consumers on the impact of donation size on CM success. The authors find that for brand choice, increasing donation size has a positive effect if consumers face no financial trade-off, but the effect is negative if a higher donation comes at higher costs. Donation framing has no substantial impact on brand choice. For brand image, nonmonetary frames are more successful than monetary frames. A large donation may even have a negative effect if the donation frame is monetary. If campaigns use a combination of both frames, the effect of donation size on brand image reveals an inverted U shape.

Attitudes Shaped by Eye Movements: The Reading Direction Effect

En Li, Central Queensland University, Australia
Donnel Briley, University of Sydney, Australia

EXTENDED ABSTRACT

One of the most established facts in psychology and consumer research is the finding that the mind guides the body (Fazio, Powell, and Williams 1989). For example, the goals consumers have in mind can determine patterns of eye movements (Pieters and Wedel 2007). The present research, however, breaks this traditional perspective by looking at the influence of the body on the mind. Specifically, we posit that eye movements, despite being a subtle bodily process, can play a critical role in shaping consumer attitudes toward moving stimuli.

Consumers frequently encounter alphanumeric stimuli moving horizontally across their fields of vision in the course of everyday life. This research examines whether consumers' habitual reading direction affects their evaluations of such stimuli. Based on visual perception and fluency literature we hypothesize and demonstrate a "reading direction effect," whereby consumers' evaluations of an alphanumeric stimulus are more positive when its movement direction coincides rather than conflicts with their habitual reading direction (study 1). Importantly, we show that this directional effect is driven by motor fluency rather than conceptual fluency (study 2), and its processes involve activation of reading knowledge (i.e., the procedural knowledge used to perform reading activities; study 3).

Predictions

Foundational Prediction. Two modes of eye movement need to be considered to make the foundational prediction: a habitual and a situational mode. On the one hand, evidence from examining human reading behavior suggests that the dominant eye movements in processing alphanumeric characters are made in habitual reading direction (Rayner 1998). Hence, eye movements in such habitual direction are acted more frequently, and possibly, more fluently than eye movements in other directions. On the other hand, when an alphanumeric stimulus moves horizontally across a consumer's field of vision, it evokes eye movements of identical direction (Palmer 1999). If the direction of evoked eye movements coincides (vs. conflicts) with the viewer's habitual reading direction, she might experience a sense of "feeling right" due to heightened motor fluency, as the direction of situational eye movements in this case fits with her habitual eye movement direction. This process might yield enhanced evaluations of the stimulus when the viewer misattributes her fluency experience to the quality of the stimulus itself (Bornstein and D'Agostino 1994).

"Conceptual Fluency" or "Motor Fluency". It is theorized that stimulus movement speed provides a useful criterion for teasing apart conceptual and motor fluency effects. Therefore, if conceptual fluency is the only mechanism driving the reading direction effect, a horizontally moving brand name will always be favored when its movement direction matches the viewer's habitual reading direction, irrespective of its moving speed. However, if the reading direction effect disappears or even becomes reversed when evaluated brands move faster than the threshold speed (i.e., three to four degrees per second; Leigh and Zee 1999), then motor fluency should be an indispensable driving force behind the reading direction effect.

"Always Online" or "Context Sensitive". When people encounter and respond to a moving alphanumeric stimulus, certain knowledge representations stored in memory will be activated and used as they formulate responses to this event. The tendency to be more comfortable engaging in eye movements following rather than opposing habitual reading direction, which derives from such representations, might be chronically accessible and context independent (Higgins, King, and Mavin 1982), or "always online," as a result of such tendency being innate or becoming very well learned via repeated applications across different contexts.

Another possibility is that the context in which a moving stimulus is encountered determines whether the reading direction tendency is accessed. It could be that the knowledge that drives this tendency is not "always online," but becomes activated when a context associated with reading is encountered. That is, the reading direction tendency may only arise when the viewer is in contexts that facilitate reading, but disappear when reading knowledge is less readily available.

Overview of Studies

The results of three studies found support for the reading direction effect, on both pure (brand name; study 1) and mixed alphanumeric stimuli (brand logo; studies 2 and 3). Moreover, it was found that processing fluency mediated the effect in question (studies 1 to 3).

Studies 2 and 3 provided deeper understanding of the reading direction effect. In study 2, the preferences for direction matching only emerged when the stimulus moved at a normal speed. Exposure to a fast moving stimulus, nonetheless, reversed this directional effect. These findings are consistent with the notion that motor, instead of conceptual fluency, is the indispensable driving force of the reading direction effect.

Study 3 pitted "always online" against "context sensitive" model by investigating whether the reading direction effect could arise irrespective of contexts. Participants in this study completed two seemingly unrelated tasks: firstly a reading or pictorial priming task that facilitated or impeded reading knowledge activation, then an evaluation task on a brand logo that moved horizontally. It was demonstrated that the reading direction effect was replicated among reading primed participants, but was removed among pictorial primed participants. These findings suggest that the effect in question should only be sensitive to contexts where reading knowledge is sufficiently accessible.

In summary, consumer attitudes can be shaped by chronic patterns of eye movements, which, despite involving only subtle bodily processes, could nevertheless be quite pervasive in their influence.

Materialism and Consumeristic Philanthropy

Robert Kreuzbauer, Nanyang Technological University, Singapore
Chi-yue Chiu, Nanyang Technological University, Singapore

EXTENDED ABSTRACT

Major charity organizations offer products for donors to communicate their philanthropic intentions and behaviors through consumption. Examples are backpacks, shirts or various accessories from the Red Cross or the Salvation Army with prominent display of the charitable organization's logo on the products. Some charitable organizations even license their logo to for-profit companies and consumers can buy these logos to express their support for charitable causes (Varadarajan and Menon 1988). A notable example is Product (Red), a consumer brand licensed to American Express, Apple, Emporio Armani and other partner companies to raise money for the Global Fund to Fight AIDS, Tuberculosis and Malaria. Each partner company creates a product with the Product (Red) logo and agrees to donate a percentage of the profit to the Global Fund. We posit that consumer support for this kind of *consumeristic philanthropy* arises in part from the need to signal one's status through brand consumption. Because according to previous research (cf. Belk 1988) materialistic consumers, compared to the less materialistic ones, have a greater need for status signaling through consumption, we hypothesize that more materialistic consumers would value consumeristic philanthropy more. However, although materialistic consumers may lack an intrinsic motive to engage in philanthropic behaviors, they may be motivated by the need to signal their status through engaging in such behaviors. Indeed, aside from altruism, charitable giving can be motivated by other motives. For example, individuals may engage in charitable giving because it allows them to project a certain social image to others (Aaker and Akutsu 2009). Thus, although materialistic consumers may not be motivated to give to charity out of intrinsic motivation, they may do so if the charitable giving activity is congruent with their value orientations. We posit that materialistic consumers will find campaigns that couple charitable contributions with appeals to material possessions particularly appealing because they confer opportunities for signaling their status through consumption. As our three studies will show when materialistic consumers are given the opportunity to signal their status through consumeristic philanthropy (i.e. a charitable contribution combined with a material possession or consumer object such as Gap Red), these individuals are even more generous than non-materialistic individuals.

We tested our hypotheses in three studies that used different methods. In study one, we surveyed consumers' levels of materialism, support for consumeristic philanthropy and non-consumeristic philanthropy, and their motivation to signal status through consumption. The results showed that materialism is positively correlated with the motivation to signal status and the support for consumeristic philanthropy. We also show that this positive relationship between materialism and support for consumeristic philanthropy is mediated by the motivation to signal status via consumption.

Studies 2 and 3 use a variant of Haidt's (2007) monetary evaluation task to assess the value consumers attached to status signaling through consumption (study 2) and to consumeristic philanthropy (study 3).

Inspired by this idea, Haidt (2007) designed the monetary evaluation task to assess the "cash values" individuals assigned to moral values. The task consists of two parts. Part 1 assesses the baseline value respondents would assign to a certain action ("How much money would it take to get you to stick a pin into your palm?"). Part 2 assesses the value respondents would assign to the same action when it implicates a certain moral value (e.g., "How much money would it take to get you to stick a pin into the palm of a child you don't know?"). The discrepancy between the two values is used to indicate the value the respondents assign to the moral value under assessment (inflicting harm to innocent people). This assessment technique has been found to be useful for overcoming socially desirable responding and hence useful for capturing socially sensitive responses (e.g., moral values). The current research concerns the value consumers attach to prosocial behaviors. To avoid potential validity threats caused by socially desirable responding, we modified Haidt's monetary evaluation task to assess the values consumers attach to status signaling through consumption (study 2) and the values consumers attach to consumeristic philanthropy (study 3). In both studies, we also measured the participants' levels of materialism. Also study 2 and 3 confirmed our main predictions that levels of materialism will is positively correlated with the values consumers attach to status signaling through consumption and to consumeristic philanthropy.

The current research makes three major contributions. First, it seeks to show that consumeristic philanthropy is mediated by a greater need to signal status through consumption among materialistic consumers. This knowledge is useful because it examines the role of consumer values in the support for charitable sales promotions. In this context the current research studies consumer support for consumeristic philanthropy to materialism which can explain why charitable sales promotions tend to be more successful for conspicuous luxury products (Strahilevitz 1999; Strahilevitz and Myers 1998).

Second, Rindfleisch et al. (2009) commented that materialism research has focused on the nature, antecedents and well-being consequences of materialism. Relatively little is known about the relationship of materialism to other consumer behaviors. The current research fills this gap by examining how materialism and its attendant need to signal status predict consumer support for consumeristic philanthropy.

Finally, the present research may challenge the stereotypic portrayal of materialistic consumers as individuals who care only about acquisition and possession of materialistic goods and who are therefore indifferent to social concerns (Van Hiel et al. 2010). The current research seeks to show that both materialistic and non-materialistic consumers can be motivated to support charitable giving. Our proposition gives rise to the counterintuitive prediction that when given the opportunity to signal their status through consumeristic philanthropy, materialistic consumers may be even more motivated than non-materialistic ones to support charitable activities.

Findings from a survey of 259 American consumers (study 1) support this hypothesis and show that the status signaling mediates the hypothesized relationship. Two experiments (studies 2 and 3) that used a modified monetary evaluation task revealed that more materialistic consumers assign greater value to status signaling through brand consumption and consumeristic philanthropy. These results offer a motivational explanation of consumeristic philanthropy and further clarify the role of materialism in brand consumption.

Contrast and Assimilation in Response to a Brand Association Prime:
The Case of Cross-Category Brand Alliances

Laura Smarandescu, Iowa State University, USA
Randall Rose, University of South Carolina, USA
Douglas Wedell, University of South Carolina, USA

EXTENDED ABSTRACT

Recent years have witnessed a significant increase in various forms of inter-firm cooperation (e.g., joint ventures, promotional agreements, advertising brand alliances), through which firms pool resources to pursue specific market opportunities. Advertising brand alliances are appealing to firms because they lead to competitive advantages that otherwise would be beyond a company's reach, such as access to new markets and increased demand through leveraging the strengths of two brands (Cooke and Ryan 2000; Eisenhardt and Schoonhoven 1996; Hagedoorn 1993). Little is known about the effect of these alliances on perceptions of brand attributes, or about the inferences made by individuals when primed with these associations. This work focuses on the inference processes used by individuals when they are primed with associations of brands with different memory schemas, belonging to different product categories. Examples of such alliances are between Hewlett Packard and Starbucks, Tide and Oshkosh, Whirlpool and Day Runner, Nike and iPod.

Although research in the area of brand extensions and comparative advertising has previously investigated consumer brand inference, the present work focuses on the inferences that take place when individuals are exposed to an associative prime featuring different brands, with different memory associations (unlike brand extension research), belonging to different product categories (unlike comparative advertising), and in the absence of an explicit comparative claim.

Context plays an important role in a variety of consumer judgments. Context effects have been examined in the areas of consumer choice (Huber, Payne, and Puto 1982; Huber and Puto 1983; Simonson and Tversky 1992), comparative advertising (Manning et al. 2001; Rose et al. 1993), product judgment (Janiszewski, Silk, and Cooke 2003), and product assortment (Chernev 2003). Two types of context effects on people's judgment of a stimulus have been reliably demonstrated in the marketing and social sciences literature: assimilation and contrast. Assimilation is known to occur when judgments of a stimulus are displaced toward a contextual stimulus and refers to a positive relation between the value assigned to the contextual stimulus and the value attributed to the target. On the other hand, contrast occurs when judgments of a stimulus are displaced away from the contextual stimulus, and refers to a negative relation between the values assigned to the contextual stimulus and the target.

Our research shows that each brand partner in a cross-category brand alliance creates a context that is used as an anchor for judgments of the other brand attributes, and we provide evidence that the inference processes that occur are moderated by individual differences in information processing strategy, associated with differences in need for cognition (NFC). As such, allied brand attributes may produce assimilative anchor effects that move perceptions toward the ally's attribute value, or the anchors may serve as standards of comparison that produce contrast and move perceptions away from the ally's attribute value (Wedell, Hicklin, and Smarandescu 2007).

Study 1 was a 2 (alliance present/ absent) x 2 (high/ low NFC, based on a median split) between-subjects design, and examined how priming a brand association influences judgments of non-alignable brand attributes. We found that low and high NFC individuals adopt different inference making strategies when they are primed with a brand alliance. The effects are driven by the more extreme, and thus salient, user ratings provided for the contextual brand. Data indicate that low NFC individuals used the non-alignable information provided about the contextual brand as an anchor for their judgments of the target brand attributes. On the other hand, high NFC individuals partialed out the non-alignable information given about the contextual brand from their judgment of the target brand on a salient attribute and adjusted their evaluations of this target attribute in a direction opposite to the contextual brand.

Study 2 was a 3 (no alliance control/ low load alliance/ high load alliance) x 2 (high/ low NFC, based on a median split) between-subjects experimental design, and investigated whether the effects of a brand alliance prime on perceptions of a target non-alignable attribute are moderated by individuals' ability (manipulated by cognitive load) and processing motivation (measured by NFC) to process the alliance information. We found that individuals' responses to cross-category brand alliances are sensitive to situational and individual difference factors. Low NFC individuals assimilated their judgments in the direction of the contextual brand irrespective of cognitive load. This result is in line with Martin, Seta, and Crelia (1990) and provides support that assimilation is the default judgment for low NFC. Responses of high NFC individuals were influenced by the amount of cognitive resources they had available at brand alliance encoding. In conditions of limited cognitive ability, high NFC individuals formed unbiased judgments that were not affected by the contextual partner. However, when they had the ability to correct their initial judgment for the *perceived* bias introduced by presence of the alliance partner they over-adjusted their judgment of the target attribute in a direction opposite to the context of the brand ally, a finding supporting Wegener and Petty's (1993) flexible correction model. One key aspect of the flexible correction model is that it assumes that corrections are aimed at removing *perceived* rather than *actual* bias. Hence, high NFC individuals made unbiased judgments under high load, but corrected their judgments for the perceived bias introduced by the contextual brand when they had extra cognitive resources.

Finally, results of study 2 suggest that given enough cognitive resources, high NFC individuals engage in correction at the stage of brand alliance encoding, through a memory updating mechanism and not at the judgment stage. This provides evidence that context effects observed in brand alliances are due to background context and not to the effect of the recent context as observed in classic priming studies.

The Impact of Research Design on the Compromise Effect

Nico Neumann, University of New South Wales, Australia
Ashish Sinha, University of New South Wales, Australia
Ulf Böckenholt, Northwestern University, USA

EXTENDED ABSTRACT

The compromise effect, which is a symmetric extremeness aversion context effect (Simonson and Tversky 1992), has been referred to as one of the most relevant and robust behavioral phenomena in marketing (Kivetz, Netzer, and Srinivasan 2004). However, even though the compromise effect has been proven to be sizeable and robust across many scenarios, recent articles have raised concerns: in a critical essay, Simonson (2008) initiates a debate about the external validity of work dealing with constructed preferences, making no exemption for extremeness aversion. He argues that the ease of demonstrating certain preference reversals may have caused many scholars to overstate the role of constructed preferences. Simonson (2008) receives support from Kivetz, Netzer, and Schrift (2008) and Dhar and Novemsky (2008) for many of his arguments.

In this study, we attempt to advance the debate on the meaning of different methodologies for this research area. Using meta-analytic evidence, we examine the impact of research design variables on the results of the compromise effect. We test moderators related to sample and experimental characteristics, such as the influence of attribute-types, choice set comparison types, extension types, the range effect (i.e. distance of options from the middle), sample size and choice tasks (e.g. within- Vs. between-subject designs).

For our analysis, we synthesized 83 cases from 13 studies and modeled the difference between the log-odds ratios (Lipsey and Wilson 2001; Van Houwelingen, Arends, and Stijnen 2002) of the middle option in the experimental condition (middle option share/ others' share) and that in the control condition (share of option that becomes middle option/ other's share) for the absolute and relative shares (two effect sizes from one case). To account for the dependencies of the two effect sizes that stem from the same observation and for the dependency of each case on the corresponding study, we estimated a bivariate multilevel model: the first level consists of the two outcome measures, the second level of the observations, and the third level of the studies that provide the observations. We carried out maximum likelihood estimation for the 3- level model, using the inverse sampling variances as weights.

The results of the meta-analysis confirm that extremeness aversion significantly affects choice behavior and is likely to result in context effects. Across 83 comparisons of choice sets, the introduction of another option leads on average to both absolute and relative share increases of the product that becomes the compromise option when controlling for research design effects. This means that the included studies represent evident violations of the IIA principle, which assumes the relative share of options to stay constant across choice sets. Strategically, the significant increase in relative share demonstrates that the introduction of another product is assumed to take more share away from the other extreme product than from the more similar compromise option.

On average, extremeness aversion also enhances the absolute share of the middle option. However, this effect is more likely for the comparison of two triplets than for the addition of another option to a binary choice set. Nevertheless, we can conclude that there are compromise effects that can violate the regularity axiom, in particular for durable product categories.

In line with previous work (Simonson and Tversky 1992), the present study demonstrates asymmetry in extremeness aversion for price and quality. Relative share changes are likely to be smaller for choice tasks that involve price-quality trade-offs, whereby this impact is moderated by the extension type. For high-extensions, the relative share of the compromise option after the treatment tends to be greater than for low-extensions. Hence, on average, the introduction of a high-quality product takes away more share from the other extreme than the introduction of a low-quality product does. These findings are in agreement with the concept of loss aversion, which was argued to be less strong or not evident for price (Novemsky and Kahneman 2005a, 2005b).

In addition, the results of our model do not suggest a range effect of options on the compromise effect strength. This finding is in agreement with the work of Tsetsos, Usher, and Chater (2010), who find mixed results for the choice of a compromise option as a function of the distance between extreme options in computational simulations.

According to our meta-analysis, there are no significant differences between undergraduates and other sample groups or between within- and between-subject designs for the compromise effect. Sample size appears not to significantly affect the size of the compromise effect either.

Overall, the results suggest that experimental characteristics have a major impact on the obtained extremeness aversion results, while sample characteristics have little impact. We conclude with a discussion of the practical implications of the individual research design effects for future studies. We hope that this work offers a fertile ground and helpful recommendations for further studying extremeness aversion.

Film Festival 2011

Marylouise Caldwell and Paul Henry
The University of Sydney.

The ACR Film Festival has now been running for over ten years. This milestone has been achieved in no small measure due to the enormous encouragement and perseverance of the founding co-chairs—Russell Belk and Robert Kozinets. These innovative consumer researchers consistently propelled the growth of audiovisual representation across many years through foundation of the ACR Film Festival, running numerous audiovisual training workshops, publishing several special audiovisual issues in Consumption, Markets, and Culture, publishing articles about how to do video ethnography; as well as production and presentation of a substantial body of their own high quality consumer films. Their personal encouragement also sparked a passionate interest amongst many other researchers in diverse part of the globe. Over this period the Film Festival has attracted entries from every continent, across a broad range of consumer topics, and employing a wide variety of filmic styles.

This global diversity has continued with the 2011 program. Successful entries were drawn from Austria, Canada, Finland, Mexico, New Zealand, and the USA. Two awards were presented. The Judges Choice award went to Joel Hietanen, Joonas Rokka, and Risto Roman from Finland. This was a marvellous piece of filmmaking shot in Helsinki, New York, and London, which explored adherents of the electronic music genre called dubstep. The work really showed the benefits of carefully planning the shoot in advance, the use of insiders as interviewers and guides, and the importance of clearly defining the style and pacing of the film before production begins. The result was an impressive piece of work that held the audience's attention throughout, immersed them in the subculture, and also revealed substantial tensions of theoretical interest. This is the kind of work that demonstrates the fantastic potential of film ethnography in consumer research—the kind of work that we would love to see a lot more of. The second award was for the People's Choice. This was decided by audience vote. The winners were Tracy Harmon and Merlyn Griffiths from the USA. This film explored the reinterpretation of commercial brands for personal expression in ways that were not intended by the marketers. It was a very interesting site of study where informants often situated branded characters in new stories. The Film Festival submissions included a diverse set of other interesting topics that ranged across audience reaction to flash mobs, instilling dietary awareness in preschoolers, religious fervour of sports fans, generational views about respect, dressing up, self actualisation in the workplace, and impact of mobile communications.

This year a workshop session was also held in which participants discussed future opportunities and directions for use of audiovisual formats in consumer research. The session sought to further illuminate Belk and Kozinets' four criteria for assessing consumer ethnography films. These include Topical, Theoretical, Theatrical, and Technical. Participants proposed alternative ways in which these four qualities can be simultaneously advanced in future ACR Film Festivals. In particular, this discussion focussed on ways to reconcile both the theoretical and theatrical ambitions to produce both more rigorous and compelling audiovisual outputs. It has now been clearly demonstrated in numerous wonderful productions that the two qualities can indeed be reconciled. Audiovisual has been shown to be a particularly strong vehicle in fostering visceral responses in audiences and amplifying emotional understandings of informants' social conditions and lived experiences. Really great audiovisual productions strive to tell compelling stories that take the audience along with them in an immersive manner—much like the performative idea of cathartic experience. The additional challenge is to ensure that these stories also have compelling theoretical relevance. There is certainly no conceptual reason why this cannot be achieved in audiovisual presentations. The combination of researcher insights, attention to storytelling, and technical training will ensure this goal is further advanced. In sum, as the technology continues to become even more accessible and user friendly we see tremendous scope for a discipline that studies the socio-emotional determinates of consumer life.

The Customer is Always Right
Kathleen O'Donnell, San Francisco State University, USA

As a kid, Kathy never got the whole "dress up thing." So who would have predicted that 40 years later she would find herself searching for understanding on the playa at Burning Man? Join her as she seeks to uncover the truth about the women of Burning Man, their costumes, and herself in The Costumer is Always Right.

Being Connected: Perceived Customer Value in the Smartphone Age
Monika Koller, WU Vienna, Austria
Alexander Zauner, WU Vienna, Austria
Arne Floh, WU Vienna, Austria
Camillo Foramitti, WU Vienna, Austria

This film explores the role of multidimensional perceived customer value in the field of wireless telecommunications. Consumers' value perceptions derived from their cell phones and wireless services are analyzed along the framework of four value dimensions (functional, economical, emotional, and social) introduced by Sweeney and Soutar in 2001.

'Pushing the Scene': Tensions and Emergence in an Accelerated Marketplace Culture

Joel Hietanen, Aalto University School of Economics, Finland
Joonas Rokka, Aalto University School of Economics, Finland
Risto Roman, Helsinki University, Finland

We consider how contemporary marketplace cultures emerge and unfold in the accelerated tensions of cultural capital and the proliferation of access through digitalization and the global reach of the internet. Our context is the negotiation between producers/consumers in the emergent and vibrant scene of an electronic music genre called dubstep.

'Post-Materialist Work': Emerging Self-Actualization in the Video Industry

Joel Hietanen, Aalto University School of Economics, Finland
Hannu Uotila, Aalto University School of Economics, Finland

Post-materialist consumption has to date received limited interest in consumer research. This videography investigates how post-materialism is negotiated from the perspective of one's mundane work life in the context of small TV video production companies. Specifically, we uncovered how pursuits of self-actualization and emancipation occur in the practices of professionals.

Impact of an Operatic Flash Mob on Consumer Behavior

Philip Grant, Simon Fraser University, Canada
Anjali Bal, Simon Fraser University, Canada
Leyland Pitt, Simon Fraser University, Canada
Michael Parent, Simon Fraser University, Canada

This film examines the influence of an operatic flash mob on consumer behavior and consumer experience in a public market. Results of a field experiment indicate that the flash mob enhanced consumer arousal, connectedness and positive emotions, as well as consumer-to-consumer interaction.

Brand My Ride: Donks, Bubbles and Boxes:
Extended Self-Brand Connections Among Auto Expressionists

Tracy Harmon, University of Dayton, USA
Merlyn Griffiths, University of North Carolina - Greensboro, USA

This film explores the symbolic phenomenon of car branding. We interview consumers who have branded their cars in an effort to present some aspect of themselves to others. We uncover hidden brand connections that are related to various aspects of their extended self-concepts.

Changing Consumer Behavior in Diet and Health: A Video Case Study on Local Matters

Anne Hu, Ohio State University, USA
Curtis Haugtvedt, The Ohio State University, USA

To combat diabetes and obesity in America's youth, Columbus, Ohio non-profit organization Local Matters' aims to change children's behavior and thoughts regarding food through a unique early education program that utilizes sensory and social activities involving food. Parents, teachers, students, and the organization's personnel were interviewed and taped. This short film documents their experiences and provides commentary on the efforts.

Soccer in Mexico: A Sacred Experience?

Claudia Quintanilla, Tecnologico de Monterrey, EGADE Business School, Mexico
Raquel Castaño, Tecnologico de Monterrey, EGADE Business School, Mexico
Maria Eugenia Perez, Tecnologico de Monterrey, EGADE Business School, Mexico

This film explores how devoted fans can turn a soccer game into an experience rich in sacred elements. The differences between "spectators" and "devoted fans" will help us understand the processes underlying distinctions between the sacred and the profane in Mexican fans' soccer experience.

Respect and the Media: A Generational View

Pippa Russell, University of Waikato, New Zealand
Carolyn Costley, University of Waikato, New Zealand
Lorraine Friend, University of Waikato, New Zealand

Respect is an important value for society. It shapes personal, social and business relationships. In our world of technology and social media are the values of respect changing? Do younger and older individuals experience respect differently? This film explores respect and media from the perspectives of Baby Boomers and Generation

Roundtable Summaries

Sheth Foundation 20th Anniversary Celebration

Chairs:
David Mick, University of Virginia, USA
Richard Lutz, University of Florida, USA

Participants:
Natalie Adkins, Drake University, USA
Russell Belk, York University
Dipayan Biswas, University of South Florida, USA
Larry Feick, University of Pittsburgh, USA
Joel Huber, Duke University, USA
Wes Hutchinson, University of Pennsylvania, USA
Richard Lutz, University of Florida, USA
Brett McFarren, University of Michigan, USA
David Mick, University of Virginia, USA
Chris Puto, University of Saint Thomas, USA
Carlos Torelli, University of Minnesota, USA

It is widely acknowledged that Jagdish Sheth was, and continues to be, one of the true pioneers of the field of consumer research, publishing in 1969 a landmark book with John Howard called *The Theory of Buyer Behavior* (New York: John Wiley & Sons). Based on the success of this book and other achievements in his career, Jag Sheth created the Sheth Foundation in 1991 with his wife, Madhuri.

The mission of the Sheth Foundation is to support the academic scholarship, publications, education, and research of tax-exempt, publicly-supported educational organizations, primarily focusing on the discipline of marketing, by providing support to grant awarding Recipient Organizations. Additionally, the Foundation provides support to other tax-exempt, publicly-supported organizations that are closely related in purpose or function to one or more of the Recipient Organizations and the activities of which carry out the purposes of one or more of the Primary Supported Organizations.

The Madhuri and Jagdish N. Sheth Foundation has had a long and strong affiliation with the Association for Consumer Research. For over a decade the Foundation has been providing support to rising scholars in the context of the ACR/Sheth Foundation Dissertation Grants, on the broad topics of public purpose research and global consumer research. All told, over 25 graduate students have been supported, totaling around $45,000. These students have come from an array of universities, including, for example, University of Illinois, University of Minnesota, Georgia Institute of Technology, University of British Columbia, and Concordia University-Montreal. The Foundation has also served to sponsor and support the Long-Term Contribution Award for articles published in the *Journal of Consumer Research* that are considered—after several years of retrospect—to have been among the most influential over time. Moreover, the Foundation has provided the monies to support the Franco Nicosia award, which is given to the authors of the best competitive paper submission each year at the North American Conference of ACR. Recently, the Foundation also gave a $9,500 matching grant to support Transformative Consumer Research at ACR, which focuses on the intersection of consumer behavior and well-being. In addition, the Foundation for several years paid for the distribution of the *Journal of Consumer Research* to over 100 academic libraries in developing nations worldwide. In total, the Foundation has given over $120,000 for a variety of purposes to support the mission and members of the Association for Consumer Research.

Unfortunately, as the Association for Consumer Research has grown, the range of its members who are aware of the Sheth Foundation's contributions and influence has inevitably shrunk, and among them many may not know about future opportunities for themselves or their doctoral students in seeking support from the Sheth Foundation via ACR. At the same time, there has to date been limited opportunities at ACR conferences for prior recipients of Sheth Foundation support to share their appreciation and to talk about the direct value of the support to their work, in specific projects and in going forward. To address these gaps of communication and solidarity within the context of the partnership between the Sheth Foundation and ACR, this roundtable will bring together past recipients of grants and awards funded by the Foundation and celebrate its role in consumer research. the roundtable will be structured to allow each panel member to discuss (a) the support they received, (b) its role in their career generally, (c) its positive influence on the trajectory of their work, and (d) the practical advice they would give to other ACR members in regard to writing/using grants as well as increasing their chances of making lasting scholarly contributions to the field.

The panel will consist of four seasoned and well-respected consumer researchers who have previously won the ACR/Sheth Long-Term Contribution Award at the *Journal of Consumer Research*. They are: Russ Belk, Joel Huber, Chris Puto, and Wes Hutchinson. These panel members will be especially encouraged, through the moderators and audience participation, to consider why and how they went about their award-winning work in the manner they did, particularly why and how it came to be widely regarded as both important and enduring.

The panel will also consist of four prior recipients of ACR/Sheth Dissertation Grants. They are Natalie Adkins, Dipayan Biswas, Brent McFerran, and Carlos Torelli. These panel members will be especially encouraged, based on their personal experiences, to discuss the process and best practices of writing an award-winning grant proposal for their dissertation. They will also offer advice on using grant monies in the most efficient and effective ways, for improving the potential success of consumer research.

The roundtable panel will be moderated by the current liaison of ACR to the Sheth Foundation, David Mick, and the previous liaison, Rich Lutz. Attendees of the roundtable will benefit not only from the panel's expertise, but also from the purposefully-selected, cross-fertilizing array of different topical and methodological interests among the panel members (e.g., experimentalists; qualitative researchers; attitudes, perception, and choice research; public policy issues; international marketing). Prior to the conference, the organizers of the roundtable (David Mick and Rich Lutz) will use the ACR's Knowledge Exchange forum to invite forthcoming conference attendees to post the kinds of questions and issues they would most like the panel members to address, in case there are any that the organizers would not have otherwise anticipated.

The session will begin with Rich Lutz giving a concise overview of the history of the Sheth Foundation and its partnership with ACR. Then each of the panel members will have approximately 5 – 7 minutes to talk about the value/meaning of their Sheth Foundation support, including how to maximize writing and using dissertation grants (dissertation grant recipients) or how to maximize the opportunity to make lasting contributions in the field (the long-term contribution award recipients). Rich and David will moderate questions from the audience. Then David will close with a summary and discussion about the future opportunities for maintaining and enhancing the partnership of ACR with the Sheth Foundation, looking also for suggestions from the panel and audience.

Overall, the intended benefits of this session are to (a) celebrate and spread the word about the partnership of ACR with the Sheth Foundation; (b) offer the opportunity for past Foundation support recipients to share their research experiences, accomplishments, and, advice; and (c) discuss how ACR and the Foundation might further enhance their partnership in moving forward.

Nudging our Way to a Better Tomorrow: Bridging the Gap between Consumer Behavior Research and Public Policy

Chair:
Avni Shah, Duke University, USA

Participants:
Jennifer Aaker, Stanford University, USA
Alan Andreasen, Georgetown University, USA
Dan Ariely, Duke University, USA
Paul Bloom, Duke University, USA
Julie Edell Britton, Duke University, USA
Darren Dahl, University of British Columbia, Canada
Gavan Fitzsimons, Duke University, USA
Vladas Griskevicius, University of Minnesota, USA
J. Jeffery Inman, University of Pittsburgh, USA
Punam Keller, Dartmouth College, USA
Angela Lee, Northwestern University, USA
Geeta Menon, New York University, USA
Baba Shiv, Stanford University, USA
Deborah Small, University of Pennsylvania, USA

Purpose

The purpose of this session is to bring together individuals who have contributed to research at the intersection between consumer behavior, marketing, and public policy initiatives. This roundtable discussion will focus on how marketing and consumer behavior researchers have been successful in the past at working with public policy makers to develop methods to influence consumer well-being. Discussion will also focus on ways to encourage researchers to ask research questions that can influence the policy arena and will serve as a forum for individuals to discuss directions for future research.

Rationale

Marketing and consumer research has transformed from an area that received little attention from public policy makers (Greyser, 1973; Wilkie & Gardner, 1974) to becoming a major player in decision-making in government and policy agencies, such as the Federal Trade Commission, the Food and Drug Administration, and Centers for Disease Control and Prevention. Policy makers are attracted to consumer research due to the ability to use multiple methodological approaches to determine what may influence consumer behavior and psychology and subsequently influence problems of interest to the public sector. Furthermore, the popularization of books such as Predictably Irrational and Nudge have elucidated the multitude of ways that consumer behavior research can successfully aid in the effort to improve consumer well being. As the confluence of consumer research and public policy initiatives becomes increasingly apparent, a roundtable session is crucial to showcase how researchers have successfully implemented and executed consumer research in a manner that is both theoretically and experimentally rigorous and yet influential in a spectrum of policy initiatives.

The relationship between public policy makers and consumer research is not a new one. The 1980s marked a major shift in the integration of consumer behavior research into public policy.

One specific example was the use of consumer research methods to investigate the prevalence of deception in advertisements (Maronick, 1990). In the 1990s, consumer research played an important role in providing research in food advertising (FTC 1994), telemarketing sales rules (FTC 1995), and also for the FDA's (1996) regulation for the distribution and sale of cigarettes to minors. More recently, consumer research has influenced food and calorie labeling. After several consumer research groups found that labeling diminished consumption behavior both pre- and post-purchase of an unhealthy high-calorie food item, the U.S. Food and Drug Administration is working to propose guidelines that will require more than 20 chain restaurants to include calorie counts for all menu items, including drinks. Despite the development of academic special interest groups and the important contributions from the *Journal of Public Policy and Marketing*, there is still much improvement to be made.

While, many of these initiatives have resulted in large-scale consumer welfare improvement efforts, there are still critics on both the policy side and the academic side. Academically, only about 3% of articles published in top tier journals concern issues of consumer research and policy (Hill, 2011). A survey conducted at the 1996 AMA/Sheth Doctoral Consortium showed that while two-thirds of doctoral students have an interest in learning about marketing and society, fewer than one in ten had ever taken a single course in this area (Wilkie & Moore, 1997). However, a shift is occurring in academia, with policy issues becoming increasingly popular. Leading researchers are focused on using behavioral techniques to aid in the effort to improve consumer health and welfare issues, retirement planning, fiscal policy, and environmental policy among others.

The timeliness of this roundtable session provides a unique opportunity. As a new generation of consumer researchers emerges, the need to push towards improving policy through research is ever increasing. Scholars who have already played a large role in shaping policy initiatives can productively discuss successful past methodologies. Directing research towards this domain is imperative, and a conference setting is the perfect venue for an integrative and multifaceted discussion amongst some of the preeminent scholars in the field. The researchers in this roundtable session have contributed substantially to public policy initiatives. Thus, they can shed light on how to be successful

in this interdisciplinary area and also can provide valuable insight on some of the potential pitfalls, concerns, and questions raised by both reviewers and policy makers.

Our hope is that this roundtable will provide a launchpad for individuals at all stages in their career to brainstorm how consumer behavior research can further influence public policy initiatives. The experience that all of the session participants have should prove invaluable to students, young faculty members, and even those in the later stages of their career for developing ideas that can potentially have a large impact outside of academia.

Prosocial behavior is the label for a broad category of actions that are defined by society as generally beneficial to other people and to the ongoing political system (Dovidio et al. 2006). The interest in prosocial behavior has increased in the last 15 years since Bendapudi, Singh, and Bendapudi's (1996) review article noted a dearth of marketing literature in this area. Gaining an understanding of the factors influencing prosocial behavior by consumers is important for charities, such as United Way, that need to compete vigorously for donor dollars. Such an understanding is crucial because individual giving is always the largest single source of donation to charitable organizations (Giving USA Foundation 2007). Furthermore, many companies and consumers are paying attention to the impact of their choices on society at large. Consequently, an increasing number of consumer behavior scholars have begun to look at the causes and consequences of prosocial behavior among consumers and companies.

The goal of this roundtable is to foster an engaging discussion on the antecedents and consequences of prosocial behaviors, by bringing together researchers who are currently approaching different aspects of the topic, from different theoretical perspectives. Consistent with the conference theme of "building connections," we aim to unite researchers under a common goal of providing insights into the study of charitable giving, volunteerism, sustainability, and CSR responses. This roundtable will appeal broadly to those scholars interested in the individual (e.g., personal values; Torelli and Kaikati 2009) and social (e.g., relationships; Small and Simonsohn 2008) factors influencing different types of prosocial behavior as well as the effects of different types of prosocial behavior on consumers' lives. Beyond this, it will also appeal to those interested in research examining the effects on both employees and consumers of prosocial behavior initiated and communicated by organizations (via CSR messages). Our distinguished panel of committed attendees purposely includes scholars from a diverse range of research areas relating to understanding the causes and effects of prosocial behavior. Our panelists are conducting research on many important subjects that fit under the "prosocial" umbrella. These include exploring factors affecting charitable giving and volunteerism, the effects of charitable behavior on consumer welfare and satisfaction, sustainability, how prosocial activities within organizations affect employee morale and job satisfaction, and the many factors influencing consumer responses to corporate social responsibility (including the nature of the product, the nature of the consumer, the communication strategy, and prior CSR activities by the organization). Our panel includes scholars with diverse backgrounds and interests, so that we can learn from each other and foster a community that keeps the big picture in mind, rather than focusing on one narrow research area.

We aim to encourage dialogue before, during, and after the roundtable. This will include identifying key areas of current research, discussing potential synergies between different streams of work, identifying directions for future research, and discussing the challenges of doing research in this area. Due to the huge appeal of this topic to many scholars with diverse perspectives, we hope to not only attract a wide range of scholars from different backgrounds and interests, but also to help foster a community that will continue to be active even after ACR 2011. This roundtable will also draw interest from proponents of Transformative Consumer Research, which has been described as "consumer research in the service of quality of life" (Mick 2006, p. 3). We hope to appeal to a large portion of the TCR community, but will also attract a range of scholars who are not (currently) part of the TCR group. The topics covered will be relevant to those interested in broadening our theoretical understanding of prosocial behavior, those dedicated to doing research with prosocial benefits (TCR), and those focused on managerial implications. Indeed, many on our panel are dedicated to doing research that addresses all three of these goals.

One of the "big picture" questions we will address in our discussion is whether it is prosocial to study prosocial behavior. Indeed, while some have demonstrated the connection between prosocial behavior and happiness (Liu and Aaker 2008, Dunn Aknin and Norton 2008), some are troubled by the idea that nonprofits should focus on keeping their donors and volunteers feeling appreciated and happy, if not downright entertained by their acts of kindness (Strahilevitz 2010). Others worry that research on prosocial behavior is not always taken seriously, particularly in the context of a business school. Given the importance of these topics, we will discuss the potential value of doing research in this area, with a focus on work that is both rigorous in terms of theory, but also potentially helpful in terms of service to society. We will also, as a group, discuss strategies for promoting the value of research on prosocial behavior within a business school setting. Finally, several of the roundtable members will share their experiences and lessons learned from adding a prosocial dimension to their course offerings. This will include sharing experiences on introducing courses centered around CSR and nonprofit principals, and sharing advice on adding prosocial content to existing courses.

Before and after the conference, continued dialogue will be facilitated via a combination of email exchanges (facilitated by the roundtable chairs), postings on the ACR Knowledge Exchange Forum, and postings on the Facebook group "Prosocial Consumer Research." This Facebook group is open to any scholar interested in research in this area. In our pre-ACR dialogue, we will develop a plan for breakout sessions focusing on issues such as consumer responses to CSR, causes and consequences of prosocial behavior by consumers, the prosocial nature of research on prosocial behavior, and the challenges that come with research in this area.

This roundtable is proposed to continue dialogue engaged in the 2011 gathering in Geneva on connections between giving, sharing and consuming practices and to bring them to a wider audience.

Nowadays, associations, foundations and other NGO's, but also families are supporting numerous social, health and cultural causes. Even if recent humanitarian disasters have confirmed the generosity of individuals, firms and States, they have also highlighted the need for actors involved in charity and humanitarian missions to find new ways to become known, to differentiate themselves and to create a special relationship with donators. The growing concurrence between charities and causes suggests the emergence of a donator who is more attentive to the social as well as economic issues of his or her behavior.

This phenomenon is also accompanied with tensions between giving outside/inside the private sphere (Bajde, 2006, 2009), between giving and sharing (Belk, 2010), between giving/receiving and consuming (Marcoux, 2009; Le Gall-Ely and Urbain, 2011) as well as with the increasing interest for a more sustainable consumption (Bécheur and Toulouse, 2009). In view of the diversity of topics and the rising interest in these fields, it is now time to clearly stipulate the tensions and convergences between each topic.

This roundtable has been proposed to determine what can be done to best address the objectives, first defined in the discussions in the *Observatoire International Don et Consommation*[1] (OIDC) research group created in Geneva (Switzerland) and Brest (France) and bringing together researchers from all over Europe and North-America.

The roundtable will follow on from the 1ˢᵗ colloquium of the OIDC that has taken place in Geneva in June 2011. The current roundtable will focus on the importance of studying the diversity of consumers' behaviors and cultures, what obstacles or issues are specific to giving, sharing and consuming practices researchers, and how research projects can benefit from, and contribute to sharing knowledge with our colleagues based in other parts of the world. To meet this aim, the proposed panel consists of both senior and emerging researchers from all over the world interested in giving, sharing and consuming practices.

Background

Giving and sharing are without doubt topics of growing interest in consumer research, as well as in the fields of anthropology, sociology, psychology, economics and philosophy. A growing number of articles published in the *Journal of Consumer Research* has exposed research regarding these topics in recent years (e.g. Marcoux, 2009; Belk, 2010). Furthermore, the French National Research Agency (ANR) has financed research on these topics and the French Marketing Association (AFM) has provided support to sponsor the latest Price, Free and Gift conference held at Tours University in 2010.

Furthermore, a book published in 2011 (Bergadaà, Le Gall-Ely, and Urien, 2011) is dedicated to essays and research on giving, demonstrating substantial growth in the field. A number of ACR researchers are actively engaged in these research areas (including those named as participants for this roundtable) and further collaboration and dialogue are necessary to better understand how to facilitate developments in the future.

Roundtable Purpose

Rather than focusing on one or two 'experts' in the field, the proposed roundtable will be interactive in nature to encourage a flow of dialogue between attendees. The proposed roundtable will:

1. Encourage active and critical dialogue between persons engaged with giving, sharing and consuming research. Participants will discuss what has and has not been achieved in the past years (in both Europe and North America as well as in other parts of the world).
2. Identify the conceptual, theoretical and methodological tensions and convergences between these topics.
3. Address what specific issues or obstacles consumer researchers face. How can we learn from one another to ensure these obstacles are minimized or removed altogether for researchers in the field? One particular aim is to see how researchers based in different continents could share experiences.

---

[1] http://www.oidc.unige.ch/

Roundtable Structure and Content

The proposed Giving, Sharing and Consuming roundtable will encourage open dialogue from all panel members and attendees. The role of the discussant will be to ensure free-flowing dialogue and to lead the discussion as needed. We propose focusing on three discussion areas to help guide the session and ensure that contributions are made from all participants. The proposed discussion questions are:

1. What has been achieved, in consumer research, to understand the connections between diverse consumers' practices as giving, sharing and consuming in the past?
2. What related research will be forthcoming? (research nearly completed, books to be published…)
3. What avenues for high quality, high impact research collaboration exist among the attendees that can ensure that dialogue continues beyond the roundtable setting?

Contributions and Implications

One of the key contributions of this roundtable will be its assessment of research regarding diverse consumers' practices and their connections. With this roundtable, we hope to expose ACR members to topics besides self-focused consumption and identify the tensions and convergences between the diverse consumers' behavior. Strategies to encourage high impact research on these issues will be discussed at the roundtable, offering participants alike opportunities to continue growing the field of giving, sharing and consuming research. We hope that the roundtable encourages collaborations between researchers by creating networks, facilitating research opportunities by the identification of a research agenda, and promoting further dialogue, and these collaborations will develop across borders.

Researchers have long argued whether emotions should be understood as cognitive appraisals (e.g., Frijda, Kuipers, and Ter Schure 1989; Smith and Ellsworth 1985) or perceptions of changes in bodily states (e.g., James 1884; Lange 1885). Specifically, cognitive appraisal theory posits that emotions are elicited by evaluating (appraising) certain objects or events in the environment in terms of their congruence with one's goals (Roseman and Smith 2001). For example, happiness occurs after indulging in a delicious meal because it contributes to one's eating goals. Guilt is elicited in consumers after overeating because it violates goals of staying healthy and slim. On the contrary, bodily perception theory argues that emotions may arise without the intervening process of cognitive appraisal but on the basis of physiological changes in the body (James 1884; Lange 1885) and based on motor action such as muscle flexion/extension or facial expressions (Maxwell and Davidson 2007; Niedenthal 2007). For example, a consumer feels content from eating because of being filled and one feels sad because of crying.

Are emotions cognitive appraisals or bodily perceptions? Both views seem to be partly correct. Recent advances in neuroscience indicate that the brain carries out such cognitive appraisals and bodily perceptions simultaneously, integrating them with cognitive representations such as concepts and beliefs (Bechara 2005; Bechara and Damasio 2005; Reimann and Bechara 2010) and helping modify and guide downstream processing of judgments and decision-making (Bechara et al. 1997).

The central role of bodily perceptions has been shared by the theory of embodied or grounded cognition. This theory typically hold that the body exerts a strong influence on shaping an individual's cognitive representations (Barsalou 2008; Glenberg 1997; Malter 1996). For example, early research wondered why nodding one's head (vs. shaking it) influences the degree to which one agrees with a persuasive message (Wells and Petty 1980) or why standing upright (vs. slumping) increases persistence on an insolvable puzzle task (Riskind and Gotay 1982). More recent research indicated that moving one's eyes helped solve brainteasers (Thomas and Lleras 2007), moving one's hand facilitated solving math problems and increases math performance (Broaders et al. 2007; Goldin-Meadow, Cook, and Mitchell 2009), and firming one's muscles also firms one's willpower and improves self-regulation (Hung and Labroo 2011).

These bodily influences on cognitive representations not only function through actually experiencing physiological and motoric changes but also through merely remembering them and, thus, reexperiencing them (Reimann and Bechara 2010). We extend this notion of bodily influence on cognitive representations and argue that bodily feedback—whether actually experienced or remembered—is also necessary for accurately appraising the goal-congruence of an object or event. For example, standing upright (vs. slumping) lead individuals to evaluate an achievement with greater pride (Stepper and Strack 1993) and, thus, may foster performance-related goals. Individuals who sat on ergonomic chairs (vs. a smaller, forward-tilted chair) appraised the situation as a more powerful leader (Huang et al. 2011), supporting goals of getting ahead in life.

We expect that embodiment theory will contribute significantly to the extant literature as it helps integrate previously competing views of emotion as either cognitive appraisals or perceptions of bodily changes. The notion of embodiment is in line with the Jamesian view of emotion, which argues that a range of bodily states—visceral changes, facial expressions, and muscle action—can cause the brain to interpret emotion (James 1884, 1894). Yet, we additionally argue in the Damasian view, which posits that these bodily states must not necessarily be experienced on the spot but can be merely remembered (Bechara and Damasio 2005; Damasio 1994). This view allows for an integration of both bodily perceptions and cognitive appraisals. It is argued today that cognitive appraisals are a necessary stage between bodily perceptions and downstream processes that trigger behaviors. Although these filtering appraisal processes can be brief and nonconscious, they need

to be recognized (Damasio, 2010). We further argue that the mechanisms of embodiment have a profound impact on downstream processes of consumers' judgments and decision-making such as more embodiment leading to more advantageous financial choices (Bechara et al. 1997), resisting the temptation of drugs (Bechara 2005) or calorie-rich foods (Hung and Labroo 2011), and predicting future consequences (Bechara et al. 1994).

Motivation for Organizing the Roundtable Discussion

Despite important previous work on embodiment, several important conceptual and methodological questions remain unanswered. First, how do affect and cognition interact in embodiment? Prior research under the label of 'embodied cognition' postulated that knowledge and thoughts arise from physical interaction with the environment (Glenberg 1997; Glenberg et al. 2003). Are these embodied cognitions purely 'embodied cognitions of affect' in the sense of cognitive appraisal theory?

Second, for which consumer behaviors is embodiment most relevant? Previous work has studied embodiment in a wide variety of consumer behaviors, including product and brand evaluations (Kreuzbauer and Malter 2005), food appraisals (Labroo and Nielsen 2010), donations (Hung and Labroo 2011), and financial decision-making (Bechara et al. 1997; Kuhnen and Knutson 2005). As such, does embodiment apply more broadly as an overarching phenomenon or is it merely domain-specific?

Third, which methodological manipulations work most effectively in the study of embodiment and its role in consumer judgment and decision-making? Published work has applied a broad spectrum of strategies to manipulate embodiment, ranging from muscle action (e.g., arm flexion and extension, movement of head or hand), via facial expressions, to the recording of neurophysiological processes such as heart rate, skin conductance, and brain activity.

Taken together, we propose this roundtable discussion (1) to attain clarity on the aforementioned conceptual and methodological issues, (2) to arrive at an integrative view on the topic of embodiment in consumer judgment and decision-making, and (3) to stimulate the ACR community and discuss ideas and directions for further consumer research on the topic. Additionally, pre-conference discussions are facilitated by participants' e-mail exchanges moderated by the roundtable organizer.

Benefit from Attending the Roundtable Discussion

This roundtable discussion will offer an opportunity for researchers from different backgrounds (i.e., consumer research, marketing, psychology, and neuroscience) to identify mutual interests and develop new collegial relationships. Key benefits of this roundtable discussion will be an exchange of state-of-the-art insights on embodiment between psychology/neuroscience and consumer behavior/marketing scholars and an identification of areas for collaboration to advance the research agenda on this topic.

ROUNDTABLE
Dorita, this is not Kansas! Is Latin America!

Chair:
Silvia Gonzalez, ITESM Campus, Monterrey, Mexico

Participants:
Enrique Manzur, Universidad de Chile, Chile
Rodrigo Uribe, Universidad de Chile, Chile
Eduardo Torres, Universidad de Chile, Chile
Christian Felzsenztein, Universidad de Chile, Chile
Claudio Aquevque, Universidad de Chile, Chile
Constanza Bianchi, Universidad Adolfo Inañez, Chile
Sandra Milberg, Universidad Adolfo Inañez, Chile
Sergio Olavarrieta, Universidad de Chile, Chile

The first Latin American Conference of the Association for Consumer Research (ACR) was held in Monterrey, Mexico, in 2006. This conference was an important first step for ACR to be present in a new region. The conference was a success in that it promoted exchanges of ideas among researchers from around the world. The ACR LA started with 120 attendees, half of them from Latin American Universities. In 2008, in Sao Paulo, Brazil, was held the second Latin American Conference of the Association for Consumer Research. This time, along with the competitive sessions, methodological workshops, film festival, roundtables and posters, and meet-the-editors sessions, we had the addition of a one-day Transformative Consumer Research pre-conference and a retail expedition. Again, half of the attendees were from Latin American Universities.

In both Conferences, we had participants from all over the world, presenting work relevant to a great variety of countries, and representing a variety of research paradigms and methodologies.

However, we need to ensure that we are in the right track to fulfill its objective of fostering consumer research in the region with the highest ACR standards.

Extraordinary experiences are highly enjoyable (Csikszentmihalyi 1990: 1997). They involve absorbing mental states of being that exceed consumers' day-to-day levels of emotional intensity (Allen, Massiah, Cascio and Johnoson 2008). These type of experiences are crucial in the formation and maintenance of consumer communities (McAlexander and 1998; Schouten and Alexander 1995). Thanks to many supporters, in both Conferences we were able to hold interesting receptions, the off-site reception at the Museum of Contemporary Art in Monterrey, the performance of "The Traveler" a Mexican traditional dances show, a great Samba Night and great Mexican and Brazilian food.. Receptions were very well attended and the dances were spectacular! Now, it is time to question if these enjoyable experiences have had a positive influence in strengthen relationships in the Latin American research community and increased ACR participation that we want to foster in the region. In this roundtable we invite participants to discuss if we are making progress to attract talented Latin American researchers, who do not regularly participate in ACR events. In addition, we want to discuss the organization of the third possible Latin America conference in Chile.

<div align="center">

ROUNDTABLE
Fellows Roundtable

Chair:
James Burroughs, University of Virginia, USA

Participants:
Don Lehmann, Columbia University, USA
Brian Sternthal, Northwestern University, USA
John Lynch, University of Colorado, USA
Russell Belk, York University, Canada
Jim Bettman, Duke University, USA
Beth Hirschman, Rutgers University, USA

</div>

Roundtable Summaries

Roundtable One
Grant Workshop (Chair: Rucker).
Brief Description: Bring in representatives from major grant making agencies (e.g. NSF, NIH, Templeton) and overview the process of applying for grants.

Roundtable Two
Fellows Session (Chair: Burroughs).
Brief Description: ACR Fellows will share their wisdom and insights related to building a research career. Topics will include building a research program, balancing early career pressures, and mistakes made that might be avoided. Session will be restricted to doctoral students and junior faculty (i.e. Assistant Professors in the first three years).

Roundtable Three
JCR Reviewer Training (Chair: Twist).
Brief Description: Managing Editor Mary-Ann Twist, along with a team of Editors and Associate Editors from the *Journal of Consumer Research* will help to train faculty who are relatively new to journal reviewing on how to perform a quality review. Session will include examples, best practices, and how to avoid submitting problematic reviews.

Roundtable Four
MSI Celebration (Chair: Keller).
Brief Description: A group of faculty closely involved with the Marketing Science Institute will conduct a roundtable to discuss the contributions (and future) of MSI in the marketing and consumer research community. The roundtable will mark the 50th anniversary of the founding of MSI and a celebratory reception will follow the roundtable.

Roundtable Five
Sheth Foundation Resources (Chair: Mick).
Brief Description: A group of former and current recipients of Sheth Foundation grants will discuss how the Foundation has influenced their work, and how to access Sheth Foundation resources for doctoral dissertation research.

Roundtable Six
Embodiment in Consumer Behavior (Chair: Reimann).
Brief Description: A group of researchers interested in the intersection of embodiment (i.e. embodied cognition, embodied emotion) and consumer behavior will meet to discuss and share research ideas and critiques.

Roundtable Seven
Latin America Consumer Research Interest Group (Chair: Gonzalez and Olvarietta).
Brief Description: There have now been two ACR Latin America Conferences. This has produced a vibrant group of scholars both from and interested in consumer research in Latin America. The session hopes to continue to keep the nucleus formed by these conferences thriving by staying connected at the ACR Annual (formerly North American) conference.

Roundtable Eight
Bridging the Gap between Consumer Research and Public Policy (Chair: Shah).
Brief Description: This sessions seeks to bridge the gap between consumer research and shaping public policy, including ways to study marketing from a public policy context, and future research opportunities at the intersection of these two issues.

Roundtable Nine

When Companies and Consumers do Good (Chair: Kaikati).

Brief Description: Consistent with the conference theme of "building connections", this session will unite researchers studying the psychology of charitable giving, volunteerism, sustainability, and CSR responses.

Roundtable Ten

Charity and Gift Giving (Chair: Le Gail-Ely).

Brief Description: Purpose is to continue dialogue initiated by the OIDC (*Observatoire International Don et Consommation*), group of researchers from all over Europe and North-America with an interest in charitable giving and pro-social behaviors, including exploring the tension between pro-social behaviors and traditional self-interested (indulgent) behaviors.

ROUNDTABLE
Grant Writing Roundtable

Chair:
Derek Rucker, Northwestern University, USA

Participants:
John Deighton, Harvard Business School, USA
Deborah Olster, NIH, USA
Brett Pelham, NSF, USA

This roundtable will familiarize faculty and doctoral students with grant writing opportunities and strategies. The discussion will be led by an excellent set of representatives from MSI, the Templeton Foundation, NIH, and NSF. These scholars will be present to discuss the opportunities available from their respective institutions to consumer researchers as well as discuss questions about the grant writing process.

MSI 50th Anniversary Celebratory Session

Chairs:
Donna Hoffman, UC Riverside, USA
Punam Keller, Dartmouth College, USA

Participants:
John Deighton, Harvard Business School, USA
Don Lehman, Columbia University, USA
Rohit Deshpande, Harvard Business School, USA
John Lynch, University of Colorado, USA
Barbara Kahn, University of Pennsylvania, USA
Page Moreau, University of Colorado, USA
Darren Dahl, University of British Columbia
Kristin Diehl, University of Southern California, USA
Jonah Berger, University of Pennsylvania, USA
Gavan Fitzsimons, Duke University, USA

This unique session will celebrate the Marketing Science Institute's support of consumer research. 2011 marks the year the Marketing Science Institute (MSI) commemorates 50 years of generating and disseminating knowledge that advances the theory, science, and practice of marketing. This celebratory session is designed to stimulate conversations about consumer behavior challenges and opportunities in the years ahead. To achieve these goals, a baker's dozen of the leading CB scholars will highlight their work with MSI in a series of very short, high impact TED-style talks. All of these consumer researchers have strong connections to MSI, with each representing different paradigms, career stages and types of MSI collaborations. The short presentations will emphasize the key aspects of each scholar's MSI research collaboration. In addition to celebrating MSI's contributions over the past 50 years, we hope the session will expose ACR members to the many exciting opportunities MSI offers consumer behavior scholars in support of academic research. Past collaborations with CB scholars have included monetary awards for research and conferences, distribution of research to practitioners, recognition of young scholars, data sets from companies, teaching materials, and idea exchanges.

Report of the 2011 ACR Long-Term Planning Task Force
(Open to all)

Co-Chairs:
Sharon Shavitt, Walter H. Stellner Professor of Marketing, University of Illinois at Urbana-Champaign, USA
J. Jeffrey Inman, University of Pittsburgh, USA

Participants:
Joel Huber, Duke University, USA
Don Lehmann, Columbia University, USA
John Deighton, Harvard Business School, USA
Linda Price, University of Arizona, USA

Recently an ACR Strategic Task force was created to address the growth, internationalization, and relevance of our field. The task force conducted a member survey and generated recommendations and issues to consider in the future. These outputs plus data on conference submissions will be discussed. We seek input on several recommendations for ACR initiatives to scale up and enhance the field as it rapidly expands, including recommendations for new and existing publication outlets and conference structures.

Working Papers

Bollywood: A 'Consumer Reacculturation Agent'

Amandeep Takhar, University of Bedfordshire, UK

This research investigates the concept of reacculturation, whereby ethnic individuals focus on adopting the customs and traditions of their ethnic minority culture, within an environment that is not their ancestral homeland. The focus within this research is on how third generation, UK born British Sikhs, consume Bollywood films and how the consumption of Bollywood films lead to reacculturation towards their ancestral homeland culture and customs. It is not that research relating to the quest for roots in the construction of one's identity (Nitsch, 1987; Jairath, 1984; Russell, 2007) is new found, but that it previously tended to focus on, individuals experiences as they returned to their ancestral homeland, to get in touch with their roots. However this research focuses on reacculturation that is taking place towards an Eastern (Sikh) culture, within a western (UK) host culture. What's more with the increasing 'crossing of borders' Penaloza, (1994) and diminishing immigrant boundaries it is evident through consumer research within the area of acculturation (Penaloza, 1989, 1994; Oswald, 1999; Askegaard et al., 2005; Ustuner and Holt, 2007), that reacculturation to homeland cultures is becoming a significant factor that influences the consumption processes of individuals from multiple cultural backgrounds. There has been increasing consumer research into the notion of reterritorialization (Askegaard et al., 2005; Ustuner and Holt) whereby migrants "recraft a sense of community and cultural identity in new socio-geographic contexts" (Punathambekar, 2005, p.152); however reacculturation is a term that has been scarcely used by consumer researchers (Wamwara-Mbgua, 2006). I believe the term is particularly appropriate to describe how third generation (i.e. those born in the country to which their family (grandparents and parents) immigrated) immigrants feel a need to reconnect with their roots. To this end I use the 3rd generation of the British Sikh community and their relationship with Bollywood as the research context to generate thoughts in relation to their reacculturation processes.

Significantly Bollywood is recognised as a creative and significant world cinema, the Indian version of Bollywood offers an enormous production output (1000 films/year). It seems the "fascination for all things Bollywood seeped into mainstream Western music, theatre, fashion and television" (Dudrah, 2006, P.17) (e.g. the Westend show Bollywood dreams). According to Prasad (2003) Bombay-based Hindi cinema (Bollywood) has brought "the NRI (Non Resident Indian) decisively into the centre of the picture as a more stable figure of Indian identity" (P.153). Bollywood attempts to convey a "new sense of Indianness" Rajadhyaksha (2003) (p.32), a sense of Indianness that resonates deeply with members of the British Sikh community. There has been little consumer research that examines the impact of this ethnic film medium (Bollywood), especially in terms of how it encourages young British Sikhs to reconnect and reacculturate with the Indian culture. Given the increasing presence of the Bollywood film medium within the UK and the availability of Bollywood films through mainstream chains such as the Odeon, UCI, Vue and Virgin cinemas due to increasing demand from British audiences, it is important to gain insights into the impact of the Bollywood film medium on the third generation of the British Sikh community, in order to understand how Bollywood influences them to reconnect with their ethnic roots and how this may impact their identity projects (Ustuner and Holt, 2007).

The overall research question for this study was how are Bollywood films influencing the third generation of British Sikhs and how is the sense of Indianness conveyed in Bollywood films assisting reacculturation? The study adopts an interpretive research strategy and multi-method research design as advocated by Gill and Johnson, (2002), as a useful means to generate theory-building. It was carried out longitudinally over two and a half years. Stage 1 of the research was conducted through a netnographic approach (Kozinets, 2002), which consisted of online observations of an online film blog known as hindustanlink.com; it involved observations and participant observation of participants (aged 22-35) of the website. Stage 2 focused on the third generation of British Sikhs and involved participant observation, netnography (Kozinets, 2002), in-depth, face to face interviews and autoethnographic accounts. Stage 3 evolved dependent on the emergent constructs from stage 2 and involved online and offline interviews with the third generation of the British Sikh community as well as the participation in the online community of hindustanlink.com. Stage 4, the final stage also involved online interviews with the third generation and participant observation of hindustanlink.com. It adopted a theoretical sampling approach which requires continually comparing and contrasting the data being collected and seeking informants on the basis of the emergent constructs, in line with Cresswell, (2007). Interviews sought to gain in-depth insight into the influence of the Bollywood medium and to encourage informants to explore how the consumption of Bollywood films encouraged them to reacculturate to the Indian culture and traditions. In total the dataset consists of 15 online interviews, 15 face to face interviews, online participant observation, autoethnographic accounts and substantial fieldnotes. The data analysis and interpretation progressed in an iterative and interrelated manner between the online and offline environments, following the analysis and interpretation of qualitative data as recommended by Spiggle (1994) and others (Strauss and Corbin, 1990; Arnould and Wallendorf, 1994).

There were three key themes that emerged in answer to our core research question, 1) the role of Bollywood in the reacculturation and reconnection with the Indian culture, 2) the role of Bollywood films in bringing the family together and 3) the role of Bollywood in enabling third generation British Sikhs to become aware of their diasporic consciousness and in constructing a hybrid East and West Identity.

A prominent theme that is emerging as a result of exposure to Bollywood films is the reacculturation and reconnection with the Indian culture. Young British Sikhs draw on the teachings of Bollywood (Dudrah, 2006; Mehta, 2005) to understand Indian traditions such as how to maintain family honour. Through Bollywood films they also learn about this perfect, once in a lifetime, innocent, Bollywood love and romance. Where the reacculturation to the Indian culture through Bollywood is specifically useful, is in its power to influence the third generation of British Sikhs in relation to their identity projects (Ustuner and Holt, 2007) as Non Resident Indians (Prasad, 2003). Evident from the fieldnotes young third generation British Sikhs became highly self reflexive as they were exposed to scenes from Bollywood movies and questioned their own identity and goals in life. They became highly aware of the importance of their ethnic culture and identity. Third generation British Sikhs were aware of the crucial role of Bollywood in reconnecting them with the Indian culture.

Another important theme that emerged was the role of Bollywood movies in bringing the family together. Bollywood films were consumed and experienced as families and then reflected on as a family (Dudrah, 2006). Though there was an intergenerational conflict between the second generation, India born parents and the third generation, UK born children, Bollywood was used by the second generation to keep their children in touch with the Indian culture. In fact mothers often used the consumption of Bollywood movies to encourage their third generation children to resist acculturation to the Western world and maintain their Indian identity.

The third and final theme to materialize was the role of Bollywood in enabling young British Sikhs to become aware of their diasporic consciousness and therefore understand their hybrid, East/West identities as UK born British Sikhs. The Western and British culture was the dominant culture in the lives of young British Sikhs, however through exposure to Bollywood movies, they learnt about the significance of the Indian culture in their lives and identity. Through exposure to the Bollywood film medium they learnt that they did not have to choose either the Western or Eastern culture and were very aware of their diasporic consciousness and the transcultural mixtures. Young British Sikhs learnt that they were in fact able to adopt traits and characteristics of both the Eastern and Western cultures, therefore enabling them to comprehend and construct hybrid identities they were comfortable with as British Sikhs.

You make me feel bad about myself: Shaken self-view through observing a merged other act inconsistent with one's self-view

Ali Faraji-Rad, BI Norwegian School of Management, Norway

Imagine Nick, a PhD student who has a strong belief that eating healthy is an important attribute that one should possess and truly believes that he actually possesses that attribute.One day, on his way to the cafeteria, Nick sees his friend Jeff, another PhD student at Nick's department to whom he really identifies, carrying a big bucket of French fries and toasted chicken in one hand and a big Coke in the other. How would this observation affect Nick's choice (healthy vs. unhealthy) in the cafeteria?

The consensus in persuasion literature is that similarity of one individual to another increases the propensity of him being influenced by the other person. Therefore, it would be reasonable to predict that in the previous scenario Nick would be influenced by Jeff and take an unhealthy snack in the cafeteria. Yet, we suggest that exactly due to the high degree of merged identity between Nick and Jeff, Nick is more likely to choose a healthy food in contradiction to the above-mentioned prediction.

People have the motivation to maintain a positive and consistent self-view (Aronson 1999). Therefore, any temporal threat to this self-view could result in motivation to restore this confidence (Gao, Wheeler, and Shiv 2009). For example, if someone believes that he has a healthy life-style, by reminding him that he had junk food yesterday, we would be able to shake his self-view confidence and create the motivation in him to restore his self-view by choosing a healthy snack next time. In this research, building on the spyglass-self model (Goldstein and Cialdini 2007) and merged identity theory (Aron et al. 1991) we propose that we necessarily need not remind an individual of his *own* self-view inconsistent behavior. The threat to self-view could be created by merely observing a merged-other behave in self-view inconsistent behavior. And this will result in changed behavior to restore one's own self-confidence. In the scenario above, when Nick sees Jeff, a merged other, indulge in unhealthy eating behavior; he automatically makes a self-perception that he *himself* is an unhealthy eater. But this inference is contrary to Nick's self-view and therefore it is a threat to his self-image. To restore his self-image, he will be more inclined to buy a healthy snack at the cafeteria.

Feeling of merged identity can be enhanced by perspective taking (Cialdini t al. 1997). A number of studies support this notion (Ku, Wang, andGalinsky 2010;Goldstein and Cialdini2007). Based on this evidence, we propose that participants high in chronic belief of health consciousness, when instructed to take the perspective of another individual, will showhigher preference for healthy products if they see that individual engage in unhealthy eating behavior. As the sense of merged identity is necessary for the effects of shaken self-view to emerge, we propose that this effect will not be observed in non-perspective taking individuals. Also, participants who do not see health-consciousness as central to their self-view, do not feel any treat to their self by observing a merged other act in unhealthy manner.

Design and procedure:One hundred and fifty one online panel members participated in a 2-group (perspective taker vs. observer) study for a fixed payment of 0.75$ and also "a chance to be included in a lottery for a price of around 15$". Perspective taking was manipulated between subjects and attitude towards healthy eating was measured as a continuous-measure for all participants.

First, under the disguise of a study on personalities and lifestyles, participants completed a 20-item questionnaire. Three of these items were of interest to us and were related to healthy eating andwere averaged to come up with a single measure for health consciousness (α= 0.864). As the next step, participants had to "read a transcript of an interview and to answer some questions about he interviewee" (always the same sex as participant). Depending on the condition, half of the participants were given perspective taking instructions and the other half did not get any particular instructions on how to read the interview. Perspective taking instructions and the interview were adopted (and slightly modified) from the ones previously used by Goldstein and Cialdini(2007). The interview was ostensibly a transcript of an audio recording and included some questions that the interviewee answered with generic responses. In the answer to the last question the interviewee showed unhealthy eating behavior.Then, participants wrote down three first thoughts that came to their mind about the interviewee. Then, they had to indicate their preference for either a 56 oz. bag of M&M or a black Fisher Space Pen (to receive incase they won the lottery). Also, they were (truly) informed that both products are worth around 15 dollars.

A logistic regression on choice data showed a significant interaction between perspective taking and health consciousness (B=-0.61, Wald=3.975, p= 0.046),a simple effect of health consciousness (B= 0.847, Wald=12.6, p= 0.000) and a non-significant effect of perspective taking (B=2.32, Wald=2.61, p>.106). Therefore, our hypothesis was supported by the data. To illustrate the difference between the conditions, we performed a median split on the health consciousness measure and calculated the percentage of participants who chose the M&M over the pen in each of the four conditions. In the non-perspective taking condition the health consciousparticipants chose the M&M 47% of the time while the non-health conscious participants chose it 50% of the time. However in the perspective taking condition the non-health conscious participants chose the M&M 58% of the time compared to only 26% of the health conscious participants who chose the M&M.

Further experiments are already on the way to further establish the effect and also to shed light on the process. The authors are currently running an experiment with a manipulation of merged identity other than perspective taking.

More Ambient Scent, Less Product Scent?

Fan Liu, University of Central Florida, USA

Scent literature has shed light on ambient scent and product scent. As described by Orth and Bourrain (2005), ambient scent is scent or odor that is not emanating from a particular object but is present in the environment (Spangenberg et al., 1996), whereas product-specific scent derives from the product itself. According to Krishna et al. (2010), scent research has focused primarily on the effects of ambient scent on consumer evaluations, but they emphasize instead the effects of product scent on memory enhancement. It could be explained as memory for odors is assumed to have a unique system (Zucco 2003). Morrin and Ratneshwar (2000, 2003, 2010) find that ambient scent improves recall and recognition of familiar and unfamiliar brands and the retrieval of brand memory, while product scent has a stronger effect on memory enhancement due to the fact that scent-related associations are focusing on a single subject.

The project attempts to bridge the gap between ambient scent and product scent, except that scent intensity is the key variable in the manipulations, not in the position to support the findings of Spangenberg, Crowley and Henderson (1996) that only the presence or absence (not the nature or intensity) of a scent affects evaluations and behaviors. The importance of intensity should derive from individual differences, sensitivity to scent (STS) (Cupchik, Phillips, and Truong 2005). An importance question is rooted: with or without the presence of ambient scent, how differently would consumers choose scented product?

This research aims to create a framework linking ambient scent with product scent. Individuals' STS and temperature in the stores as moderators, are found to predict how the intensity of ambient scent influences consumers' attitudes and choice of scented products. Need for Stimulation (NFS) is proposed to be the underlying mechanism for variety seeking behaviors of product scent (McAlister and Pessemier 1982; Menon and Kahn 1995). Based on Menon and Kahn (1995) who are in line with previous researchers developing their theories out of Optimum Stimulation Level (OSL), when the environment provides low (high) stimulation below (above) OSL, the individual desires for increasing (decreasing) stimulation and seeks (avoids) variety and novelty. Thus, NFS (consumer actual stimulation minus OSL) refers to the tendency to maintain OSL, otherwise, simulation seeking (avoidance) will rise in order to reduce or augment incoming stimulation (Sales 1971). In the system of Stimulus Intensity Modulation, the augmenters amplify stimulus intensity, the reducers attenuate the intensity, and the moderates have no effect on the intensity (Sales 1971). Align with Sales's strength-of-the-nervous-system but not the formulation of Zuckerman that argues augmenters (reducers) are high (low) in sensation seeking, Goldman, Kohn and Hunt (1983) prove that high sensation seekers tend to be reducers, lacking sensitivity to weak stimulation (low sensitivity also means strong nervous system). This paper is more prone to apply this strength-of-the-nervous-system so as to explain the effect of ambient scent intensity on variety seeking behavior of product scent. That is to say, individuals with low STS have strong olfactory systems and high NFS, hence tend to be variety seekers. On the contrary, those with high STS have weak olfactory systems, need less stimulation and tend to seek less variety.

In Study 1, three groups of people are expected out of measuring individual differences on STS: low STS, high STS with pleasant disposition, and high STS with unpleasant disposition (neglected in the experiment). In the absence (presence) of ambient scent, STS is positively (negatively) related to variety seeking behaviors of product scent. As the ambient scent intensity increases, consumers with high STS show a greater reduction in variety seeking than those with low STS, while NFS decreases in both groups. In addition, it is hypothesized that temperature is likely to moderate the effect, as NFS could be changeable. This intuitive assumption comes from the cold and warm types of fragrance illustrated by Milotic (2003). In the cold condition, the olfactory system is stronger with increasing NFS that leads to increasing variety seeking, whereas the warm condition tends to weaken the olfactory system with lower NFS and less variety seeking. Study 2 is a 2 (ambient scent intensity: absence vs. moderate presence) x 2 (STS: high vs. low) x 2 (temperature: cold vs. warm) factorial design. In the absence (presence) of ambient scent, warmness is more likely to increase (decrease) NFS, resulting in variety seeking (avoidance) behaviors as well as supporting the results of study 1.

The research hypotheses will be empirically tested by involving undergraduate students in laboratory settings. Completion of data collection is expected by December 2011. Analysis of variance will be utilized to analyze the data and a completed manuscript is expected by April 2011. The implications of this research will advance both theoretical and managerial knowledge in scent, in light of growing concerns about scent research and marketing.

The Tense of the Question Matters: Asking about the Past Leads to Personally Typical Future Behavior

Kate E. Min, Duke University, USA
Tanya L. Chartrand, Duke University, USA
Gavan J. Fitzsimons, Duke University, USA

How likely are you to visit the gym in the coming week? How often did you visit the gym in the past week? Both of these questions are about visiting the gym, but the key difference is that the former asks about visits intended in the future whereas the latter asks about visits already made in the past. According to existing research, when you are asked about future intentions to visit the gym, you are more likely to visit the gym more often than if you were not asked. That is, you are more likely to behave in the socially desirable way and align with social norms. However, extant research does not address what happens to your subsequent gym attendance when you are asked about your past gym visits. In the present research, we theorized that being asked about your past gym visits (or lack thereof) will lead you to go to the gym as frequently (or infrequently) as you did in the past. In other words, your subsequent gym visits will be aligned with how often you typically visit the gym, or what is personally typical for you.

Research has demonstrated that the simple act of asking future intention questions leads to biased responses on the part of respondents (e.g., Simmons, Bickart, and Lynch 1993) and it can even change the underlying behavior itself (e.g., Morwitz, Johnson, and Schmittlein 1993; Sherman 1980). This phenomenon has been referred to as the "question-behavior effect," (for a review, see Sprott, Spangenberg, Block, Fitzsimons, Morwitz, and Williams 2006) although it was originally referred to as the "self-erasing nature of errors of prediction" (Sherman 1980) and later referred to as "self-prophecy" (Spangenberg & Greenwald, 1999) and "mere-measurement" (Morwitz, Johnson, and Schmittlein 1993). This robust phenomenon has been demonstrated for a wide range of socially normative (desirable and undesirable) behaviors, including increasing voter registration and turnout (Greenwald, Carnot, Beach, and Young 1987), increasing volunteering for a charitable organization (Sherman 1980; Williams, Fitzsimons, and Block 2004), reducing cheating in a college classroom (Spangenberg and Obermiller 1996), and reducing gender stereotyping (Spangenberg and Greenwald 1999). Past research has repeatedly demonstrated that the simple act of answering a question about socially normative behaviors causes behavioral change aligned with social norms.

Still, it is questionable whether questions always lead to behavioral change aligned with social norms. Past research has shown that individuals align to social norms after answering questions about their future behaviors. However, in the present research, we predict and find that individuals align with personally typical behavior after answering questions about their past behaviors. We argue that this is because asking individuals about past behaviors (but not future behaviors) simply reminds them of the various past instances in which they have engaged (or not) in the target behavior and makes salient how typical it is for them to engage in that behavior. This thought of personally typical behavior then directs behavior accordingly (studies 1 and 2). We test this mechanism for the observed effects (study 3). If it is the case that asking about past behaviors makes salient what is personally typical and then aligns behavior in that way, then it should be possible to wipe out the effect when we make the discrepancy between what is personally typical and socially normative clear. Thus, we test for this possibility. We find that even when individuals are asked about their behavior in the past (and reminded of what they have typically done in the past), simply informing them that what is personally typical is not socially normative (i.e., they are doing "worse" than the average peer) leads their behavior to be more socially normative (than personally typical).

In three studies, we demonstrate that asking about future intentions to engage in behavior alters subsequent behavior differently than being asked about behavior already engaged in in the past. While extant research on the effect of questions on behavior has typically focused on asking about *future* behaviors, the present research raises the issue of asking about *past* behaviors. Our data suggest that asking about the past has significant behavioral consequences for the respondent, namely that asking about the past leads the respondent to engage in behavior one typically engages in (personally typical behavior). Furthermore, we provide support that the observed effects are due to a "consistency" mechanism whereby individuals strive to be consistent with thoughts they have about a behavior and their actual behavior.

Although our focus was on asking about the past, these findings raise the broader issue of how mental travel has consequences for what thoughts are made salient in the mind and ultimately actual behavior. As theorized by construal level theory (Liberman and Trope 2008), an event, object, or target of any sort can be removed from one's sense of immediate experience through psychological distance, with time being one dimension. Thus, an event that is to occur in the far future is experienced differently than one that is to occur in the near future. It would be interesting to test whether psychological distance from an event (near future vs. distant future) would alter behavior differently. One possibility is that asking about the distant future is construed in an abstract manner and corresponds more to abstract information, such as social norms, ultimately leading to behavior aligned with social norm. In contrast, asking about the near future may be construed in a concrete manner and correspond more to concrete information, such as behavior one normally engages in (what is personally typical), eventually leading one to engage in personally typical behavior.

In sum, the present findings contribute to the literature on how asking questions has behavioral consequences by identifying that the tense of the question matters: Asking about the past leads to personally typical future behavior. Importantly, providing feedback that one's

personally typical behavior is not the social norm and providing information on the social norm, alters behaviors to be aligned with social norms. More broadly, this research provides a unique perspective on the power of social influence.

Don't Lose Your Edge: The Subculture Hard-Core as Prevention-Focused Consumers

Sommer Kapitan, University of Texas at San Antonio, USA
Kristin Trask, University of Texas at San Antonio, USA

Western society no longer revolves around town hall meetings and church socials (Belk, 1985). In the modern consumer society, instead, those in need of social interaction self-select into identity subgroups that become part social, part image-projection, and at their base, material-driven. In a subculture of consumption - formed around any brand or consumption activity, from riding Harley Davidson motorcycles and skateboarding to quilting bees, rock-climbing, kayaking, and listening to heavy metal - the "hard-core" members at the center of the subculture are the opinion leaders. They are the cultural disseminators who strictly set, maintain and adhere to a code of conduct for their group and enforce its upkeep among junior members (Fox 1987). As keepers of the faith, the hard-core are role models for the aspirant peripheral culture and probationary soft-core members who revolve around their leadership (Schouten & McAlexander 1995).

Aspiring, fringe members and those among the mainstream who are lured into the periphery of any subculture of consumption are hopeful about their possible entry into the hard-core. Their reverence and adulation of the hard-core supports the concentric structure of the subculture (Fox 1987). In this way, hard-core members operate with a prevention focus in their subculture (Higgins 1998) are sensitive to the duties and obligations of maintaining values, are on guard for negative outcomes for themselves, and may eject non-followers formally or via social ostracizing. Their role is of vigilant avoidance, which Semin, Higgins, Gil de Montes and Valencia (2005) associate with regulatory focus. Fringe members and peripheral aspirants flirting with the subculture of consumption are by definition hopeful and aspiring, sensitive to what Semin et al. (2005) note is the positive outcome orientation and eager approach of the promotion-focused strategy. Semin et al. chart responses to the different goals-based language strategies of prevention- and promotion-focused individuals that sheds insight into research on consumption subcultures and brand communities: Prevention-focused consumers are more responsive to concrete, avoidance language, whereas promotion-focused consumers are more responsive to abstract, approach-oriented language.

Since individuals speak in different ways depending on their goals, consumers are more influenced by wording that matches their goal-focus. This is especially the case in a subculture formed around a particular brand or an activity dominated by a few specialty brands. Those in the outer rings of membership are hopeful, and need encouragement from brands to pursue those hopes and rise to the ideals of the subcultures. Those in the hard-core inner circle no longer need such encouragement to stay with the brand or consumption activity, but instead are focused on the penalties of losing touch with the group or their responsibilities now that they are at the top of their game.

In this research, we hypothesize that advertising must reflect prevention language to achieve the most influence among the hard-core in any consumption subculture. Advertisements must also reflect promotion language for beginner-level products to gain market share with new converts.

Is abstract, aspiration language enough to influence all members of the subculture—especially if advertising is framed to evoke the wonderment peripheral parties have for the endurance, uniqueness, or values displayed by the subculture (Schouten & McAlexander 1995)? The literature shows further evidence to support our prediction that abstract language is not enough for members of the hard-core inner circle. Maheswaran, Sternnthal, and Gurhan-Cali (1996) find that experts only lend higher evaluations to advertisements that catalog both benefit and attribute features. Only novices, like Adidas' enthusiastic new running converts, respond positively to broad, unsupported statements like "cushioning for an amazingly smooth ride."

Thus, we predict that while abstract language may have a positive influence on the hard-core, concrete language with specific prevention orientation will engender the most favorable response from the hard-core.

In fall 2010, we assessed how members of the "gym rat" campus recreation center subculture— those who report going the most to the center and taking advantage of the machines, basketball courts, classes, and outdoor trips— respond to advertisements for a new fitness class. The 196 lab respondents (55% male, mean age=23.4) were randomly assigned to the abstract-language (i.e., "the new class works all your muscles to tone and sculpt your physique. Feel better, look better. Guaranteed") or the concrete-language (i.e., the class "combines CrossFit training with powerlifting

to improve your BMI and stamina. Visible results, guaranteed") version of the advertisement, then asked to evaluate their interest in attending the class as well as their intent to recommend the class to other students. We find a significant difference between how hard-core users view the ad versus aspiring users, $F(1, 194)=9.34$, $p<.01$. Aspirant or fringe users expressed more interest in attending the advertised class when the language was abstract (M=4.38) versus concrete (M=3.12), whereas hard-core gym rats preferred the class when expressed in concrete terms (M=4.71) vs. abstract (M=4.29). Simple effects tests show that there is no significant difference between preference for abstract language, which confirms our hypothesis that hard-core users still respond positively to abstract, promotion-focused language. However, they respond significantly more to concrete language advertisements.

Our next step takes this examination beyond the lab setting to explore how members of subcultures of consumption become initiated into a subculture, and what activities (focused on key purchase moments) keep them engaged and invested with the subculture. We are conducting a study of newcomers to the triathlon community, charting their training, goals, and purchase behaviors via online diaries to capture what levels of engagement result in subsequent subculture-specific purchasing behavior (from technical gear to health food). In addition, semi-structured interviews with elite, hard-core runners are planned to understand how a member of the running subculture identifies worthy events, recognizes a runner, and incidentally reveals purchase behavior. Our hypotheses revolve around investment: Once members of a subculture reach a certain purchase threshold (i.e.,$100 for a pair of technical shoes, $1,000 for a respectable canoe or kayak, $1,000 for a top-of-the-line sewing machine), they are "in" the subculture and can work toward becoming hard-core with increasingly specialized purchases.

Is your Product in the Right Place? The Effect of Objects' Elongation and Spatial Disposition on Size Perception

Soumaya Cheikhrouhou, Concordia University, Canada
Bianca Grohmann, Concordia University, Canada

Product packaging is a key source of information consumers use to make choices and inferential judgments about products (Greenleaf and Raghubir 2008). Consumers rarely read volume labels or unitary prices (Yang and Raghubir 2005). They rely instead on visual cues in product assessment and are subject to evaluation biases. Raghubir and Krishna (1999) and Wansink and Van Ittersum (2003) find support for an elongation bias, that is, a positive and consistent bias in size estimation as elongation (i.e., ratio of height to width) increases. However, both the process underlying the elongation bias and its boundaries still remain unexplored.

Based on past work in experimental psychology (Goto et al. 2007; Marr 1977; Quinlan and Humphreys 1993; Sutherland 1968), this research seeks to demonstrate, through five studies, that the positive effect of elongation on size perception stems from a combination of assimilation/contrast judgments and a spatial disposition bias. We propose that when comparing the size of two identically-sized two-dimensional items, people first try to detect both their similar and discriminant geometrical dimensions. If no difference in the length of the two dimensions is apparent (i.e., assimilation), individuals are expected to perceive them as identical. If a difference between the two figures on the length of one dimension (e.g., height) is perceptible (i.e., contrast) while no noticeable difference appears on the other dimension (i.e., assimilation), individuals are expected to base their size assessment on the contrasting dimension solely. It is argued that side by side presentation favours the adoption of such a process where the height dimension is contrasted and the width is assimilated, which simplifies decision making. When objects are presented side by side, this process leads to the elongation bias reported in past literature. When objects are presented one above the other, width dimension is likely to contrast at low elongation difference between objects and the elongation effect is expected to be reversed.

When both dimensions' lengths contrast, the simpler assimilation/contrast mechanism does not allow for size assessment and more complex processing is needed. First, individuals are expected to fruitlessly try to use both dimensions in a compensatory manner, thus leading to no difference in choice share. When a significant difference between elongations exists and the easier assimilation/contrast processing cannot be used, another heuristic is likely to be adopted. We propose that the spatial disposition of objects triggers the salience of one dimension, leading to a hypothesized "spatial disposition bias" where horizontal presentation, for instance, increases salience of width. It is argued that this bias operates progressively as differences between the dimensions of the two objects increase, until the object presenting the longer salient dimension will be more often selected as the bigger one (i.e., the wider object in side by side presentation and the taller one in a one above the other presentation).

In study 1 (n=51), participants were shown ten pairs of rectangles of identical size and presented side by side, successively and in a random order. Each pair contained a baseline figure, which elongation (EL_{BF}=1.5) remained unchanged, and a manipulated figure, which

elongation (EL$_{MF}$=1.6, 1.7, 1.8, 1.9, 2, 2.1, 2.2, 2.3, 2.4, and 2.5) varied. Participants were instructed to select the bigger figure in each pair. As expected, a positive effect of elongation on size perception was found when EL$_{MF}$=1.6, a level close to the baseline figure, thus illustrating the initial assimilation/contrast processing. Choice share (CS$_{MF}$) was significantly different from 50% (CS$_{MF}$ =78.43%, Z=2.75, p<.01). At EL$_{MF}$=2.5, this effect was reversed, as hypothesized (CS$_{MF}$= 27.45%, Z=2.17, p<.05), reflecting the spatial disposition bias.

In study 2 (n=52), participants evaluated the same pairs, but rotated by 90 degrees. Choice share for the same figure but rotated significantly dropped from 78.43% in study 1 (EL$_{MF}$=1.6) to 36% in study 3 (EL$_{MF}$=1/1.6). Similar to study 1, the more elongated figure (which is the baseline figure here) was significantly more often chosen than 50% when EL$_{MF}$=1/1.7 (CS$_{BF}$=75%, Z=2.43, p=.01) and less often selected when EL$_{MF}$=1/2.4 (CS$_{BF}$=26.92%, Z=2.21, p<.05).

In study 3 (n=50), participants saw the same pairs presented one above the other. As expected, the elongation positive effect was reversed. At EL$_{MF}$=1.7 for instance, the choice share for the same more elongated figure dropped from 62.75% in study 1 to 20% in study 3 (Z=2.93, p<.01). Starting EL$_{MF}$=2, although steadily increasing as elongation increases, choice share for the more elongated figure was significantly different from 50%.

In study 4 (n=50), participants evaluated the same pairs of study 2, but presented one above the other. Again, the elongation effect significantly reversed when EL$_{MF}$ =1/2.5 (CS$_{MF}$=28%, Z=2.05, p<.05).

Finally, in study 5 (n=50), study 1 results were replicated with a shampoo bottle image, for the sake of generalizability. The positive effect of elongation on size perception was found when EL$_{MF}$=1.6 (CS$_{MF}$=72%, Z=2, p<.05). This effect reversed more rapidly than with rectangles (starting EL$_{MF}$=2: CS$_{MF}$= 18%, Z=3.16, p<.01).

In conclusion, the elongation bias holds only for levels close to the baseline elongation, when objects are presented side by side (study 1). This effect is reversed at higher levels of elongation due to the hypothesized spatial disposition bias. When objects are rotated by 90 degrees in study 2, the more elongated object in study 1 became the less elongated one. Shifts in choice shares replicate the elongation bias and its boundaries demonstrated in study 1. When objects are presented one above the other (study 3), contrasting width led to a negative effect of elongation at lower levels of elongation difference, which disappeared at higher levels due to the absence of one contrasting dimension. These results were also found after a 90 degrees rotation (study 4). The elongation bias and its reversal were replicated with a more complex shape, where the effect reversed more rapidly than with the rectangular shape in study 5, as expected. These findings add to the cognitive psychology and consumer behavior literatures. They have critical managerial implications in terms of packaging, visual display merchandising, and positioning.

Would Petty Crime Be More Acceptable In The Red Light District? The Effect Of Conceptual Fluency On Moral Judgment

Tine De Bock, Ghent University, Belgium
Mario Pandelaere, Ghent University, Belgium
Patrick Van Kenhove, Ghent University, Belgium

Moral judgments have traditionally been considered as the result of rational and deliberate reasoning processes (e.g., Jones, 1991). More recently, however, scholars have argued that moral decision making is also influenced by intuitive factors (e.g., Reynolds, 2006). Like many other judgments, moral judgments are guided by not only rational thought, but also by feelings that are present at the time of judgment (Schwarz & Clore, 2007). One important class of feelings which influence people's judgments involves metacognitive experiences, which are the experiences that arise during information processing. Conceptual and perceptual fluency are a specific instance of what is called processing fluency (Tulving & Schacter, 1990), a metacognitive experience which refers to the subjective experience of ease versus difficulty while processing information and stimuli. Experiencing fluency evokes a positive affective state which people attribute to the judgmental stimuli they are evaluating (Winkielman, et al., 2003). In particular, perceptual fluency refers to the ease with which people perceive and identify the physical characteristics of stimuli, which can be enhanced through for example figure-ground contrast (e.g., Reber, Winkielman, & Schwarz,

1998). A stimulus is conceptually fluent when its mental representation is easier to activate due to the semantic relatedness with the context in which the stimulus appears (e.g., Whittlesea, 1993).

Considering the role of feelings in moral judgment, we expect feelings that stem from conceptual fluency to affect these moral judgments. In particular, a context associated with something *good* activates the concept of *good* which, in turn, should render the processing of good behavior (i.e., moral behavior) more conceptually fluent. In contrast, a context associated with something *bad* activates the concept of *bad* which should make it easier to process bad behavior (i.e., immoral behavior). The resulting enhanced conceptual fluency (i.e., good behavior in a good context; bad behavior in a bad context) should result in enhanced processing fluency which, in turn, triggers a positive affective state. This positive affect leads subsequently to a more positive evaluation of the good and bad (i.e., moral and immoral) behavior at hand. In sum, people should judge a given moral or immoral behavior more positively when the valence of the context in which the behavior is evaluated matches the valence of the target behavior.

In the current paper, conceptual fluency was manipulated by means of a match versus non-match between the valence (negative vs. positive) of consumer behaviors to be evaluated, and the valence (negative vs. positive) of the background color on which these behaviors were described. In the first study, participants viewed descriptions of (im)moral consumer behaviors on either a red (negative valence) or green (positive valence) background color. We used the colors red and green as these two colors are often used as cues signaling bad and good, respectively (e.g., Dijksterhuis & Smith, 2002). Findings reveal that immoral behaviors were perceived as more acceptable when described on a red (vs. green) background color while the opposite was true for moral behaviors. In the second study, instead of using the "moral colors" red and green, we relied on two colors that were initially perceived as neutral but which were endowed with either a negative or positive valence. Results of this second study confirm those of the first: A match between the valence of the behavior to be evaluated and the valence of the background color on which the behavior appears, renders processing more conceptually fluent. The resulting enhanced processing fluency translates into a positive affective state and, subsequently, a more positive evaluation of the (im)moral consumer behavior at hand.

These results contribute to the literature in at least two respects. First, while moral judgments are traditionally considered to result from rational deliberation, our findings add to the emerging stream of research that shows that these judgments are also affected by more intuitive elements (e.g., Haidt, 2001). Second, most research dealing with processing fluency focused on perceptual fluency. Although perceptual and conceptual fluency are independent, distinct constructs, with each their own unique antecedents and consequences (e.g., Lee, 2002), processing fluency is typically studied through manipulations that trigger perceptual fluency. Nevertheless, processing fluency can also be conceptually driven. While the impact of perceptual fluency has been investigated on a wide array of domains, research on conceptual fluency has been limited (Lee & Labroo, 2004). Our findings therefore add to the limited literature on conceptual fluency. Further, to the best of our knowledge, this is the first research that operationalizes conceptual fluency through a *valence* match between a stimulus and its context, rather than through a semantic association.

Conceptual fluency may also underlie some other recent findings testifying to the impact of intuitive elements in the moral domain. For instance, conceptual fluency may also explain why darkness increases dishonesty and self-interested behavior (Zhong, Bohns & Gino, 2010). In particular, Zhong et al. (2010) found that participants in a room with slightly dimmed lighting cheated more and, consequently, earned more undeserved money than those in a well-lit room. As darkness is often related to badness (Meier, Robinson, & Clore, 2004), dishonest behavior may be deemed more acceptable in a dark room than in a well-lit room (for reasons of conceptual fluency). This may have led to a more positive rate of dishonest behavior.

Given the omnipresent and far-ranging consequences of moral judgment (Hofmann & Baumert, 2010), it is highly important to gain a more comprehensive insight into the various aspects that might influence these moral judgments. This paper shows that conceptual fluency may affect the acceptability of (im)moral behaviors. In addition, our studies show that conceptual fluency may lead to paradoxical effects. For instance, messages to deter undesirable behavior may inadvertently render that behavior more acceptable if some message elements carry a negative connotation (e.g., when written in a red font). In addition, undesirable behavior, like petty crime, may be more likely if the physical environment is evaluated negatively (e.g., Bronx or Red light district). An important goal for future research might be to identify physical elements that promote or prevent (im)moral behavior due to their evaluative connotation.

Social Exclusion and Consumer Product Preferences

Jessie Wang, Indiana University, USA
Shuoyang Zhang, Colorado State Univeristy, USA

Human beings have fundamental needs to feel included and to belong to social groups (Baumeister and Leary 1995). Prior research indicates that socially excluded people have an increased desire to reconnect (Maner et al. 2007). The impact of social exclusion on consumption has attracted consumer researchers' interests in recent years. Mead et al. (2011) suggest that people use consumption to seek potential affiliation when they are excluded. Specifically, the experience of social exclusion increases people's tendency to conform to their potential affiliations' consumption preferences in order to seek inclusion. In the current research, we take a closer look at consumers' reaction to social exclusion and examine whether their conformity behavior is product domain specific.

We propose that excluded consumers conform to their potential affiliations' product preferences only in the value-expressive product domain, and not in the utilitarian product domain. Previous studies have shown that people make inferences about others' social identity and preferences based on their product preferences and purchase decisions (Belk, Bahn, and Mayer 1982; Calder and Burnkrant 1977; Holman 1981). However, people do not infer identities equally in all product domains (Shavitt and Nelson 1999; Berger and Heath, 2007; Belk, 1981). Instead, people are more likely to make inferences or to communicate with others through product preferences in the value-expressive product domain rather than in the utilitarian product domain (Shavitt and Nelson 1999; Berger and Heath, 2007). Mead at al., (2011) have found that high self-monitors align their product preferences to potential affiliations' preferences but not low self-monitors. We thus predict that when excluded consumers are high in self-monitoring they are more likely to conform in the value-expressive domain, to infer identity while seeking inclusion from their potential affiliation, but not in the utilitarian domain.

METHOD

Study 1 was a 3 (social exclusion: exclusion vs. acceptance vs. control) x 2 (product domain: value-expressive vs. utilitarian) x 2 (self-monitoring: high vs. low) mixed factorial design. Social exclusion and self-monitoring were between-subject factors; while product domain was a within-subject factor. The social exclusion manipulation was adopted from Gardner et al. (2000). Participants arrived in the lab for ostensibly separate studies, and they were randomly assigned to one of the three essay conditions: social exclusion, social acceptance, or neutral control. Participants were told to engage in a memory task and asked to write an essay of a personal experience when they either felt excluded, accepted or neutral (a lunch experience). Participants were then led to believe they were engaging in a separate study that was interested in their momentary feelings. They responded to a mood measure using the positive and negative affect schedule (PANAS) scale (Watson, Clark, and Tellegen 1988), which served as our manipulation check on social exclusion.

Following the mood measure, participants were led to believe that the next study was a product evaluation study and they would complete it with an assigned partner. They then were given a sheet that indicates their partners' product preferences on a series of 12 sample products. They were also told that their response would be revealed to the partner before the face to face meeting (Mead et al. 2011). After reading their partners' product preferences, all the participants were asked to choose one of two options for 12 product sets, including 6 in the value-expressive and 6 in the utilitarian domain. The order of the product categories is randomized. For example, in the utilitarian product domain, participants were given choices between two brands of bike light that have similar functionality. In the value-expressive product domain, participants are given choices between two music genres.

After the product evaluation task, participants were told to engage in one more independent study before meeting their partners. All participants were led to believe that the purpose of the next study was to find out how people feel about themselves in relationships with others. We used Snyder and Gangestad (1986)'s revised self-monitoring scale to measure people's self-monitoring levels. Finally, participants were debriefed and released.

RESULTS

74 undergraduate students in a public university participated in exchange for partial course credit. We used the number of participants conformed in each product category as the dependent measure. Consistent with our hypothesis, we found that in the social exclusion condition significantly more participants who are high self-monitors conform to their partners' product preferences in the value-expressive product domain compared to low self-monitors. We did not find such difference in utilitarian product domain.

CONCLUSION

In the current research, we investigate excluded consumers' conformity behavior in different product domains. We identified that consumers' desire to reconnect is more likely to be satisfied in the value-expressive domain. Our finding adds to the current literature by

suggesting that excluded consumers selectively align their product preferences to their potential affiliations' in the specific product domain that communicates their identity most effectively. In future studies, we plan to use different social exclusion manipulation methods to test the robustness of the hypothesis in the first study. We also intend to further explore excluded consumers' consumption behaviors in addition to conformity in the value expressive product domain.

Doing non-transcendent go green: the moderating role of identity on value-behavior relationship.

Diego Costa-Pinto, Reims Management School, France
Adilson Borges, Reims Management School, France
Walter Nique, UFRGS, Brazil
Márcia Herter, Reims Management School, France

VALUES–BEHAVIOR AND THE MODERATING ROLE OF IDENTITY-BASED MOTIVATION

Values are preceded by culture, society and personality, and extant research has shown that value leads to behavioral outcomes (Rokeach, 1973; Schwartz, 1992, 1994). Although numerous empirical studies support a value–behavior relation (e.g., Rokeach, 1973; Schwartz, 1996) the variability of this relationship may be impacted by facilitating or impeding factors, such as construal level (Torelli and Kaikati, 2009). According to situated social cognition perspective, cognition and action are dynamically shaped by contexts (Schwarz, 2007, 2009). In this sense, we argue that the value–behavior relation maybe affected by evoked identities.

Identity-based motivation is the readiness to engage in identity-congruent action (Oyserman, 2007), using identity-congruent mindsets in making sense of the world (Oyserman *et al.*, 2009). As part of the self-concept, the identity presents a basis for making predictions about oneself and about others' response to the self. Personal identities focus on traits, characteristics and goals that are not connected to a social group. The salience of a personal identity facilitates one to construe the situation in terms of values that are relevant to the self, leading to value-congruent judgments and behaviors (Oyserman, 2009). In contrast, when the social identity is salient, the self is contextualized and linked to a social group, which in turn downplay the personal values and increase in-group conformity (Briley, 2001).

DOING NON-TRANSCENDENT PEOPLE GO GREENER

The present study examines the interactional effect of identity and self-transcendence values on green consumption. We suggest that the fit between values and evoked identities can influence green consumption of non-transcendent values. Specifically, we expect that in social (vs. personal) identity situation, people will increase their pro-social evaluations and intentions. This mechanism will change values influence on behavior, doing non-transcendence values take into green consumption.

One hundred and fifty three participants were randomly assigned to one of the four conditions of a 2 values (transcendent vs. non-transcendent) x 2 identities (personal vs. social) between-subjects design. In this study, evoked identities were manipulated using as priming, similarities and differences between family and friends – SDFF (Oyserman and Lee, 2007). Values were chronically accessed by values index: transcendence ($\alpha = 0.714$) - Non-transcendent values ($\alpha = 0.640$; Schwartz, 1992). Transcendence and non-transcendence values were obtained by median split of composite values index. The main dependent variable is the preference for green products. This DV has been

computed by asking subjects to indicate their preference for a green or a non-green option for three product categories (batteries, lamp and backpack) (adapted from Griskevicius *et al.*, 2010).

Manipulation checks were made by self-construal index (Singelis, 1994). A 2x2 ANOVA interaction between values and identity for the manipulation checks was significant (F (1.154) = 6:35, p <.05).

Results show that values and identity have an interactional effect on green consumption, as predicted (F (1, 153) = 10.36, $p <$ .01). As expected, when personal identity was salient, transcendent participants reported more green consumption than non-transcendent participants ($M_{transcendent}$ = 4.92, $M_{non-transcendent}$ = 3.48; $p <$.001). More interesting though, when social identity was salient, participants in both transcendent and non-transcendent values reported similar green consumption intention (M_t = 4.69, M_{nt} = 4.56; *n.s.*). That is, in a social identity, congruent and incongruent values took into more green consumption.

IMPLICATIONS

Our findings indicate the hypothesized moderating role of identity on value-behavior relationship. First, we show that identity salience can change values influence on behavior, increasing green consumption in non-transcendent values condition. In doing so, provide new evidence for values-behavior relation strengthen or weaken factors, using identity-based motivation as a boundary condition (Briley and Wyer, 2001; Torelli and Kaikati, 2009).

Second, although past research indicates that values-behavior congruence will lead to action-readiness (Allen *et al.*, 2008), our results demonstrate that people can take action even under incongruent values-behavior situations. Specifically, we show that non-transcendent values can increase green consumption, when the social identity is activated.

Third, we highlight a new path for research, the value-identity-behavior approach. Specifically, we suggest that personal identity salience reinforce the role that values will have on intention formation. In contrast, social identity reinforces social context, increasing social action-readiness. That can result in more positive green consumption even when values and behavior are incongruent.

One alternative explanation for this mechanism is that social identity can place in evidence the social values systems (Rohan, 2000), increasing social value priorities attachment. Further studies can investigate this possibility.

Going green for friends, family or community?
How different levels of subject norms and identity influence green behavior.

Márcia Herter, Reims Management School, France
Diego Costa-Pinto, Reims Management School, France
Adilson Borges, Reims Management School, France
Walter Nique, UFRGS, Brazil

This paper has two main goals. First, this study aims to examine how the interaction between identity and different subjective norms influences the green behavior. Specifically, it is expected that green behavior, typically a social behavior, produce larger effects in social (vs. personal) identity, because it activates subjective norms. Second, we analyze how different subjective norms influence green behavior. In this sense we investigate whether people go green for friends, family or community.

IDENTITY-BASED MOTIVATION AND SUBJECTIVE NORMS

The identity-based motivation model (IBM) provides an integrative review of how the identity active processes and content (Oyserman, 2009). In this sense, people interpret situations and problems in ways that are congruent with the activated (personal or social) identity. Subjective norms regulate behavior and act as informal social controls (Ajzen, 1991). However, according to the identity-based motivation (IBM), the influence of subjective norms on behavior can be intensified or weakened depending on the evoked identity (Oyserman, 2009). As consequence, when personal identity is evoked, people are less prone to be influenced by norms. However, when the social identity is evoked, norms will present a great importance on behavior. Thus, it is expect that identity has a moderating role in influencing subjective norms.

SUBJECTIVE NORMS LEVELS

Prior research suggests that the self is composed by different levels of inclusion (Markus and Kitayama, 1991). In this sense, Harb and Smith (2008) extend the concept of self-construal (independent and interdependent), suggesting four different layers of the self (personal, relational, collective and humanity). These four levels of self-inclusion can have different importance in consumer decisions.

In this study we investigated how relational and collective subjective norms influence green behavior. According to Goldstein *et al.* (2008) it is expected that relational norms (family and friends) will be more influential on the green behavior than collective norms (community).

In contrast, construal level theory predicts that individuals in an abstract construal were more inclined to perceive their relevant high-level goals (Freitas *et al.*, 2009). In this sense, conversely to Goldstein *et al.* (2008) proposition, people would engage on green behavior when abstract norms are salient (collective vs. relational norms). Then, how these different levels of subject norms and identity influence green behavior?

RESULTS

One hundred and fifty nine participants were randomly assigned to one of four conditions in a 2 (subjective norms: high and low) x 2 (identities: social and personal) design. Three different ANOVA's 2x2 were performed for each of the different subjective norms (friends, family and community). In this study, evoked identities were primed through similarities and differences between family and friends task – SDFF (Oyserman and Lee, 2007). Subjective norms were chronically accessed by green subjective norms items (Van Birgelen *et al.*, 2008). High and low subjective norms were obtained by median split of each norm. The main dependent variable (DV) is the behavioral choice between recycled and regular paper. This measure was obtained when participants chose the second questionnaire booklet between a green or a non-green paper option. The interaction of identity and subjective norms in the choice of paper (recycled) was performed using generalized linear models (GLM) binomial distribution in a logistic function.

First, we analyzed the interaction between identity and relational norms. In contrast to expectations, the interaction between identity and friends norms (Wald χ^2 (1) =.78; *ns*) and between identity and family norms (Wald χ^2 (1) =.78; *ns*) were not significant.

Second, we analyzed the interactional effect of identity and collective norms. Results provide support for this interaction (Wald χ^2 (1) =4.42; *p*<.05). As expected, when a personal identity was salient, community norms had not impacted green behavior (M_{high} = 0.64, M_{low} = 0.68; *ns*). Conversely, when social identity was salient, high norms participants reported more green behavior than low norms participants (M_{high} = 0.84, M_{low} = 0.59; *p*<.01).

CONCLUSIONS

Our findings indicate the hypothesized moderating role of identity on subjective norms activation. Specifically, we show that social identity (vs. personal identity) activates the influence of subjective norms on green behavior.

In addition we investigated how different subjective norms can influence the green behavior. In contrast with predicted by theory (Goldstein *et al.*, 2008), we found that collective (vs. relational) social norms were more influential on the green behavior. In our results, subjective norms were more effective for the layers more distant to the self, increasing the use of recycled paper.

A proposed mechanism for that is social identity activates social goals, making the choice to help the environment something relevant to the communitarian goals (Briley and Wyer, 2001). In one hand, the effects of relational norms (family and friends) would occur in situations where the green behavior could improve the social image for closer social identity. On the other hand collective norms will be more important for green behavior than relational norms because is a typical pro-social behavior. This could be the reason why collective (vs. relational norms) were more important on increasing green behavior.

These unexpected results can open space for new interpretations. One alternative suggested mechanism is that social identity takes into more abstract way of thinking (Eyal *et al.*, 2008). Moreover, Torelli and Kaikati (2009) found that and abstract (and not a concrete) mindset

led participants to engage in behaviors that were consistent with an abstract mindset. Then, we expect that the interaction between an abstract identity (social) and an abstract norm (collective) could lead into more green behavior. Further studies can investigate this possibility.

When Vices Make You Feel Less Guilty Than Virtues:
The Discarding of Vice and Virtue Products

Olivia (Wan-Ting) Lin, Texas A&M University, USA

Most people (93%) are guilty of abandoning products they have purchased but never used (Wansink, Basel, and Amjab 2000). Living in this materialistic society, consumers make daily decisions not only about buying and consuming products but also about disposing of them. Depending on the price and the type of the product, consumers may form differential perceptions and feelings toward its disposal. For instance, discarding a jar of spoiled Russian caviar usually induces more regret than dumping a dozen of rotten chicken eggs. As manifested by the sunk cost psychology (Arkes and Blumer 1985), missing the opportunity benefits of the $300 caviar is generally more painful than failing to reap the benefits of the $3 chicken eggs. However, is trashing a $10 pack of cigarettes the same as discarding a $10 bottle of vitamins? This research investigates if consumers perceive and feel differently about the disposal of two relative goods: a vice (product with immediate benefits and delayed costs) and a virtue (product with immediate costs and delayed benefits) (Wertenbroch 1998). We propose that the discarding of a vice induces less guilt than that of a virtue because the former can be justified as "good riddance" while the latter is regarded as "bad rubbish."

While haste makes waste, so does procrastination. Purchase impulsiveness and consumption procrastination can create huge waste. Owing to their present-biased preferences, consumers are vulnerable to making impulse purchases of vices and putting off the consumption of virtues (e.g., Ainslie 1975; Milkman, Rogers, and Bazerman 2009; Read, Loewenstein, and Kalyanaraman 1999). Thus, decisions regarding the disposal of expired virtues and vices can often confront consumers, who knowingly defer or negligently forget consuming the products, or simply fail to use them because of competing alternatives. For example, many people do their grocery shopping on weekends but barely use their perishables during the week because they are too tired or too busy to cook after work (Jones 2004). Not surprisingly, they eventually find virtues (e.g., broccolis, cabbage sprouts, grapefruits, etc.), vices (e.g., bacon, butter, cake, etc.), or other things go bad in their refrigerators. In fact, "a*s much as 25% of the food we bring into our homes is wasted. So a family of four that spends $175 a week on groceries squanders more than $40 worth of food each week and $2,275 a year,*" estimated Bloom (2010) based on various studies such as the three-decade-long Garbage Project of the University of Arizona. Arkes and Blumer (1985) claim that people fall for the sunk cost fallacy because they do not want to be or appear to be wasteful. Aversion to waste is widely assumed to prevail among consumers (Arkes 1996; Bolton and Alba 2007) because of economic, environmental, religious, ethical, psychological, or other reasons (Lastovicka et al. 1999; DeYoung 1986). Nevertheless, wasteful consumption of foods and other goods remains a tough global challenge (UNEP 2011).

This research first adopts a "refrigerator cleaning" scenario to test if consumers feel differential when finding a bag of rotten grapefruits (expired virtue) and a box of stale chocolate cake (expired vice) in their refrigerators. We employ a within-subject experimental design in which the sequence of the products is counterbalanced. For checking the effects of different price levels, we randomly assigned our college student participants to three price conditions. The first condition provides no price information, while the second (third) indicates $5 ($10) for each product. We ask our participants to imagine being in the scenario, answer Likert-scale questions about their guilt levels for the discarding of each product, and then explain why they feel so in an open-ended question. They also rate how enjoyable or beneficial they normally think about the consumption of fresh grapefruits and chocolate cakes. After rating their preference for some filler pictures for distraction purposes, participants are presented a grocery shopping scenario and are asked their intention for purchasing grapefruits or chocolate cakes. Finally, participants respond to some basic demographic questions and are thanked for their participation.

Our results show that consumers generally feel less guilty about the disposal of a vice than that of a virtue. Guilt levels do not vary significantly across the three price levels or account for the variances of repurchase intention. Perceived hedonic (e.g., enjoyable) and utilitarian (e.g., beneficial) values do predict the guilt level and the repurchase intention. The more consumers perceive the product as enjoyable or beneficial, the higher their guilt levels for its discarding and the stronger their repurchase intentions for the product.

Belk (1988) argues that consumers' possessions play an important role in shaping their self-concept. Consumers may acquire (Richins 1994) or discard (Roster 2001) products to express or reinforce their sense of self. Hence, in the parlance of mental accounting theory, both virtue and vice buyers may regret their monetary loss. However, vice buyers may mentally label the expired vice as "good riddance", something that was harmful and had better be thrown away. Some of the vice discarders might even feel a slight joy because of the illusion that they might have exerted self-control to resist the consumption of the vice. Conversely, virtue buyers may label the expired virtue as "bad rubbish", something that was valuable and beneficial and should not have ended up in a trash bin. Virtue buyers may regret their consumption procrastination, waste of money and resources, and failure to reap the benefits of the virtue product. A purchase decision, originally intended to better the consumers' *actual selves*, seems to expose their failure to live up to their *ought selves* and push them farther away from their *ideal selves*. As a result, a vice discarder feels less guilty than does a virtue discarder although they both paid the same price to acquire the products.

Facets of Distress Tolerance as Predictors of Buying in Response to Self-esteem Threats

Paul Rose, Southern Illinois University Edwardsville, USA
Dan Segrist, Southern Illinois University Edwardville, USA

Many people use buying as a means of coping with emotionally-distressing events. One type of emotionally-distressing event that may be particularly likely to lead to buying is self-esteem threat. Buying can serve important identity-regulation functions (Dittmar, 2004) and an enormous social psychological literature suggests that threats to self-esteem lead to defensive responses (e.g., Tesser, 2001). In consumerist cultures in particular, "retail therapy" may be used to restore a desired identity following self-threat.

One purpose of the present study is to identify who might be especially prone to buying in response to threatened self-esteem. Our focus was on individual differences in distress tolerance, a variable that has begun to attract attention in the addictions literature because of observations that some people use substances as a means of coping with negative emotions. Simons and Gaher (2005) define distress tolerance as "the capacity to experience and withstand negative psychological states" (p. 83). They further conceptualize distress tolerance as encompassing four facets—tolerance, regulation, appraisal, and absorption. Tolerance refers to the degree to which an individual considers aversive emotions intolerable and unmanageable. Regulation involves a tendency to engage in behaviors to avoid or distract oneself from distress. Appraisal is an individual's perception of the acceptability of negative emotions and self-perceived ability to deal with them. Absorption refers to the degree to which an individual becomes preoccupied with and dominated by aversive emotions.

To support the prevention and treatment of excessive buying problems, we focused our analysis of self-threat-induced buying on the facets of distress tolerance. By doing so, we hoped to identify specific, malleable beliefs that might promote or inhibit self-threat-induced buying. Of the facets, it seemed to us that *regulation* would be a particularly important predictor because people who believe that action must be immediately taken to alleviate distress might be most prone to making rash purchases in order to feel better.

METHOD

One-hundred-fifty-eight college students (70% female) wrote about two personal events from the last year, a minor self-esteem threat and a major self-esteem threat. (Order of these two event descriptions, which were adapted from Campbell, Baumeister, Dhavale & Tice, 2003, was counterbalanced. We asked about both event types to explore the generalizability of effects across experience intensity.) Participants then reported (within a table that listed numerous post-event coping behaviors) the degree to which they bought things to make themselves feel better (1 = not at all, 7 = very much). After several filler measures, participants completed the 15-item Simons and Gaher (2005) Distress Tolerance Scale, which includes tolerance, regulation, appraisal, and absorption subscales.

RESULTS

Because participants described a major and a minor self-esteem threat and what they did to make themselves feel better after these events, major vs. minor event was treated as a within-participants factor. The distress tolerance subscales were between-participants factors. Thus, the results were analyzed with a mixed-model, hierarchical multiple regression analysis (Judd, 2000). Order of event description (major event first vs. minor event first) and sex were entered in a first block but neither of these predictors was significant. Tolerance (β = -.17), absorption (β = .24), appraisal (β = .11) and regulation (β = .29) were added in a second block. Absorption produced an unexpected marginally significant main effect (p = .07) and, as predicted, regulation produced a significant main effect (p = .01). Interaction terms for appraisal (β = -.28) and regulation (β = .21) approached significance (.05 > p's <.06) because the associations between the appraisal and regulation predictors and self-threat-induced buying varied in strength across major and minor events. (Unexpectedly, the association between appraisal and buying in response to a minor self-esteem threat was strong enough to reach significance, β = .21, p = .04. We hesitate to interpret this finding because it is not clear why appraisal should matter only when a self-threat is minor.) However, the slopes for appraisal and (most importantly) regulation were uniformly positive. The most noteworthy results for understanding buying in response to self-threat, therefore, are the marginally significant main effect of absorption and the significant main effect of regulation.

DISCUSSION

Averaging across major and minor events, the regulation facet of distress tolerance (i.e., the belief that distress must be alleviated through urgent action) emerged as an important predictor of buying in response to self-esteem threat. Lynch and Mizon (2011) have pointed out that the appraisal, absorption, and tolerance components of distress tolerance focus on internal cognitive and emotional processes but regulation focuses on behavior—"the tendency to act with urgency to avoid feeling upset" (p. 61). The emergence of regulation as a significant predictor suggests that some consumers with excessive buying problems may be helped by learning to think of occasional self-esteem threats as normal life events rather than crises. They may also be helped by learning that if quick action really is necessary to feel better, there are healthier options than making rash purchases (such as seeking social support).

Future research may confirm that absorption, which was a marginally significant predictor in our analysis, also plays an important role in self-threat-induced buying. It may be that some consumers feel so overwhelmed by threats to their self-esteem that they struggle to think of the many coping options available to them. If this is true, consumers with excessive buying problems may benefit from practicing more flexible thinking (e.g., "I feel terrible about myself, but I can call my friend or get some exercise rather than going shopping").

The Fluency of Consumer Incidental Emotion on Nine-Ending Prices

Shih-Chieh Chuang, National Chung Cheng University, Taiwan
Yin-Hui Cheng, National Taichung University of Education, Taiwan
Chia-Jung Chang, National Chung Cheng University, Taiwan
Molly Chien-Jung Huang, National Chung Cheng University, Taiwan

Previous studies on nine-ending prices have focused on level effect, which results in an underestimation of the magnitude perception of a price and leads consumers to lower purchase intentions (e.g., Manning and Sprott 2009). However, level effect can only explain the degree of influence on nine-ending effect, but can not explain the reasons why some studies showed inversing results on purchasing intentions. In order to clarify such condition, researchers consider that price-image and quality-image effect may be regarded as other possible reasons. In these studies, researchers merely focus on the influence of cognitive effort, but ignore the importance of incidental emotion.

Therefore, first, this article argues that the asymmetric effects of positive and negative emotion on nine-ending prices influence the level effect via the cognitive processing of information. People experiencing a positive emotion are likely to engage in high processing fluency,

and will ignore, or give very little attention to the ending digits of a price. For example, an item priced at $2.99 will be viewed as priced at $2.00. In contrast, people experiencing a negative emotion may engage in effortful and low processing fluency of information, which results in highly accurate price cognition. In the case noted above, such individuals will perceive the price to be $2.99 rather than $2.00.

Second, this emotional effect will also produce image effects that influence purchase intention related to nine-ending prices. Positive emotion is associated with price image effects and negative emotion is associated with quality image effects. When people experience a positive emotion, a high processing fluency will induce them to recall various pleasant events in and view an event in a positive way. In other words, they will view a nine-ending price as the retailer giving a small amount back to the consumer (price image effect), and providing therefore an opportunity to buy the product for less, which will greatly increase their purchase intention. In contrast, when experiencing a negative emotion, consumers will view the nine-ending price as a signal of inferior quality or an indicator of the quality loss (quality image effect), which will reduce their purchase intention. In order to demonstrate our hypotheses, four studies are investigated.

Study 1: 1a and 1b

The purpose of Study 1a is to test whether prices ending in different digits (rightmost effect) results in different purchase intentions in consumers experiencing positive/negative emotional states that are induced by the recalling method adapted from Smith and Ellsworth (1985). In order to extend the generalizability of our findings, Study 1b further explores if the different emotional induction method adapted from Forgas and Ciarrochi (2001) has the same influence on leftmost effect, and demonstrates the mediating role of processing fluency.

Both of Studies 1a and 1b use 3 (emotion: positive, neutral and negative) x 2 (digit: nine, zero) between-subjects designs. A total of 240 undergraduate students from a large southern university are randomly assigned to Studies 1a and 1b, and are paid $5.

As we expected, no matter what emotional induction methods are used, the analysis reveals a significantly robust effect of incidental emotion on both of rightmost and leftmost effect. Besides, the mediation analysis of processing fluency is also supported.

Study 2

The purpose of Study 2 is first to examine the moderating role of processing fluency manipulated by writing down two or ten reasons adapted from Novemsky et al. (2007). Second, Study 2 tests if consumers with positive (negative) emotions will evaluate the extent of the perceived monetary gain is greater (less) than the extent of the perceived quality loss.

Study 2 use 3 (emotion: positive, neutral and negative) x 2 (digit: nine, zero) x 2 (fluency: high, low) between-subjects designs. A total of 240 undergraduate students from a large southern university are randomly assigned to Study 2, and are paid $5 for their participation. As expected, the analysis proves all of the inference.

Study 3

According to the results of Studies 1a, 1b, and 2, one possible question may occur: Do all positive or negative emotions have the same influence on nine-ending price effect? To solve this question, Study 3 manipulates certainty versus uncertainty emotions as Tiedens and Linton (2001). Besides, quantitative estimations developed by Bizer and Schindler (2005) with the nine-ending prices are also examined to avoid two major causes of failures in research into the nine-ending pricing effect. These two causes are high variation among open-ended responses in free-recall tasks and unrealistic conditions.

Therefore, Study 3 uses 2 (valance: positive, negative) x 2 (certainty: certainty, uncertainty) x 2 (digit: nine, zero) between-subjects designs to examine the inference. A total of 160 undergraduate students from a large southern university are randomly assigned to Study 3.

As expected, the analysis demonstrates that the differences of quantitative estimations for individuals in the certain emotion condition induced high processing fluency are greater than in uncertain emotion condition induced low processing fluency, when people have positive emotions, compared to those who have negative emotions. Combined with the results of Studies 1a, 1b, and 2, incidental emotion undoubtedly can be classified as an important role on the nine-ending price effect.

The Influence of Humor on Sharing

Caleb Warren, Bocconi University, Italy
Jonah Berger, University of Pennsylvania, USA

Consumers frequently share content through email, text messages, Facebook, Twitter, and other forms of social media (Allsop, Bassett, and Hopkins 2007). Because social transmission has a powerful influence on attitudes, product adoption, and sales (Asch 1956; Chevalier and Mayzlin 2006; Godes and Mayzlin 2009), understanding why some content is shared and other content is not is important for marketers and consumers researchers.

We investigate if and when humor influences the likelihood that something is shared. There are at least two reasons to suspect that humor increases sharing. First, consumers share content as a way to build and maintain social relationships, and research suggests that humor is an effective way to invite further social interaction (Martin 2007). Second, humor typically involves a positive emotional response to potentially negative stimuli (McGraw and Warren 2010; Ramuchandran 1998; Veatch 1998). Consequently, humorous content may be shared more both because negative information attracts more attention than positive information (Baumeister et al. 2001) and because consumers are more likely to share content that elicits positive rather than negative emotions (Berger and Milkman 2011).

The benign violation theory argues that humor occurs when a violation simultaneously seems benign (Warren and McGraw 2010). Violations are threats to your beliefs about how things should be (Veatch 1998). They include threats to physical well-being (e.g., attacks), self-concept (e.g., insults), social norms (e.g., flatulence), cultural norms (e.g., not wearing pants), linguistic norms (e.g., unusual accents), and moral norms (e.g., bestiality). In order to be humorous, violations must simultaneously seem benign, or okay. Three factors that increase the benignity of a violation are: (1) alternate norms suggesting the violation is acceptable, (2) weak commitment to the violated belief, and (3) psychological distance from the violation (McGraw and Warren 2010). We predict that the violation severity (i.e., the extent to which something seems wrong) and benignity (i.e., the extent to which it seems okay) of content jointly determine its humorousness and that more humorous content is more frequently shared than less humorous content.

Our first study investigated the relationship between violation severity, humor, and sharing in a sample of Youtube videos. Importantly, these videos are psychologically distant. Most are hypothetical and nearly all portray other people at some other place and time. Consequently, we suspected that the videos would seem benign and that the ones depicting more severe violations would be funnier and, thus, shared more often (i.e., have a high number of views) than videos depicting milder violations.

We assembled a sample of 76 videos by using two generic pronouns as search words on youtube.com: "the" and "a." Trained coders rated the level of humor ($\alpha = .694$) and violation severity ($\alpha = .751$) in each of the videos. The number of views was highly skewed, so we took its log as the main dependent variable. As hypothesized, videos with more severe violations were seen as more humorous (b = .46) and were shared more frequently (b = .36). Further analysis using Preacher and Hayes's (2008) bootsrapping algorithm shows that humor mediated the effect of violation severity on sharing (mean indirect effect = .31; 95% CI = .14 to .61).

While these results indicate that more severe violations are shared more, this strategy may not apply when content feels psychologically closer. When psychologically close, severe violations may be difficult to see as benign, and, thus, seem less humorous than milder violations (McGraw and Warren 2010; McGraw et al. 2011). Consequently, violation severity might decrease the virality of psychologically close content, like a text message from a friend.

We tested this by asking 93 student participants to rate the violation severity, humor, and their likelihood of sharing several text messages posted on a website (socially distant condition) or sent by a friend (socially close condition). As expected, when the texts were ostensibly from a friend, milder violations (e.g., "tell me why there is a bowl of oatmeal from starbucks in my purse") were seen as more humorous ($M = 5.3$ vs. 2.1) and were more likely to be shared ($M = 4.0$ vs. 1.9) than severe violations (e.g., "He waited till after we had sex to tell me he had herpes… Ugh I hate being drunk"). However, when the texts were ostensibly on a website, there was little difference between the mild and severe violations on perceived humor ($M = 3.4$ vs. 2.6) or sharing ($M = 2.9$ vs. 2.5). We suspect that unlike the Youtube videos in the previous studies, the severe text messages may not have seemed benign even at a distance.

Another important question is *when* does humor increase sharing? Because perceptions about what is wrong (i.e, a violation) and what is okay (i.e., benign) vary considerably across individuals, not all consumers share the same sense of humor. Consequently, the recipients of shared content may not find the same things humorous as the sender, and this is especially likely when the recipient and sender are dissimilar. Recipients may fail to perceive humor in transmitted online content either because they do not perceive a violation (benign content) or because they perceive a violation that does not seem benign (malign violation). Because the costs of sharing a failed humor attempt are likely higher for malign violations than for benign content (Warren and McGraw 2011), we suspect that consumers will be hesitant to share severe violations with dissimilar recipients even when they personally consider the violations humorous. Thus, we also plan to investigate whether the recipient of the shared content moderates the relationship between humor and sharing.

Consumers often share content that they find humorous, and humor depends on the consumer's perception that a violation is benign. Consequently, the severity of a portrayed violation, the consumer's psychological distance, and the consumer's similarity to the intended recipient jointly influence the likelihood that something is shared.

Can I Pay More?: The Moderating Effect of Gender and Self-Esteem Following Consumer Rejection

Hamed Aghakhani, University of Manitoba, Canada
Kelley Main, University of Manitoba, Canada
Fang Wan, University of Manitoba, Canada

Human beings look to communicate with others and to belong to a group. Unfortunately, though, there are many situations that make people feel rejected and, therefore, feel pain and sadness (Blackhart 2009). Rejection occurs when a person is deliberately excluded by a group (Blackhart 2009). Some cosumer researchers demonstrated that rejected consumers are more conservative with their spending (Baumeister et al. 2005), but others evidenced that excluded consumers spend their money more selectively and more lavishly (Mead et al., 2011). Excluded consumers tend to spend more for products that are more symbolic and enhance their group membership. Further, excluded people are willing to spend money on products that enhance their feeling of acceptance and attractiveness (Baumeister et al. 2005, Mead et al. forthcoming). The goal of this research is to investigate the boundary conditions of whether exclusion affects spending positively and negatively. We particularly examined the moderating effects of self esteem and gender, two understudied factors in prior research.

The literature reveals that consumers use their money to impress others and as a way to enhance their status with friends and other groups (Ariely and Levav 2000; Berger and Heath, 2007). This idea leads excluded persons to spend their money to gain social status, so there is a trade-off between one's social well-being and one's monetary well-being (Baumeiseter and Leary, 1995). Also from the literature, it is known that social exclusion reduces a person's level of self-regulation (Baumiester et al., 2005). Based on this, it is presumed that impaired self-regulation leads to spending money unwisely. Although higher levels of self-esteem do not guarantee better performance and success, people with higher self-esteem have greater self-regulation (Baumiester et al., 2005). From the previous research, it is known that social exclusion can lead to a decrease in self-regulation (Baumeister et al. 2005) and lower levels of self-regulation may lead consumers to spend more.

In addition to the effects self-esteem may have on consumer's spending following rejection, the literature suggests gender may also play a moderating role. Research on gender differences with respect to positive and negative emotions revealed that men and women have equal levels of happiness towards stimuli (Myers 1993), but regarding sadness, it seems that women are more willing to show sadness and negative emotions than men (Fujita, Diener and Sandvik 1991). In addition women not only show more negative emotions regarding unpleasant events, but also have a greater tendency to ruminate in comparison to men, therefore causing difficulties in solving current problems (Nolen-Hoeksema, Larson and Grayson 1999). When consumers are rejected, this negative event requires a solution, a way to repair one's negative feelings. Therefore, it is expected that women will be more likely than men to experience negative emotion following a rejecting event. However, this response is expected to be moderated by self-esteem.

Therefore, it is expected that when women with higher self-esteem face rejection, they will try to boost their negative emotion by spending money for products, but women with lower self-esteem will be less likely to make a significant attempt to overcome this negative emotion through spending. In comparison with women, the influence of rejection on men will be attenuated.

EXPERIMENT

This study was a 2 (rejection: yes vs. no) × 2 (Self-esteem: high vs. low) × 2 (gender: female vs. male) between-subjects design with a total of 155 participants (49% Male and 51% Female). Rejection was manipulated by asking participants to imagine an interaction with a salesclerk where they were going to buy a jacket and all participants receive a store credit card offer from clerk. Half of the participants were told that they applied for the store credit card and then after a few minutes the clerk tells them they were rejected (rejection) and the other half of participants were told that they decided not to apply for the store credit card (no rejection). Self-esteem was measured through a self-report scale (Rosnberg 1965). Individuals were categorized as high or low in self-esteem by a median split. The dependent variable was participant's willingness to pay for a small household appliance (a toaster).

The results showed a significant main effect of self-esteem $(M_{high}= 21.64, M_{low}=17.62, F(1,154)=5.222, p<.02),$ and a marginally significant effect of gender $(M_{male}=32.080, M_{women}=36.06, F(1,154)=3.57, p<.061).$ The results also revealed marginally significant interaction between self-esteem and rejection $(F(1,155)=3.656, p<.058),$ self-esteem and gender $(F(1,155)=3.606, p<.060),$ and a marginally significant three way interaction $(F(1,155)=3.635, p<.059).$ Further simple effect analysis revealed no interaction effect for men $(p>.9),$ but a significant interaction for women $(F(1,80)=6.055, p<.016).$ As expected women with high self-esteem were willing to pay a higher price for the appliance, whereas low self-esteem women showed no significant difference in the amount of money they were willing to pay.

GENERAL DISCUSSION

The present research contributes to the literature by demonstrating the interactive effects of gender and self-esteem on consumer spending behavior. Future research in this area can examine other product categories in addition to examining the effects of rejection on people's risky behavior (e.g.: investing in the stock market). Furthermore it is important to compare the effects of rejection with exclusion and inclusion as well as comparing different types of rejection (e.g.: interpersonal vs. romantic) and the subsequent influence on consumer behavior.

Moral dynamics in consumer behavior – the moderating effect of ethical frameworks

Gert Cornelissen, Universitat Pompeu Fabra, Spain
Michael Bashshur, Universitat Pompeu Fabra, Spain
Julian Rode, Universidad Autónoma de Barcelona, Spain
Marc Le Menestrel, Universitat Pompeu Fabra, Spain

The ethical dimension of consumption has gained prominence in the light of the ecological and economical crisis we currently suffer. In recent years, the dynamics of moral behavior has received much attention, including in marketing and consumer behavior literature (e.g., Khan & Dhar, 2006; Mazar, Amir, & Ariely, 2008). Moral balancing (Nisan, 1991), refers to the observation that engaging in a moral behavior at one point in time reduces the likelihood of doing so in a subsequent situation (Effron, Cameron, & Monin, 2009; Merritt, Effron, & Monin, 2010; Sachdeva, Iliev, & Medin, 2009). For example, after committing to helping a foreign student, participants in a study donated less money to charity (Khan & Dhar, 2006). Other studies, however, demonstrate the opposite phenomenon, something we can refer to as moral consistency. For example, in a study by Gino, Norton, and Ariely (in press), participants who wore counterfeit sunglasses were more likely to cheat on a number of tasks, compared to participants who wore branded sunglasses. These examples show that previous behavior may have opposite effects on current decisions. In the current paper, we investigate whether the ethical frameworks or mindsets one uses – thinking of moral behavior in terms of consequences versus in terms of rules or principles – moderates whether initial behavior will lead to moral balancing or moral consistency.

Two prominent frameworks in (Western) moral philosophy are deontological and consequentialist ethics. We predict that an outcome-based mindset (i.e., consequentialism) favors a moral balancing effect. Thinking in terms of outcomes allows the individual to make tradeoffs involving the moral self, which may demand acting in the interest of others, and immediate self-interest, and make flexible computations regarding the current status of the moral self. After choosing an ethical course of action which benefitted mostly others, the individual feels licensed to compensate and benefit the self. On the other hand, we expect that rule-based thinking (i.e., deontology) will favor a moral consistency effect. In general, rules are less flexible to be traded off with selfish benefits (Baron & Spranca, 1997; Tetlock, Kristel, Elson, Green, & Lerner, 2000). Inconsistency regarding following (ethical) rules would threaten an individual's personal integrity (Festinger, 1957). Therefore, we predict that individuals, when in a rule-based mindset, are more likely to behave morally consistent.

To test this hypothesis, we asked our participants to remember an episode in the past in which they did an (un)ethical thing. By defining ethics in terms of consequences or rules we brought them in a consequential or deontological mindset. We then observed whether participants subsequently behaved consistent with the act they recollected from their past, or whether they showed a balancing effect. We manipulated Ethical Framework (deontological versus consequential) and Valence of an initial act (positive or negative). To do so, we asked half of our participants to remember an episode in the past where they did something ethical, and we asked the others to think about something unethical they did. Half of the individuals in each group were instructed to think about a behavior that was (un)ethical "*because it benefitted/hurt other people*" (i.e., the Consequential condition). The others thought about a behavior that was (un)ethical "*because you did (not) do your duty to follow an ethical norm or principle*" (i.e., the deontological condition).

As a dependent measure, we used a modified Prisoner's Dilemma Game (PDG; Smeesters, Warlop, Van Avermaet, Corneille, & Yzerbyt, 2003). We performed a two-way ANOVA with Moral Framework (deontological versus consequential) and Valence of the recollected behavior (positive or negative) as between-subject factors and number of coins given in the PDG as the dependent variable using. We did not find a main effect of Moral Framework or Valence, but we did find a significant interaction effect of both factors ($F(1, 87) = 9.53, p < 0.01$). When participants were successfully instructed to be in a consequentialist mindset, they gave more coins in the PDG if they recalled a moment in the past in which they behaved unethically ($M = 2.89, SD = 1.71$) than those who recollected an ethical act ($M = 1.77, SD = 1.97; F(1, 87) = 5.05, p < 0.03$). In other words, those participants who were in an outcome-based mindset showed a moral balancing effect. When participants were brought into a deontological mindset, they gave more coins in the PDG if they had recollected an ethical act ($M = 2.74, SD = 1.52$) than when the recalled an unethical act ($M = 1.71, SD = 1.24; F(1, 87) = 4.48, p < 0.04$). In other words, these participants showed a moral consistency effect. For participants who were asked to remember an ethical act in the past, those who were in a consequentialist mindset gave less yellow coins than those in a deontological mindset ($F(1, 87) = 3.89, p = 0.05$). For participants who were asked to remember an unethical act in the past, those who were in a consequentialist mindset gave more yellow coins than those in a deontological mindset ($F(1, 87) = 5.72, p < 0.01$).

The study supported our hypothesis that a consequentialist, outcome-based mindset leads to moral balancing and a deontological, rule-based thinking mindset leads to moral consistency. This finding provides an interesting suggestion to explain the inconsistent findings in the recent literature on moral dynamics. Many of these articles indeed employ a rather consequential definition of ethical behavior, and therefore may present a somewhat distorted view on the moral dynamics of everyday life. In some cases an individual's behavior might be preceded by rule-based reasoning about how to interpret their previous behavior.

Status-relevant cues and conspicuous consumption – the moderating role of prenatal androgen exposure

Xavier Palacios, Universitat Pompeu Fabra, Spain
Gert Cornelissen, Universitat Pompeu Fabra, Spain

Consumer psychologists have suggested that individual differences exist between people regarding their need to display status (Stenstrom et al., 2010), and some of them seem to be grounded in biological mechanisms (Miller et al., 2007; Griskevicius et al., 2007). We investigated how status-relevant experiences influence an individual's need to display status. We contrasted two types of status-relevant experiences. Both provoke the activation of a status goal, but in one case the goal of attaining a dominant status was achieved (i.e., football supporters vicariously experiencing a victory of their preferred team; Bernhart et al., 1998), and in another such a goal remained unsatisfied (i.e., individuals on their way to the beach). We also tested the moderating effect of exposure to prenatal androgens on the response to these experiences. In previous studies, Digit Ratio (i.e., the ratio of the length of the index finger (2D) compared to the ring finger (4D); DR) has been negatively related to the prenatal level of testosterone (Manning, 2002; Hönekopp et al., 2007). Low DR is associated with more com-

petitive and dominant behaviors in humans (Manning, 2002; Millet, 2009). Therefore, we expect that the effect of status-relevant experiences on status oriented behavior will be more pronounced in low DR individuals.

In a first study, we randomly approached 51 individuals on their way to ($N = 19$), or going home from ($N = 32$), a popular beach, located in the vicinity of a large size cosmopolitan city. Their age varied from 15 to 47 (M = 26, SD = 10.9); 29 participants were male and 22 were female. We expected those who are on their way to the beach to anticipate being exposed to "hot stimuli" (Van den Berg, 2008). The anticipation of such a mating cue activates a goal to display status (Jansens et al., 2010). We measured participants' goal to display status using a visual recognition task. An activated goal leads to a perceptual "readiness" to recognize those items that may help the individual to achieve that goal (Roskos-Ewoldsen and Fazio, 1992). Therefore it is assumed that a higher need to display status will lead to faster recognition of luxury consumer products. Participants were asked to look at ten displays which appeared on the screen for 1 second. Each display contained five different products, one of which was a luxury product. After being exposed to each display, participants were given the time to write down which objects they had recognized.

Based on the number of luxury products that participants recognized, we created an index for the *Goal to Display Status*. We performed a two-way ANCOVA on this index including the discrete variable Status Cue (on the way to the beach versus going away from the beach), and the continuous variable DR as predictors. The analysis revealed a marginal interaction effect between the presence of a Status Cue and DR ($F(1, 43) = 3.36$, $p = 0.07$). In the control condition, we do not find a correlation between DR and attention to luxury products (r(29) = 0.07, ns), whereas there was a correlation when participants are going towards the beach (r(16) = -0.48, $p < 0.05$). This suggests that when a status cue is present, those with a lower DR have a larger need to display status, resulting in recognizing more luxury products.

In a second study, we tested whether we would replicate the pattern of data of Study 1 in a context where the status-relevant experience provides a satisfaction of the status goal. We invited 56 university students to participate in a lab experiment (23 males and 33 females). Half of our participants viewed a compilation of videos in which their favorite football team won an important match against their strongest rival (Madrigal et al., 2008). It has been shown that the testosterone level of football supporters increase when they see their favorite team win (Carré, 2009). Previous research has further demonstrated that testosterone levels influence the tendency to display status through the purchase of luxury products (Janssens et al, 2010). In the control condition, participants did not see any video. Then participants in both conditions completed the recognition task we used in Study 1. We performed a two-way ANOVA on this *Goal to Display Status* index including the variables Status Cue (video versus no video) and DR (high versus low). We find an interaction effect of both variables on the proportion of luxury products recognized ($F(1,37) = 7.26$, $p = 0.01$). In the control condition, participants with a low DR (M = 0.17, SD = 0.06) indentified fewer luxury products than those with a high DR (M = 0.21, SD = 0.03). The effect was marginally significant ($F(1,37) = 3.50$, $p < 0.07$). In the Status Cue condition, after being exposed to the two videos, participants with a low DR (M = 0.21, SD = 0.06) see more luxury products than those with a high DR (M = 0.17, SD = 0.05). This difference was marginally significant ($F(1,37) = 3.83$, $p < 0.06$). The status cue had a significant effect on participants with a low DR ($F(1,37) = 4.00$, $p = 0.05$). After being exposed to the status cue, they recognized more luxury products than in the control condition. The reverse is true for participants with a low DR. After being exposed to the status cue they recognized less luxury products than in the control condition. This effect was only marginally significant ($F(1,37) = 3.30$, $p < 0.08$).

In both studies an individual difference variable (i.e., exposure to prenatal androgens) moderated the effect of status cues on individual's tendency to achieve and display status. Our findings suggest that cues that activate a status goal, whether or not the status goal is satisfied, increase the need to achieve and display status, but only for individuals who received higher levels of prenatal androgens. Follow-up studies that extend these findings are currently ongoing and will be completed by the date of the conference.

Multicomponent Bundle Pricing: Partitioned or Consolidated Presentation?

Marit Gundersen Engeset, Buskerud University College, Norway
Birger Opstad, Buskerud University College, Norway

Product bundling is a pervasive marketing strategy across industries. Managers choose between two forms of price presentations; assign price tags for each item (partitioned pricing), or present the bundle with one single price tag (consolidated pricing). Economic theory predicts that price presentation should not affect evaluation as long as the total price is identical. However, a growing body of literature shows that price presentation influence consumer evaluation of product bundles (Hamilton and Srivastava 2008). Bundles with partitioned price presentations are preferred over identical offerings with consolidated presentations (Chakravarti et al. 2002), but a variety of context factors may influence how consumers attend to and process price information (Suri and Monroe 1999), and partitioned pricing may not be the optimal strategy in every situation. In this research we build on the empirical law of sensation (Stevens 1985) and propose that the size of the bundle (i.e., number of items) will moderate the effect of price presentation on evaluation. This law states that a percentage change in objective magnitude leads to the same percentage change in subjective magnitude – implying that estimations increase at a slower rate than do actual magnitudes. When presented with a bundled offering, consumers will evaluate its price relative to an expected price – and following the law of sensations, it is likely that the expected price will be relatively smaller for bigger bundles. When the price is partitioned, the consumer will evaluate the offering relative to the expected price for each individual item which will be more accurate than if they are to compare the actual price to an expected price for a consolidated bundle. When presented with an offering, the consumer is likely to evaluate the offering more positively if its price is perceived as equal to or lower than the expected price. Hence, we propose that consumers will evaluate a partitioned offering more favorably than a consolidated offering, and that this effect will be stronger for larger bundles.

We report two experiments testing our predictions. In the first experiment 67 participants were presented with a vacation offering consisting of 2 (small bundle) or 6 (large bundle) products, and the prices were given as one price tag (consolidated) or individual tags (partitioned). Then they evaluated the offering on a 3-item scale (α=.92). The results showed a marginally significant difference in evaluation depending on bundle size (M_{small}=4.39, M_{large}=3.79; $F(1, 66) = 3.39$, $p <.1$), and no difference in evaluation depending on price presentation ($M_{consolidated} = 3.85$, $M_{partitioned} = 4.33$, $F = 2.15$, NS). We found a significant effect of the size x presentation interaction on evaluation ($F(1, 66) = 4.75$, $p <.05$). For the large bundle, the partitioned offering was evaluated best ($M_{partitioned} = 4.77$, $M_{consolidated} = 3.27$), while there was no difference in evaluation for the small bundle ($M_{partitioned} = 4.69$, $M_{consolidated} = 4.71$). These results support our predictions that bundle size moderates the effect of price presentation on evaluation. We proposed that this effect would be due to relatively lower price expectations for larger bundles. In experiment 2 the price was not presented up front, instead 70 participants were asked to guess the price of either the consolidated offering (guess one price) or the partitioned offering (guess one price for each product in the bundle). After guessing the price, they evaluated the offering on the 3-item scale ($\alpha= .90$), and after answering questions about demographics, they were informed about the actual price and asked to evaluate the offering again. Average relative difference between actual and expected price was calculated to form a measure of discrepancy from actual price for each offering. Difference in average discrepancy depending on price presentation was marginally significant ($M_{consolidated} = 33\%$, $M_{partitioned} = 22\%$, $F(1,69) = 3.93$, $p <.05$), but there were no difference in discrepancy depending on bundle size ($M_{large} = 32\%$, $M_{small} = 23\%$, $F(1,69) = 2.39$, NS). We found a significant effect of size x presentation interaction on discrepancy ($F(1,69) = 4.06$, $p < .05$). The actual price for the large bundle was NOK 7476, and there was a big difference in average price guessed depending on price presentation ($M_{consolidated} = $ NOK 4667, $M_{partitioned} = $ NOK 7800). For the small bundle, the actual price was NOK 4820, and the differences in guessed price was smaller ($M_{consolidated} = $ NOK 4027, $M_{partitioned} = $ NOK 5441). This supports our predictions that prices are expected to be lower for consolidated than partitioned offerings, and that this effect will be stronger for larger bundles. We expected participants to evaluate the offering with their expected price in mind. There was a significant size x presentation interaction effect on evaluation ($F(1,69) = 4.70$, $p < .05$), for the large bundle, the partitioned offering was evaluated lower than the consolidated ($M_{consolidated} = 5.02$, $M_{partitioned} = 3.96$), for the small bundle the difference in evaluation was much smaller and in the opposite direction ($M_{consolidated} = 5.00$, $M_{partitioned} = 5.36$). To see how the price expectations in turn affected evaluation after the price was disclosed, participants were presented with the actual price and again asked to evaluate the offerings on the same 3-item scale ($\alpha= .93$). We performed a repeated measures test to test the difference in evaluation from before and after price disclosure, and found a significant effect of the presentation x time of evaluation effect on evaluation ($F(1,69) = 21.24$, $p < .01$). For the consolidated presentation, evaluation changed substantially ($M_{price\ not\ disclosed}$=5.01 to $M_{price\ disclosed} = 3.39$), while the change in evaluation of the partitioned presentation was only marginal ($M_{price\ not\ disclosed}$=4.61 to $M_{price\ disclosed} = 4.63$).

When marketing product bundles managers need to decide whether to present the offering with partitioned or consolidated prices. The results presented here shows that bundle size is an important factor to consider when deciding on price presentation. We need more research to understand the mechanisms and how it affects evaluation across product categories, with different bundle sizes and in situations where consumers are not asked to reflect on the price at all.

Affect Evaluation or Regulation in Visual Art Consumption?
The Influence of Pure and Mixed Emotions

Jianping Liang, Sun Yat-sen University, China
Zengxiang Chen, Ph.D., Nankai University, China

Imagine that you are watching two visual art pieces in an art exhibition. One is about a happy person and the other is about an upset person. Which one would you like better? Would you have different opinions when you are in positive (e.g., feeling strong) or negative (feeling upset) emotions incidentally? More importantly, would you react differently when you have pure positive/negative emotion or mixed emotions (feeling upset and strong at the same time)?

Previous research seems to have partial and mixed answers to the above questions. Affect evaluation theories, including affect-as-information (Schwarz and Clore 1983) and emotion-congruency effect (Bower 1981, Isen et al., 1978), argue that people have higher evaluation of an object that has positive (negative) emotional valence when they are in positive (negative) emotions. However, affect regulation theories (Andrade and Cohen 2007, Andrade 2005) propose that people tend to maintain their positive emotions and they will try to repair any negative emotions. Thus, people have higher evaluation of an object that has positive emotional valence even if they are in negative emotions.

Some recent studies provided supportive evidence to affect evaluation theories. For example, Martin et al. (1997) found that a story is evaluated more favorably when consumers have feelings that match the story's emotional valence, because a sad (happy) story is supposed to make consumers feel sad (happy), which is consistent with the affect-as-information effect. Kim, Park and Schwarz (2010) found that consumers have higher evaluation of vacation products with adventurous (serene) appeals when they are in excited (peaceful) than peaceful (excited) emotion, which is consistent with the emotion-congruency effect. Nevertheless, Martin et al. (1997) only studied pure *happy vs. sad* emotion *during* a *verbal* consumption experience, and Kim, Park and Schwarz (2010) only studied two pure *positive* emotions *before* direct consumption experience.

On the other hand, some other recent studies found supportive evidence to affect regulation theories. In particular, Agrawal and Duhachek (2010) found that because of a defensive processing to reduce the existing negative emotion, it was less effective to use compatible appeals in advertisements, which elicit the same emotion (e.g., shame or guilt) as the one experienced by consumers. However, Agrawal and Duhachek (2010) only used two pure *negative* emotions.

It is important to note that in most of our daily life, it is much more common to experience mixed emotions than pure positive or negative emotions. In addition, as Hagtvedt and Patrick (2008) found, visual art has a content-independent spillover effect in product evaluations. Thus, it is unclear whether visual art consumption experiences per se would be different from its spillover effect and from the verbal consumption experiences in this context. Therefore, this paper attempts to explore (1) whether *affect evaluation* theories could predict consumers' reactions *during visual art* consumption when emotions are *pure* positive or negative; and (2) whether *mixed* emotions may lead to *affect regulation* so that consumers react more favorably to visual arts with positive emotions instead of negative emotions. To the best of our knowledge, this is the first paper to investigate the effects of mixed emotions, in particular, feeling upset and strong simultaneously, on experiential consumption.

STUDY ONE

In Study One, we wanted to test whether affect evaluation theories or affect regulation theories could predict experiential consumptions on visual art. Thus, we ran a 2 (emotion: upset vs. happy) X 2 (consumption experience: upset vs. happy) between-subjects design experiment. After manipulating their emotions, participants were asked to appreciate one of two paintings (i.e., the manipulation of consumption experience on paintings with upset vs. happy valence), which the participants have not seen before. Then participants were asked to complete a questionnaire, including the control (e.g., whether they have seen the painting before, whether they like paintings, etc.) and dependent variables, as well as manipulation checks.

We found that when participants were upset (happy), they spent more time and effort to appreciate, and have better evaluations of the upset ("happy") painting. In other words, participants were more likely to have better consumption experiences when their emotions were congruent with the paintings' emotional valence, which is consistent with the affect evaluation theories.

STUDY TWO

In Study Two, we wanted to test whether mixed emotions, in particular, feeling upset (negative emotion) and feeling strong (positive emotion) at the same time, will make consumers have the same consumption experiences as the pure positive emotion (i.e., feeling strong) will do. This result will be consistent with affect regulation theories, because participants may be discomfort with mixed emotions and they want to get rid of the negative emotions instead of the positive emotions. We ran a 2 (emotion: mixed vs. strong) X 2 (consumption experience: upset vs. happy) between-subjects experiment. Similar procedures were used as in Study One.

We found that when participants were in mixed emotions, they spent more time and effort to appreciate, and have better evaluations of the "happy" painting than the "upset" painting. This result is consistent with the situation when participants were in pure positive emotion, and is also consistent with the affect regulation theories.

With a Little Help from my Friends: Friends Reduce Excessive Consumption by Promoting Self-Control

Eline L.E. de Vries, University of Groningen
Debra Trampe, University of Groningen
Bob M. Fennis, University of Groningen

Failures to override impulses lie at the heart of many problematic consumer behaviors. Failures to control impulses to eat unhealthy food, drink alcohol or smoke cigarettes for instance (Friese, Hofmann, and Wiers 2011), but also failures to resist impulses to buy. The continuous proximity of consumption temptations constitutes what we term a *buyogenic environment*. By provoking irresistible consumption impulses, this buyogenic environment composes a serious challenge to the exercise of self-control of consumers (Faber and Vohs 2011; Hoch and Loewenstein 1991). Especially for consumers with self-regulatory deficits, the buyogenic environment makes it extremely difficult to inhibit consumption impulses, resulting in excessive consumption. In its extreme case, such difficulties with inhibiting consumption impulses can lead to adverse consequences for both the individual and others (Faber and Vohs 2011).

Given that consumption behaviors like shopping and dining almost never happen in a social vacuum, it is surprising that little research has examined the role of close friendship on excessive consumption. After all, friends have been consistently linked to good mental and physical health (Cohen and Wills 1985; Hawkley et al. 2003) and just ordinary, day-to-day activities with friends have been found to be sufficient to be of beneficial influence (Lakey and Orehek 2011).

In the present research we conceptualize excessive consumption as a form of self-regulatory failure. The interplay between irresistible consumption impulses evoked by the buyogenic environment and insufficient self-control strength to inhibit these impulses, results into excessive consumption. In four experiments we show that the (psychological) presence of a friend reduces excessive consumption, by enhancing the capacity to inhibit (consumption) impulses when confronted with (consumption) temptations. In addition, we demonstrate that this beneficial influence of friendship on self-control is the result of a dual process; improved self-control as a result of both reduced impulses and conserved self-control strength.

The first study was a scenario study and observed that among individuals classified as compulsive buyers (Ridgway, Kukar-Kinney, and Monroe 2008), the presence of a close friend reduced both the buying urge and buying intention. That is, when compulsive buyers were asked to imagine themselves in a shopping situation, their buying urge and intention to buy a desirable pair of jeans that were on sale, was significantly lower when they imagined being accompanied by a close friend (M_{urge} = 5.06; $M_{intention}$ = 5.00) compared to when they imagined being alone (M_{urge} = 5.74; $M_{intention}$ = 5.89).

The second study (N = 106; all female) confirmed that self-regulatory processes underlie our findings of study 1, by demonstrating that the *actual* presence of a friend enhances compulsive buyers' self-control. Compulsive buyers who were in the actual presence of a close friend had significantly less difficulty with suppressing impulses (i.e., made significantly fewer errors on the Color Word Stroop Task, M = 0.00) compared to compulsive buyers that performed the task alone (M = 0.41) or in the presence of a stranger (M = 0.36). In fact, the presence of a friend enhanced the self-control of compulsive buyers to a 'normal' level, i.e. comparable to the self-control of non-compulsive buyers who were alone.

In the last two studies we generalized our findings to consumers not chronically, like compulsive buyers, but temporarily prone to self-regulatory failure by resource depletion (Faber and Vohs 2011). Moreover, study 3A showed that the beneficial influence of friends generalizes to a behavioral measure of self-control, i.e. candy consumption. In both studies, participants in the friendship condition were first primed with friendship, by asking them to write about a close friendship. Participants in the control condition were asked to write about the manufacturing process of a wooden table. Next, participants were depleted by performing an e-circling task or not.

After the friendship and depletion manipulation, participants in study 3A (N = 80; 37 female, 43 male) were tempted by a bowl filled with M&Ms, from which they could consume as much as they desired. Results showed that while depleted consumers ate more candy (M = 18.54 grams) than non-depleted consumers in the control condition (M = 11.86), depleted consumers ate significantly less candy after being

primed with friendship ($M = 11.31$). Although friendship had no influence on non-depleted consumers, friendship thus enhanced self-control of depleted consumers. Reminding people of friendship seemed to conserve their self-control strength.

Finally, if excessive consumption is the result of the interplay between self-control strength and impulse strength, the most effective intervention to reduce excessive consumption may be one that improves both factors (Friese et al. 2011). In study 3B (N = 80; 34 female, 46 male) we show that reminding people of friendship is such an intervention.

After the friendship and depletion manipulation, participants in study 3B first received an Implicit Association Test to measure their impulse strength towards hedonic products (Friese et al. 2011; Wiers et al. 2011). Subsequently, their willingness-to-pay (WTP) regarding these products was measured.

In line with Vohs and Faber (2007), participants depleted of their self-regulatory resources showed higher WTP for hedonic products than non-depleted participants. However, depleted participants reminded of friendship did not show this increase in WTP. Moreover, the relationship between depletion and friendship on WTP was mediated by impulse strength as measured by the IAT. Again friendship had no influence on non-depleted consumers.

The present research shows that the (psychological) presence of a friend reduces excessive consumption, and gives insight in the underlying process. By influencing both sides of the self-control struggle, i.e. conserving self-control strength and reducing impulse strength, the (psychological) presence of a friend satisfies an important condition for effective intervention (Friese et al. 2011). Friendship did not influence the self-control of non-compulsive and non-depleted individuals, suggesting that it only promotes self-control of individuals with self-regulatory deficits, either at the trait or state level (i.e. compulsive buyers or depleted consumers respectively). Non-compulsive and non-depleted consumers do not need much help in situations requiring self-control; they were capable of resisting temptations themselves. For the other consumers however, the (psychological) presence of a friend seems a valuable buffer against the temptations from our buyogenic environment.

Mere Exposure Effect in Sponsorship?
A Field Investigation Involving a Highly Familiar Brand

Jean-Luc Herrmann, Université Paul Verlaine-Metz, CEREFIGE, France
Mathieu Kacha, Université Paul Verlaine-Metz, CEREFIGE, France
Björn Walliser, Université de Nancy, CEREFIGE, France
Jonathan Dedonder, Université Catholique de Louvain, Belgium
Olivier Corneille, Université Catholique de Louvain, Belgium

Does a sponsorship influence decisions about a sponsor brand for people unable to recall that they were exposed to it? And is this mere exposure effect observed for prominent, highly familiar, brands that can afford to sponsor widely broadcasted events (e.g., Olympus for the US Open tennis tournament)? Mere exposure studies provide abundant evidence that repeated exposure to a stimulus may increase its liking without its recall (e.g., Bornstein 1989; Monahan, Murphy and Zajonc 2001). However, most of these studies were conducted in the lab with students and/or involved low-familiarity, fictive or novel brands and ads stimuli. Among a very few field studies that examined mere exposure effects of sponsorship in naturalistic environments (e.g., Bennet 1999), none involved highly familiar brands. Hence, it is currently unclear whether a sponsorship may influence decisions about a highly familiar brand in the absence of recall of this sponsoring brand.

To our knowledge, this research is one of the first to investigate this possibility. In order to secure statistical power, it involved a large sample of 1084 visitors of an international Tennis Tournament. Measures were collected for brand recall and brand preference, along with two additional factors, which we reasoned might qualify the effects: consumer status (consumer or non-consumer of the brand) and choice condition (free or comparative choice). We anticipated that mere exposure effects could be observed for a highly familiar brand, at least

for non-consumers of the brand who can be assumed to have relatively weak attitudes about this brand. We also reasoned that comparative choices might disrupt fluency effects of sponsorship exposure (and so be detrimental to mere exposure effects).

METHOD

Data collection took place during an international tennis tournament. The research focuses on one of the 10 official sponsors of the event, an extremely familiar brand of mineral water present on the court. During this event, face-to-face interviews were conducted with a sample of more than one thousand visitors on site. The control group (n=276) interviews took place before the spectators had entered the stadium. Interviews for the larger experimental group (n=808) took place inside the arena, after the respondents attended one or several matches. No respondent was exposed to any sponsorship stimulus during the interviews.

Within each group, respondents were randomly assigned to a free or comparative choice condition. In the first condition, respondents were asked to mention which brands they would consider choosing if they were in need of mineral water. In the second condition, respondents were asked the same question, but this time they were presented with a list of 16 highly familiar mineral water brands (including the target brand). Purchase consideration for other product categories were measured as filler decisions preceding a free recall test of the sponsors. Respondents were also asked whether they were consumers of the brand or not.

RESULTS

The mere exposure effect was assessed by considering respondents who failed to mention the brand as a sponsor (n=995). Among those, brand consumers were more likely to choose the brand than non-consumers, $\chi^2(1)$=169.06, p<.001. More importantly, exposure to the sponsoring brand almost doubled the probability of choosing it among non-consumers making a free choice, $\chi^2(1)$=4.271, p<.04. No such mere exposure effect was observed for brand consumers, or for non-consumers making a comparative choice (all ps = ns).

DISCUSSION

While previous mere exposure studies generally involved lab experiments with students and/or exposure to fictive or low-familiarity stimuli and ads (e.g., Janiszewski 1988; Karremans, Stroebe and Klaus 2006; Olson and ThjØmØe 2003; Shapiro, MacInnis and Heckler 1997), the present field research shows that mere exposure effects of sponsorship may be observed in naturalistic settings for prominent brands. This original finding importantly suggests that measures of sponsorship recall traditionally used in marketing may fail to fully capture the effectiveness of sponsorship.

Of interest too, these effects were limited to non-consumers of the brand making a free choice. Hence, these effects may be observed whenever non-consumers of a brand think of which brand to purchase, but may not be observed when they make choices in front of supermarket shelves or internet sites displaying the target brand among competitors (at least in the short-term). Theoretical reasons for this may be (1) that mere exposure effects only influence individuals who have no strong established preferences about the target stimulus (Bornstein 1989), and (2) that non-consumers engage in an analytic processing of the respective brands' merits when choosing a sponsoring brand among competitors. Such analytic processing mode typically disrupts fluency effects (Whittlesea and Price 2001).

The present findings suggest that sponsorship may affect consumer choices through processes that are more subtle and implicit than deliberate inferences made about the brand or explicit reminders of it (Cornwell, Weeks and Roy 2005). However, one should be careful in concluding about the unconscious nature of the present effects. It is likely that spectators watching the matches paid at least shallow attention to the sponsor, too shallow to guarantee its spontaneous recall, but strong enough to secure its encoding in memory (see also Ferraro, Bettman and Chartrand 2009). There is strong evidence that fluency resulting from mere exposure increases both liking and familiarity, which are dissociated only when individuals apply different processing strategies (i.e., holistic versus analytic) for evaluative and recognition tasks (e.g., Whittlesea and Price 2001; Willems, Salmon and Van der Linden 2008).

In sum, the present field research provides original evidence (1) that sponsoring may influence consumer decisions in naturalistic environments even without explicit recall of a highly familiar sponsor, and (2) that the latter effect is constrained by the status of the consumer and the nature of the choice.

Is More Always Better?
Examining the Effects of Highly Attentive Service

Hean Tat Keh, Beijing University, China
Maggie Wenjing Liu, Tsinghua University, China
Lijun Zhang, Beijing University, China

The services marketing literature generally indicates that attentive, friendly, and personalized services can help improve customer satisfaction (Bitner, 1990; Bitner, Booms, & Mohr, 1994; Hui, Au, & Fock, 2004; Price, Arnould & Tierney, 1995; Surprenant & Solomon, 1987). Some researchers even suggest that firms should attempt to transcend customer expectations by delighting them (Oliver, Rust, & Varki, 1997; Rust & Oliver, 2000). Consequently, it has become imperative for many service firms to invest in customer-focused procedures or programs in order to create more competitive service offerings (Lemmink & Mattsson, 2002), and some of them are even willing to go the extra mile in serving customers. For example, the wait staff of many restaurants is trained to get to know their customers, frequently drop by customer tables and enquire if things were going well (Scanlon, 1998).

The underlying assumption is that such outwardly concern for consumers and personalization would be well received. Yet, some customers may find such efforts to be overwhelming and disruptive of their service experience. As observed by Solomon, Surprenant, Czepiel, and Gutman (1985, p. 107), "greater personalization of service does not necessarily result in a more positive service expectation." Indeed, there is considerable anecdotal evidence suggesting that, rather than increasing customer satisfaction, highly attentive service may lead to customer complaints, dissatisfaction, and even switching behavior. This raises the paradox that more attentive service is not always better. From the perspective of the organization, Schneider, Paul, and White (1998) suggest that an overemphasis on service quality for end users may be detrimental to the organization in the long-term as overemphasis on a single constituent will be in conflict with the expectations and demands of other constituents such as employees and shareholders.

The literature in related areas indicates that too much of a good thing may not always turn out well. For instance, in the context of product choices, Iyengar and Lepper (2000) challenge the popular notion that "the more choice, the better." They find that consumers faced with extensive choices may find them to be initially more appealing but are subsequently less satisfied with their choices compared with those in the limited-choice condition. Similarly, when manufacturers put too many features into a product, it can be overwhelming for consumers and result in "feature fatigue" (Thompson, Hamilton, & Rust, 2005). We expect the effects of highly attentive service to be analogous to such choice overload effects.

Our review of the literature yields surprisingly little insight into the paradox of highly attentive service (see Estelami & De Maeyer, 2002). Questions on how customers respond to highly warm or generous service attention, and to what extent should firms attend to their customers, have not been systematically addressed. Knowing the answers would be relevant and important for both managerial practice and marketing scholars. Accordingly, our objective in this research is to understand the nature of highly attentive service and how it affects customers' responses and evaluations of service providers. As little has been done in this area, we use a two-phase research design in conducting this study (Creswell, 1994). We first perform an exploratory qualitative research to define the concept of highly attentive service from the perspective of the customer. Based on the dimensions identified, we then proceed to conduct two experiments to better understand customers' response mechanisms. Specifically, we address the following research questions:

1. How do customers define or perceive highly attentive service?

2. How does highly attentive service influence customer affective response and evaluation of the provider?

3. Do customers' characteristics and situational factors influence their affective response and evaluation of highly attentive services?

Based on the related literature and content analysis of our qualitative study, we establish a conceptual model of highly attentive service and develop the relevant hypotheses. We conduct two experiments to test the model. Finally, we discuss the results, the theoretical and managerial implications, and conclude with the limitations of this study and directions for further research.

We contribute to the literature by expanding the scope of investigation beyond monetary generosity. As the literature is sparse on the "attentiveness fatigue" problem, our exploratory study on the nature and consequences of highly attentive service fills a major theoretical void. The main results of our empirical analysis are that highly attentive services have an inverted U-shaped relationship with customer satisfaction, and this relationship is partially mediated by customers' affect and moderated by customers' need for interaction. These findings are new to the literature, and impel us to reconsider the received wisdom of providing services that exceed the desired level (Zeithaml, Berry, & Parasuraman, 1993, 1996).

Specifically, our results confirm the affective satisfaction model (Oliver, 1993; Westbrook, 1987; Westbrook & Oliver, 1991); service attributes influence customer satisfaction both directly and indirectly via positive and negative affects. While past research highlights the effect of positive affect on satisfaction (Lemmink & Mattsson, 2002; Price, Arnould, & Tierney, 1995), our study reveals the crossover effects between service attributes and positive and negative affects simultaneously. Our factor analysis elicits one positive affect, "warmth," and two

types of negative affects, "pressure" and "sadness/anger." This is in line with Russell's (1980) "circumplex model of affect," which posits two dimensions of affective structure, pleasure/displeasure and arousal/boredom. In our three-factor affect model, "warmth" and "sadness/anger" are almost polar opposites on the same continuum, and are independent of (orthogonal to) "pressure." Additionally, we find that while both negative affects, "pressure" and "sadness/anger," are evoked by unfavorable service attentiveness conditions, the underlying mechanisms are different. Results show that "pressure" is more likely to be evoked by highly attentive services, but "sadness/anger" is not significantly different for either excessive or too little attention.

Humorous Complaining

Christina Kan, University of Colorado, USA
Caleb Warren, Bocconi University, Italy
A. Peter McGraw, University of Colorado, USA

"I should have flown with someone else or gone by car… 'cause United breaks guitars."

When United Airlines was unresponsive to David Carroll's complaint, he did what consumers are increasingly doing – he turned to the Internet. But rather than taking a strictly negative tone, the little-known musician and owner of a Taylor guitar broken during a United flight created a music video parody, "United Breaks Guitars." His humorous complaint became an Internet sensation, spurring international media coverage and an immediate response from United (Deighton and Kornfeld 2010).

Marketers, consumer researchers, and consumers know the power of complaints. Negative word-of-mouth, a complaint about a product or service directed toward other consumers, can have significant detrimental effects on brand attitudes and sales (Chevalier and Mayzlin 2006; Mizerski 1982). For example, United's stock dropped 10% after Carrol's video went viral (Deighton and Kornfeld 2010).

Although a complaint by its nature is the expression of a negative experience, we highlight that not all complaints are strictly negative. A simple internet search illustrates how some complaints have a humorous element (e.g., ATT steals oranges; Comcast technician sleeping on my couch). We introduce the concept of humorous complaining and differentiate it from strict complaints by investigating its audience, antecedents, and implications.

To derive our predictions, we draw on a theory that proposes that humor occurs when a violation is simultaneously perceived as benign (McGraw and Warren 2010). A violation refers to anything that threatens one's belief about how things should be (Veatch 1998). Violations are seen as benign when the perceived threat also seems okay. Play fighting and tickling are prototypical examples of benign violations: both are physically threatening but harmless attacks (Gervais and Wilson 2005). In a similar manner, we suspect that unlike serious complaints, which only highlight a violation committed by a firm, humorous complaints also involve an element that makes the violation seem benign.

We present two studies that explore how the audience, antecedents, and consequences of humorous complaints differ from serious complaints.

1) Audience. Consistent with anecdotal evidence in the marketplace, we investigate whether consumers are more likely to complain humorously to other consumers rather than the offending firm or third party agencies. Consumers typically complain to firms and third party agencies in order to motivate reparative actions. Because humor softens criticism by suggesting the violation is benign (Keltner et al. 2001; McGraw and Warren 2010), humorous complaints may be less likely than serious complaints to prompt action. Thus, consumers should be more likely to direct humorous complaints to other consumers rather than firms or third-party agencies.

We randomly assigned members (*N*=83) of an online survey panel to imagine themselves in a hypothetical scenario depicting either an extreme or a mild customer service violation at a restaurant. In the extreme violation scenario, the patron receives the wrong order, the food is completely overcooked, and the waiter, who is very rude, does not rectify the mistake. In the mild violation scenario, the food is mildly overcooked, and the waiter eventually brings the correct order.

We asked participants how likely they would be to complain, both humorously and seriously (order counterbalanced), about their experience to the following audiences (1=Very Unlikely, 7 = Very Likely): 1) other consumers in person, 2) other consumers via the Internet, 3) the

firm, and 4) a third party agency. Although participants were likely to complain seriously directly to the firm (M=3.9), they were significantly more likely to complain humorously to other consumers, either in person (M=4.2) or via the Internet (M=3.4), than to a third party agency (M=1.8) or the firm (M=1.6).

2) Antecedents. In accordance with the benign violation theory, we expect that humor will be more prevalent in mildly negative than extremely negative experiences. Extremely negative experiences are less likely to be perceived as benign making it more difficult for consumers to complain about them in a humorous manner (McGraw et al. 2011).

We asked participants who read about the negative restaurant experience how easy or difficult it would be to recount their experiences in a humorous manner (1=Very Difficult, 7=Very Easy). Participants who read about a mildly negative experience reported that it would be easier to complain in a humorous manner than participants who read about an extremely negative experience (M_{mild}=4.83, $M_{extreme}$=3.91).

3) Consequences. Because humor is attention getting, enjoyable, and memorable (Alden, Mukherjee and Hoyer 2000; Eisend 2009), we suspect that humorous complaints are more likely to go viral than serious complaints.

We asked 63 undergraduate students to read either a serious or humorous version of a letter complaining about a bank's poor service. This letter was selected based on a search conducted by members of an online panel (N=50) asked to submit an example of the funniest consumer complaint that they could find on the Internet. Two research assistants blind to the study's hypothesis ranked the written complaints based on their humor and selected the letter with the average highest ranking. One of the assistants then rewrote the complaint letter highlighting the same reasons but removing any humorous content.

Subjects read either the humorous or the serious version of the complaint. As expected, participants found the humorous version of the letter significantly more humorous than the serious version ($M_{humorous}$=4.9, $M_{non-humorous}$=2.1). Importantly, participants also enjoyed the humorous version significantly more ($M_{humorous}$=4.9, $M_{non-humorous}$=3.0) and, as a result, were more likely to share this version with other consumers ($M_{humorous}$=3.6, $M_{non-humorous}$=2.6; indirect effect (a x b) = .67, 95% CI = .19 to 1.29).

Our findings suggest that firms should be wary of consumers complaining humorously about their products and services. The spread of humorous complaints is more difficult for firms to control than the spread of serious complaints not only because the humorous complaints tend to be directed at other consumers, but also because their enjoyable nature makes them more likely to be circulated, thereby increasing the number of consumers exposed to negative information about the firm.

In the Aftermath of an Earthquake: The Interactive Role of Self-construal and Victim Group-Status in Charitable Behavior

Rod Duclos, Hong KongThe Hong Kong University of Science & Technology, Hong Kong
Alixandra Barasch, Wharton, University of Pennsylvania, USA

When a natural disaster strikes a community, consumers often face countless appeals to donate time or money to help the victims. Only a small percentage of people who view these advertisements, however, will investigate the cause further, and an even smaller percentage will end up offering resources to aid the rescue and rebuilding efforts. What factors influence whether individuals will help victims of natural disasters and other disadvantaged populations? The present research attempts to answer this question by investigating the interactive effects of self-construal and victim origin on prosocial behavior.

Fundamental to people's emotional and cognitive responses, self-construal characterizes the extent to which one considers oneself separate from vs. connected with others (Markus and Kitayama 1991). Hence, individuals vary on the self-construal continuum from interdependent to independent (Singelis 1994, Stapel and Koomen 2001). Because the *interdependent* self is more meaningful in the context of social relationships or as part of a larger social unit, one might expect interdependent (independent) individuals to be more (less) generous when faced with calls for help. Consistent with this view, several studies found positive correlations between interdependence and charitable behavior (Moorman and Blakely 2006; Eckstein 2001; Skarmeas and Shabbir 2011).

Drawing from work in psychology, we contrast from the above view and argue that interdependent individuals may not necessarily be more connected to or generous toward others. Much self-construal research has indeed underscored the importance of group status (*in* vs. *out*) for the interdependent self (Markus and Kitayama 1991; Iyengar and Lepper 1999; Kitayama et al. 1997). I.e., interdependent individuals are more motivated to integrate themselves with and meet the expectations of others, but only when these others are considered *relevant* (e.g., family members, peers, significant groups; Heine and Lehman 1997).

Accordingly, the present study investigates the interaction of self-construal and victim group-status on donation behavior. We propose that, when individuals are faced with a plea to support victims of a severe earthquake, victims' status (in- vs. out-group) will interact with donors' self-concept. Specifically, we predict that victims' group-status should influence interdependents' willingness to help more than independents' (since the latter see themselves as more separate from others, regardless of group-status).

Design & procedures. To test these propositions, we randomly assigned 112 students from a large East Asian university to one of four conditions. Our experiment followed a 2 (Self-construal: Independent vs. Interdependent) by 2 (Victim status: In- vs. Out-group) between-subjects design. To manipulate self-construal, we asked participants to complete an alleged emotional empathy questionnaire. To this effect, subjects read a short story written either in the first person (e.g., I, my, me) or in the inclusive plural form (e.g., we, our, us) before completing a series of manipulation checks intended to assess their ensuing self-construal orientation and mood.

Next, participants viewed an appeal from "Global Relief", a fictitious charity collecting money to help victims of earthquakes. Vivid in nature, the advertisement featured death toll statistics (e.g., "over 100,000 killed and 1 million others homeless"), a description of the victims' needs (e.g., "food and medicine for vulnerable children and devastated families"), and the pictures of two suffering victims underneath the text. The ad concluded by asking participants to visit the charity's website to make a donation.

Since our sample was composed almost exclusively of south-east Chinese, we manipulated victims' status by featuring pictures from the recent Sichuan (in-group) vs. Haiti (out-group) earthquakes. Of note, the pictures included in each advertisement were identical in every aspect except, of course, race. I.e., based on pretests, the victims depicted in our ads matched in all regards (e.g., age, gender, apparent suffering, etc). This was further confirmed through multiple affect-related manipulation checks.

Results. An analysis of variance on participants' willingness to help revealed no main effects (Fs < 1, NS) but a significant crossover interaction ((F1, 111) = 5.333, p = .023). On average, independents were neither more nor less likely to donate than interdependents. Similarly, Haitian victims were neither more nor less likely than their Sichuan counterparts to elicit donations. Follow-up contrast analyses, however, revealed that, while victims' origin did not seem to matter for independents (F (1 ,111) = 1.294, p = NS), it did so for interdependents (F (1 ,111) = 4.542, p = .0353). That is, whereas independent participants were just as likely to make a donation regardless of victims' origin, interdependent participants donated significantly more to in-group (i.e., Sichuan) than to out-group (i.e., Haitian) victims. Of note, this simple effect was driven by interdependents' increased generosity toward Sichuan victims (F (1 ,111) = 3.040, p = .084), not their reduced benevolence toward Haitians (F (1 ,111) = 2.319, NS). Also of note, these findings were not driven by affective considerations. Indeed, none of our manipulation checks (e.g., PANAS, sadness, anxiety, depression, nervousness, mood, etc) revealed any main effect or interaction capable of explaining our results.

So to account for these findings, we next turned to cognitive aspects of decision-making. Building on Duclos et al. (2011), we tested whether participants' beliefs about happiness and prosocial behavior could mediate the interaction described above. Following Baron and Kenny's (1986) four-step approach to mediated moderation, we were able to confirm that participants' willingness to assist earthquake victims depended on the interactive influences of self-construal and victims' group-status, and this interaction was mediated by the degree to which participants believed that helping others promotes happiness (Sobel test: z = 1.609, p = .1).

By highlighting the interactive effects of self-construal orientation and victim group-status on donation behavior, the present study bridges the gap between and offers novel theoretical insights for two important and burgeoning research areas. Furthermore, by identifying the mediating role of cognitions vs. affect in consumers' decision to donate money, our findings provide charities actionable insights into the psychology of donors (e.g., matching recipients of help to donors' profile in interdependent contexts, highlighting the happiness derived from helping others). Hence, for its contributions to both theory and practice, we believe this poster would be of interest to a wide audience at ACR.

The Endowment Effect: Deciding for Oneself versus Deciding for Others

Shih-Chieh Chuang, National Chung Cheng University, Taiwan
Yin-Hui Cheng, National Taichung University, Taiwan
Sui-Min Wang, National Chung Cheng University, Taiwan
Kuo-shu Hwang, National Yunlin University of Science and Technology, Taiwan

Research into the individual decision-making process has examined potential gains or losses, measured relative to the individual's status quo position (Kahneman & Tversky, 1979), and found that sellers tend to overvalue objects relative to buyers. Thaler (1980) and Kahneman, Knetsch, and Thaler (1990) call this tendency to place a larger value on an item that is in one's possession the "endowment effect." The essential idea is that individuals are more reluctant to lose something they own than they are to gain something they do not. Hence, although buyers generally value goods objectively, due to seller behavior (Inder & O'Brien, 2003), there is a discrepancy between the minimum price a seller will accept and the maximum price a buyer will pay. Given the importance of the endowment effect in everyday economic behavior, it is expected that people's perceptions of that effect may be equally important.

In recent years, business transactions appear to occur more frequently when self-other differences exist, as such differences influence consumer behavior. Much of the research on the endowment effect has focused on the valuations an individual makes for him or herself. It has generally failed to address how it affects valuations made for others and whether there are self-other differences. Making decisions for others is quite common. For example, parents regularly make decisions for their children, and friends frequently make decisions for one another. Thus, it is important to identify the factors that differentiate decisions made for oneself from those made for others. Also of interest is whether the endowment effect is larger or smaller on business transactions in which sellers and buyers make decisions for others. The research reported herein examines both issues. The findings of this study will also contribute to the literature on the influence of psychophysical properties by providing a better understanding of the factors that mediate the effects of self-other differences on willingness to accept (WTA) and willingness to pay (WTP). It is founded on the premise that knowledge of self-other differences concerning perceived stimuli may arise from the different valuation levels that are due to varying degrees of personal involvement in the decision-making process. The study's findings will also facilitate assessment of the psychological underpinnings of ownership and the effects of the self-other discrepancy on the endowment effect. An understanding of these mechanisms will not only identify the factors determining the self-other differences that appear to follow a trade-off strategy between sellers and buyers, but also provide direction for marketers interested in increasing the transaction amount gained. If individuals are capable of correctly predicting others' needs and desires, then these predictions may well affect the decisions they make during the transaction process.

Building on the concepts of perceived ownership and the features of focus, the authors predict that individuals will make decisions for another person differently than they will for themselves, thus eliminating the disparity between the selling and buying price. They also employ the theory of self-other differences to determine whether sellers and buyers are differentially sensitive to item changes and, if so, whether this difference in sensitivity depends on the presence of a market price.

In the first study, 136 university students (68 of whom were male) were given a coffee mug and asked to estimate the price they would be willing to pay/accept for it in the self and other conditions. The experimenter asked participants in the self condition: "If you were to sell/ buy this coffee mug , how much would you be willing to accept/pay for it?" A similar question was asked of those in the other condition: "If you were to sell/buy this coffee mug for a friend, how much would you be willing to accept/pay for it?" Results supported the hypothesis that the selling price will decrease and the buying price increase when one is acting on behalf of another (and that the opposite will be true when one is acting on one's own behalf).

In the second study, we investigated the proposed perceived ownership and features of focus effects could account for the observed decrease in the endowment effect in the others condition. Thus, this study employed a 2 (role: seller versus buyer) × 2 (valence features: positive versus negative) × 2 (target person: self-focused frame versus others-focused frame) design, with the first and third factors varying between participants and the second within participants. Results from this study indicate that the participants were more likely to consider positive features when they were acting as a seller for themselves than when they were acting as a buyer. In addition, we found that perceived ownership and the features of focus work together to partially mediate the relationship between the endowment effect and the effect of trading for others,

In the final study, the aim of broadening our knowledge of the "other" on whose behalf a transaction is made. It tested whether the level of intimacy between owner and seller/buyer influences the endowment effect and whether this influence depends on the presence of a reference price. The participants were told that they were taking part in an experimental auction. A description of self-other differences was given in each of the eight experimental conditions, with each participant presented with a different version of the screen, that is, one of the four self-other conditions: valuing the object for oneself, for a family member, for a friend, or for a stranger. They were then asked to provide a selling/buying price. Results showed that the endowment effect on the estimation varies with the level of intimacy of the relationship the seller/buyer has with the target other, although the difference is less in the presence of a reference price.

To conclude, the results of three studies demonstrate the existence of differing perceptions of the self-other discrepancy among buyers and sellers. More specifically, we hypothesized that when valuation outcomes are explicitly framed in terms of seller/buyer gains and losses, consumers are more loss-averse when acting for themselves rather than others in contexts involving losses. The endowment effect does appear to reflect self-other biases, thereby providing us with a deeper understanding of the mental processes involved. Our results also have

implications for social psychology and prospect theory, as they identify the greater hedonic impact of losses, although this impact is lessened in situations in which one is acting on behalf of another. The effect found in the others condition was inconsistent with the expectations of status quo reference dependence and loss aversion, although that in the self condition was consistent with them, as no endowment effect was observed. It is clear that individuals' perceptions of others' behavior are closely linked to their valuations of the selling price. These findings are important for the transactions of market that can help seller and buyer to improve asymmetric information and biased information integration, solve the lemon problem, and ensure a more successful experience by enhancing trade-offs and interpersonal mechanisms.

How to Motivate People: The Influence of Perceived Goal Progress on Construal Level

Jooyoung Park, University of Iowa, USA
William M. Hedgcock, University of Iowa, USA

The primary purpose of this study is to understand the relationship between perceived goal progress and mental construal. Previous studies on self-regulation have investigated the relationship between goal progress and subsequent goal pursuit. However, the studies have not examined how goal progress influences individuals' information processing. Our findings of the relationship between goal progress and construal level suggest that people can more easily process information and be persuaded by messages construed at different levels depending on goal progress.

CONCEPTUAL BACKGROUND

Construal level theory suggests that people construe (represent) an object or event at different levels. For example, people can describe reading either in terms of a low-level aspect ("following lines of print") or a high-level aspect ("gaining knowledge").

In the context of consumer behavior, Labroo and Patrick (2008) showed that construal level is influenced by moods. They hypothesized that positive moods signal that all is currently well and allow people to see the big picture. They found that positive moods evoke an abstract construal level and that participants in a positive mood prefer a product when its benefits are described in an abstract manner rather than in a concrete manner.

Previous studies on the relationship between moods and goal progress suggest that positive affect compared to negative affect reduces persistence in focal goal and increases cognitive flexibility and attention toward novel stimuli (Dreishbach and Goschke 2004). Also, Louro, Pieters, and Zeelenberg (2007) proposed that people tend to have positive moods when they experience significant goal progress.

These studies suggest that significant goal progress can evoke positive moods and in turn increase cognitive flexibility and construal level. Accordingly, we predict that greater goal progress can produce positive moods and thus increase construal level.

METHODOLOGY

Perceived goal progress is frequently manipulated through social comparison (e.g., Fishbach, Dhar, and Zhang 2006). Using a goal of keeping in shape, we predict that a comparison to a low social standard (1 hour of exercise) suggests that one has successfully pursued the goal, whereas a comparison to a high social standard (10 hours of exercise) suggests that one did not successfully pursue the goal. Following previous studies (e.g., Fishbach and Dhar 2005), we informed our participants that prior participants answered only the first question, and we were reusing their paper. When they received their booklet, participants were asked to first report the amount of time they had spent working out during the previous week. On the following page, they found a fictitious participant's answer for the amount of time he or she had spent working out (either 1 hour or 10 hours). Then, participants reported their perceived goal progress.

Louro et al. (2007) measured positive and negative moods about individuals' progress using eight items (e.g., I feel "proud of myself, "good about myself," "regretful," I am "happy with myself," "satisfied with myself," "ashamed with myself," and "angry with myself"). We used the items on 7-point scales ranging from not at all (1) to very much (7).

Researchers often use a classification task to measure construal level based on the premise that an abstract, higher-level construal leads to broader, more inclusive categories (Liberman, Sagristano, and Trope 2002). Following previous research, we asked participants to classify twenty-five items for each of two scenarios (i.e., going camping and organizing a yard sale). Last, they reported age, gender, and the importance of the goal of keeping in shape.

FINDINGS

Seventy-seven undergraduate students participated in the study (forty-nine were males). We first compared perceived progress depending on the manipulation (a high versus a low social standard) using t-test. Consistent with our expectations, participants who were exposed to a low social standard (1 hour, $M = 4.41$) perceived greater goal progress than those exposed to a high social standard (10 hour, $M = 3.65$) ($t (75) = 1.998$, $p = .049$). Also, participants under the low standard condition (camping trip, M = 5.16; yard sale, $M = 5.24$) used a fewer number of categories than participants under the high standard condition (camping trip, $M = 6.13$; yard sale, $M = 6.53$); camping trip, $t (75) = -.2.306$, $p = .024$; yard sale, $t (75) = -2.884$; $p = .005$). Similarly, we found consistent results from correlation analyses. The correlation between social standards and the number of categories (camping trip, $r = .257$, $p = .024 < .05$; yard sale, $r = .316$, $p=.005$) suggests that a

lower social standard leads to a fewer number of categories (a higher construal level) than a higher social standard. Following Louro et al. (2007), we combined positive and negative moods into a single index (i.e., the difference between positive and negative moods, positive scores indicate net positive moods). We found significant correlation between standard and moods ($r = -.276$, $p = .015$) and between progress and moods ($r = .383$, $p = .001$). However, we did not find significant relationship between moods and construal level (camping trip, $r = -.113$, $p = .328$; yard sale, $r = .109$, $p = .343$).

DISCUSSION

Lee et al. (2009) showed that fit between individuals' regulatory focus and the construal level of a message can enhance engagement in information processing and in turn lead to processing fluency and intensified reactions. In this study, we found that greater goal progress increases construal level. This implies that individuals are likely to construe information at different levels depending on goal progress and that different messages represented either at a high or a low construal level can be more influential in goal pursuit. In the subsequent studies, we intend to examine the persuasiveness of messages focusing on different construal levels depending on goal progress. Different from our expectation, we did not find a mediating role of moods in the relationship between goal progress and construal level. This may suggest goal progress may expand individuals' cognitive flexibility and thus increase construal level. We will elaborate on the underlying processes in subsequent studies.

Do People Spend More in a Crowded Store?
A Field Experiment on Control Deprivation and Compensatory Spending

Charlene Chen, Columbia University, USA
Leonard Lee, Columbia University, USA
Andy Yap, Columbia University, USA

Desire for control over the environment is a fundamental human motive (White, 1959). Violation of this need provokes distress that initiates efforts to reassert control (Skinner, 1996). Recent research has shown that people might compensate for their perceived lack of control through an increase in acquisition behaviors to feel a sense of ownership and control (Chen, Lee, & Yap, 2011). The current study extends this research by investigating whether control deprivation induced by a crowded supermarket could affect buying and spending behaviors similarly. Crowding in retail settings has been found to diminish one's sense of control because it frustrates one's shopping goals of moving freely and locating products (Langer & Saegart, 1977). Hence, we expected shoppers in a crowded (vs. uncrowded) store to buy and spend more.

Another goal of this experiment was to demonstrate that control restoration in the crowded store would attenuate these effects, thus strengthening our confidence that loss of control indeed drives increased purchasing behavior. In a study by Langer and Saegert (1977), participants given information about the psychological effects of being in crowded situations (e.g., physiological arousal) did not exhibit the same decrements on a simulated shopping task in a crowded store as those who were not given such information. The authors argued that information provision raises people's control of the situation by allowing them to anticipate the onset of the stressor and to initiate cognitive preparation (see also Schmidt & Keating, 1979). In our experiment, a similar intervention was introduced to alleviate control deprivation caused by crowding. We predicted that giving shoppers information related to retail store environments (e.g., crowding) would reverse their tendency to buy and spend more in a crowded store.

METHODOLOGY

Regular shoppers were recruited during crowded and uncrowded periods at the entrance of a supermarket, and were given a $3-coupon for participating. Based on communication with the store, we were able to ascertain beforehand time intervals in the afternoon that were either crowded or uncrowded. Shoppers in crowded periods were randomly assigned to either receive or not receive any intervention before shopping. Those that received the intervention were given this information: "Research studies in the area of marketing have shown that retail store environments can influence consumers' shopping behavior. Certain characteristics of a store like crowding for example can cause customers to shop differently." Overall, there were three conditions: (a) uncrowded; (b) crowded and no information was given (no-info); and (c) crowded and information was given (info). All shoppers were told to redeem their coupons and answer a survey regarding their experiences

after shopping. Eighteen shoppers did not redeem the coupon and were removed from the sample (non-redemption rates were equivalent across conditions). The final sample comprised 57 shoppers (22 males) between 18-70 years of age (*M*=29.79; *SD*=15.79).

RESULTS

To analyze the data, we conducted planned contrast tests comparing the crowded/no-info condition with the other two conditions. A contrast weight sequence of 2, -1, -1 was used for all outcome variables (sense of control, number of items bought, expenditure, and number of utilitarian items bought) across: the crowded/no-info, uncrowded, and crowded/info conditions (respectively). Crowded/no-info shoppers perceived lower control over their environment (*M*=3.59; *SD*=2.06; *n*=17) than uncrowded shoppers (*M*=4.90; *SD*=1.25; *n*=20) and crowded/info shoppers (*M*=4.50; *SD*=1.67; *n*=20), *t*(54)=2.30, *p*<.05. Therefore, crowding did reduce perceived control but this was prevented when shoppers received the information.

Support was obtained for our prediction that crowded/no-info shoppers would buy and spend more than shoppers in the other conditions. Crowded/no-info bought more items (*M*=6.12; *SD*=5.72) than uncrowded shoppers (*M*=2.80; *SD*=1.58) and crowded/info shoppers (*M*=3.30; *SD*=1.81), *t*(54)=3.09, *p*<.005. They also spent more money (*M*=$17.28; *SD* =15.49) than uncrowded shoppers (*M*=$7.04; *SD*=4.62) and crowded/info shoppers (*M*=$8.34; *SD*=5.14), *t*(54)=3.53, *p*<.005. Two independent raters classified each product purchased by participants as "utilitarian", "hedonic", or "either utilitarian or hedonic" (Kappa=.72). For each participant, the quantity of items in each category was computed. Crowded/no-info shoppers bought significantly more utilitarian products (*M*=4.12; *SD*=4.40) than uncrowded shoppers (*M*=1.55; *SD*=1.28) and crowded/info shoppers (*M*=1.90; *SD*=1.62), *t*(54)=3.07, *p*<.005. The contrast test did not show any significant difference in number of hedonic products purchased, *p*=.83. Controlling for emotions and shopper characteristics (e.g., buying more because of long queues) did not alter the results.

DISCUSSION

Lacking control in crowded situations without an opportunity to restore it through information provision led shoppers to buy more and spend more. A finding by Chen et al. that control-deprived individuals tend to buy more utilitarian products was also replicated in this study. According to these authors, such products are typically viewed as means to certain ends, and thus help people feel that they are accomplishing some intended effect on the environment. In this experiment, shoppers who were not given the information bought more utilitarian products when the store was crowded. Shoppers in crowded situations who had the chance to regain it through information provision however resembled shoppers in the uncrowded situations in what they bought and spent. Hence, the current findings support our claim that control motivation underlies our effects.

Shopping opportunities in contemporary life makes buying a convenient channel for compensating for one's lack of control. While prudent use of this strategy may be helpful for control-deprived individuals, frequent employment may result in excessive spending. From a policy standpoint, shoppers should be informed that certain retail environments (e.g., crowding) can instill feelings of control loss that in turn may propel them to increase their purchasing.

Should Santa Still Wear Red? Investigating the Effects of Color on Impulsive Buying Behavior

Liangyan Wang, Antai Management School, Shanghai Jiao Tong University, China
Dante M. Pirouz, The Richard Ivey School of Business,University of Western Ontario, Canada
Xinan Zhang, Antai Management School, Shanghai Jiao Tong University

Impulsiveness or impulsivity has long been extensively studied as a general trait by psychologists, educators and criminologists (Rook and Fisher 1995; Eysenck and McGurk 1980). Accordingly, to a large extent, impulsive buying behavior has been examined involving with long-term predisposed factors such as norms (Rook and Fisher 1995), cultural orientations (Kacen and Lee 2002), and fashion-involvement and lifestyle (Park et al., 2006). Scant research has empirically examined the environmental cue's impact on consumers' impulsive buying behavior. Also, large body of research on impulse buying has been studied in the developed western contexts. Attempting to fill the gaps in this area of consumer behavior, this research, contrast to prior research involving with predisposition factors, aims to examine the impact of brief exposure to color (blue vs. red) on impulsive buying behavior in China- a developing country recently with much transitions and many new international market experiences.

Color is ubiquitous in people's life. And it influences human perception, cognition and behavior (Meth and Zhu 2009; Elliot et al 2007). As to research studying color topics, most of them have focused on "two of the three primary colors-red versus blue (green)" (P.1226, Meth and Zhu 2009). Elliot et al 2007 demonstrated that prior to an anagram test, participants briefly exposed to red performed worse than those briefly exposed to green. Meth and Zhu 2009 suggested that short exposure to red (versus blue) could enhance performance on detail-oriented (versus creative) cognitive tasks. Gorn et al 2004 found that participants who were exposed to the blue background screen perceived the page

download as quicker than did participants exposed to the red background screen. The empirically examined consequence differences between brief exposure to red versus blue (green) result from different learned associations, which are likely to activate different motivations (approach vs. avoidance) and possibly different levels of relaxations (Meth and Zhu 2009; Elliot et al 2007; Gorn et al 2004). In line with prior research, we propose that compared to individuals briefly exposed to red, individuals briefly exposed to blue have higher impulsive buying intent in general.

Two experimental studies were conducted among several hundred subjects to test our hypothesis using both online and traditional paper-and-pencil surveys. In experiment 1, 68 participants were randomly assigned to one of the two between-subjects experimental conditions: the red condition or the blue condition. The study was conducted by an experimenter blind to the experimental hypothesis. Impulsive purchase decision served as the dependent measure. The impulsive purchase decision measure was used and justified by Rook and Fishier 2004. An imaginary shopping situation was provided and participants were asked to make a purchase choice out of five purchase decision alternatives ranging from low to high impulsiveness. Participants assigned to the red condition filled up a survey printed in red paper whereas participants assigned to the blue condition filled up a survey printed in blue paper. The two groups were asked to fill in the paper-and-pencil survey starting with some filler questions first, followed by the dependent measure and demographic information. A unifactorial (color condition: red vs. blue) between subjects analysis of covariance was conducted on impulsive purchase decision. The analysis revealed an effect of color on impulsive purchase decision, $F(1, 66)=5.10$, $p<.05$. More specifically, consistent with our hypothesis, participants in the blue condition achieved higher impulsiveness on specific impulsive purchase decision (means=3.16 vs. 2.44).

In experiment 2, we verified our findings by conducting an online survey. Rather than to fill up a paper-and-pencil survey respectively in red or blue, 122 participants were randomly assigned to fill up an online survey respectively with blue or red computer background screen. The procedure was similar with the first experiment. Similarly a unifactorial (color condition: red vs. blue) between subjects analysis of covariance revealed an effect of color on impulsive purchase decision, means=2.87 vs. 2.45; $F(1, 120)=3.71$, $p=.05$.

In sum, in this study, through two experiments, conducted among almost 200 participants, we consistently found that color (blue vs. red) did influence individual's impulsive buying behavior. Specifically, compared to individuals briefly exposed to red, individuals briefly exposed to blue had higher impulsive buying intent. The findings suggest that color can serve as an important environmental cue that has large impact on consumer impulsive buying behavior. Our findings contribute to the literatures both on consumer impulsive buying behavior and color psychology. Also our findings have practical implications on how to help retailing stores to create an environment to enhance consumer impulsive buying and also bring up the question that whether Santa Clause still wears red in the large shopping malls when the shopping spree season comes.

The Influence of Framing and Processing Fluency on the Estimates of Conjunctive Events

Ahmad Daryanto, Lancaster University, UK
Peter Hampson, Northumbria University, UK

Many events in life constitute conjunctive events (e.g., getting tenure). A conjunctive event consists of more than simple event (e.g., getting a paper published). The likelihood of a conjunctive event is the probability that all simple events occur. Past research has examined how people interpret the probability occurence of the conjunctive events (e.g., Bar-Hillel, 1972; Brockner et al. 2002; Mandel, 2008). For instance, Bar Hillel (1973) has found that people overestimate the likelihood of conjunctive events. Research by Brockner et al. (2002) demonstrates that promotion-focused individuals may do better at estimating conjunctive events than prevention-focused individuals. The present research aims at extending the previous research. We posit that estimates of a conjunctive event may be affected by the framing of its simple events (i.e., gain e.g., accepted vs. loss, e.g., not rejected) and the effect is mediated by processing fluency. We aim at making contribution to framing and consumer decision making literature.

Recent research has examined a strict refocusing framing effect (Mandel, 2008), which refers to the description of a conjunctive event as consisting a series of simple event framed as either a gain or loss (e.g., two acceptances out of three paper submissions or its complementarity of one rejection out of three paper submissions). Despite extant research on framing, strict refocusing framing effect was paid little attention. The main aim of the present research is to examine the effect of strict refocusing framing on the estimation of conjunctive events.

SIGNIFICANCE AND IMPLICATIONS OF THE RESEARCH

In this study, we examine how people's judgment on the probability of a conjunctive event influences their subsequent inference (e.g., after successfully getting five papers accepted what is the probability of getting tenure?). Our study demonstrates that a conjunctive event that contains series of success events was judged more probable if they were supported with positive evidence, whereas its complementary event that contains a series of failure events was judged more probable if they were supported with negative evidence. We provide support for our theory in empirical setting involving hypothetical scenarios. We study the role of processing fluency as a cognitive mechanism of the strict refocusing framing effect and test the prediction in more naturalistic settings.

To test our prediction, we designed a 2×2 between-subjects experiment in which we manipulate frame (success vs. failure) and base rate information (33% vs. 67%). This prediction was tested in a study involving hypothetical scenarios. A total of 104 undergraduates (49 men and 55 women) participated in the study. Participants in the success condition read information about the chance of selling a product in the first week of employment of a new sales person who has never participated in a sales training program before joining a company. Next, they read a paragraph about Linda, who is a new employee of a company X. During the first week of her employment, she has contacted six customers where four of them had decided to buy one unit product each from Linda (coded as event A). Participants in the failure condition read the negation of event A (i.e., two of them had decided not to buy from Linda. In all four conditions, the probabilities of the events are exact, which can be calculated from binomial theorem. After reading the scenario, participants indicated their subjective probability regarding the chance that Linda had participated in a sales training program before joining the company by putting a cross (X) in a single line mark as 0% or never in one end and 100% or certain in the other end. These responses were transformed to probabilities by taking the ratio of the length of the marked line from origin with the total length of the line. We also included items for measuring message processing, and processing fluency using 7-point scale, anchored by strongly disagree [1] and strongly agree [7].

RESULTS

With regard to frame, the results show a non-significant difference between the gain (M_{LOSS} = 0.53, SD=0.17) and loss (M_{LOSS} = 0.61, (t(97)=0.165, p>0.05). With regard to base rate, the results show a significant difference between the low base rate ($M_{p=0.33}$ = 0.61, SD=0.17) and high base rate ($M_{p=0.67}$ = 0.53, SD=0.17, (t(97)=2.12, p<0.05). This result highlights respondents' subjective judgments were affected by the base rate, i.e., the chance of occurrence of one event. A 2(frame: gain, loss) x 2(base rate: p=0.33, p=0.67) ANOVA revealed the frame x base rate interaction on the subjective probability judgment (F(1,99)=4.7, p=0.036). Contrast analysis shows that, albeit the four events are equally likely, participants' subjective judgment is higher when presented with event A (i.e., where the probability of making one success is low and the information regarding Linda's performance is described in gain) than its negation of event ~A (i.e., where the probability of making one failure is low and information regarding Linda's performance is described in loss). In contrast, participants' subjective judgment were higher when they read event ~B (i.e., where the probability of making one failure is low and the information regarding Linda's performance is described as a loss) than event B (i.e., where the probability of making one success is high and the information regarding Linda's performance is described as a gain). To examine the role of processing fluency as a potential mediator of the framing effect, a structural equation model was developed. Our results confirmed our hypotheses.

GENERAL DISCUSSION

Our study examines people's subjective probability judgment on the estimates of conjunctive events that consists of an independent series of simple events. The results of our empirical study confirm our prediction and extend previous findings of Brockner (2002) and Mandel (2008). Further research is needed to generalize the findings to another consumer research setting (e.g., estimates of resolving product complaints after filing five complaints).

Why Retail Therapy Works: It is Choice, Not Acquisition, That Primarily Alleviates Sadness

Beatriz Pereira, University of Michigan, USA
Scott Rick, University of Michigan, USA

People often engage in shopping activities when feeling sad. Indeed, folk wisdom suggests that negative affect can be healed by going shopping, a phenomenon labeled as retail therapy (Underhill 1999, Gardner and Rook 1988, Atalay and Meloy 2011). Although it is increasingly clear that sadness stimulates spending (e.g., Cryder et al. 2008; Lerner, Small and Loewenstein 2004), it is less clear whether and why shopping actually helps to alleviate negative affect.

Answering the question of whether retail therapy "works" is complicated by the fact that the shopping experience consists of several components (e.g., browsing, choosing, acquiring, and consuming), some of which may be more hedonically influential than others. Previous qualitative work in marketing suggests that consumers might shop in an effort to regain a sense of control over their life (e.g., Pavia and Mason 2004), which is somewhat ironic given that the act of spending while sad is itself often viewed as a loss of self-control (cf. Faber and

Vohs 2004). Nevertheless, this work suggests that it is the act of choosing whether or how to spend, rather than the acquisition of products, that primarily alleviates sadness. The primary focus of our work is to show experimentally that choosing repairs sadness. If that is the case, we can argue that the choice component of retail therapy contributes to the alleviation of sadness, whereas mere acquisition does not.

Indeed, prior work suggests that small amounts of choice can be energizing and hedonically beneficial (e.g., Botti and Iyengar 2004; Moller, Deci, and Ryan 2006). However, none of this prior work has examined whether choice alleviates negative affect. Moreover, much of this work compares choice conditions to conditions that arguably highlight the absence of choice (e.g., by informing participants that someone else has made a choice on their behalf, or that the outcome was randomly determined). Thus, a secondary purpose of our work is to provide a more conservative test of the hedonic benefits of choice, by comparing choice conditions to conditions that do not highlight absence of choice.

To examine whether choice can help to reduce sadness, we conducted two experiments that induced sadness and then manipulated whether or not participants made monetarily consequential choices. In Experiment 1A, 41 participants learned that they would receive $1 in exchange for watching a sad video clip. The clip, from *The Champ*, portrayed a boy watching his mentor die, and is a common sadness induction (e.g., Gross and Levenson 1995). In the No Choice condition, participants watched the full three-minute clip uninterrupted. In the Choice condition, participants watched the first two minutes, and then the computer gave them the choice to stop watching (and return their $1 to the experimenter) or to continue watching (and keep their $1). Participants subsequently rated their current level of sadness (and other emotions) on a modified Positive and Negative Affect Schedule (PANAS; Watson, Clark and Tellegen 1988). The three items of interest were averaged to form a sadness index ("sad", "blue", and "depressed", α = 0.88). Only two participants chose to stop watching the video. (Their data are excluded from the analyses.)

As predicted, reported sadness was significantly lower in the Choice condition than in the No Choice condition (3.54 vs. 4.71, $t(37)$ = 2.12, $p < .05$, $d = 0.68$). Participants with a chance to exert control reported lower levels of sadness than participants who did not have a choice, even though both groups performed a sadness induction of equal content and duration. No significant differences were found in the other emotions. Although the results are consistent with our hypothesis, Experiment 1A cannot rule out an artifactual explanation, namely that it was the interruption in the video (rather than the opportunity to choose) that helped to alleviate sadness. In Experiment 1B we told all participants that we were studying how people respond to emotional flip clips when there is an interruption in the clip, but gave only half of them the choice to stop watching in the intermission. Similar to Experiment 1A, the results showed that participants in the Choice condition reported lower levels of sadness. The replication suggests that the benefits of choosing observed in study 1 were not an artifact of an interruption. It also suggests that the reduction in reported sadness is not due to distraction.

To speak more directly to the effectiveness of retail therapy, Experiment 2 examined whether choosing between money and products can be similarly healing. Sadness was induced by showing all 77 participants the clip from *The Champ*. Next, we told participants that they would receive a small reward as a thank-you for participating. In the No Choice conditions, participants either learned that they would receive $2.50 or a shot glass emblazoned with their school's logo. Participants were not made aware that there were two possible rewards or that their reward was randomly determined. In the Choice condition, participants chose whether they wanted to receive the cash or the glass. (Participants were only slightly, and not significantly, more likely to choose the glass than the cash.) Finally, participants rated their current feelings on the modified PANAS.

Consistent with our prediction, the ANOVA revealed a significant main effect of choice ($F(1,73) = 3.98$, $p < .05$). Pooling across gift type, sadness index (α = .88) was significantly lower when participants chose their gift than when their gift was assigned (2.91 vs. 3.75; $t(75)$ = 2.06, $p < .05$; $d = .47$). The main effect of gift type and the interation were non-significant. Consistent with our hypothesis, the opportunity to exert a choice in a consumption domain yielded lower reported levels of sadness, regardless of whether a product or cash was chosen.

Taken together, the results suggest that shopping can help to alleviate sadness. Specifically, it appears that choosing, rather than merely acquiring, is the primary healing component of retail therapy. Although retail therapy can surely be taken to dangerous extremes, our results suggest that moderate amounts of shopping might actually be an effective emotion regulation strategy, and not a failure of self-control.

No Good Deed Goes Unpunished:
Citing Sources in Print Advertisement Claims

Catherine Armstrong Soule, University of Oregon, USA
Leslie Koppenhafer, University of Oregon, USA

Discovering how to best protect consumers from deception in the marketplace has steadily increased in importance to business practitioners, government policy, and academics in the consumer behavior field. The Federal Trade Commission current requires advertisers to have factual data to justify all claims made in print advertisements (for example, "Brand XYZ is 77% more effective than the leading competitor"), but it is not necessary for that information to actually be present in the copy of the ad. However, many media companies, such as Hearst Publications and Time Inc., now require companies to print this claim citation information in order to assist consumers in making correct judgments about the real meaning of claims. Some companies are also voluntarily including this "fine print" in order to appear more trustworthy to consumers. This research investigates whether these well-intentioned actions may in reality be harmful to these forthright companies by inadvertently and erroneously increasing consumers' perceptions of deception.

Advertisements that make claims without substantiating the source of the information are deceptive, according to many experts on the subject (Boush, Friestad, and Wright 2009). This can be viewed as a case of omission, which is the act of failing to include relevant information, such as context, sample sizes, and/or where and when the supporting data were collected that a consumer needs in order to correctly interpret the claim (Boush et al. 2009) Also, these types of advertising claims often include numerical information presented in a conditional probability (such as 77% improvement) that is meaningless without more information and is very difficult for most individuals to interpret (Gigerenzor 2002). This research aims to provide direction for the important societal need of teaching consumers to recognize and protect against deceptive marketing attempts and make better marketplace decisions. Consumers must learn to protect themselves in both low and high financial risk scenarios. While consumers are more involved in high financial risk situations and are more likely to engage in more in depth processing by definition (Evans 2003), inexpensive purchases are made much more frequently and therefore in totality also have the potential to cause serious harm to consumers in the long run.

Two issues explored in this research are the effects of advertising skepticism and innumeracy on consumer perceptions of deception. Individuals naturally develop skepticism towards marketing attempts throughout their lives which can be seen as a protection mechanism against deception (Friedman, 1998; Obermiller and Spangenberg 2005). Knowing that consumers are rightfully skeptical of ad claims, truthful advertisers often seek to provide additional information to overcome the initial distrust (Ford, Smith, and Swasy 1990). Unfortunately, skepticism has been shown to decrease trust in advertisements regardless of the content or actual truthfulness (Koslow 2000). Adding to the problems arising from skepticism, people's inability to process numbers in a meaningful way, or statistically illiteracy, can also lead to distrust of claims which contain numbers (Sowey 2003). We expect individuals with high advertising skepticism to perceive higher levels of deception (H_{1a}) and those with low numeracy skills to perceive higher levels of deception (H_{1b}).

After examining how individual differences influence deception perception, our main interest was to examine how the presence of source citations affected perceptions of deception. We expect, contrary to common wisdom and current advertising practice, consumers to perceive higher levels of perceived deception when the advertiser provides source citation (H_2).

Data were obtained via a lab experiment from undergraduate university students in exchange for course credit (n=110, 42% female). The experiment was a 2 (source citation present/absent) x 2 (financial risk low/high) between subjects design. Participants randomly viewed one of two advertisements for headphones, one with a conditional probability claim ("77% improvement in sound quality") and no source citation and the other with the same claim with an asterisk and fine print citing the scientific research to prove the claim. Half the subjects were told the headphones cost $34.99 (low financial risk) and the other half were told the cost was $199.99 (high financial risk). The participants evaluated the ad on the dimensions of purchase intent, attitude toward the product and advertisement, claim and source credibility and perceived deceptiveness. Participants also completed separate scales for individual difference measures on skepticism, financial risk and innumeracy.

H_{1a} was not supported, since level of skepticism towards advertising was not a significant predictor of perceived deception level ($F_{cha}(1,105)=0.186$, p=0.770). Supporting H_{1b}, score on the numeracy scale was a significant predictor of perceived deception level, with those answering more questions correctly perceiving less deception ($F_{cha}(1,104)=7.578$, p=0.007). This indicates that an ability to actually understand a number used in a claim and how advertisers arrived at that number in the citation increases consumer ability to detect deception.

An ANOVA was used to test H2 and partial support was found. There was no significant main effect for source citation (F(1,108)=0.360, p=0.550) or financial risk (F(1,108)=0.139, p=0.710), but the interaction was significant (F (1,106)= 4.019, p=0.048). When the product was less expensive, those in the condition with correct source citation perceived higher levels of deception, but when the product was more expensive, those in the source citation absent condition correctly perceived more deception.

Our findings regarding skepticism and innumeracy are encouraging for consumers. Because high skepticism did not increase perceived deception, there is less reason to be concerned that marketplace deception teaching interventions are detrimental. Also, numeracy findings indicate that teaching consumers probability and other basic math skills could be extremely helpful in increasing accuracy in detecting deception. Perhaps more importantly, knowing that differences exist in interpretation of source citation depending on the financial risk involved with the advertised product has serious implications for researchers and practitioners. Requiring source citation for all products, while well-intentioned, may actually be detrimental to honest marketers.

Green Consumption and Materialism among Young Consumers

Liyanage Perera, Melbourne University, Australia
Jill Klein, Melbourne University, Australia

Green consumption refers to environmentally conscious consumption (Autioet al. 2009 ; Gilget al. 2005 ; Stern 2000) and has recently gained significant scholarly attention due to environmental issues such as climate change. Some of these studies are concerned with the relationship between materialism and green consumption and provide mixed findings. Materialism – the excessive regard for worldly possessions, and the accumulation of possessions to gain happiness (Belk 1984 ; Belk 2001 ; Kasseret al. 2004 ; Richins 2004 ; Richins & Dawson 1992) - is thought to be negatively associated with green consumption (Kilbourne & Pickett 2008). Some argue that green consumers hold postmaterialistic values (Inglehart 1995) which relate to simplistic life styles (Richins & Dawson 1992). There is, however, no consistent findings on the relationship between materialism or postmaterialism and green consumption (i.e.,Dietzet al. 1998 ; Dunlap & York 2008).

SELF EXPRESSION AND MATERIALISM

A close scrutiny of studies on materialism shows that consumers express a 'sense of self' through consumer materials (Ahuvia 2005 ; Belk 1988 ; Dolfsma 2004 ; Giddens 1991 ; Kleineet al. 1995 ; McCracken 1986 ; Oyserman 2009). More recent studies also relate green consumption to the formation and expression of consumer identities (Connolly & Prothero 2008 ; Horton 2003 ; Soron 2010). Andreou (2010) theoretically argues that materialism is not antithetical to green consumption as happiness from materialistic consumption relies on an emotional, not material level. Furthermore, green consumption conveys a 'costly signal' and therefore there is a strong association between high social status and green consumption (Griskeviciuset al. 2010).

Building on the above research, we argue materialism may not be negatively related to green consumption. Green consumers expect and enjoy emotional benefits such as self expression and social interaction through their consumption (i.e.,Bourdieu & Nice 1984 ; Holt 1995 ; McCracken 1986), regardless of whether they are materialists or postmaterialists (Douglas & Isherwood 1996). Thus, the purpose of this scholarship is to explore the emotional benefits or symbolic reproductions of green consumption.

Young consumers have often been criticized for their materialistic consumption (Miles 2000 ; O'Shaughnessy & O'Shaughnessy 2007). Criticisms of young consumers' understanding of the environmental impacts of their consumption (Autio & Heinonen 2004), or the extent to which they actually engage in green consumption (Hume 2009) coexist in the literature with characterizations of young consumers as socially, culturally and environmentally conscious consumers (Sheahan 2009 ; Sullivan & Heitmeyer 2008). These contradictory findings suggest the need for further study of young consumers' green consumption. To this end, we investigate: What does it mean to a young consumer to be a green consumer? And, how does he/she engage in green consumption practices?

METHODOLOGICAL CONSIDERATION AND ANALYSIS

Twenty photo-elicited, semi-structured interviews ranging from 1.5-3 hours were conducted with young consumers (aged between 19-25 years) in a large Australian city. Purposive and snowball sampling techniques were used to ensure respondent diversity and gain access to 'information *rich'* cases of youth engaged in environmental groups, activism and consumption practices (Patton 2002). The interviews were audio recorded and transcripts were made. Line-by-line analysis was completed after the first 12 interviews to refine the interview protocol for subsequent cases. After analyzing all the interviews thematic categories (Strauss & Corbin 1990) were derived and tested with respondents in member check interviews.

FINDINGS: THE MEANING OF GREEN CONSUMPTION

Green consumption among young consumers is constructed as having an awareness of each stage of production and consumption cycles, and concern about environmental problems such as climate change. Drastically withdrawing from environmentally destructive consumption through adoption of a green lifestyle is considered important. Respondents described green consumption as a conscience-driven consumption practice, which predominantly moves them away from making 'new' mass-market commodity purchases and towards alternative consumption practices. In unavoidable purchase occasions, they use mobile phone applications to access information about environmentally unfriendly production and consumption practices. Green consumption with a positive appeal (i.e., a means of fun, happiness, social networking and adventure) instead of a negative appeal (i.e., restricted or controlled consumption) is preferred.

1. Connection to Nature

Our informants frequently engage in activities related to the natural environment both individually and collectively (i.e., bushwalking, camping). They enjoy the connectedness with the natural environment and strive to participate in sustainable practices that maintain ecologi-

cal balance (i.e., permaculture). Thus, they discursively construct themselves as *contributors* to ecological balance instead of *consumers* which usually conveys the meaning of being a passive *end user* (i.e.,Firat & Venkatesh 1995).

2. Expression of the self

Engaging in green consumption helps these young consumers to express their identities as environmentally conscious individuals. Since the meaning of green consumption among them is constructed through awareness of environment-related issues, they try to value being highly informed and share information with other individuals similarly engaging in green consumption. They perceive climate change problems as a massive phenomenon that is somewhat overwhelming. By engaging in green consumption they see themselves as people who deal with this massive phenomenon (Connolly & Prothero 2008 ; Giddens 1991).−

3. Social costs of green consumption

Informants believe that green consumption is yet to be practiced by mainstream society. They describe difficult experiences in social interactions, in which they are criticized for their green consumption. Criticisms from friends and family lead to feelings of disconnection, and informants navigate a difficult balance between self-expression and accusations that they are preaching to others. While some informants try to avoid associating with non-green consumers, some make compromises to keep up with mainstream consumer expectations (i.e., wearing second-hand t-shirts with a leading brand).

4. Empowered consumption

These consumers try remove themselves from existing market systems through (1) not making new purchases and trying to grow, make or build whatever they need (2) boycotting popular supermarkets, buying from farmers' markets or engaging in *dumpster diving* (procuring goods that have been thrown away), (3) staying updated with environmental issues through information technologies and (4) finding alternative exchange methods (i.e., clothing swaps, barter systems among friends). They are also skeptical about green labeled products and perceived them as profit-driven corporate *greenwashing*. By avoiding *greenwashed consumption*, these consumers enjoy a greater amount of power and control over their personal consumption in being able to act against environmentally unfavorable marketing practices. However, consistent with previous studies (i.e.,Autio,et al. 2009 ; Clevelandet al. 2005), anxiety about not being able to make a significant positive impact on environmental sustainability is common among these consumers.

DISCUSSION AND CONCLUSION

We found that the meaning of green consumption among young consumers involves being aware of every aspect of consumption/ production cycles through critical information processing. Our interpretive analysis revealed green consumption is practiced as a means of self-expression, identity performance and has positive associations, such as having fun, being happy, social networking and engaging in adventurous activities (i.e.,Andreou 2010 ; Autio,et al. 2009). Enjoying the positive connotations of green consumption, such as discovering alternative means of consumption, taking challenges, enjoying the natural environment, contributing to sustaining the ecological balance and feeling empowered by withdrawing from existing market systems seems to be more prominent for our informants than negative connotations, such as limiting, restricting or controlling consumption.

Doers Conform, Perceivers Counteract:
The Effect of Synchrony on Uniqueness Seeking

Xianchi Dai, The Chinese University of Hong Kong, China
Ping Dong, The Chinese University of Hong Kong, China

In our daily life, we come across synchronous activities (e.g. chorus, dancing, marching, and so on) very often. Given the ubiquity of these behaviors, it is surprising that little is known in the existing literature how it affects subsequent behavior. In this paper we try to answer the following questions: 1) how does interpersonal synchrony with others affect subsequent uniqueness seeking behavior? 2) Is the effect the same for doers and for perceivers of the synchronous behavior? In answering these questions, we also try to understand the processes underlying these behaviors.

Synchronized behaviors refer to behaviors or actions that are matched in time (Hove and Risen, 2009). Acting in synchrony with others requires individuals to surrender self-centered behaviors and fit into group norm, which in fact imposes a pressure towards people's behavioral freedom. Thus, after engaging in synchronized behavior, a reactance may occur (Brehm 1966; Brehm and Brehm 1981), which leads to greater uniqueness seeking (i.e., the opposite of conformity). Similarly, watching a group of people's synchrony behavior may also elicit a feeling of "forced uniformity" from the observers' perspective. We thus predict the same effect for the perceivers. On the other hand, synchrony has been shown to enhance group cohesion and subsequently strengthens social attachment, fosters cooperation within groups (Haidt 2007; Wiltermuth and Heath 2009; Hove and Risen 2009). As a consequence, those who engage in synchronous behavior would be more likely to conform.

These two forces thus make opposite predictions regarding the effect of synchrony on subsequent preferences. For the doers who engage in interpersonal synchrony, the two forces jointly affect their preferences. We predict that the force that leads to conformity would be stronger and thus dominate the opposite force (i.e., the reactance). Thus, doers would be less uniqueness seeking after engaging in synchronous behavior than after engaging in non-synchronous behavior. The situation is quite different for the perceivers. Perceivers also experience a sense of threat after seeing synchrony, but they do not engage in any action that could increase conformity. That is, for them the psychological reactance would still persist but the action induced conformity would be absent. Thus, perceivers would be more uniqueness seeking after seeing synchronous behavior than after seeing non-synchronous behavior. Furthermore, when the synchronous behavior is perceived to be a result of forced choice rather than free choice, the levels of psychological reactance should be higher. Thus, after forced (versus freely chosen) synchronous behavior, people's preference for uniqueness would be stronger as a consequence of stronger psychological reactance.

Two studies were conducted to test the predictions and the underlying mechanism that governs the different synchrony effect for doers and perceivers. Study 1 was a 2 (synchrony: synchrony vs. non-synchrony) x 2 (role: doer vs. perceiver) between-subjects design.

Undergraduate students from a major Hong Kong university were recruited to participate in the experiment. The students participated in the study in a group of 10-12 people. Participants in each group were randomly assigned to be either doers or perceivers. Doers were instructed to do some exercises and perceivers simply observe the doers' behavior. The groups were randomly decided to be either synchrony group or non-synchrony group. In the synchrony group, all the doers were instructed to do the exercise synchronously; whereas in the non-synchrony group, all the doers were instructed to do the same exercise, but they were not instructed to do them synchronously. After this task, participants moved to a second task, in which they were asked to make several choices of different product categories. In each choice, they were presented with three brands, each with different market share. For example, in a typical choice, option (A) was preferred by around 65% of people, option (B) was preferred by around 25% of people, and option (C) was owned by around 10% of people. Participants' choice were coded as 1, 2, or 3 depending on which option they chose (1 = brand with highest market share; 3 = brand with lowest market share). The sum of these numbers formed a uniqueness seeking index (the higher the score, the higher is the uniqueness seeking motivation). The results confirmed our prediction. Perceivers were more uniqueness seeking under synchrony condition than under non-synchrony condition. Conversely, doers were less uniqueness seeking under synchrony condition than under non-synchrony condition

Study 2 manipulated the perceived freedom of choices of the doers acting in synchrony with each other to detect the source of "synchrony reactance". The study adopted a 2 (role: doer vs. perceiver) x 2 (choice freedom: forced choice vs. free choice) full factorial design. Similar to study 1, the students participated in the study in a group of 10-12 persons and were randomly assigned to be perceivers or doers. In this study all the doers were instructed to do the exercise synchronously. The doers were randomly assigned to the forced or free choice conditions. In the forced choice condition, participants were required to do the exercise synchronously. In the free choice condition, the participants were asked to choose from two tasks: the synchrony task, or an essay writing task in which they were asked to write an essay of about 500 words on "The Individual and the Cosmos in Renaissance Philosophy." All the participants in the free choice condition actually chose to do the synchrony task (which is identical to the one in the forced choice condition). Perceivers were either instructed that the doers were required to do the synchrony task, or that the doers chose to do the synchrony task. The measure of uniqueness seeking was identical to that in study 1. Again, the results were consistent with our prediction. First, perceivers showed stronger preference for unique options than doers. Second, those in the forced choice condition demonstrated stronger preference for uniqueness than those in the free choice condition – this conclusion was true for both doers and perceivers. These results suggest that reactance due to threat to behavioral freedom was the process underlying such effects.

When One's Death Awareness Involves Others:
The Role of Relationship Closeness in Luxury Consumption

Shuoyang Zhang, Colorado State University, USA
Aditi Grover, Plymouth State University, USA

Death is a reality of life. While people are fundamentally aware of death, there coexists an inherent will to survive. Terror Management Theory (Greenberg et al. 1986, 1994) posits that people manage these conflicting thoughts (and associated emotions) to maintain order, continuity, and permanence.

While research has shown that reminder of death or mortality salience can significantly impact human behavior (Niemiec et al. 2010), one's awareness of death has never been investigated in the relationship context in terms of how one connects to others. According to evolutionary theory, individuals do not so much attempt to ensure their own welfare and survival as to ensure the welfare and survival of their genes, which are collectively shared with others (Cialdini et al. 1997; Hamilton's 1964). Therefore, one's relationship with others inevitably plays a role when one has the awareness of death.

The purpose of the current study is to examine how relationship closeness influences consumers' attitude toward luxury goods when they experience death anxiety. Specifically, we propose: a) in general, people with close relationships are less likely to consume luxury goods than people with weak relationships; b) under mortality salience, people with close relationships are even less likely to consumer luxury goods than people with weak relationships. This study contributes to the literature by emphasizing the role of relationship closeness in luxury consumption under the condition of mortality salience.

Hypotheses Development

Mortality salience has been found to induce intense feelings of anxiety and terror. To buffer against this death-related anxiety, people attempt to live up to their cultural values or norms there-by increasing their self-esteem (Greenberg et al. 1986) and value. In fact, prior research has demonstrated that under conditions of mortality salience people are more likely to show preference towards high status (vs. low status) products (Mandel and Heine 1999).

When individuals experience a strong relationship, the perceived closeness could indicate relationship cues—kinship, friendship, similarity, and familiarity—that signal relatively high genetic commonality (Rushton, Russell, and Wells 1984). They are less likely to be threatened by the mortality salience due to the sense of gene overlap and continuity carried by the close other. Research has shown that when people feel close the other, the enhanced closeness could arise from attachment and perspective taking that causes the expansion of the self into the other (Aron, Aron, and Smollan 1992). Because their need for permanence is met by their connection with close others, they are less likely to rely on luxury consumption to maintain self-esteem comparing with people with weak relationships. More specifically, people in weak relationships are more likely to meet their need for self-preservation through more favorable attitudes and intentions towards luxury products (Mandel and Heine 1999).

METHOD

The experiment will use a 2 (mortality salience vs. control) * 2 (close friend vs. acquaintance) between-participants design. Participants are randomly assigned to one of the four experiment conditions using Qualtrics in a behavioral lab.

Participants are told that the experiment session involves several unrelated studies. They are let to believe that the purpose of the first study was to understand their feelings about death. Following Greenberg et al. (1997)'s procedure, mortality salience is induced by two open-ended questions: "Please briefly describe the emotions that the thought of your own death arouses in you" and "Jot down as specifically as you can, what you think will happen to you when you physically die." Participants in the control condition answer the same questions concerning taking a difficult exam. Previous research has shown that mortality salience effects mainly occur after distraction from conscious thought about death (Greenberg et al 1994), therefore participant are asked to proceed to the next study, which intends to understand their interpersonal relationships.

Following the approach of Starzyk et al. (2006), participants read one of the two sets of instructions that asked them to choose someone to focus on during the study. In the *strong* relationship condition, participants choose someone with whom they have a strong relationship, for example, a close friend. In the *weak* relationship condition, participants choose someone with whom they have a weak relationship, for example, a casual acquaintance. Participants are asked to indicate the chosen person's initials, age, and gender, how long they had known the person, and the kind of relationship they had with the person. With this person in mind, they answer some questions that intended to measure the strength of the tie that they have with the chosen person, including the Inclusion of Other in the Self (IOS) scale (Aron et al. 1992), the adapted Subjective Closeness Index and the Relationship Closeness Inventory (RCI) (Berscheid, Snyder, and Omoto1989), and the Personal Acquaintance Measure (PAM) (Starzyk et al. 2006).

Participants then precede to the last study to collect their product evaluations. While participants review a series of luxury products, the initials of their chosen person show up in the background to strengthen the manipulation of relationship closeness. Participants respond to three 10-point semantic scales to reveal their attitude about the product: bad/good, negative/positive, unfavorable/favorable. They also indicate their likelihood of buying the product and recommending the product, each on a 10-point scale: very unlikely/very likely.

CONCLUSION

People are often reminded of death—either due to natural or man-made causes. People are also social animals who are embedded in their relationship networks all the time. Therefore, it is important to understand how people respond to mortality salience in the context of relationship closeness. Our research demonstrates that people's attitudes and intentions toward luxury goods depend on how salient people are aware of death as well as how close people are connected with others.

Increased Sensitivity to Specific Disabilities via Matched Psychomotor Experience

Ab Litt, Stanford University, USA
Taly Reich, Stanford University, USA

More than 30% of US adults suffer from at least one basic-actions difficulty or complex-activity limitation, including 61% of those 65 and older (Centers for Disease Control and Prevention, 2010). As populations age worldwide, the proportion of individuals living with physical, sensory, mental-capacity, and illness-related disabilities is rising even further. It is thus of both current and growing importance for products, services, and environments to incorporate accessibility features which ensure they can be used by as many people as possible.

Accessibility accommodations can increase costs to deliver products and services that all consumers must bear, whether or not they themselves would currently benefit from them (e.g., adding wheelchair-lifts to buses, manufacturing foods in special facilities free of common allergens). It is therefore valuable that able-bodied people be able to understand, empathize with, and better appreciate and maintain sensitivity to challenges those afflicted with disabilities face in navigating their daily lives. How can we increase consumers' motivation to help improve the lives and lessen obstacles faced by the disabled, such as via increased willingness to pay to incorporate accessibility accommodations into products and services?

We demonstrate that consumers' incidental psychomotor actions and experiences can increase their sensitivity to *specifically aligned* disabilities, manifesting itself in increased willingness-to-pay to add product-accessibility accommodations. By "aligned" we mean in the sense that the psychomotor experience of having to walk up and down a flight of stairs matches with sensitivity to mobility disabilities, versus having to squint and struggle to read a blurred text matches with vision disabilities. This result builds on growing research showing that motor actions or simulations, such as pulling products toward oneself, can alter judgments and feelings (e.g., Hung & Labroo, 2011; Labroo & Nielsen, 2010). We show such effects of a completely novel nature—induced sensitivity to others' disabilities specifically matched to one's own incidental psychomotor experience. Whereas Bargh et al. (1996) showed that priming elderly stereotypes caused individuals to walk slower, we propose that essentially reversed effects might also hold: that the motor behavior of walking slowly might influence thoughts and feelings regarding the elderly.

STUDY METHOD

Part 1 of the experiment was described as investigating the effects of change of location on task completion. Participants moved up and down three times from the basement to the third-floor of a building, completing a word-puzzle at each location. Participants either took the elevator up and down each time (*n*=21), or walked up and down three flights of stairs each time (*n*=20).

In part 2, participants were asked to report their willingness-to-pay "to allow for features and enhancements to various goods and services that would make them more useful and appealing to different groups of people". For each, they indicated the maximum percentage above regular price they would be willing to pay extra to make possible the proposed change to the product. Each of the cases (presented in random order) involved adding an accommodation for a specific disability or usability-need:

- providing a Braille version of a textbook (*vision*, % above book price)
- adding wheelchair-ramp access to the main entrance of your favorite restaurant (*mobility*, % above average meal price)
- a museum hiring guides who can communicate in sign language (*hearing*, % above admission price)
- producing a DVD of a popular movie with closed captioning in multiple languages (*linguistic*, % above DVD price)
- producing a candy bar with nut-free processes and facilities for the benefit of those with allergies (*health condition*, % above candy price)
- adding a sensor system to a furnace that could remind those with dementia to turn off the gas, and/or alert a caregiver of unlit gas (*cognitive*, % above furnace price)

These primary DVs of interest were encountered among some unrelated filler questions. Afterwards, participants also reported on one-to-nine scales of how physically tired they felt, and how difficult or physically demanding they found moving around between the different locations in the change of scenery portion of the study.

RESULTS

In debriefing, no participants reported awareness or guessing of our manipulation, experimental intentions, or hypotheses. For the mobility-related accessibility accommodation (wheelchair access), participants in the Stairs condition reported a significantly higher willingness-to-pay than those in the Elevator condition (M_S=16.16 vs. M_E=10.86; $t(39)$=2.14, p=.04). However, no such differences were observed for any of the other accessibility accommodation measures (t's< .58, p's>.56). Thus, walking up and down the stairs (relative to taking the elevator) induced a higher premium that able-bodied consumers were willing to pay to specifically help those with mobility disabilities, but not those with other needs.

Participants in the two conditions did not report any difference in how tired they felt (M_S=3.65 vs. M_E=3.05; $t(39)$=.89, p=.38), but those in the Stairs condition did report the experiment to be more physically difficult/demanding (M_S=3.10 vs. M_E=1.67; $t(39)$=2.89, p=.01). There was a marginal correlation between this measure and the wheelchair-ramp WTP measure (r=.289, p=.07), though with this small sample the Sobel test of mediation of stairs/elevator condition by felt difficulty was not significant (z=1.04,p=.29).

ONGOING WORK AND EXTENSIONS

In follow-up studies we are exploring new psychomotor manipulations to test for specific sensitivity-induction to other forms of disability: for example, reading blurry text and specific sensitivity to visual disability, listening to muffled sound and sensitivity to hearing disabilities, and performing difficult memory tasks and sensitivity to cognitive and memory impairments. We are also planning more investiga-

tion of the underlying process for this effect—is it due to induced *empathy* or *sympathy* for those with aligned disabilities, higher attention to semantic content associated with preceding psychomotor experience, or some other mechanism? To test possible explanations as well as explore other practical consequences, we are also developing an expanded array of dependant measures. For instance, participants' perceptions of how difficult it is to live with various disabilities, how easy/difficult they find imagining living with various disabilities, implicit measures of their sensitivity to disabilities, and measures with real consequences (e.g., soliciting donations to charities helping those with specific disabilities).

Investigating the Effects of Multiple Country of Origins Label

Yupin Patara, Chulalongkorn University, Thailand
Kent B Monroe, University of Richmond and University of Illinois at Urbana Champaign, USA

Research on the influence of a product's country of origin has been based on the premise that country of origin as an external cue, similar to brand name and price, has an influence on consumers' product evaluations and willingness to buy (Verleigh and Steenkamp, 1999). However, the role of the *country of ingredients origin* as an extrinsic cue has not been studied previously.

The main research questions in the preliminary stage are: -- (1) How do consumers utilize the ingredient country of origin information along with *brand and price* when evaluating products' quality? (2) How do consumers evaluate "Made in …" label if various ingredients of the product were made in multiple countries?

CONCEPTUALIZATION AND THEORETICAL FRAMEWORK

When consumers are uncertain about the quality of products, they may use extrinsic cues to judge the quality claims made by the sellers (Monroe 2003). A product's *brand name* is a cue for customers representing images that they have formed about the brand and may be used as an indicator of quality (Rao and Monroe 1989). Brucks, Zeithaml and Naylor (2000) find that when price is paired with a consistent brand cue, the quality evaluation is enhanced. Chao (1989) finds the same enhancement when pairing price with positive country of origin brand.

According to cue consistency theory (Slovic 1966; Maheswaran and Chaiken 1991; Miyazaki, Grewal, and Goodstein 2000) when a set of cues is consistent each cue will reinforce a subsequent judgment. If a brand name is capable of signaling quality, then the presence of country of origin as an additional signal to endorse and signal the primary brand's product quality may enhance quality perceptions. It is because they provide enhancing impact and are likely to be used jointly in overall evaluations.

Similarly, *country of origin* cues can also influence consumers' quality perceptions and their confidence in the quality of the product. People form an initial concept of a product on the basis of its country of origin and this concept once formed can influence how information about the product's specific attributes is interpreted (Hong and Wyer 1990).

On the other hand, inconsistent cues may signal contradictory information. Moreover, evaluations with inconsistent cues may depend upon some consistent subset of the inconsistent cues. Consumers may focus on the negative cue and anchor their perceptions of quality based more on the negative cues (Ahluwalia 2002; Campbell and Goodstein 2001).

RESEARCH DESIGN

Utilizing cues consistency theory as the conceptual basis for the research, three experimental between subjects studies using three different products are planned to examine how multiple extrinsic cues to influence consumers' perceptions of product quality and value and their behavioral intentions.

Study 1 is a 2 (Price: high and low) x 2 (Certification: yes and no) x 2 (Ingredient Origin: USA and China) between subjects, factorial design.

Study 2 is a 2 (Price: high and low) x 2 (Brand Familiarity: high and low) x 2 (Ingredient Origin: USA and China) between subjects, factorial design.

Study 3 is a 2 (Price: high and low) x 3 (Ingredient Origin: 100% USA, 50% USA 50% China, 100% China) between subjects, factorial design.

PRELIMINARY RESULTS

Study 1 Results -- Manipulation check results indicate that price (Low = 3.67, High = 6.28; F (168) = 3.54, p<.05) and ingredient origin (China = 3.59, USA = 6.62; F (168) = 3.26, p<.05) were manipulated as intended. The hypothesized effect from H1 reveals a significant price x ingredient origin information interaction on perceived quality (F (170) = 6.95, p<.001, see figure 4). We found no mean differences for the inconsistent conditions relative to price and ingredient origin pairing (F <1, NSP). The effect of either cue will be stronger when paired with

a consistent (i.e., High price/ Strong country of ingredient origin) versus inconsistent cue (i.e., High price/ Weak country of ingredient origin or Low price/ Strong country of ingredient origin.)

Study 2 Results -- Manipulation check results indicate that brand (Low familiarity = 5.28, High familiarity = 6.28; F (162) = 10.19, p<.001) and ingredient origin (China = 3.50, USA = 6.74; F (162) = 3.08, p<.03) were manipulated as intended. The hypothesized effect from H2 reveals a significant brand x ingredient origin information interaction on perceived quality (F (162) = 5.51, p<.01, see figure 5). We found no mean differences for the inconsistent conditions relative to brand and ingredient origin pairing (F <1, NSP). The effect of either cue will be stronger when paired with a consistent (i.e., Highly familiar brand/ Weak country of ingredient origin) versus inconsistent cue (i.e., High price/ Weak country of ingredient origin or Low price/ Strong country of ingredient origin.)

Study 3 Results -- Manipulation check results indicate that price (Low = 4.53, High = 7.40; F (1,151) = 8.69, p<.01) and ingredient origin (100% China = 3.52, 50% China and 50% USA = 5.22, USA = 6.56; t (150) = 1.88, p=0.03) were manipulated as intended. The hypothesized effect from H3 reveals that when the brand is highly familiar cobranded with a reputable certification agency, an increase in proportion of ingredients from a strong country of origin will result in an increase in the perception of quality (t (150) = 3.83, p<0.001), increase in the perception of value (t (150) = 4.73, p<0.001), and willingness to buy (t (150) = 1.88, p<0.05).

DISCUSSION

Study 1 and 2 provide strong support for the consistency hypotheses. The target cue is a stronger predictor of perceived quality when paired with a consistent versus an inconsistent alternative cues. Study 3 provide support for the proportion of the ingredient origin hypotheses that when the brand is highly familiar cobranded with a reputable certification agency, an increase in proportion of ingredients from a strong country of origin will result in an increase in the perception of quality, value and willingness to buy.

The Different Effects of Lay Theory of Gender Differences on Gift Shopping Behavior

Jianping Liang, Sun Yat-sen Business School, Sun Yat-sen University, China

If you want to buy a gift, what kinds of attributes of a gift would you look for? Would you look for different kinds of attributes if you want to buy a gift for a person with the same vs. different gender from yours? More importantly, does it matter whether you naively believe that males (females) prefer functionality (aesthetics) over aesthetics (functionality)? Would the extent to which you hold these naive beliefs matter? What is the psychological mechanism of such a naive theory on our behavior? Does it matter if we buy a product for ourselves and for others?

Previous research indicates that people may have a stereotypical perception that male (female) consumers prefer functionality (form) over form (functionality), and as a result, the access of such a stereotypical perception may influence male and female consumers' choice behavior (Liang and Murray 2010). However, Liang and Murray (2010) only conducted an in-depth interview to examine the potential relationships between such a stereotypical perception and choice behavior. We still have no much more knowledge about this stereotypical perception.

According to Dweck (1996), this stereotypical perception may be considered as a lay theory, also called implicit theory, which is a framework for meaning-constructions, a naive or lay system of beliefs that ordinary consumers use in daily life to interpret and evaluate the world around them, including events and experiences (No et al. 2008; Mukhopadhyay and Yeung 2010). Based on No et al. (2008), a similar lay theory of gender differences on preferences of functionality and aesthetics could be proposed. In particular, some consumers have the "essentialist theory of gender" that the gender difference is biologically based and historically invariant. In contrast, the other consumers have the "social constructionist theory of gender" that the gender differences are not deep-seated and inalterable disposition but alterable social constructions. Similarly, most research on the behavioral effects of lay theories by Dweck (see Dweck 1999) makes categorizations of "incremental theories" (i.e., beliefs that people have malleable quantities of ability and intelligence improvable through effort) and "entity theorists" (i.e., beliefs that people have fixed quantities of ability and intelligence that cannot be improved) (Mukhopadhyay and Yeung

2010). Based on the above categorization, Mukhopadhyay and Johar (2005) identify two theoretically orthogonal dimensions: the quantum (limited or unlimited amount of ability) and the changeability (fixed or malleable over time). Subsequently, they further draw distinction on four types of lay theories: limited-fixed, limited-malleable, unlimited-fixed, and unlimited-malleable. In this paper, we investigated these four types of lay theories of gender differences in responses to functionality and aesthetics, and their different impacts on consumers' gift shopping behavior. Interestingly, we found that the different gift shopping behaviors result from lay theories instead of actual preferences. In other words, the lay theories only influence consumers' gift shopping behavior for others but NOT for shopping behavior for themselves.

STUDY ONE

In this study, we recruited one hundred and seventy-five volunteer consumers at a large shopping mall and asked them to complete a short survey about their gifting shopping behavior during the Christmas and New Year holiday in 2010, a busy time of gift shopping for many consumers. In particular, we asked them whether they have shopped or are planning to shop for one gift recently, what the gift was or would be, the gender and age of the person who would receive the gift. Then they were asked to indicate whether they focus more on the functionality or aesthetics of the gift in an 11-point scale. Subsequently, they completed a questionnaire on the measure of the limited/unlimited (two items) and fixed/malleable (two items) lay theories of gender differences in responding to functionality and aesthetics in seven-point scales anchored by "strongly disagree/strongly agree" adapted from Mukhopadhyay and Johar (2005) and Mukhopadhyay and Yeung (2010). Finally, they answered some demographic questions related to age, gender, etc. We also took record of the day and time when they completed the survey. The types of gifts were mentioned in a variety of product categories, including cell phone, necklace, clothes, shoes, MP3, laptop, mug, gloves, backpack, handbag, wallet, etc.

We found that *limited-fixed* male theorists on functionality who believe that females have limited and fixed ability to functionality are more likely to focus on aesthetics instead of functionality when choosing a gift for females. *Limited-malleable* male theorists on functionality focus more highly on functionality instead of aesthetics when choosing a gift for females.

However, *limited-malleable* female theorists on functionality who believe that females have limited and malleable ability to functionality are more likely to focus on aesthetics instead of functionality when choosing a gift for females. *Unlimited-malleable* female theorists on functionality focus more highly on functionality instead of aesthetics when choosing a gift for females.

STUDY TWO

This study aims to investigate the influence of lay theories on product choices consumers make for themselves. It is possible that male (female) consumers choose a gift that reflects their lay theories because their actual preferences influence their decision. Hence, in Study Two, we wanted to test this consideration, which may pose as an alternative explanation for the findings in Study One.

As in Study One, we measured the four types of lay theories. We also asked the degree to which participants pay attention to the functionality and aesthetics of a series of 10 product categories when they shop for products for THEMSELVES, including jackets, jeans, shoes, backpacks, wallets/purses, digital cameras, cell phones, laptops, watches, and table lamps. Interestingly, we found that the four types of lay theorists, limited-fixed, limited-malleable, unlimited-fixed, and unlimited-malleable theorists have no significant different preferences for functionality and aesthetics when they shop for these products for themselves. Therefore, it seems that lay theory of gender differences does not influence the actual shopping behavior for consumers themselves.

The Road Traveled, the Road Ahead, or Simply on the Road? When Progress Framing Affects Motivation in Goal Pursuit

Jacob H. Wiebenga, Department of Marketing, Faculty of Economics and Business, University of Groningen, the Netherlands
Bob M. Fennis, Department of Marketing, Faculty of Economics and Business, University of Groningen, the Netherlands

Most of our behavior starts with goal setting through which we get involved in goal pursuit (Locke and Latham, 1990). After this initial step we monitor our progress toward these goals, such as rewards in loyalty programs (Fishbach and Dhar, 2005). Progress can be conceived as the distance traveled from the initial state to the present state (i.e. work-done) and/or the remaining distance from the present state toward the end state (i.e. work-left; Carver and Scheier, 1998). Although both frames imply one another and thus are logically equivalent, research

on their impact on motivation in goal pursuit has failed to yield unequivocal results. The present work seeks to extend previous research by examining when progress framing affects motivation in goal pursuit.

In essence, information on goal progress can only be perceived as 'diagnostic' when it is construed in relation to an initial state that is removed from the presence and some end state that is not yet attained. Under these conditions, information on progress may affect motivation in goal pursuit because it informs people on the accomplished and remaining distance and thus on the attainability of the goal and on the investments already made in order to attain it (Koo and Fishbach, 2008).

However, there is reason to assume that these effects of progress framing on motivation in goal striving will not hold for all people in all circumstances. That is, in order to have an effect, it requires that people actively relate information about where they are now to an initial state and/or to an end state, both of which are distant from the here and now (Bar-Anan, Liberman, and Trope, 2006). We propose that this tendency to actively relate progress information to distal states removed from the presence may be a function of people's construal level (Trope and Liberman, 2010).

Thus, since progress cues inform people of the distance traveled from the initial state and/or the distance left to attain the end state, and since perceiving such goal distances as meaningful in goal pursuit requires people to actively transcend the here and now, it follows that if progress framing has an effect on motivation in goal pursuit it will mainly have so under high, rather than low construal level conditions when people have an abstract, rather than concrete mindset.

EXPERIMENT 1

Experiment 1 was designed to test the hypothesis that the effect of progress framing on motivation is stronger for people induced with an abstract (vs. concrete) mindset. One hundred and fourteen undergraduate students were randomly assigned to the condition of a 2 x (progress framing: work-left vs. work-done) x 2 (construal level: abstract vs. concrete) between-participants design. We used a letter identification task (Navon, 1977) to vary participants' construal levels. Next, the manipulation of progress framing was administered as an evaluation task of a loyalty program (cf. Koo and Fishbach, 2008), followed by measuring participants' motivation in goal pursuit.

Motivation was submitted to a 2 x 2 ANOVA with progress framing and construal level as independent variables. No main effect of construal level ($F(1,110) = 1.45$, *n.s.*) or progress framing ($F(1,110) = 2.59$, *n.s.*) was observed. However, the progress framing by construal level interaction was significant ($F(1,110) = 7.52$, $p = .007$). More specifically, under conditions of an abstract mindset, goal progress framed as work done produced higher motivation levels ($M = 4.00$; $F(1,110) = 9.46$, $p = .003$) than progress framed as work left ($M = 2.89$). For participants with a concrete mindset, type of progress framing failed to affect motivation in goal pursuit ($M_{\text{work-done}} = 3.61$ vs. $M_{\text{work-left}} = 3.90$; $F(1,110) = 1.19$, n.s.).

EXPERIMENT 2

A key objective for the second study was to provide converging evidence, by using a trait measure of construal level. In addition, Experiment 2 sought to directly test the psychological process assumed to underlie the proposed effects.

A sample of one hundred twenty four loyalty card members were randomly assigned to a design with progress framing (work-done vs. work-left) as a between-subjects factor, and construal level as a continuous individual difference variable. The first part pertained to the manipulation of progress framing, presented as an evaluation task of a loyalty program, albeit with a different set-up than the one used in Experiment 1. This was followed by measures of perceived goal distance and motivation. For the second part, participants completed the trait construal level measure (BIF; Vallacher and Wegner, 1989).

A regression analysis with progress framing and construal level as the independent variables and motivation as the dependent variable replicated our findings from Experiment 1. Furthermore, the main effect of construal level on perceived goal distance was significant ($\beta = .18$, $t(120) = 1.98$, $p = .05$), in that people with a more abstract mindset perceived goal distance as larger. Additionally, a significant progress framing by construal level interaction was found ($\beta = -.27$, $t(120) = -2.91$, $p = .004$). In order to test for moderated mediation, we performed a simultaneous regression analysis in which the interaction, goal distance, and the progress framing and construal level main effect terms served as predictors for motivation. The results showed that the effect of the interaction disappeared ($t < 1$), whereas perceived goal distance remained a strong predictor ($\beta = -.66$, $t(119) = -9.37$, $p < .001$).

GENERAL DISCUSSION

In two experiments we found that both state and chronic differences in experienced construal level modulate the impact of progress framing on motivation to pursue a reward in loyalty programs, such that type of framing only affected motivation of people with an abstract, but not a concrete mindset. Under these conditions, progress framed in terms of work-done produced increased motivation compared to a work-left frame. Moreover, perceived goal distance was found to mediate the impact of progress framing on motivation for individuals with an abstract, but not a concrete mindset. As such, the present work aids in resolving inconsistencies in the literature on the motivational impact of goal progress information, by identifying conditions where progress cues affect motivation and when they do not.

The Configuration and Interplay of Consumer Practices within Consumer-Constituted Communities in Kenya

Fredah Mwiti, Lancaster University, United Kingdom
Dr. Maria Piacentini, Lancaster University, United Kingdom
Dr. Andrew Pressey, Lancaster University, United Kingdom

This paper explores the interplay and configuration of practices as enacted by consumers within the context of 'Chama', a form of consumer-constituted community in Kenya. 'Chama' is the specific word used to refer to collectives very similar to the Rotating Savings and Credit Associations (ROSCAs), and is the term to be used in this paper to refer to ROSCA and other similar collectives. The roles of the Chama (and the rotating pot inherent therein) in enabling members to interact as consumers and fulfill their need to be part of a community (Cova 1997), to engage in consumption practices and ultimately meet varied consumption goals, position it as a fitting context to highlight how consumer practices emerge on a bedrock of such social-historically patterned collectives. The study is hence considered to fall within the consumer culture theory domain (Arnould and Thompson, 2005).

CONSUMER COMMUNITIES LITERATURE

Within consumer behavior literature, an increasing number of studies now focus on ways in which consumers organize themselves into social collectives or communities to meet various consumption goals. Such studies have been placed in the context of brand communities, both on virtual and physical space (e.g. Muniz Jnr and O'Guinn 2001) and consumer tribes (e.g. Cova et al. 2007). This literature has been useful in illuminating how such groups emerge and are maintained, and how different consumer practices consequently emerge (Schau et al, 2009). These studies have however been limited to western contexts, and there is a paucity of studies highlighting consumer-based collectives in non-western developing country contexts, and especially Africa. Despite their absence in consumer literature however, these collective do exist, albeit in different forms from those discussed in western contexts. Whereas brand communities and consumer tribes are 'market-facing' and constituted around marketplace resources and brands (Schau et al, 2009), those in non-western contexts are constituted along non-commercial lines, and are significantly influenced by the socio-historical structures within which they are (re)produced (Johnson 2004). These non-market based non-western forms of collectives are however understudied, and the study seeks to fill in this gap.

The study draws on the precepts of Actor Network Theory, which considers the interaction of both human and non-human elements key in the constitution of entities (Latour 2005). This is because existing literature on Chama presents it as an entity consisting of a number of elements including human participants, documents used (constitutions, rules and regulations); objects (the pot representing consumer savings, consumer durables acquired by participant); or actions (attending meetings, entertaining) (Ardener 1964). By using ANT lens to analyze these interactions it is possible to account for outcomes that impact on consumer behaviour.

THE STUDY

This was a pilot study which employed an interpretivist perspective in order to understand the consumer environment and their lived experiences (Holbrook and O'Shaughnessy, 1988). Consistent with similar studies focusing on consumer communities (Schouten and McAlexander 1995) ethnographic methods were used, employing multiple data collection methods which included participant observation, individual as well as group interviews, informal conversations and photographs. In total, three Chama meetings were attended in participants' homes; one with an urban middle-class group of professionals, one with a semi-urban group of affluent women and one with women from the slum area. The findings revealed three practices consistent across the three groups.

The first set, maintenance practices, revolved around activities that ensured that the Chama was constantly performed and maintained. For instance, in order to distribute saved funds, consumer participants met in one of their homes and feasted together. It was clear that the social benefits gained from entertaining and interacting with others during such meetings was more important for the consumers than receiving the funds. This is consistent with what Holt (1995) refers to as consumption as play, where consumers interact purely for autotelic purposes.

Support practices also emerged as important, as the participating consumers were actively involved in offering support to others in the group during occasions such as death of a loved one, birth, weddings and even during job losses. Such benevolent acts emanate from practices in the wider society in which members of the community participate in collective efforts to assist those facing misfortunes, in what is referred to as 'Harambee' in Kenya (Johnson 2004). As part of this practice for instance, members engaged in shopping activities, which required certain skills in identifying the appropriate items for the particular cause being supported. As posited by Warde (2005) to be a competent 'practitioner' requires one to possess the requisite goods and services, as well as the skills and competencies to be able to appropriate and deploy them as per the conventions of the practice.

Also prevalent were consumption control practices. Consumer self-control was highlighted as a significant reason for participating in Chama, as the consumers needed discipline to save for future purchases benefited from the collective support in Chama to do so. Some of the less affluent women indicated that they would go hungry on some nights in order to set aside some money for the Chama pot, as failure to do this incurred heavy fines from the others. Control was also enforced on how the funds saved were spent. In some instances, the group would buy household utensils for the consumer rather than give them the savings to enforce discipline. Chama hence acts as a pre-commitment

avenue (Ambec and Treich, 2005) but not for necessarily to control hedonic consumption (Hirschman and Holbrook 1982), but to reinforce goal-oriented and deliberate consumption practices.

CONCLUSION

The study reveals that Chama is a conduit in which a number of practices interact to produce outcomes that are of interest to consumer research. As evidenced, consumption opportunities arise, consumption behaviours are patterned and practices (and practitioners) are configured, social and cultural capital necessary for consumer practice are accrued and demonstrated, and ultimately consumption goals are met. By focusing on the Chama context the contribution has been in revealing that consumer collectives can be formed and thrive outside brand influence, reinforced by society-wide norms and practices that have implications for consumer behaviour.

The Importance of Multisensory Integration to Understand Products Appreciation: fMRI Study

Laura Romoli, Illycaffè S.P.A., Italy
Furio Suggi Liverani, Illycaffè S.P.A., Italy
Piero Paolo Battaglini, University of Trieste, Italy

It is well known that flavour is a psychological construct. Flavour, in fact, is an example of multisensory integration, because is a taste/odour combination. Rarely individual components are perceived independently. Manifestations of interactions include smell/taste confusions, attribution of taste properties to odours, and the enhancement and suppression of taste by such odours. Moreover, food is characterized by visual properties, above all colour. Colour, in fact, has a profound effect on the perception of odors (1).

In everyday life the existence of cross-modal association between vision and olfaction is obvious; if you are in a market and suddenly noticed a wonderful smell of ripe strawberries you would look for a fruit that was red rather than a fruit that was orange. Even if these associations between vision and olfaction would appear obvious, to date little research has attempted to investigate this potentially important topic. Gottfried et al (2) has shown that the presentation of visual stimuli can influence olfactory information processing; but what it is known about the contrary? Could a smell stimulus influence visual perception?

To address this complex topic, it is important to understand which is the role of higher-level cognitive factor in the appreciation and comprehension of a smell or a taste stimulus.

In this study, we investigated, with the fMRI technique, how the citrus aroma is processed by the brain, at the cortical level. There is a large amount of study in psychophysical literature underlying the cross-modal association between colors and odors. Many of the odors that we come across everyday life can be readily described by means of colors. But, what happen into our brain when we smell the citrus aroma? Does the brain elaborate the aroma just as a smell stimulus, or elaborate also others perceptual characteristics of it? We address this issue, investigating 13 healthy subjects with fMRI technique while they were sniffing the citrus aroma.

MATERIALS & METHODS

2 stimuli were chosen in this experiment: citrus fruit and neutral (pure air).

The experiment consisted of 3 sessions of about 10 min duration each; each sessions consisted of alternation of citrus aroma and pure air.

Participants received 2 seconds of aroma's stimulation directly in their nose through 2 polythene tubes converging in a facial mask. Subjects were previously instructed to do not move and pay attention to the aroma, trying to recognize it. Timing, amount and order of presentation were controlled by an fMRI compatible, computerized, olfactometer.

Imaging was conducted using a 1,5 Tesla fMRI scanner at the Radiology Unit of Cattinara Hospital, Trieste.

The fMRI data were analysed using SPM5 package. The images were first corrected to remove the effects of subject's moving whilst in the MR scanner; then the brain images for each subject were morphed to make them all the same shape; finally we carried out statistical analysis to detect the particular effect that we were interested in (e.g. smelling citrus aroma compared with smelling neutral).

The analyses were conducted for citrus aroma compared to neutral during the timing in which subjects received the aroma and the few seconds immediately after.

RESULTS & DISCUSSION

We demonstrated that citrus aroma stimulate cerebral regions according to its semantic characteristics; citrus is an edible stimulus, generally associated with the orange or the lemon; it is extremely scented. This stimulus is characterized by the colour, varying from orange to yellow (all nuances belonging to the same family of colour); in fact citrus is a typical example of colour-material colour.

Specifically, while subjects were receiving the stimulus, the brain's response is characterized by the perceptual aspects, especially visual: MNI coordinates: right/left BA 17 and 18, right middle occipital gyrus, left BA 2/1; these areas are involved in the elaboration of visual and somatosensory aspects of stimuli, specifically BA 17 is the primary visual cortex involved in the elaboration of colour, and BA 18 is the secondary visual cortex involved in the elaboration of shape and implicated, also, in visual imagery.

In the "after" period, corresponding to the few seconds after the olfactory stimulation, the cerebral response changes, becoming canonical for a smell stimulus, involving the left superior frontal gyrus and the left middle frontal gyrus, both areas involved in the cortical elaboration of familiar odours.

CONCLUSIONS

To date, all previous studies of colour-odor correspondences have required participants to make explicit matches between specific colours and particular odors (3;4), or how chromatic stimuli modulate odor response in the human brain (1), whereas in the present study, we demonstrated how a odor stimulus could produce a brain activation typically associated to visual stimuli while subjects are sniffing the aroma. These results, even if preliminary, underlying how certain aspects of a product could work as synesthetic cues in the human brain. This interest in odor-visual interactions is an example of areas where future research might be directed, particularly in terms of implications for the study of individual differences, the role of mental imagery, the promise of more neurocognitive approaches, and the need for more consideration of the multy-sensory interactions of our senses on consumption behavior.

The Influence of Self-construal on Managing Conflicting Saving and Spending Goals

Wei Lu, Shanghai Jiao Tong University, China
Li Pan, Shanghai Jiao Tong University, China
Liangyan Wang, Shanghai Jiao Tong University, China

We propose that independent and interdependent differ on how they manage conflicting goals. We demonstrate interdependent are more likely to highlight saving in two sequential choices, while independent are more likely to adopt balancing mode by preferring spending first and intending to achieve the saving goal at next opportunity.

Researchers in North America often focus on how to help consumers to succeed in their personal saving goals (e.g., Bayuk, Janiszewski, and Leboeuf 2010; Loibl 2009). However, contrary to North American's difficulty in saving money, economic growth of some countries has long been hindered by their residents' high saving rates, such as China. So understanding what factors account for such big difference in saving and spending across countries would be of great importance to governments, financial service firms and consumers. In this research we suggest that individuals with different self-construals (independent vs. interdependent) differ on how they manage conflicting saving and spending goals, which in turn leads to the difference described above.

Consumers often have spending goal and saving goal at the same time. Saving is a goal with more virtue, which can provide people with financial safety. Spending is a temptation which can provide immediate satisfaction to consumers. Pursuing either one of them could not completely abandon the other. We have to save money while constantly spend. When managing two conflicting goals, people can highlight one goal and continue to behave in the same way consistent with this focal goal, or they might also balance between two goals and their behavior varies (Fishbach and Dhar 2008). Highlighting a focal goal in two sequential choices would benefit the pursuing of the focal goal, while balancing the focal goal and temptation by preferring the tempting option that can provide immediate satisfaction first and intending to choose a goal option at the next opportunity would probably hurt the achieving of the focal goal, as people might constantly postpone the goal-congruent choices (Fishbach and Zhang 2008).

Research on cross-cultural differences suggest that individuals with an interdependent self-construal might be better at handling intrapersonal conflict and mixed emotions than those with an independent self-construal (Hong and Lee 2010; Kyoungmi and Shavitt 2004; Williams

and Aaker 2002). And conflicting vice and virtuous goals are often associated with ambivalence and mixed emotions (Emmons and King 1988), which would make consumers feel a lot of tension and give in to the buying impulse (Rook 1987). It's possible that the advantage of interdependent on coping with intrapersonal conflict and mixed emotions makes them less torn by the temptation and better focus on the more important goal. Findings from Zhang and Shrum (2009) also suggested that individuals with interdependent self-construal exhibited less impulsive consumption tendencies than those with independent self-construal. In line with prior research, we propose that when managing conflicting saving and spending goals, individuals with interdependent self-construal would be more likely to adopt a highlighting mode, while individuals with independent self-construal are more likely to adopt a balancing mode.

Two experimental studies were conducted to test our hypothesis using both chronic and situational self-construals. In experiment 1, we tested whether chronic self-construals resulted in different managing mode when facing conflicting goals. 217 Full-time MBA students were asked to imagine that they were trying hard to save money now and could save about one third of their monthly income. However, both this month and next month there would be a product on sale they like equally, which will make them save nothing that month. Respondents were asked to choose whether they would buy or not buy the product specifically this month and next month. Then respondents' self-construals were measured (Singelis 1994). Demographic information, such as personal and household incomes, is also recorded at the end of the survey. 51 (53) participants were classified as independence-dominated (interdependence-dominated) whose independence (interdependence) score fell above the median and whose interdependence (independence) score fell below the median. ANOVA analysis with self-construal as a between-subjects factor and time-order choice as a within-subjects factor showed that there was a main effect of time order (p<0.05) and no main effect of self-construal. More specifically to our hypothesis, the interaction between self-construal and time order is significant (p<0.05). Further analysis showed that respondents are less likely to choose not to buy the product (behavior consistent with the saving goal) in this month (32.7%) than in next month (44.2%) (p<0.05). Among individuals with interdependent self-construal, respondents' intention to choose behavior consistent with their saving goal did not differ between this month (43.4%) and next month (43.4%), a pattern that indicates highlighting saving. While among individuals with independent self-construal, significantly less respondents chose saving goal this month (21.6%) than next month (45.1%) (p<0.01), a pattern that indicates balancing saving and spending by preferring immediate satisfaction and intending to pursue the saving goal later. And as to this month's choice, significantly more individuals with interdependent self-construal (43.4%) chose to save than those with independent self-construal(21.6%) (p<0.05).

In the second experiment, we verified our findings by situationally activating individuals' self-construals. The procedure was similar with the first experiment, except that rather than measured, independent or interdependent self-construal was primed at the very beginning of the experiment. We used the same Chinese priming materials used by Sui and Han (2007). 97 adult college students were asked to circulate all the pronouns in a travel story. The same text was presented with almost all of the pronouns being either independent pronouns (e.g. I) or interdependent pronouns (e.g. we) to prime the two selves. The result is similar as those in experiment 1 with approaching significance (p<0.10), except that the main effect of time-order is not significant.

In sum, the two studies both demonstrated that individuals with independent self-construal are more likely to adopt a balancing mode and individuals with interdependent self-construal are more likely to adopt a highlighting mode when facing conflicting saving sand spending goals. Our new findings contribute to the literature both on self-construal and goal system theory. Also our findings have practical implications on how to encourage spending in those countries with high saving rate and how to help consumers to save in those countries with low saving rate.

Do health claims always lead to obesity? The role of consumers' lay theories about low-nutrients food in quality and quantity estimation

Pierrick Gomez, Reims Management School and Université Paris Dauphine, France

Past research has indicated that consumers' evaluation of health claims is prone to bias. These judgments errors affect both quality and quantity estimation of food products. For example, when making inferences from nutrition information, consumers tend to overestimate the health benefits of food products (Roe, Levy and Derby, 1999). Thus, consumers tend to rate higher a product on other nutrition attribute when a health claim is displayed. Recent research has also pointed to the role of health halos, created by health claims or food stereotyping, in calories overestimation (Chandon and Wansink, 2007; Chernev and Gal, 2010).

The impact of low-fat claims has often been studied in past research (e.g., Chandon and Wansink, 2006; Finkelstein and Fishbach, 2010). To our knowledge, the effect of low-sugar claims has not yet been addressed. However, there is a differential perception between fat and sugar. Fat is perceived as an unhealthy ingredient whereas sugar is strongly associated to hedonic pleasure (Fischler, 2001). One can argue that low-fat claims may reduce anticipated consumption guilt whereas low sugar claims may decrease anticipated consumption pleasure. For this reason, we suggest that low-sugar claims lead less to judgment errors in quantity estimation. This research highlights the underlying role of lay theories about low-nutrients food. We suggest that people can subscribe to the view that low-nutrients food is associated with healthiness or to the view that low-nutrients food and tastiness are inversely correlated. We examine this in three field studies.

In study 1, we tested our basic proposition. Ninety eight people (N=98, 27 years old, male 51%, 22.3 BMI) took part to the survey. Our objective was twofold: to demonstrate that people hold lay theory about low-nutrients food and to test the difference of perception between sugar and fat. People tend to believe (those who rated their agreement from 5 to 7 on a 7 points scale) that low-nutrients food are less pleasurable (65.3%), have bad taste (44.8%), are healthier than regular food (38.8%) and are food that can help them to overcome weight problem (55.1%). This is initial evidence supporting the prevalence of our lay theories about low-nutrients food. It should be noted that difference has been found among dieters and people who believe that healthiness and tastiness are negatively correlated. Results revealed that high fat foods are perceived to be less healthy (t=-5.957; p<0.001) and less tasty than high sugar foods (t=-6.626; p<0.001).

Study 2 was designed to test whether estimation of nutrition quality and quantity decisions differs when the product is labeled as "low sugar". Respondents were 86 students recruited to participate in a survey on consumer food preferences (N=86, female 52%, age 20, BMI 21.4). Participants were assigned to one of three conditions and saw low-sugar cookies, low-fat cookies or regular cookies. Consistent with our hypothesis, analysis revealed that participants who saw cookies labeled as low-sugar claim (vs. regular) believed that it was healthier (8.291; p<0.01) but intended to consume it less frequently (F=13.492; p<0.001). This result may occur because of a decrease of anticipated consumption pleasure when participants are exposed to a low-sugar label (F=7.964; p<0.01). Further analysis show that anticipated consumption pleasure induces lower frequency of consumption (r=-0.466; p<0.01) and higher perceived serving-size (r=0.28; p<0.05).

Study 3 tested whether lay theories about low-nutrients food may reverse this finding. Following past research on lay beliefs (e.g. Mukhopadhyay & Johar, 2005), participants (N=148, 56% male, 32 years old, BMI 22.6) read a paragraph, based on available scientific information, which either stated that low-nutrients food are useful to reduce calories intake (low-nutrients food=healthy belief) or that nutrients-reducing technology diminishes food tastiness (low-nutrients food=untasty belief). As expected, respondents who read the low-nutrients food=healthy passage (vs. low-nutrients food=untasty) are more likely to believe that low-nutrients food help people to manage their weight (F=5.276; p<0.05) and less likely to believe that low-nutrients food are pleasurable (F=4.958; p<0.05). Then, the experimental task involved estimating the calories content and appropriate consumption (frequency consumption and appropriate serving size) of low-sugar and low-fat cookies. Our results show that low-nutrients labelling do not influence consumers' estimation of nutrition quality and quantity. The results revealed a significant main effect of lay beliefs about low-nutrients food. Respondents in the low-nutrients food=healthy condition tend to overestimate the number of calories of cookies (by 26 calories or 35%; F=4.257; p<0.05) and the amount they believe to be an appropriate serving-size (by 27%; F=4.023; p<0.05). Importantly, lay conception of low-nutrients food affect anticipated consumption pleasure. Confirming our supposition, anticipated pleasure (marginally so, F=3.600; p=0.06) is higher in the low-nutrients food=healthy condition (vs. low-nutrients food=untasty condition). Again, analysis revealed that lower anticipated consumption pleasure decrease perceived serving-size (r=0.29; p<0.01) and frequency of use estimation (r=-0.31; p<0.01). The data further show that dieters intend to consume more frequently low-nutrients food if they had read the unhealthy article than the untasty one (F=4.568; p<0.05).

Across three studies, we provide evidence that people hold mainly two lay conceptions of low-nutrients food and that these beliefs may underlie the difference of perception between low-fat and low-sugar food products. Thus, low-sugar labels reduce frequency of consumption because of a decrease of anticipated consumption pleasure. The accessibility of these beliefs can be influenced and affect people's perception of health claims.

Are modern Chinese getting more materialistic? – A study of materialism with longitude and cross-cultural comparisons

Chunyan Xie, Stord/Haugesund University College, Norway
Richard P. Bagozzi, University of Michigan, USA
Zhi Yang, Hunan University, China
Ping Wu, University of Michigan, USA

China, as one of the fast-growing developing economies, has experienced strong economic development in recent years. The up-surging materialism brought forth by the economic growth in China has attracted attentions from both practitioners and academics. However, most existent research on materialism has been conducted in Western, developed economies dominated by individualistic values. Few studies on materialism in developing economies are available in the literature. Although there has been some recent attention to the historic rise of consumer culture and materialism in China (Clunas 1991), both the popular and scholarly prototypes of materialism is either Western European or American. Some researchers have also explored cultural variation in materialism to some degree (Ger and Belk, 1996), but there is still a surprising lack of highly culture-specific understandings of materialism. Therefore, a challenging for both practitioners and academics is how to understand the materialism phenomenon in countries with fast-growing economies and dominant collective values (e.g., China).

The aim of this study is to understand the materialism tendency in modern China. We look for answers to such questions as "Is the current Chinese generation becoming more materialistic than the earlier generation?" and "Are they becoming more materialistic than their Western counterparts?" To do so, we first applied the Model of Goal-directed Behavior (MGB) (Perugini and Bagozzi 2001)) to examine the decision making process of people's actual choice between materialist and non-materialist lifestyles. Then, we developed cognitive schemas to map the motivations underlying such choices. In order to explore how rapid economic growth influences materialism tendencies, we conduct a longitude comparison of cognitive schemas between two samples of Chinese respondents with a ten-year period difference (Year 1998 vs. Year 2008). Finally, a cross-cultural comparison of cognitive schemas between Chinese and American respondents was conducted in order to understand how modern Chinese differ from their Western counterparts in materialism tendencies.

THEORY

Materialism is defined as "a set of centrally held beliefs about the importance of possessions in one's life" (Richins and Dawson, 1992). It has been treated as general values that are presumed to apply universally across contexts. Richins and Dawson (1992) measured three dimensions of materialism: acquisition centrality, acquisition as the pursuit of happiness, possession-defined success. Further, some researchers explored cultural variation in materialism (Ger and Belk 1996) and claimed people from collective cultures are less materialistic than those from individual cultures. Inglehart (1990) also argued that materialism relates to affluence: materialism will peak and begin to decline after a certain level of affluence is reached and lower order needs have been met.

In this study, instead for studying materialism as general values, we investigate an actual choice between materialistic vs. non-materialistic lifestyles. The model of goal-directed behavior (MGB), an extension of the theory of planned behavior (TPB), was applied to capture the decision making process. In the MGB, anticipated positive and negative emotions and past behavior are included in addition to attitudes, subjective norms, and perceived behavioral control. Further, desire is added as the mediator between all antecedents and intentions, and functions as the central motivational process transforming reasons for acting into actual decisions to act.

Cognitive schemas were further developed to map the motivations underlying such lifestyle choices. Cognitive schemas are "learned, internalized patterns of though-feeling that mediate both the interpretation of on-going experience and the reconstruction of memories" (Strauss 1992). We argue the motives constitute the reasons for behavior and justify or rationalize one's chosen behavior. They are presented in a hierarchical cognitive schema, connected through means-ends linkages.

METHOD

Two waves of survey were conducted. The first was conducted in both China and US in Year 1998. Respondents from two Chinese Universities in South-eastern China and from one US University in Middle-West answered a qualitative motive elicitation part in the questionnaire and provided motives for choosing between a materialistic vs. a non-materialist lifestyle. 330 complete questionnaires were obtained in China and 362 in US. The second wave of survey was conducted in one Chinese University in Southern China in Year 2008, where 322 complete questionnaires were collected. The survey included an identical qualitative part for eliciting motives for lifestyle choice and a quantitative inventory of closed-ended questions measuring variable in the MGB.

RESULTS

The finding from the MGB (Year 2008) showed that in the decision making process of lifestyle choices, subjective norms, anticipated positive emotions and perceived behavioral control are significant predictors of desire and intentions to pursue a materialistic lifestyle for Chinese respondents. On the other hand, desire and intentions to pursue a non-materialistic lifestyle were significantly affected by attitudes, anticipated positive emotions and perceived behavioral control. In order to understand why social norms are important for Chinese respondents to choose a materialist lifestyle, we developed cognitive schemas to further explore their motivations underlying the choices. The results

of t-tests also provided preliminary evidence supporting the argument that motives and linkages between motives in cognitive schemas can impact variables in the MGB for both Chinese materialists and non-materialists.

We also got interesting results from a longitude comparison of Chinese materialists over a ten-year period with rapid economic growth (Year 1998 vs. Year 2008). The cognitive schemas of Chinese materialists have become more well-defined as their affluence increase over time. While personal motives remained relatively stable over time, social motives are more contingent on economic development. A cross-cultural comparison of Chinese materialists with their American counterparts showed that Chinese materialists not only have a more complex structure of social motives but also have some unique motives such as socially defined success.

Transcultural Tourism: Role of Cultural Metaphors
in Enhancing Destination Image

</div>

<div align="center">

</div>

In recent times, immigration and globalization has resulted in a *transcultural* consumer era (Penaloza, 1994) that calls for enriching transcultural attractions to enhance destination image. *Transculture* is a new sphere of cultural development that transcends the borders of traditional cultures (Epstein, 2009). A destination's image is the "composite of various products (attractions) and attributes woven into a total impression" (MacKay and Fesenmaeir, 1997, p. 2). This paper investigates transcultural tourism as an alternative to conventional cultural tourism. The paper considers the use of cultural metaphors to influence consumer mental models, which in turn enhances their perception of the destination image. *Cultural metaphors* are associations that convey shared beliefs and understandings of a particular society (Gannon, 2002). The term metaphor refers to associations that relate abstract concepts to physical things and are used to construct conceptual understandings (Lakoff and Johnson, 1980). The symbolic anthropological construal of metaphor is grounded in cultural images (Hirschman 2007) and has been noted for its ability to create new mental models and to overcome entrenched perspectives (Barret & Cooperrider, 1990). Consumers' mental models are structures of meaning, which includes beliefs and feelings, activated when a consumption situation takes place (Christensen and Olson, 2002).

This study makes three theoretical contributions. First, this study examines how transcultural metaphors enhance the destination image. A number of studies have examined cultural tourism and the enhancement of destination image such as iconic structures (e.g. Thakara, 2002), megaevents (e.g. Allen et al., 2002), thematisation (e.g. (e.g. Arnould and Price, 1993; Joy and Sherry, 2003; Hughes, 2000) and heritage mining (e.g. Russo, 2002). However, there have been minimal studies that diverge from the traditional cultural tourism to discover other non-conventional ways of leveraging culture to enhance the destination image. This study diverges from the traditional cultural tourism perspective to investigate transcultural tourism that enhances destination image by leading consumers to transcend cultural differences and to incorporate new concepts and visions from alternative cultures. This is important because according to Richards and Wilson (2005), consumers are increasingly searching for alternatives to traditional cultural tourism.

Second, this study considers how metaphors can be used to transcend consumer mental models. A number of researchers have examined metaphors and their effects on consumer mental models (e.g. Zaltman and Coulter, 1995; Christensen and Olson, 2002). These studies have exposed the fact that metaphors assist in shaping consumer mental models. However, "what about transformative experiences that falls outside the range of consumer mental models?" The current study addresses this gap by introducing the concept of mental model transcendence. Transcendence is "the capacity of individuals to stand outside of their immediate sense of time and place to view life from a larger, more objective perspective" (Piedmont 1999, p.988). We argue that incorporation of transcultural perspectives has a potential to lead to a transcendent state that falls outside of existing mental models.

Third, this study extends the role of cultural metaphors. Some studies have also been conducted on the role of cultural metaphors as a consumer research tool (e.g. Denny and Sunderland, 2005). Others have examined the role of cultural metaphors in understanding cultural differences (e.g. Gannon, 2002). Although these studies have exposed the fact that cultural metaphors are tools for understanding cultural complexities, they do not explain how the cultural metaphors lead to consumer mental model transcendence. The introduction of mental model transcendence in this paper extends the current literature to include a transcendent experience in the mental models of consumers that is made possible by transcultural metaphors. It also captures the psychological perspectives embedded in transcultural interactions and acknowledges the importance of these perspectives in understanding consumer behavior.

To examine consumer use of cultural metaphors, the investigation was conducted with artisans as well as American tourists in the Pilsen Mexican community in Chicago. A qualitative approach, in the form of phenomenological interviews, observations and photography, was

adopted to address the research objectives. The Pilsen community, with a rich cultural heritage, predominantly Latino is selected for the investigation. Three thematic dimensions are discovered that explain the concept of mental model transcendence. These are: 1) an awareness of a transcultural identity 2) an awakening to a sense of self, and 3) an inspiration of universal ideals. We utilize Teichart et al's (2006) theory on metaphor roles and Fauconnier and Turner's (2002) Blending theory to inform our argument. While Teichart et al's (2006) theory of how metaphors influence and alter mental models is crucial to our argument, we extend it to accommodate the process of mental model transcendence evident in our data.

The Power of One in Mindful Consumer Behavior

Nada Nasr Bechwati, Bentley University, USA
Imad Baalbaki, American University of Beirut, Lebanon

The purpose of this research is to (1) introduce *mindful consumer behavior* and (2) identify the underlying mechanisms, i.e., what drives consumers to behave mindfully or mindlessly. We define mindful consumers as individuals who, in all stages of consumer behavior, are aware of themselves, their communities and the society at large and behave in ways that contribute to the well-being of all these entities. The concept of well-being goes beyond instant satisfaction to involve good health, sustainability including financial sustainability, social responsibility and self-actualization.

Mindful consumer behavior involves an internal facet and an external one. The internal facet pertains to the individual such as her/his health, financial sustainability, and happiness. The external facet is related to the environment and society at large. Hence, issues related to nutrition, exercise, medical information and treatments, budgeting and frugality are all examples of internal aspects. Consuming in a socially responsible way including going green and donating for noble causes are examples of external aspects. The two are not unrelated. For instance, a mindful spending might enable a consumer to have the ability to donate money to support those in need.

Mindful consumer behavior can be practiced at all stages of consumption. The stages of consumer behavior include acquisition, consumption including possession and maintenance, and disposal of goods and services (Hoyer and MacInnis 2010). At the acquisition stage, consumers can be mindful while making product and brand choices and, e.g., choose healthy food, environmentally friendly goods and be cautious about the way they invest their time and money. At the consumption stage, mindful consumers consume moderately, share, and take care of their possessions. Finally, consumers can recycle, donate and pass possessions to others at the disposal stage.

To understand what drives conscious consumer behavior, we draw on research in sociology, psychology and social psychology. We argue that consumers' tendency to behave mindfully is contingent on their (1) temporal focus, and (2) perception of self-efficacy.

Temporal focus is *"the attention individuals devote to thinking about the past, present, and future."* (Shipp et al. 2009). The concept is important because it affects how people incorporate perceptions about past experiences, current situations, and future expectations into their attitudes, cognitions and behavior (Zimbardo & Boyd 1999). Mindful behavior usually involves thinking about the future and the consequences of one's actions such as over-eating or consuming a particular product. Strathman et al. (1994) demonstrated that the extent to which people consider distant vs. immediate consequences of potential behaviors impact these behaviors. Hence, we expect the following:

H₁: *Individuals who tend to focus on the future behave more mindfully as consumers than individuals who tend to focus on the present or the past.*

Self-efficacy refers to one's perception that s/he is can make enough difference (Kinnear, Taylor and Ahmed 1974). Studies show that making individuals believe they can make a difference results in them behaving more actively such as voting and sharing their opinions publically (Crain et al. 1987), acting in a more environmentally conscious manner (Roberts 1996; Webster 1975), and resisting overeating (Kinard, Webster and White 2007). On the other hand, fatalistic individuals do not do much as they believe that their lives are driven by fate, i.e., predetermined (Zimbardo & Boyd 1999). Mindful behavior involves making decisions while inherently believing that these decisions impact one's life and others'. Hence, we propose:

H$_2$: *The higher consumers' perception of self efficacy the more likely they are to behave mindfully.*

In Study 1, we survey consumers in two phases separated by four weeks. In the first phase, we measure participants' tendency to behave as mindful consumers on all aspects of mindfulness and in all stages of consumer behavior. One month later, we measure the same participants' temporal focus and perceptions of their ability to make a difference as well as possibly relevant variables such as locus of control, ability to restrain desires, and values. To measure mindful consumer behavior, we build on the internal and external facets in our definition and draw on several scales to design a 49-item 7-point Likert-type scale.

One hundred and one undergraduate students at a Northeastern university participated in both phases of Study 1. An exploratory factor analysis of the 49 items designed to measure different aspects of mindful consumer behavior revealed the following twelve dimensions: (1) concern for the environment, (2) making the most of one's possessions, (3) contributing through donations and choice of socially responsible firms, (4) passing on used possessions to others, (5) minimizing waste in consumption, (6) concern for one's health, (7) concern for one's wealth, (8) cautious buying, (9) sharing possessions with others, (10) concern for impact of actions on other humans, (11) interest in exercising, and (12) interest in healthy eating.

To test our hypotheses we conduct a series of regression analyses. Contrary to our expectations in H$_1$, our findings reveal a non-significant role for temporal focus on the future in mindful consumer behavior except for the three dimensions pertaining to minimizing waste in consumption, passing on used possessions to others and interest in exercising. The weak role of temporal focus on the future could be attributed to temporal discounting (Critchfield and Kollins 2001). Our results, however, lend strong support to H$_2$. Running stepwise regressions with dimensions of mindful behavior as the dependent variables and a set of variables including temporal focus, self-efficacy, locus of control, materialism, ability to restrain desires, and Kahle's (1984) list of values as our independent variables resulted in significant models containing self-efficacy. Interestingly, for most of the dependent variables pertaining to the external facet of mindful behavior such as effect on other humans, sharing, and concern for the environment, self-efficacy was the only significant predictor in the regression models.

In the second study, we run an experiment to further examine the impact of self-efficacy on mindful consumer behavior. We manipulate self-efficacy through priming and empowering participants. We also have participants make choices reflecting mindful (or mindless) consumer behavior. Results from Study 2 should be ready for sharing at the Conference.

The Effect of Color on Cognitive Resource Depletion

Dante Pirouz, University of Western Ontario, USA
Liangyan Wang, Antai Management School, Shanghai Jiao Tong University

Much of what consumers see – advertising, packaging, brand logos, products, websites, retail environments – are imbued with color. Given the ubiquitous nature of color, there is a wide range of research on the physics and physiology of color and visual processing (Elliot et al. 2007). However, there has been relatively little attention given in the consumer behavior literature to the effect of color on behavior, despite the fact that color is a key executional decision of marketing managers, product designers, and creative directors. Thus, there remain a number of unanswered questions regarding the effects of color on behavior and more specifically on consumer behavior (Fehrman and Fehrman 2004; Whitfield and Wiltshire 1990). Understanding how color hue influences risky choices by consumers would provide an important contribution to theory in addition to allowing for a better understanding of consumer behavior in general (Bellizzi and Hite 1992; Gorn et al. 1997).

This research investigates whether differences in color hue – defined as the wavelength or actual pigment or color visually perceived, such as red, blue, green and yellow (Gorn et al. 1997; Valdez and Mehrabian 1994) – lead to changes in behavior related to risky choices in the consumption domain. More specifically, this research investigates the question of whether exposure to red or blue stimuli in a realistic format (advertising in a magazine) will result in cognitive resource depletion, which in turn leads to an increased preference for risky choices.

Recent research has demonstrated that color may influence cognitive performance. For example, Mehta and Zhu (2009) examined the effect of color hue on approach and avoidance behavior. Red has been shown to increase vigilance and attention to detail and avoidance motivation (Elliot et al. 2007; Mehta and Zhu 2009), while blue has been shown to increase relaxation, creative thinking and approach motivation (Gorn et al. 2004; Mehta and Zhu 2009) consistent with regulatory focus theory (Higgins 1997; Higgins 1998).

Additionally, there has been some evidence in the literature that avoidance motivation can instigate a cognitive resource depletion effect (Hamilton et al. 2010; Trawalter and Richeson 2006). Resource depletion results from the exertion of limited cognitive resources in the process of self-regulation to resist tempting stimuli and/or behavioral impulses. The literature has demonstrated a robust resource depletion effect in a number of different consumer domains including impulsive purchasing (Baumeister 2002; Vohs and Faber 2007), eating (Hofmann et al. 2007) and financial decision making (Oaten and Cheng 2007) among others. This study tests whether exposure to color hue and the subsequent activation of an avoidance motivation results in an exertion of self-regulatory maintenance resulting in cognitive resource depletion – a theoretical connection that has not yet been established in the literature and which could have profound managerial and public policy implications.

Building on the theoretical model outlined by Elliot and Maier (2007), the empirical work of Mehta and Zhu (2009), and cognitive resource depletion (Baumeister and Heatherton 1996; Muraven and Baumeister 2000), this research examines whether color hue in the form of red or blue can impair cognitive processing and if so how this exposure impacts subsequent behavior. A key construct will be cognitive resource depletion, defined as a limited capacity for and a subsequent weakness in exerting willpower and resisting temptations for risk in unrelated domains (Baumeister 2002; Baumeister et al. 1998). This research extends the current theory on the effects of hue on behavior by determining whether the effects lead to cognitive resource depletion, which may lead to risky behaviors such as smoking and unhealthy eating.

METHOD

The study was a two (color hue: red vs. blue) x two (cognitive load: high vs. low) between-subjects experimental design. Participants were exposed to a mock magazine format and asked for their opinion on a new magazine being launched. Each page of the magazine was surrounded by either a red or blue background panel with saturation and value held constant. It has been stressed that saturation and value must be controlled when examining the effects of color hue on behavior because they have been shown to have their own distinctive psychological effects (Elliot et al. 2007). The dependent variables were a 7-point measure of urge to smoke cigarettes (Choi et al. 1997) and a 7-point measure of preference for unhealthy over healthy snack foods modified from the measure used in Vohs and Faber (2007). Four hundred seventy five participants aged 18-28 years old took part in the study for partial course credit.

RESULTS

The study results show that exposure to red (vs. blue) stimuli resulted in a higher urge to smoke cigarettes and a higher preference for unhealthy over healthy snack foods. These results indicate a cognitive resource depletion effect. There was no effect for the cognitive load moderator. Additional studies are currently ongoing to determine if this effect is mediated by regulatory focus using a response time measure for solving approach or avoidance anagrams (Mehta and Zhu 2009) and whether the effect is moderated by any personality traits such as need for cognition (Cacioppo et al. 1984).

IMPLICATIONS

The results of this study contribute theoretically to the current literature by testing whether the connection between color hue exposure and the activation of regulatory focus motivation leads to cognitive resource depletion effects. This research also has potentially important practical implications. Marketing managers will have a better understanding of the effect of color hue in advertising, product packaging, product design and the subsequent effects of consumer behavior. In addition, for product categories where regulatory control over marketing materials is being considered – such as for tobacco, alcohol, or pharmaceuticals – or for health campaigns that strive to promote or deter consumers from risky behaviors, there may be some benefit to utilizing particular color hues in order to facilitate self-regulatory control.

Consumer Usage of Green Products

Ying-ching Lin, National Dong-Hua University, Taiwan
Chiu-chi Angela Chang, Shippensburg University, USA
Jyun-jhih Huang, National Dong-Hua University, Taiwan

Prior research has extensively explored the consumer motivation for *acquiring* green products, as well as how to orchestrate marketing programs to influence consumer purchase of green products (e.g., Bonini & Oppenheim, 2008; Griskevicius, Tybur, and de Bergh, 2010). Extending the marketing literature, the focus of the present research is on consumer *usage* of green products. We define green products investigated in this study to be those in product categories where strength is a major determinant of product choice and where there is a possibility of over-using without consumers' realizing it.

What determines the usage amount of a green product? Prior research has suggested factors, such as package size, container shape, and partitioning, that can influence the amount of consumption (e.g., Wansink, 1996; Cheema & Soman, 2008). In contrast, the present research proposes that the status of a green product itself is an influential heuristic cue for determining its usage. In fact, there is evidence to suggest that the status or type of a product may relate to its usage. For example, Scott, Nowlis, and Mandel (2009) suggest that consumers overuse the ultra-concentrated product relative to the regular-strength version. Along similar lines, we propose that consumers see green products differently and make differential inferences about them compared to regular products. Recent research provides some evidence to support this assertion. Aaker, Vohs, and Mogilner (2010) show that consumers hold stereotypical views of organizations: nonprofits are perceived as being warmer than for-profits, whereas for-profits are perceived as being more competent than nonprofits. The emphasis of green products on the environment or social cause may be regarded as more of a signal of generosity, trustworthiness, and sincerity, but less of a signal of

competency, efficiency, and effectiveness (cf. Aaker et al., 2010). Such impressions on green products may decrease perceptions of product performance, which, in turn, may increase the product usage amount to compensate for the perceived low-effectiveness and still achieve the end-goal. Furthermore, Luchs, Naylor, Irwin, and Raghunathan (2010) argue that consumers infer a positive association between ethicality and gentleness and a negative association between ethicality and strength. Therefore, in product categories in which strength-related attributes are valued, products advertised as being green and/or ethical could be a liability because of their low perceived strength or effectiveness. The above reasoning leads to our hypothesis that consumers may use a larger amount of a green product relative to its regular counterpart in order to make up for its low level of effectiveness.

To overcome the perception of green products being less effective, a logical strategy is to boost their perceived effectiveness. Prior research has demonstrated that an endorsement by a highly credible source can boost a nonprofit's perceived competence and result in a greater willingness to buy from a not-for-profit organization (Aaker et al., 2010). A highly credible source of information, such as *Consumer Reports*, also influences consumers' product usage, as evidenced in the decreased over-use of ultra-concentrated detergent (Scott et al., 2009). When explicit information about product strength such as a product guarantee is provided, consumers rely less on inferences of a negative relationship between ethicality and strength and they will have a more favorable attitude toward ethical products (Luchs et al., 2010). Therefore, we hypothesize that providing information on the product effectiveness should mitigate the usage amount of green products.

Three studies were designed to test our research hypotheses. Both studies 1A and 1B had a one factor (product type: green versus regular) between-subjects design. In study 1A, product type was manipulated by the presence or absence of a green/eco label. In study 1B, brand names were used to manipulate a green (Green Angel) versus a regular (Dr. Strong) product. The participants in study 1A were asked to evaluate a glass cleaner product and presented with a description of a window cleaning task. Similarly, the participants in study 1B were asked to evaluate a toilet bowl cleaner and presented with a toilet cleaning task description. Study 2, where a dish-washing task was involved, had a 2 (product type: green versus regular) x 2 (product effectiveness cue: endorsement versus no endorsement) between-subjects design. While product label colors (green versus red) conveyed a green versus regular product dish-washing detergent, the presence or absence of an endorsement from *Consumer Reports* represented the presence or absence of a product effectiveness cue, respectively. In all studies, participants gave their estimates regarding the number of times they thought they would press the nozzle of the cleaning product in order to get the task done. In addition, participants rated their perceptions of product effectiveness, attitude toward the product, purchase intentions, as well as their attitude toward the environment (Dunlap & Van Liere, 1978).

The results of the three studies show that consumers use more of a green product, compared with its conventional counterpart, in order to accomplish a given task. In addition, consumers exhibit differences in their usage of a green versus a regular product. Consumers who have a more favorable environmental attitude overuse a green product, while consumers who have a less favorable environmental attitude don't. This phenomenon of using more of a green than a regular product is driven by consumers' perception of a product's effectiveness. Consequently, when the perceived effectiveness of a green product is boosted by a credible endorsement, the discrepancy between green and regular product usage disappears.

This research advances the understanding of consumer usage of green products in several ways. First, extending the literature on product usage, this work demonstrates that product type influences product usage amount. Consumers have a stereotypical association of green versus regular products. These perceptions affect the product usage. Second, this work demonstrates an unintended, potentially detrimental, and nuanced effect of green products, that is, product overuse. In addition, this work uncovers a somewhat unexpected effect of environmental attitude: high (versus low) environmental attitude consumers actually use more of a green product. Finally, our findings demonstrate that supplying explicit information about a product's effectiveness has an effect on that product's usage as well (cf. Luchs et al. 2010).

Expressive Oriented Relationships:
A New Type of Commercial Friendships

Bryan R. Johnson, Creighton University, USA
William T. Ross, University of Connecticut, USA
Robin Coulter, University of Connecticut, USA

CONCEPTUALIZATION & THEORY

The development of relationships between firms and their customers has received considerable attention in the marketing literature. Interestingly, these relationships are not always limited to traditional commercial relationships. For example, in response to Bagozzi's (1995) call for marketing scholars to identify additional types of relationships fundamental to marketing, Price and Arnould (1999) identified a new and important type of marketing relationship – "commercial friendships." These relationships, which are characterized as friendships that form between customers and a firm's representatives over time, as a result of economic transactions, move beyond the boundaries of traditional commercial relationships.

Interestingly, commercial friendships that develop as a result of ongoing economic exchanges (Price and Arnould 1999) aren't the only type of commercial friendships operating between consumers and representatives of firms in the marketplace. As demonstrated by DiMaggio and Louche (1998), friendship relationships oftentimes exist between consumers and firm representatives, before a single transaction ever takes place. Such occurrences, in which consumers draw upon pre-existing friendship ties with a firm's employees to make purchases, represent a new and important type of commercial friendship.

Surprisingly, this type of pre-existing commercial friendship has not been examined in the marketing literature. Accordingly, the purpose of this study is to investigate this new class of marketing relationships and demonstrate how such relationships impact consumption. Identifying and explicating the use of alternative types of commercial friendships provides a valuable backdrop against which other types of marketing relationships can be juxtaposed and understood. The framework that emerges from this study highlights important similarities and differences among the different types of friendships used in consumption contexts, which ultimately reveals important ways marketing relationships can be conceptualized, studied, and managed.

To demonstrate the impact of this new category of commercial friendships on consumption, and to develop a framework for understanding these friendships in the context of other marketing relationships, we draw upon social capital theory. Social capital theory asserts that individuals obtain benefits or returns as a result of their relationships with others (Lin 2001; Portes 1998). Social capital theory highlights how differences in the nature and the structure of relationships create diversity in outcomes resulting from their use. Given fundamental differences between the types of relationships used in the marketplace, social capital theory provides an effective and robust theoretical framework for understanding the friendships examined in this study.

METHOD

To investigate, explain, and develop this new category of commercial friendships in the context of existing marketing relationships, we utilized the grounded theory approach (Glaser and Strauss 1967; Strauss and Corbin 1998). We conducted semi-structured depth interviews with 26 U.S. consumers, yielding 122 consumption experiences. Participants were purposively selected according to established theoretical sampling techniques (Charmaz 2006; Glaser and Strauss 1967; Strauss and Corbin 1998). To ensure that the developing theory and framework were grounded in the data, we adhered to the constant comparative approach (Glaser and Strauss 1967). Finally, to establish trustworthiness, we conducted member checks with all study participants, as advocated in previous research (Belk, Sherry, and Wallendorf 1988; Lincoln and Guba 1985).

FINDINGS & DISCUSSION

As alluded to previously, our analysis of participants' experiences reveals an exciting new category of commercial friendships used by consumers. Our data identify important differences between this new type of commercial friendship and previously documented commercial friendships (Price and Arnould 1999). Our analysis highlights *instrumentality* (Lin, Dean, and Ensel 1981), which represents the extent to which relationships are *instrumental* or *expressive*, as a key factor distinguishing different types of commercial friendships. Conceptually, *instrumental* relationships are those in which relationships are used to achieve an end that is distinguishable from the relationship itself, such as making a purchase. Alternatively, *expressive* relationships serve as both the means and the end and do not have any extrinsic purpose beyond the relationship itself, as in the case of friendship (Lin et al. 1981).

Participants' experiences reveal that, by their very nature, commercial friendships involve both *instrumental* and *expressive* characteristics. Consequently, we develop a relationship continuum, anchored by *instrumental* and *expressive* motives at the extremes, to model these dynamic relationships. Using this framework, our analysis highlights the importance of conceptualizing commercial friendships according to their *instrumental orientation* or their *expressive orientation*, in order to account for the dynamic underlying factors driving these relationships.

Drawing upon this framework, our analysis also reveals that the nature of commercial friendships, at the time they are initially established, anchors the relationships as they develop and evolve in the future. Our data demonstrate that relationships that begin *instrumentally* will continue to be dominated by the *instrumental* dimension over time. Although they may move toward the *expressive* end of the continuum, they rarely make the jump and become *expressive oriented* commercial friendships. Alternatively, relationships that begin as *expressive* relationships, and are later introduced into consumption contexts, continue to be dominated by the *expressive* dimension of the relationship. Although they may move toward the *instrumental* end of the continuum and receive important consumption related benefits, they rarely become *instrumental oriented* commercial friendships, due to consumers' efforts to compartmentalize, maintain, and protect their *expressive* relationships. These differences, ultimately derived from the nature of the relationships at the time of their inception, frame the

way consumers perceive, categorize, and use their relationships for consumption purposes, even as the relationships fluctuate and operate at different points along the relationship continuum over time.

CONCLUSION

The identification and examination of a new class of commercial friendships illuminates important theoretical differences underlying the various types of relationships between consumers and firm representatives. This study demonstrates the importance of conceptualizing commercial friendships as multi-dimensional phenomena that are both determined and constrained by *instrumental* and *expressive* components. Interestingly, we find that the nature of the relationships, at the time they are established, has a lasting and powerful impact. Ultimately, identifying the underlying features of these friendships has important implications regarding how consumers perceive their relationships with firms and how they use them for consumption purposes. Additionally, explicating these relationships also reveals important ways firms might manage customers engaged in *instrumental oriented* and *expressive oriented* marketing relationships.

Impact of Mortality Salience on Advertising Effectiveness in a Commercial Pod

Priyamvadha Rangan, University of Kansas, USA
Surendra N. Singh, University of Kansas, USA
Mark J. Landau, University of Kansas, USA
Jungsil Choi, University of Kansas, USA

A crucial media planning consideration is the nature of the program itself, as the program context influences the effectiveness of embedded advertising, with the context effect being maximal for the first ad in the ensuing commercial pod and minimal for the last ad in the pod (Murry, Lastovicka and Singh 1992). Terror management theory (Greenberg, Pyszczynski and Solomon 1986) posits that humans' innate desire for perpetual life, coupled with awareness of their mortality, creates the potential for existential anxiety. Conscious death-related thoughts instigate proximal defenses (e.g., thought suppression/denial of one's vulnerability to death; Arndt, Allen and Greenberg 2001), whereas nonconscious but accessible death-related thoughts activate distal defenses (e.g., cultural worldview bolstering; Pyszczynski, Greenberg and Solomon 1999).

Recent research in marketing (Liu and Smeesters 2010) induced mortality salience (hereafter, MS) by exposing participants to epochal news coverage (9/11 terror attacks). MS-inducing programs caused participants to prefer domestic brands over foreign brands; due to enhanced patriotism. However, the authors do not find MS effects on ad evaluation. They suggest that ad evaluations are affected by program-induced mood, and since MS does not affect mood, MS will not influence ads. Based on extant literature, we expect program-induced mood effects to be independent of program-induced MS effects, in that moods influence the first few commercials in the pod, while program-induced distal MS effects manifest themselves on the later commercials.

We investigate whether (a) archetypal death-depicting television programs trigger death-related thoughts and whether these vary over an ensuing commercial pod, (b) if and when death-related thoughts turn from being conscious to nonconscious in the pod, and (c) do distal defenses impact advertising effectiveness in the pod, and if so, what is the process mechanism? We conducted three studies. Local news from an affiliate was recorded and edited before each study. The first three-and-a-half minutes of the MS and control videos contained information on local governance etc. The last one-and-a-half minutes of the MS video contained death-related information while the control video contained sports information. Pre-tests were done to select filler ads for all studies and the target ad for the third study.

Study 1: One factor, four-level between-subjects design was used with MS-content and ads at three pod positions: beginning (MS_{BEG}), middle (MS_{MID}), and end (MS_{END}) and a control condition. Death thought accessibility (DTA; Greenberg et al. 1994) was measured after

stimulus exposure. Results showed that DTA in control condition (M_{CON} = 1.55) was similar to MS_{MID} (M_{MID} = 1.52, p = 1) but lower than at MS_{BEG} (M_{BEG} = 2.2, p = .026) and MS_{END} (M_{END} = 2.15, p = .044).

Study 2: Six-level between-subjects design was used with MS-content and ads at five pod positions: MS_{BEG}, after one ad (MS_1), after two ads (MS_2), MS_{MID}, and MS_{END}, and a control condition. Participants completed a thought-listing exercise (Greenberg et al. 1994), the Emotional Lability Inventory (ELI; Greenberg et al. 2000), and PANAS after stimulus exposure. Results showed that number of death-related thoughts in the control condition (M_{CON} = .07) was comparable to MS_{MID} (M_{MID} = .52, p = .095) and MS_{END} (M_{END} = .47, p = .161) but lower than other pod positions (ps < .001). ELI scores at MS_{END} (M_{END}= 5.83) were similar to control condition (M_{CON} = 6.01, p = .941), but lower than other pod positions (ps < .05). Positive and negative affect did not vary across conditions.

Study 3: 5 (MS: MS_{BEG}, MS_1, MS_2, MS_{MID}, MS_{END}) x 2 (AdType: Foreign vs. Domestic) + 2 (Control: Foreign vs. Domestic) between-subjects design was used. Participants viewed the video and then saw one of two ads varying *only* in the country-of-origin information in the headline, and completed DTA, attitude toward the ad and attitude toward the brand measures. There was only a treatment main effect for DTA (F (5,288) = 4.61, p < .001). Contrasts showed that DTA followed the first study's pattern. There was only an interaction effect for attitude toward the ad (F (5,288) = 2.86, p = .015). The foreign ad was rated lower than domestic ad only at end of pod (F (1, 288) = 7.5, p = .007); ps > .14 in other positions. Moderated mediation (Preacher, Rucker and Hayes 2007) showed that DTA mediated relationship between program context and attitude toward the ad for foreign ad, but not domestic ad. ANOVA results for attitude toward the brand were similar to attitude toward the ad. A multiple step, multiple mediator model (Hayes, Preacher and Myers 2010) showed that the relationship between program context and attitude toward the brand was mediated by attitude toward the ad via DTA. To summarize, we demonstrate that quotidian violent television programming makes mortality salient, triggering death-related thoughts over the ensuing pod. We find that death-related thoughts are of a conscious nature at the front of the pod and become nonconscious but accessible at the end of the pod. Further, distal defenses against death-related thoughts are activated only at the end of the pod—advertisements for foreign brands are negatively evaluated over advertisements for domestic brands—driven by nonconscious but accessible death-related thoughts.

Fourteen Research Ideas in Behavioral Pricing

Robert Schindler, Rutgers University - Camden, USA

Price is unique among marketing variables in at least two ways. First, it is the marketing variable that "harvests" the benefits created by all the others (Nagle and Holden 1995). This gives price a crucial managerial relevance that makes one wonder why courses in pricing are not more prominent in the business school curriculum. Second, its numerical nature makes price explicit and specific to a degree unmatched by any of the other marketing-mix variables (Schindler 2007). This gives the study of how consumers deal with price an extraordinary theoretical potential – the price side of things being so clear and concrete, the habits and limitations of the consumer can emerge in bold relief.

As I have been reviewing behavioral pricing research during my writing of a new pricing textbook, some particular examples of needed work in pricing-related consumer behavior have become apparent. Thinking of the many young researchers at the ACR conference, I feel it is an appropriate setting for encouraging needed research. Below are fourteen ideas that I have selected as promising opportunities for making a difference in the practice of pricing as well as in approaching more fundamental behavioral questions. It is my hope that these ideas will at least stimulate thinking in these important research areas.

1. Prospect theory suggests that framing a loss as a gain foregone reduces its negative impact. Nagle and Holden (1995) have suggested that this is illustrated by retail advertisements, often seen around April, that suggest consumers use their income tax refund to purchase a product. Is this type of advertising appeal effective?

2. Hoch and Loewenstein (1991) have found that sensory proximity can lead a quantity to be considered part of one's status quo. Could this be applied to the "dangling" of discounts commonly seen in price advertising? If dangling causes an offered discount to become part of one's "endowment," then passing up the discount could feel like a painful loss.

3. Terms such as "price points" and "price lining" are commonly used, but have received relatively little academic attention. Is the use of a small number of price points effective as means of price simplification? A recall measure could be used to test this. Are such price simplification methods more likely to be used by retailers whose prices are low?

4. Bobinski, Cox, and Cox (1996) have shown that a retailer's advertised reasons for a price decrease affect consumers. Given the commonness of price decreases and increases, it seems that further study of possible "price rationales" and their effects would be of considerable interest.

5. Sundaram, Mitra, and Webster (1998) have found that a large proportion of consumer word-of-mouth communication concerns price. Because consumer word-of-mouth communication is so important, it would be interesting to know what price information is being shared. A study of this could be carried out using consumer reviews posted on the Internet.

6. Determining the items most influential in affecting a retailer's price image is an important practical problem. There is need to build on the past research (e.g., Desai and Talukdar 2003) to develop methods to determine such "price exemplars."

7. For many years, discounts greater than five percent were illegal in Germany (Trumbull 2000). This suggests it might be interesting to carry out a comparison of pricing laws between cultures. Findings could bear on cultural universals in price fairness perceptions.

8. It is recognized that "natural monopolies," such as the delivery of electricity to homes, justify exceptions to free-market economics. Healthcare is not such a natural monopoly, but it does seem to have some difficulties with a free-market system. Could one factor be the consumer's extreme sensitivity to healthcare quality differences? For example, would people find it acceptable for price to determine who gets treatment from the best doctors?

9. Research on price promotions has tended to focus on decision processes. There seems to be a lack of research regarding decision consequences, such as whether price promotions lead people to buy things that they don't really use. For example, does the extent of a consumer's deal proneness correlate with the amount of clutter and unused items in his/her home?

10. Although there has been much written on ethics and social responsibility in pricing, there has been little academic work on the social-responsibility aspects of price promotions. More research seems needed on the role of price promotions in (1) compulsive buying, (2) over-spending, (3) borrowing, and (4) product or purchase dissatisfaction.

11. Most prices are either round numbers (e.g., $5.00) or just below round numbers (e.g., $4.99). What about all the rest of the numbers? Recently, Thomas, Simon, and Kadiyali (2010) have studied such "sharp-number" prices in real estate transactions, but what about other product categories? What questions may be evoked in consumers' minds from sharp-number prices?

12. In addition to early work on the importance of perceived risk in the consumer's use of price to indicate quality, a recent study has found evidence of more "price reliance" in countries with greater levels of risk aversion (Volckner and Hofmann 2007). It may be time to look more carefully at the role of perceived risk in supporting high prices. For example, might willingness to pay a higher price be more sensitive than measures of persuasion in assessing the effectiveness of a fear appeal?

13. Recent evidence for effects of superstitious causation (e.g., Risen and Gilovich 2008) raises the question of whether such a phenomenon may have some role in consumers' price-quality associations. Paying a premium could give consumers a sense of good luck toward receiving high quality. For example, would respondents feel more likely to win a high-quality version of a product if they paid more for the chance?

14. There has recently been some work on the practice of "pay what you want" pricing (e.g., Kim, Natter, and Spann 2009). It would be interesting to study the oldest and most common use of this practice – i.e., in the financial support of religious organizations.

Thanks for Nothing: The Dark Side of Gratitude

Waylon McGill, University of Houston, USA
Vanessa Patrick, University of Houston, USA

Despite significant public interest in gratitude (Emmons & McCullough 2003), researchers have only recently begun to rigorously examine this complex emotion (Emmons & McCullough 2003, Emmons & Crumpler 2000, McCullough et al. 2002, Bartlett & De Steno 2006). This research has identified a host of positive effects of gratitude that range from improving subjective well-being (Emmons & McCullough 2003), strengthening interpersonal relationships (Lambert et al. 2010) and promoting prosocial behavior (Froh, Bono & Emmons 2010). One question that seems to have been overlooked in the extant research is whether there is a downside to experiencing gratitude. The present research explores this question.

THEORETICAL FOUNDATION

Gratitude is a low arousal, positively valenced emotion, similar to happiness, and is characterized as having two key components (McCullough et al. 2001): (1) the person must believe that they have received a benefit to which they were not entitled, and, (2) the beneficiary must attribute responsibility for the benefit to an external source (Solomon 1977).

Emotions are frequently differentiated based on their specific action tendencies (Frijda 1986). Negative emotions can be seen as indicating that there is something wrong with the environment and that a person needs to take action to correct it. Fear, for example, mobilizes resources to escape or defend oneself, while anger promotes aggression. Conversely, positive emotions have less well-defined, non-specific action tendencies (Fredrickson & Branigan 2005). Positive affect has been found to promote inclusive thinking (Fredrickson and Branigan 2005), facilitate self-control (Tice et al. 2007) and enhance motivation (Isen & Reeve 2005).

Do all positive emotions have these same effects? The central thesis of the current research is that gratitude is actually likely to result in *decreased* motivation towards future oriented outcomes compared to a similar positive emotion like happiness. We hypothesize since gratitude is tied to a very specific outcome ("I am grateful for X"), it is a relatively more specific emotion than happiness, and consequently the experience of gratitude is likely to induce more concrete construals than happiness. Prior research has demonstrated that happiness results in the adoption of more abstract construals, which mediates the influence of happiness on the preference for future benefits (Labroo & Patrick 2008). Since concrete construals are associated with a more proximal focus, we expect that gratitude would decrease motivation for future oriented outcomes compared to happiness.

Prior research has demonstrated that emotions bias individuals' expectations regarding future outcomes. Specifically, people tend to overestimate the probability of events occurring that are consistent with the emotional state they are experiencing (Wright & Hower 1992). Accordingly, we posit that grateful people are more likely to overestimate the probability of receiving similar unearned benefits to those for which they are grateful in the future than are happy people. In other words, we hypothesize that the effects of gratitude on motivation for future oriented outcomes is domain-specific.

SUMMARY OF HYPOTHESES

We propose the following hypotheses:
1. Grateful individuals are less motivated to pursue future oriented goals than happy individuals.
2. The effect of gratitude (versus happiness) on the motivation to pursue future goals is mediated by construal level.
3. The effects of gratitude on motivation to adopt a future orientation are domain-specific.

Specifically, grateful individuals are more likely to expect to receive unearned future benefits within the domain for which they are grateful than happy individuals.

EXPERIMENTS

We propose two experiments to empirically investigate these hypotheses.

Experiment 1 will test hypotheses 1 and 3. Subjects will read the following statement(s). "When thinking about their health many people feel grateful (happy). Please indicate the extent to which you feel this way, and provide a list of reasons why your health makes you feel this way." A 7-point Likert scale will be used, and subjects will be given 5 minutes to provide reasons for their response. Upon completion they will be asked to read a health communication promoting an HPV vaccine, how it is transmitted and the risks associated with it. They will then be asked to indicate on 7-point Likert scales 1) How effective they think the communication is, 2) the likelihood that they themselves will get vaccinated, and, 3) The likelihood that they will contract the virus if they do not get vaccinated. Dependent variable (2) will assess the motivation to engage in future oriented behavior, while (3) will assess the extent to which grateful (versus happy) individuals expect future benefits for which they are not responsible.

Experiment 2 will be similar to experiment 1, but will be a 2 (gratitude versus happiness) x2 (health versus family) full factorial design designed to test hypotheses 1-3. Participants will undergo the same affect induction procedure used in experiment 1, but half the respondents will give reasons why they feel grateful (happy) when thinking about their family instead of their health. They will then see the same health communication and be given the same brief questionnaire followed by Vallacher and Wegner's (1989) personal agency questionnaire (BIF). These trait differences may be used to study differences in abstract versus concrete construals (e.g., Freitas et al. 2001; Levy, Freitas, and Salovey 2002). Construal level scores will then be calculated using the standard procedure. We would expect that grateful participants would reveal relatively more concrete construal levels than happy participants, and that construal level would mediate the influence of grateful (happy) participants on motivation to engage in future oriented behavior and the extent to which grateful (versus happy) individuals expect future benefits for which they are not responsible. We also expect that these effects will be domain-specific, such that this influence will be stronger for participants reflecting on being grateful about their health (versus family).

CONCLUSION

The purpose of this research is not to condemn gratitude, which we acknowledge as an important and adaptive emotion. Rather, it is simply to provide balance to an overwhelmingly positive body of literature on gratitude. Further, we believe that by if someone thinks about how their gratitude makes them feel in a more general sense, this negative effect of gratitude can be reversed by activating more abstract construals.

Transnational tourists consuming hyper-masculinity in the Dominican Republic: 'All inclusive'?

Nacima Ourahmoune, Reims management school (RMS), France

In locations around the world, sex tourism is a booming business. The Dominican Republic has experienced very rapid socio-cultural and economic change due to the development of tourism. The Island has become the leading destination for tourists in the Caribbean. This has a tremendous impact on local populations in terms of consumption (from the structure of purchases to brand awareness). On the other hand, western consumers in their vast majority adopt the "All inclusive" offer as a form of vacation where they maximize recreation/leisure, pleasure and exotic fantasy in huge closed resorts where everything is presented as free (in fact pre-paid…). Prostitution is often quoted as a strong motive for the choice of this destination. "Although prostitution may involve an immoral exploitation of human beings (Hirschman 1991; Truong 1990), and sex slavery certainly does so (Aisbett and Malan 1993; Hornblower 1993; Sherrill 1993), the patronage of prostitutes is plausibly the oldest form of consumer behavior. Nevertheless, prostitution has been studied to a very limited degree by consumer researchers (Ostergaard 1993)" (Belk, 1994). This research project is an attempt to research the intersection of transnational consumption behaviors and (gender) power relations.

Kamala Kempadoo (1999) suggests sex tourism provides a clear example of how power relationships are perpetuated between North/ South countries through globalization processes. In this perspective, Caribbean countries are forced into marketing their beaches and also their bodies as commodities to the tourist markets of North America and Europe as the Caribbean becomes a tropical playground for the globally powerful to explore their racialized fantasies.

More specifically, previous anthropological research has been carried out in the Dominican Republic. Denise Brennan (2004) considers why Dominican and Haitian women move to the town of Sosúa to pursue sex work and describes how sex tourists, primarily Europeans, come to Sosúa to buy sex cheaply and live out racial fantasies. Illuminating the complex world of Sosúa's sex business in rich detail, Brennan (2004) draws on extensive interviews not only with sex workers and clients, but also with others who facilitate and benefit from the sex trade. She weaves these voices into an analysis of Dominican economic and migration histories to consider the opportunities—or lack thereof— available to poor Dominican women. She shows how these women, local actors caught in a web of global economic relations, try to take advantage of the foreign men who are in Sosúa. Through her detailed study of the lives and working conditions of the women in Sosúa's sex trade, Brennan (2004) raises important questions about women's power, control, and opportunities in a globalized economy.

This research pursues this effort by examining other aspects not touched on by Brennan's research. Unlike a body of research that tackled specifically sex workers' representations in the Caribbean, the author locates this study in the context of crowded, close, safe, family resorts in Punta Cana. I specifically investigate Local men/ Tourist female interactions in the context of those resorts. Escaping usual images of female sex workers or the interactions of young male "beach boys" with aged female tourists, the research shows how it is difficult to untangle the phenomenon of prostitution from "romance tourism" when young female tourists are involved in relationships with Dominican males working in the tourism industry.

The author conducted an ethnographic research over 4 years, with over 20 weeks in the field. More specifically, a group of Dominicans who are part of the Animation staff in a typical local resort - was investigated (over 2 years, 7 weeks). The author shared activities with informants (local dances, discos, visits to native towns/family…), performed observations, in-depth interviews (with 15 Dominicans and 12 female tourists). Also, a semiotic analysis of hundreds of pictures taken in the field helped enrich the findings.

We specifically focus here on gender relations between female tourists and local male hotel staff. Those relationships raise issues of performing and consuming the body mediated by the "all inclusive" offer.

The findings show elements that reinforce power logics in both economic and racial terms in the context of local/tourists interactions. In particular a "day and night" theme emerged from the field showing how far the dominance is important while Dominican males are at work, serving client's expectations with the necessary distance to be maintained with them. In contrast, at night, when tourists and locals gather in discos as clients, relationships are complexified in terms of power logics.

For instance, Dominican male agency is emphasized through romances with young tourists. Various respondents' discourses and behaviors show how rivalry between male tourists and male locals is expressed in the reversed context of female tourists consuming the racialized fantasy of Black or Latin hyper-masculinity.

Bodies, possessions and brands are manipulated as signs to convey specific discourses on sex, gender, ethnicity and social status. At a macro-level tourism is an obligation for the Caribbean to survive against the Global North. The narratives displayed rely on four S's of tourism advertising: Sun, Sand, Sea and Sex. Those images of The Garden of Eden and old fantasies of tropical paradise and constructions of radical difference are fundamental in understanding what fuels sex tourism and drives Caribbean consumers to sell their bodies to transnational/ global consumers. At a micro-level, intimate interactions between tourists and locals reveal the reproduction of power relations while male Dominicans also show a sense of agency trying to take advantage of this situation by both emulating white male consumers and exaggerating stereotypes of hyper-masculinity. The findings aim at both contributing to the literature on transnational consumers and the growing research area in masculinity in our field.Selected Bibliography

The effects of a brand recall
on the recalled brand and its competitors

Sheila Goins, University of Iowa, USA
Catherine Cole, University of Iowa, USA
DongWoo Ko, University of Iowa, USA

THEORETICAL BACKGROUND

In prior research, manufacturer's reputation influences the extent to which consumers use extrinsic cues to make inferences (Purohit and Srivastava 2001, Dawar and Pillutal 2000). When reputation is good, consumers utilize negative information to revise attitudes, but when reputation is low, consumers don't revise their attitudes, because they interpret negative extrinsic cues as evidence consistent with their negative attitudes. So we expect that:

H1: *Product quality will moderate the effect of a recall on consumer brand evaluations such that when a low quality brand is recalled there will be no change in evaluations, but when a high quality brand is recalled there will be a decline in evaluations.*

Prior research examines how a firm's announcements affect the reputations of competitors (Goins and Gruca 2008). These competitive effects depend on the intensity of competitive rivalry. When competitive rivalry is high (e.g. brands are made from the same inputs), competitive effects are stronger than when competitive rivalry is low (e.g. brands are made from different inputs). Product quality may moderate further these competitive effects. When high quality brands are recalled, consumer may revise their judgments about low quality brands *upward*, especially if the brands are made from the same inputs. But, if low quality products are recalled, consumers may view the recall as confirming evidence about the known difference between high quality and low quality brands, regardless of whether inputs are shared or unique. We specify:

H2: *Shared inputs will moderate the competitive effect such that when a low quality brand is recalled, there will be no changes in the evaluations of the high quality brand, but when a high quality brand is recalled, the large positive increase in the evaluations of the low quality brand will be stronger when inputs are shared than when inputs are unique.*

EXPERIMENT 1

To test H1, we use a 3 level (recall condition: no recall, high quality brand recall and low quality brand recall) between subjects design, with 134 undergraduate participants randomly assigned to read one of three versions of a new camping e-magazine. The third section of the e-magazine contained reviews of fictional carabiners, describing one carabiner, made by the fictional F&G Company, as high quality and described another, made by the fictional QRB Company, as low quality. Then participants read about product recalls. In the control condition, they read about two recalls, but in the experimental conditions, participants read about an additional recall in which either F&G or QRB recalled their carabiners. As they were reading each section, respondents answered questions about the products and the e-magazine. At the end, participants again rated the quality of the reviewed products.

RESULTS

The pattern of results for the manipulation check suggests that we successfully manipulated carabiner quality. To test H1, the final carabiner evaluations were analyzed separately using one-way analysis of covariance variance (ANCOVA) with one between subjects factor (recall condition with three levels no recall, F&G carabiner recall and QRB carabiner recall), one covariate (initial evaluation) and the final carabiner evaluation. By including the initial evaluation of the brand, as a covariate, we are able to study judgment revision after a brand recall (As done by Pham and Muthukrishan 2002).

In the ANCOVA for the high quality carabiner evaluations, the covariate (first evaluations ($F(1,129)=14.18$, $p<.01$)) and the recall conditions $F(2,129)=4.8$, $p<.01$) were significant. Specifically, the F&G high quality carabiner evaluations are lower after the F&G carabiner is recalled than after there is no recall (4.01 vs. 3.60, $t=2.60$, $p<.01$). Similarly, in the ANNCOVA for the low quality carabiner evaluations, the covariate (first evaluations ($F(1,129)=87.56$, $p<.01$) and the recall conditions were significant (($F2,129)=4.97$, $p<.01$). However, there is not a significant decline in QRB carabiner evaluations after the QRB brand is recalled when compared to the evaluations in the no recall condition. Consequently, consistent with H1, product quality moderates the effects of a product recall such that when a high quality brand is recalled, there is a large negative effect on brand evaluations, but when a low quality brand is recalled, there is no effect of on low quality brand evaluations.

EXPERIMENT 2

We investigate whether the intensity of competitive rivalry and product quality moderate the competitive effects (H2). We use the same methodology as in Experiment 1, but manipulate competitive rivalry in the recall announcement. Participants either learned that inputs for all carabiner manufacturers are the same or that they are unique. Our experimental design is a one way design with 5 conditions (QRB recall-inputs shared; QRB recall inputs unique, F&G recall-inputs shared, F&G recall inputs unique, no recall).

Consistent with H2, shared inputs moderate the interaction between product quality and competitive effects. When competitive rivalry is high (inputs are shared), the evaluations of the low quality carabiners are *higher* when the high quality carabiner is recalled than in the no recall condition (5.39 vs. 4.34, $t=2.33$, $p<.02$). However, this same competitive effect is not observed in the unique inputs conditions. Additionally as stated in H2, a low quality brand recall does not affect the evaluations of a high quality brand, whether inputs are unique or shared.

DISCUSSION AND FUTURE RESEARCH DIRECTIONS

We find evidence that brand quality is critical in understanding brand recall effects. We find that lower quality brands suffer less than higher quality brands. Additionally, we find that brand quality moderates competitive effects so that when a high quality brand is recalled, the low quality brand evaluation increases, but only if inputs are shared and when a low quality brand is recalled, there is no change in high quality brand evaluations. In a 3rd planned study, we will consider the effects of a recall on other brands in the same brand family (transfer effects).

Twice the Vice

Lauren Trabold, Baruch College, CUNY Graduate Center, USA
Lauren Block, Baruch College, USA

Extant literature has often studied consumer goal pursuit, particularly in the area of self-control. This stream of research has frequently examined the pattern of consumer behavior when a person is faced with a choice between a goal-consistent and a goal-inconsistent option. Research has suggested that consumers establish a reference point based upon their self-control goal to which each choice option is compared in order to determine which choice is most consistent with their goal (Hoch and Lowenstein, 1991). Research has also studied consumers' affective response, suggesting that the choice of a goal inconsistent option will yield feelings of guilt and a goal consistent option will yield feelings of satisfaction and self-efficacy (Giner-Sorolla, 2001; Ramanathan and Williams, 2007). A common operationalization of this choice is in the context of a health goal, in which a person is given a choice between an unhealthy and healthy option such as chocolate cake and fruit salad. Given a reference point of healthiness, the fruit salad is clearly the goal-consistent choice and the chocolate cake, the goal inconsistent choice. Not surprisingly, greater guilt is experienced when a consumer chooses the chocolate cake rather than the fruit salad. Anticipation of guilt will be a driving factor in a person's ensuing willpower. Consumers make judgments about their own willpower and self-efficacy based upon their previous consumption decisions and regularly use past decisions as a precedent for how to behave when faced with a similar situation (Benabou and Tirole, 2004). If a consumer acts inconsistently with his/her goal, he/she not only risk relying on such indiscretions in the future as a precedent for further indulgence, but also will experience immediate feelings of guilt.

The current study seeks to extend this literature by observing how consumers will make a decision when they are not given an opportunity to behave consistently with their goal. Specifically, we observe the way that consumers will utilize different decision strategies to make a choice when faced with two equally goal-inconsistent options (e.g., a consumer with a health goal faced with a choice between two decadent desserts). Literature suggests that consumer choice may differ dependent upon the decision strategy used, namely, whether they select the option they want or reject the option they don't want (Shafir, 1993). By presenting two equivalently goal-inconsistent options, we hypothesize that without a goal-relevant reference point by which to compare the options, consumers will decide based upon their preference; we explore whether or not instructions to select or reject from the goal-inconsistent options will moderate whether consumers choose their least or most preferred option. We anticipated that consumers should reject their favorite item immediately and thus choose their least preferred option, whereas selection may encourage them to rationalize that each option is equally goal-inconsistent and therefore allow them to justify choosing their favorite option. Moreover, we expected participants to feel less guilt when consuming their less-preferred option relative to those consuming their favorite option. Thus, while consumers in this situation are faced with imminent goal failure, they may be able to establish a reference point that will allow them to minimize their guilt.

We conducted a 2 (goal: self-control vs. indulgence) x 2(decision strategy: select vs. reject) between subjects study. All subjects were asked to rank order a list of 10 desserts based on preference and were subsequently given a choice between their first and second ranked items. Prior to making a choice, subjects were either asked to imagine a scenario about dieting to fit into a new outfit for your high school reunion (self-control goal) or to imagine a scenario in which they are pampering themselves prior to their high school reunion and have decided to indulge at a restaurant (indulgence goal). Additionally, participants were randomly assigned to make their decision by either selecting ("Please select the dessert you want to order") or rejecting ("Please reject the dessert you do NOT want to order") one of the options. Nutrition information provided suggested that the two desserts were approximately equivalent in caloric value. After making their choice, participants were asked a variety of questions including how guilty they felt for their choice.

Findings thus far have strongly supported our hypotheses. Analysis revealed a mediated moderation suggesting that the influence of goal type (self-control or indulgence) on choice is moderated by the subjects' decision strategy (select or reject) (*p < .05)* and the influence of rejecting on those with a self-control goal on choice is mediated by feelings of guilt (*p < .01*). Subjects with a self-control goal (vs. an indulgence goal) that rejected the dessert they did not want (vs. selected the dessert they did want) were significantly more likely to choose their less preferred dessert option than those in the other three experimental conditions. Interestingly, these subjects also perceived their choice to be less indulgent (*p < .01*), although study instructions clearly indicated that the caloric value was approximately equal. Notably, these participants also experienced less post-consumption guilt over their goal failure than subjects in the other three conditions.

Our study provides an interesting account in which consumers are able to minimize their guilt in the face of imminent self-control goal failure by using a rejection strategy, ultimately resulting in the counterintuitive choice of a less preferred, yet equally goal inconsistent option.

Differences in Brand-Related User-Generated Content Across Three Social Media Sites: An Inductive Content Analysis

Andrew N. Smith, York University, Canada
Eileen Fischer, York University, Canada
Chen Yongjian, York University, Canada

Consumers today are spending more time on social media sites than ever before (Radwanick 2011). As they engage with these sites – including Facebook, Twitter, and YouTube – many become involved in the process of creating, modifying, and consuming user-generated content (UGC). UGC is an increasingly important means through which consumers express themselves and communicate with others online (boyd and Ellison 2008); it may be thought of as published content that demonstrates a degree of creative effort that is produced "outside of professional routines and practices" (OECD 2007; Kaplan and Haenlein 2010, 61). Facebook 'wall' posts, status updates, and posted photos, tweets on Twitter, and consumer-produced videos and comments on YouTube are some of the many forms UGC takes on. UGC may be facilitated by firms, or produced more spontaneously by consumers (Berthon, Pitt & Campbell 2008; Christodoulides 2009), while occasionally referencing brands and products.

Academic marketing research on UGC, while still nascent (Burmann 2010), has investigated a number of aspects of UGC, including motivations behind its creation (Daugherty, Eastin and Bright 2008), its value to firms (Dhar and Chang 2009; JPRM09), and its connection to brand communities (Muñiz and Schau 2007). Daugherty, Eastin and Bright's (2008) work is distinct in that it incorporates data about multiple types of UGC, such as videos, pictures, audio, and blogs, whereas other marketing studies typically examine a single type of UGC, or UGC originating from a particular site. However, as their focus is on motivations to produce UGC, Daugherty, Eastin and Bright (2008) provide limited insight into the distinctive characteristics of the UGC that is created in different social media channels; moreover, their focus is not exclusively on brand-related UGC, arguably the form of greatest interest to marketing and consumer researchers. Our study thus goes beyond prior research to compare and contrast the content of brand-related UGC posted on three of the most popular social media sites: Facebook, Twitter, and YouTube. Our work builds on prior research to make two valuable contributions. First, it provides a grounded framework that illuminates similarities and differences in the content that consumers create when they make posts that refer to brands. Second, it helps us to better understand how specific social media may influence or shape the brand-related messages that consumers create (cf. McLuhan 1964).

Facebook, Twitter and YouTube were chosen for this research because they are among the most popular social media sites for consumers and marketers, and because they belong to different social media niches: Facebook is a social network; Twitter is a microblogging application; and, YouTube is a content community. Each site encourages UGC of different forms, from 140-character tweets to posted photos to 8-minute videos. The data for this study consists of 600 brand-related UGC posts – 200 from each of Facebook, Twitter, and Youtube – for two brands: Lululemon and American Apparel. The posts, which were published between June, 2010 and January, 2011, were selected at random from Google search results for: 'brand' on 'site': (e.g.) 'Facebook.com'. The two brands were selected because they generate enough interest from consumers to be featured in UGC, and are in the same category: clothing manufacturing and retailing. Moreover, one brand (Lululemon) has had no major scandals or challenges, while the other (American Apparel) has come under negative scrutiny for various reasons. The project comprised three steps. Initially, a coding scheme was created inductively by the three authors who analyzed posts on each medium for both brands. The main dimensions for coding (all binary, except for valence) were whether the post reflected: consumer self-promotion; brand centrality of either Lululemon or American Apparel; presence of multiple brands; communications directed to the company; communications responding to company actions; information about the brand; and/or valenced evaluations of the brand.

Next, each post was manually coded by an independent coder, and one member of the research team, using the inductively developed coding scheme. Intercoder reliability, as calculated using Perreault and Leigh's (1989) formula, was approximately 0.9, falling within the accepted range of 0.8 to 1.0; any discrepancies in coding were examined and adjudicated by a second member of the research team.

Finally, coding frequencies were tabulated, and statistical differences were assessed using Chi-square tests. Prior to testing for differences between content on the three media sites, Chi-square analyses were run between brands, along each of the coded dimensions, to test for homogeneity. Since between-brand differences were detected, comparisons across the three media sites were run separately for the posts for the two brands.

Our findings reveal a number of differences in UGC across the three channels. For example, consumer self-promotion was most common in YouTube UGC and least common in Twitter UGC, reinforcing YouTube's slogan of 'Broadcast Yourself.' Across both brands, YouTube UGC was least likely to focus centrally on the brand of interest and was most likely to feature it alongside a constellation of other brands. For Lululemon, Youtube UGC was least likely to be used to communicate with the company (for American Apparel, no form of UGC was used to communicate with the company, which may reflect the ambivalent attitude that many consumers have with the brand's founder, and the company's social media engagement strategy). For both brands, YouTube was least likely to be used to respond to some company action made online or offline. These findings convey that, while the medium is not, strictly speaking, the message, the different social media sites and their unique cultures foster variance in the brand-related content generated by the consumers who use each medium. Our research offers other scholars a preliminary scheme upon which they may build when seeking to understand differences in brand-related UGC, and insights into the factors (characteristics of medium, as well as the perceptions and actions of the company) that shape UGC in particular ways.

Shape-Shifters: Exploring Dynamic Culture Through The Shaping of Bicultural Identity

Akon Ekpo, University of Illinois at Chicago, USA

The growing number of individuals with mixed cultural identities in the global workforce and consuming market has given rise to the awareness of and opportunities to understand biculturals and their role in the global market. Bicultural individuals are typically described as people who have internalized two cultures to the extent that both cultures are alive inside of them (Hong, Morris, Chiu, & Benet-Martinez, 2000). They are people who have deeply internalized, and operate fluidly between, two or more distinct cultural meaning systems, inherently carrying with them critical intercultural adaptability skills that guide their thoughts, feelings, and subsequently their behavior (M. Brannen, Garcia, & Thomas, 2009; Hong, et al., 2000). However, the small number of studies on biculturalism in the international marketing and management contexts have mainly focused on the adaptability skills, cultural knowledge, and metacognitions of bicultural individuals (M. Y. Brannen, 2009), assuming a fairly static perspective of culture.

Even though biculturalism is relatively new to the international marketing field, it has been examined more so from the social psychology discipline. Hong et al.'s (2000) study on Westernized Chinese students in Hong Kong found that cultural icons have the ability to prime bicultural individuals, in which a particular cultural identity is readily accessible and promote cultural frame switching (Hong, et al., 2000). Furthermore, Briley & Wyer (2001) found that even though chronically accessible cultural values and norms may influence a particular cultural identity, transitory situational factors may also activate cultural values that may be inconsistent with a person's cultural inclinations (Briley & Wyer Jr, 2001); furthermore, these activated cultural values may impact individuals' judgment or decision behaviors. Benet-Martinez et al (2002) empirically examined how bicultural individuals managed and negotiated their dual cultural identities, and found that Chinese-American biculturals who perceived their cultural identities as compatible (high bicultural identity integration or BII) responded in culturally congruent ways to cultural cues (Benet-Martinez, Leu, Lee, & Morris, 2002). However, Chinese-American biculturals who perceived their cultural identities as oppositional (low BII) exhibited a reverse priming effect (i.e. responded to cultural cues that were directly inconsistent with cultural norms). Finally, Lau-Gesk (2003) found that biculturals responded favorably to values-promoting appeals that were congruent with the activated cultural disposition; and the response differed among individuals based on whether they tended to compartmentalize or blend the two cultures (Lau-Gesk, 2003). Taken together, these studies suggest the need for a more *dynamic* view of culture.

To explore this dynamic perspective, this study proposes to understand meaning making of the bicultural identity. Specifically, the aim here is to understand the meanings bicultural consumers attach to their social identity through food consumption, in an effort to illustrate how one's culture is shaped by the socio-cultural environment. Studies have shown that food consumption is at the heart of most ethnic cultures and carries cultural meanings (Wallendorf & Reilly, 1983). However, unlike prior studies that focus on cultural meanings of food, this study focuses on the (consumption) experience to understand meanings of the bicultural identity. Because experiences are inherently dynamic, by focusing on bicultural consumers' consumption experiences, this study is able to capture the dynamic nature of culture. As such, this study seeks to understand how bicultural consumers make sense of their consumption experience by exploring their meaning interpretations to which they act/react in constructing their identities.

Meaning making has a long history in consumer research in which the investigator attempts to get at the how's and why's of consumer behavior. Meaning making is the process by which consumers interpret and make sense of their environment. It provides an understanding of the environment from the consumer's perspective. Understanding meanings are important because they provide the individual with a framework to which people then act/react. In this sense, meanings are causal. Much of the research has focused on the meanings of mono-cultural consumers, who may see things differently than bicultural consumers. Given the prevalence of bicultural individuals, it is important

to understand the perspectives of these individuals as they have gone under researched, and may paint an incomplete picture of the importance of the consumption context in consumer behavior. Therefore, this study has theoretical implications for understanding culture as dynamic (versus static), provide deeper understanding of biculturals as it relates to their consumption experiences, and highlights the potential differences and similarities between different types of consumers.

To begin to explore the research objectives, a small pilot study of two bicultural informants (both non-American born, 1 African and 1 Hispanic descent) was conducted using structured interviews, lasting 2 to 2-1/2 hours each, participation during consumption with informants, observations (of food orders, interactions within social setting, site descriptions), and informant diaries (their thoughts, reasons for consuming particular foods, and feelings about their consumption experiences), over the course of two months. Observational data was collected at the sites where informants consumed and/or prepared food, which included: restaurants, at the homes of the informant, and cafeterias/cafes. Preliminary findings showed that informants' food consumption experiences were colored by the social environment, in which interactions with others in the consumption setting invoked cultural values and customs from their respective cultures. During these experiences informants described how the consumption environment invoked fond memories of being "at home" (i.e. native country), being amongst friends and family back home, having pride in one's culture, and dreaming of going back home. During their consumption experiences, both informants described how they became more aware of their ability to function in both the American and non-American cultures and that their sense of self "shifted" depending on the consumption setting.

While this study is still in its preliminary stages, these finding suggest some evidence that the shifts between cultures by bicultural individuals are invoked through the social context and the interactions amongst individuals within the consumption setting. This shifting between cultures paints a more dynamic picture of culture that is driven by social cues in as much by psychological cues. Although identity and identification has been studied as an internal (cognitive) process, it is equally (if not more) an external interaction (i.e. social) process as well.

Nestle and Tastle: The Effect of Phonetic Similarity in Brand Name Innovation

Ann Kronrod, Massachusetts Institute of Technology, USA
Tina M. Lowrey, University of Texas at San Antonio, USA
Mark Nespoli, University of Texas at San Antonio, USA

Selection of an effective brand name is perhaps one of the most important decisions a marketing manager must make. Of course, there are many factors that affect such a decision (product category, cultural connotations, competition, etc.) One that is sometimes overlooked is phonetic sound. Past research has shown that how a brand name sounds can have a profound effect on how it is perceived and evaluated. For example, research by Chisnall (1974); Lowrey, et al. (2003); Myers-Levy et al., (1994); and Peterson and Ross (1972) has demonstrated that perceived phonetic fit between brand name and product category can increase product recall, preference, and inference.

Oftentimes, managers, especially those of international brands, prefer to select names that have no meaning in any language so as to avoid any unintended connotations. The focus of this research is to examine the effects that phonetic similarity and familiarity can have on the preference and evaluation of such "non-word" brand names. Kohli, Harich, and Leuthesser (2005) found that repeated exposure to a non-word brand name increases evaluations of its quality and other attributes (perhaps due to Zajonc's "mere exposure effect," 1968). Likewise, a number of studies have shown that when presented with a name similar to their own, that name is preferred by people more than less similar names (Jiang, et al., 2010; Burger, et al., 2004; Gueguen, 2003; and Brendl, et al., 2005).

Research on linguistic innovation proposes the Optimal Innovation Hypothesis (Giora, Fein, Kronrod et al 2004), according to which an optimally innovative stimulus that induces a novel response while allowing for the recovery of a salient one (Giora, 1997b, 2003) would be rated as more pleasing than both a more and less familiar stimulus. We test this hypothesis in relation to brand name innovation, predicting that new, non-word brand names that are highly similar to or highly distant from non-word brand names of disliked products will elicit more negative evaluations in terms of liking and WOM and purchase intentions than those that are moderately similar. Similarly, when a familiar, non-word brand name is associated with a negative attribute of a firm, we predict that a moderately similar variant would elicit more negative evaluations than more similar and distant variants and vice versa when the familiar non-word brand name is associated with a positive firm attribute.

PRETEST

A set of 30 non-word brand names were generated, each with a similar, a moderate, and a distant variant. Participants rated the original names for familiarity and valence and listed any thoughts that came to mind when they thought about each. The originals were then paired with each of their three variants, and the pairs were then rated for similarity. The ten originals (and their variants) that best exhibited the expected pattern in terms of similarity (highly similar, moderately similar, and distantly similar), were neutral in valence, and roughly equivalent in terms of familiarity; were selected for use in Studies 1 and 2.

STUDY 1

Familiarity with originals was manipulated via repeated, randomized exposure (four times each) and completion of three cognitive ordering tasks. Participants then rated their level of familiarity as a manipulation check. They then rated each of the variants in randomized order for degree of liking, purchase likelihood, and likelihood of recommendation to a friend. Of the 30 variants, they then selected the 10 they believed to: (a) belong to the most credible companies, (b) represent the most enjoyable products, (c) last the longest, (d) be the most popular, and (e) be the finalists they would recommend to a company to have as finalists for the perfect brand name. Participants then completed involvement and innovativeness scales, as well as PANAS. As expected, similarity elevated positive attitudes towards the new brand name in terms of liking, credibility evaluation, WOM intention and purchase intention.

STUDY 2

The 10 original brand names employed in Study 1 were divided into two groups, positive and negative, according to one of three attributes of the firm: the use of environmentally-friendly (unfriendly) materials, ethical (corrupt) management practices, and an excellent (poor) return policy. The same overall procedure from Study 1 was implemented. Supporting the Optimal Innovation Hypothesis, Repeated-measures ANOVAs revealed an inverted U-shaped pattern, where for liked names, highly similar and highly distant variants were significantly less favored in terms of liking, purchase intention and WOM intention, compared to moderately similar variants of these brands. For disliked names, however, a U-shape relationship emerged, with the moderately similar variants being significantly less favored than the highly similar and the highly distant variants of these brand names.

SUMMARY

This research is an attempt to clarify the question of brand name innovation in marketplace. Highly-controlled experimental design allows us to evaluate the contribution of new brand name similarity to a familiar brand name. We find that new brand names that are moderately similar to familiar liked brand names receive higher evaluations in terms of liking and WOM and purchase intentions than those that are both more close and distant phonetically (optimal innovation effect).   However, when the familiar brand name is associated with a negative firm attribute, the effect is reversed, with the moderately similar new brand name being less favored than both the phonetically close and distant new brand names. In continuation to this line of research we will employ a field experiment design to validate our laboratory results in more realistic conditions.

More than New, Creative Design Solution: Factors Necessary for Delivering a Creative Design in the New Product Development Process

JaeHwan Kwon, University of Iowa, USA
Moonkyu Lee, Yonsei University, South Korea
Hae-Ryong Kim, KonKuk University, South Korea

Many companies are struggling with successful new products development. As pointed out by Brethauer (2002), only a small percentage of new products released into the market are successful, and the creative design of a product is one of the most critical elements in the successful launching of a new product. The importance of creative design in new products has often been emphasized. Nevertheless, surprisingly little research has examined design creativity in the NPD process. In the present research, we explore the factors influencing design creativity of a new product and their relationships.

Although previous studies emphasized the relationship between firm- (e.g., market orientation)/project-level (e.g., team characteristics) variables and creativity in the NPD context (**Im and Workman, 2004; Sethi, Smith, and Park, 2001), the role of individual-level variables has not been considered.** In this study, we adopt a designer's ability factor as an independent variable and the output, design creativity, as dependent variable. So that we can answer our research question: do creative designers necessarily translate into creative designs?

In today's business, the design solutions of new products come from the interactions of individual designers (Kristensson and Norlander, 2003). Thus, we follow the view proposed by Burroughs and Mick (2004); we adopt the person-situation perspective from social psychology (e.g., Higgins, 1990). Specifically, this research focuses on defining the roles of the three person-based variables (analogical thinking ability, perceived length of experience, and self-confidence) and one situation-based variable (team culture).

Our hypotheses are as follows:

H₁: *Higher analogical thinking ability of a designer will increase the design creativity of a new product.*

H₂: *Higher self-confidence to produce a creative design will increase design creativity.*

H₃: *Self-confidence will mediate a positive relationship between analogical thinking ability and design creativity.*

H₄: *The effect of analogical thinking ability on self-confidence will be stronger when a designer's perceived length of experience is higher rather than lower.*

H₅: *The effect of self-confidence on design creativity will be stronger when team culture encourages creativity.*

This study has two different parts: one experiment with 164 design school students and another with 164 consumers. In the first part, we measure all independent variables and collect each participant's photocopy of the design output from his/her previous team project. In the second part of the study, another group of participants (consumers) is asked to evaluate the design creativity of the photocopies (dependent variables). As a result, this study is able to be free from the effect of common method bias. Also, in this way, design creativity of a new product can be examined from a consumer's perspective, not from a designer's perspective.

Upon analysis, we first conducted two-stage regression analysis to test the mediating effect of self-confidence between ATA (analogical thinking ability) and design creativity. Support for the mediating effect was expected to emerge in the last procedure of four consecutive regression procedures. ATA positively affected self-confidence (Procedure 1: $\beta = .492$, $t = 7.193$, $p < .001$), and both ATA and self-confidence positively influenced design creativity (Procedure 2: $\beta = .394$, $t = 5.462$, $p < .001$, and Procedure 3: $\beta = .356$, $t = 4.852$, $p < .001$). In the Procedure 4, however, the coefficient of ATA was insignificant ($\beta = -.005$, $t = -.553$, p, *NS*), while that of self-confidence was significant ($\beta = .136$, $t = 3.699$, $p < .001$). It was, therefore, substantiated that self-confidence has a full mediating effect between ATA and design creativity. Consequently, H₂ and H₃ were supported, but H₁ was rejected.

For testing H₄—the moderating effect of PLE (perceived length of experience) between ATA and self-confidence, Aiken and West's (1991) regression analysis was conducted. Actual length of experience was included as a control variable. Support for our predictions was emerged in the form of interaction between ATA and PLE ($\beta = .252$, $t = 3.355$, $p < .001$). Also, the effect of ATA on self-confidence was significant ($\beta = .675$, $t = 5.839$, $p < .001$), while the effect of PLE was not ($\beta = -.063$, $t = -1.068$, *NS*). Thus, it was proven that the effect of ATA on self-confidence was greater when PLE was higher rather than lower.

H₅ (the moderating effect of team culture between self-confidence and design creativity) was proven true through beta-slope tests. The effect of self-confidence on design creativity was greater when team culture was individuality-oriented, as opposed to collectivity-oriented ($t = 2.137$, $p < .05$).

The present study extends our understanding of the underlying process in which design creativity can be promoted both by the individual designer's traits and perceptions and by the design team's culture during NPD projects. Our findings contribute to research on creativity in broader contexts, as well as to on the qualified context of design creativity in the NPD. Most of the extant research on creativity has focused on the effect of analogical thinking ability on person's creativity, not on the outcome of creative process. By examining the effect of analogical thinking ability on the creativity of an outcome, we show that the ability has more direct relationship with an outcome. More importantly, we find that self-confidence should be accompanied for a creative outcome. Given that the most likely response to a new idea will be extremely negative, one needs high self-confidence to believe that he or she is right and that the rest of the world is wrong (Martindale, 1989).

However, there was little empirical evidence to the extent that individual differences in self-confidence affect creativity of an outcome. In the current study, we demonstrate that self-confidence is motivated by analogical thinking ability, and that it facilitates creative outcome.

This research also shows that both person and situation variables affect creativity in NPD settings. Burroughs and Mick (2004) showed that both influence creativity in the problem-solving settings. By extending the applicable settings, we suggest that research on creativity be approached from the person-situation perspective.

Individual Differences in Interpersonal Touch: Development of the "Comfort with Interpersonal Touch" Scale

Joann Peck, University of Wisconsin - Madison, USA
Andrea Webb, University of Wisconsin - Madison, USA

Communication is one of the cornerstones of the marketing field. While the marketing literature has heavily investigated various communication strategies between channel members, consumers, etc., nonverbal communication, specifically communication through touch, is often neglected. We often think of organizations or business units as forming alliances and partnerships, but it is really *individuals* who are interacting to form these relationships. This underscores the criticality of understanding individual preferences in communication, especially as it relates to the sense of touch.

The sense of touch can influence product decisions (McCabe and Nowlis 2003; Peck and Childers 2003a,b, 2006; Peck and Shu 2009); yet, we know relatively little about interpersonal touch, especially as it varies across individuals and cultures. This paper seeks to develop a measure of individual difference in touch, the Comfort with Interpersonal Touch (CIT) Scale. This paper is the foundation for a larger stream of research to investigate cultural- and business-specific interpersonal touch norms.

Previous research has shown that interpersonal touch can be persuasive and can greatly influence our perceptions. Some researchers suggest that more than half of the variability of response in interpersonal communication can be attributed to nonverbal factors such as touch (Mehrabian 1981). In a study done by Fisher, Rytting, and Heslin (1976), a university library clerk inadvertently touched the hand of students, and those who were touched rated the librarian, as well as the university's library facilities, more positively than those who were not touched. This effect was found even for students who hadn't noticed the touch. Interpersonal touch has also been shown to increase compliance. Hornik (1992) had an in-store marketer touch customers lightly on the upper arm, and those touched were found to be more compliant in both sampling and buying a new product. In related research, individuals who were asked to sign a petition were found to be more compliant if they were briefly touched (Willis and Hamm 1980), and shoppers who were touched were more willing to participate in mall intercept interviews (Hornik and Ellis 1988). Previous studies also show that restaurant servers who briefly touched customers received larger tips than servers who did not touch (Crusco and Wetzel 1984; Hornik 1992; Stephen and Zweigenhaft 1986). Thus, brief interpersonal touch in social exchanges can have significant effects on our perceptions. However, like product touch, some individuals are more comfortable with both touching and being touched in a social situation. We expect this individual difference to moderate the persuasive effects of interpersonal touch. As yet, there is no comprehensive scale to measure an individual's comfort with interpersonal touch.

We believe that there are five latent dimensions that underlie an individual's comfort with interpersonal touch. First is the source of the touch initiation. That is, we propose a distinction between one's comfort with touching someone else and comfort with being touched by someone else. Second, one's relationship to the other individual likely influences the perception of touch (friends, family, coworkers, etc.). Third, perceptions of touch are likely altered due to the gender of the individuals involved. Norms surrounding male-to-male touch have more variance than female-to-female or opposite gender touch. In order to understand a culture's idiosyncratic touch norms, we need to include both the gender of the person touching and the gender of the person being touched. Fourth is the type of touch. There is likely a difference between a handshake, a hug, a touch on the arm, etc. in how comfortable an individual is with the touch. Finally, the fifth dimension is the context in which the touch occurs. Whether individuals are greeting each other, saying good-bye, mid-conversation, etc. the acceptance of touch will likely vary. These five dimensions are captured in the items that were developed for the CIT Scale.

Peck and Childers (2003) developed the 'Need for Touch' (NFT) scale to identify individual differences in preference for haptic information. The 12-item NFT scale consists of two dimensions, instrumental, the outcome-directed touch in which we touch to gain more information about an object, and autotelic, the touch that is for sensory pleasure in which touch is an end in itself. The NFT scale is tailored toward product touch, which is why we believe that CIT is capturing a different aspect of touch, namely, interpersonal touch. A pre-study was conducted to ensure that the CIT construct is significantly different from the NFT construct. A pre-study was conducted with 325 undergraduate students in which we used a preliminary 11-item scale (a= .92) to measure CIT. The CIT scale and the NFT scale (a = .92) were correlated at .34 (p < .001) thus supporting the distinctness of these two constructs.

In order to more accurately capture the CIT construct, 63 scale items were developed to capture the predicted underlying five dimensions. The scale was administered to a sample of 382 undergraduate students to provide preliminary estimates for reliability and scale structure. The CIT construct was measured using a 7-point Likert scale ranging from strongly disagree to strongly agree.

Long-run future research plans involve multi-national studies of interpersonal touch in business settings. Currently, we are fostering relationships in 5 different countries in order to collect data using this CIT scale. This collaboration will allow us to understand how business practice is affected by interpersonal touch across high and low touch cultures.

We anticipate that this research will contribute greatly to the marketing field. The sense of touch or haptics has been studied, as it related to product purchases; however, there is currently no available measure that captures individual differences in comfort with interpersonal touch. Managerially, this research should inform negotiation and persuasion across cultures. For example, a culture or person comfortable with interpersonal touch may find it offensive if touch is not initiated. Conversely, the result could be true if a person is not comfortable with

touch. Regarding theory development, this proposed scale will also allow for future research in the interpersonal touch domain and will support cross-cultural understanding of nonverbal communication norms.

Good Bye, Old Self! - The Transformation of Self-Identity

Woo Jin Choi, Texas A&M University, USA
Ji Yun Kang, Texas State University, USA

Individuals may, at times, experience the transformation of their identities. For example, when students graduate from college, they may adopt a new identity as an employee of a company while, simultaneously, leaving behind their former identity as a student. Another example is that of a woman taking her husband's surname after marriage, and thereby becoming "Mrs. Man" (Penfield 1987, p.118). In this case, a woman is expected to adopt a new identity while submerging or burying her former identity (Penfield 1987). Given that one's name is strongly and personally related to one's self-identity (Penfield 1987), a surname change could cause a significant identity transformation. In this research, we investigate the courses of identity transformation after taking on a new surname and, how this affects the consumption behavior of female consumers.

Past research on social identity suggests that people have multiple identities but only those identities that are salient at a given moment influence one's consumption behavior (Escalas and Bettman 2003, 2005; White and Dhal 2007). This stream of research has shown that consumers tend to have more positive attitudes toward products that are associated with their social identities (e.g., student identity, female identity, organization identity, political affiliations, etc.) when that certain identity is salient (Forehand, Deshpandé, and Reed 2002; Reed 2004). For example, Reed (2004) showed that people are more willing to purchase an interpersonal telecommunication product that enables them to stay connected with their families when their family identity is salient. While extant research has focused on *which identity* exerts an effect on consumers' brand preferences and choices, little is known about how one is influenced during *the transformation of self-identity* and, more importantly, how this change influences consumers' brand preferences and choices.

While the traditional practice of marital surnaming still continues, the social status of women has dramatically improved as they have increasingly been taking on social roles traditionally assumed by men (Damhorst, Miller-Spillman, and Michelman 2005). Consequently, women are now more likely to 'acquire' or 'choose' their social identity as independent individuals, in contrast to the past in which women were expected to passively 'accept' their social identity given to them upon marriage to their husbands. In their research on marital name change, Kline, Stafford, and Miklosovic (1996) revealed that the self-perception that a maiden name can be equated with one's self-identity strongly influences a woman's decision to adopt her married name. Other studies also suggest that females who retain their maiden name after marriage place great emphasis on their self-identities, and they tend to be concerned that the name change might bring about the loss of their self-identities (Arliss 1991; Dralle and Mackiewicz 1981; Scanzoni and Scanzoni 1988). Therefore, it is plausible that women who adopt their married names might experience a sense of loss in regard to their self-identity, since these women may still have a feeling of attachment toward their maiden names−a symbol that represents their independence, as well as their long-time ties to their families.

An interesting question that arises next is, how can this nostalgia for their former name/identity influence consumers' brand evaluations and product choices? We expect that newly-wed female consumers will favor products that are associated with their former identity as 'single women' because of their affection for their maiden name. Defining one's self in terms of consumption behavior is more relevant when an identity is inchoate, or in other words, when an individual begins playing a new, unfamiliar role (Solomon and Rabolt 2009). It is thus likely that

the sense of loss women experience in regard to their maiden names will decrease over time, because they will gradually become accustomed to their new names and their new social roles. Therefore, the effect of a former identity will be a decay function.

We conducted a pretest to investigate whether the feeling of nostalgia toward a maiden name/single identity decreases as the length of a marriage increases. Thirty-nine females who spoke English and were U.S. residents participated in this study through MTurk for payment. The results showed that those who had been married less than five years experienced a feeling of nostalgia for their maiden names to a greater extent than those who had been married for more than five years. Therefore, the data supports our premise of the decaying effect of a former identity with time. We are now in the process of conducting a series of studies to test our predictions (a) in in-depth interviews with five married females and (b) in a survey.

The contributions of this research are as follows. First, to the best of our knowledge, the current work takes the first step in focusing on how individuals respond to the extinction phase of their former identities and the adoption of new social identities. Insights into the manner in which people respond to both former and new identities would expand our understanding of the influence of social identity on cognition and behavior. Therefore, the current research unlocks the door extending this line of research on the transformation of self-identify and to a further understanding of its effect on consumer behavior. In addition to theoretical contributions, this study has practical implications in that it could provide marketing practitioners with strategic ideas for targeting consumers in the identity transformation period, such as new persuasion points and appropriate timing of the persuasion points.

Affect, Cognition, and Consumer Charity: The Moderating Role of Social Distance

Joseph Paniculangara, University of Central Florida, USA
Xin He, University of Central Florida, USA

Charitable donation is important in transformative consumer research. This paper investigates the use of affect versus cognition in consumer donation and its interaction with social distance. We demonstrate that affect-driven consumers tend to donate more than cognition-driven consumers. In addition, the difference between affect-driven and cognition-driven consumers is more evident with greater social distance between the donating consumer and the recipient of her charity. This interactive effect is due to the differences in goals pursued by different types of consumers.

A consummatory goal is particularly relevant for affect-driven consumers (Millar and Tesser, 1986). Motivated by the consummatory goal, people engage in behavior that is intrinsically rewarding (Holbrook and Hirschman, 1982; Pham 1998). Past research shows that when a consummatory goal is made salient, people tend to make decisions based on affect (Pham 1998). In charitable donations, the consummatory goal may be manifested as maximizing "warm-glow" utility (Andreoni, 1989). In such cases, donors are primarily interested in the intrinsic satisfaction stemming from their behavior of donation of resources.

In contrast, an instrumental goal is important for cognition-driven consumers (Millar and Tesser, 1986). Such a goal is secondary - while the behavior may not be rewarding in itself, the undertaking may help to achieve another goal (Millar and Tesser, 1986). Pham (1998) shows that an instrumental goal decreases the use of affect in arriving at decisions. In the context of donation, an instrumental goal may be manifested as a desire to contribute to causes similar to "public-goods" and consequent utility (Andreoni, 1989). That is, donors may sometimes contribute so as to derive utility that comes from consumption of the cause donated to. For example, a donation made to National Public Radio (NPR) may be made to ensure adequate funding for NPR to continue broadcasting.

We argue that the consummatory goal of enhancing "warm-glow" utility and the instrumental goal of increasing the provision of "public-goods" may be differentially influenced by the social distance between donor and recipient. Social distance refers to the degree of social similarity and social connection between oneself and another (Trope, Liberman and Wakslak, 2007). While social distance is known

to be an important factor in the donation literature (Winterich, Mittal and Ross, 2009), its interaction with "warm-glow" and "public-goods" types of utilities is unclear. We reason that as social distance increases, cognition-driven donors may find it increasingly difficult to derive the "public-goods" type of utility given their instrumental goals. Consumers may not donate to a radio station at greater distance as it is unlikely that they will listen to its broadcast. In contrast, affect-driven donors may continue to satisfy their consummatory goal because they derive "warm-glow" utility regardless of the social distance between them and the recipient. For example, donating to help a starving child in a far-off community will still provide them with "warm-glow" as much as will donating to help a child in their immediate social circle. This reasoning leads to our prediction that the gap between affect-driven and cognition-driven consumers in donation becomes pronounced as the social distance between the consumer and the recipient increases. More formally,

Hypothesis: The beneficial effect of greater reliance on affect rather than cognition will be exacerbated when the donor and recipient are separated by greater social distance and attenuated when the donor and recipient are separated by lesser social distance. An interaction will exist between the relative use of affect and cognition and social distance in donation.

Support for the above hypothesis was found in three experiments with undergraduate students as participants. The stimulus for the first experiment was adapted from the work of Kogut and Ritov (2007). Participants were asked for their hypothetical donation to assist a group of either American or Indian tourists lost on an island in the Indian Ocean after the 2004 tsunami. In this manipulation physical distance is held constant. Participants reported their relative use of affect versus cognition in their decision about the donation using the five-item scale from Shiv and Fedorikhin (1999). The dependent variable was the amount out of $10 they would have donated if they were compensated with that amount for their participation. The interaction between social distance and the relative use of affect versus cognition was marginally significant, such that at closer social distance the use of affect versus cognition made little difference to the proposed donation. Whereas at greater social distance the use of affect versus cognition led to significant differences in the proposed donation. The stimulus for the second experiment was modified so that participants contemplated hypothetical donations to help either American or Russian tourists. This was done to rule out a possible confound of India not having similar resources as the USA. There was a significant interaction between the relative use of affect versus cognition and social distance. The third experiment was designed to address possible criticism of the first two experiments as not involving actual donation. Undergraduates who received ten extra points for research participation in their introductory marketing class (graded on 1,000 points) were asked how many points out of the ten they would donate to help either a marketing or a nursing student who was unable to participate in the extra credit session. Following completion of the questionnaire, participants were debriefed and reassured that they would receive their ten points. Again, a significant interaction between the relative use of affect versus cognition and social distance was found.

In three studies we find that affect-driven consumers tend to donate more and this effect is pronounced in situations of greater social distance. These results contribute to our understanding of charitable behavior, in terms of the roles of affect and cognition as well as the moderating effect of social distance. Our findings may help not-for-profit organizations that seek to maximize donations, especially those facing the difficult situation of donors reducing donations if they perceive greater social distance to the potential recipient (Burnstein, Crandall and Kitayama, 1994). This research indicates that it may be in the interest of such organizations to induce more reliance on affect by donors.

Boycotters Who Don't Boycott:
Attitude-Behavior Inconsistency in an Anti-Consumption Movement

Juan Wan, Ivey School of Business, UWO, Canada
Aimee Huff, Ivey School of Business, UWO, Canada

Consider the following fictional story: Walking across their university campus in Beijing, two Chinese girls, Hsing-yi and Linlin, encounter a group of senior students trying to gather support for a campus-wide boycott on Japanese products in protest of recent actions by a Japanese car company. The seniors are encouraging other students to demonstrate their commitment to the boycott by signing their names on a large flag. Hsing-yi and Linlin consider joining the movement, which would require them to refrain from buying Japanese products for six months, but also realize this would be difficult because they both believe Japanese products are high quality and very popular. Hsing-yi was born in a city that suffered under the Japanese invasion during World War II, and she quickly decides to participate in the boycott because of this historical and personal connection. Linlin, however, was originally less compelled by the senior students' claims that Japanese products should be boycotted, but feels pressure to join after Hsing-yi signed the flag and after seeing the hundreds of other signatures on the flag. She finally commits to the boycott. Within a few weeks, however, Hsing-yi and Linlin are surprised to discover that they each have bought a Japanese camera. Even though Hsing-yi had deliberated much longer over her purchase of a Japanese camera than Linlin did, they both made conscious decisions to break their boycott commitments. Ultimately, each girl was swayed in her purchase behavior by the high quality of Japanese cameras.

This phenomenon occurs regularly in China; Chinese students frequently organize boycotts of Japanese products, and encourage others to commit to the movement. However, it is equally common for students to purchase the boycotted Japanese brands and products. In this paper, we refer to consumers who do not behave consistently with their boycott commitments as *pseudo-boycotters*, and we seek to understand why they break from their boycott commitments. We develop a conceptual model of pseudo-boycotter behavior to explain why these consumers publically commit to anti-consumption behavior and later engage in behavior that is explicitly contradictory to their public commitment. We draw from literature on explicit and implicit attitudes (Wilson, Lindsey, and Schooler 2000; Gawronski and Bodenhausen 2006) to suggest that an underlying, favorable attitude toward the boycott target can override the conscious, explicit negative attitude toward the boycott target in a purchase situation. We suggest that boycotters' motivations to join the boycott can influence the salience of the explicit negative attitude toward the boycott target (Epley and Gilovich 1999), such that some boycotters (i.e., those motivated by social pressure) are not strongly influenced by their negative attitudes at the time of purchase. Other boycotters (i.e., those who were motivated to join by a desire for intrinsic satisfaction) experience salient, competing attitudes at the time of purchase (Kozinets and Handelman 1998), but the purchase context activates their consumer role (McLeod and Lively 2003), which boosts the underlying, favorable attitude toward the boycott target and directs purchase behavior. In the actual purchasing context, where self-interested behavior is cued, the consequences of being a boycotter become blurry while those of being a consumer (e.g., perceived usefulness of the products, low cost of the products) become more salient, which consequently triggers purchase behaviors that are congruent with the consumer role (Callero 1994; Pillutla and Chen 1999).

In the preliminary phase of data collection, we conducted semi-structured depth interviews with seven undergraduate students at a large Chinese university. We found that students do hold a stable and favorable implicit attitude toward Japanese products. However, when asked to describe their motivations for participating in boycotts, many reasons emerged, including social pressure from friends and personal desires. Regardless of the reasons for participation, our informants revealed explicitly negative attitudes toward Japanese companies by stating that Japanese companies deserve boycotts. Furthermore, many informants revealed that they did purchase Japanese product again within the boycott period, and they usually felt disappointed with themselves in the post-purchase period. However – and, perhaps, more interestingly – they did not feel the same way when purchasing, because they believed they were making the correct purchase decision. This preliminary data validates our conceptual framework. Based on these results, a series of experiments has been designed to further investigate the underlying mechanisms. Initial boycott commitment and motivations will be contrasted with subsequent behavior in a real purchasing condition. In this second phase of the research, we extend the context into a general boycotting situation, aiming to show that this phenomenon is not culturally specific and that it has broader implications for consumer behavior.

The theoretical contributions of our research are twofold. First, most traditional research focuses on the motivations of boycott participations, and the consequences of boycotts (Garrett 1987). Assuming that the attitudes and behaviors of boycotters will directly influence the effectiveness of boycotts, we focus on the individual boycotters – specifically, the pseudo-boycotters whose attitudes and behaviors are inconsistent with the boycott objectives. Second, our work dovetails with research on socially responsible consumption, where behavioral intention is influenced by the trade-offs between prosocial and individual outcomes – which are in opposition (Moisander 2007). Some research has shown that while prosocial and consumer interests are both salient in a consumption context, consumption choices are necessarily individual choices, and therefore social concerns tend to play an insignificant role when decisions need to satisfy immediate, personal needs (Warlop, Smeesters, and VandenAbeele 2000). We extend this research by accounting for this phenomenon in an anti-consumption context.

The model developed in this paper may be of use to two types of managers: those who manage boycotts, and those who manage the firms that are targeted by boycotts. Boycott organizers may find ways to reinforce the boycott objectives in ways that make the explicit, negative attitudes salient at the time of purchase – although we suggest that, even when salient, these explicit attitudes are overridden by the activation of the consumer role. Managers of the boycotted targets may find tactics to attenuate the effects of boycotts by activating the consumer role and the positive, implicit attitudes at the point of purchase.

The Bidirectional Relation between Number and Location

Fengyan Cai, The Chinese University of Hong Kong, China
Hao Shen, The Chinese University of Hong Kong, China
King-man Hui, The Chinese University of Hong Kong, China

The number-location association refers to the fact that people spontaneously think that large numbers should be located at the top or on the right hand side of a display, whereas small numbers should be put at the bottom or on the left side (Wood and Fischer 2008-Dehaene, Bossini and Giraux 1993;Zorzi, Priftis and Umilta 2002; see Fias and Fischer 2005 for review).

Extant literature already provides preliminary evidence for the existence of the number-location association. For example, Dehaene, Bossini and Giraux(1993) presented a number at a fixation, and then asked subjects to judge whether the number was odd or even by pressing the assigned response key. They found that participants responded to larger numbers faster when the assigned response key was on the right (vs. left) hand side, and that the reverse pattern was true for small numbers.

However, extant research usually focuses on uni-directional relation between number and location—from numerical magnitude to location. This paper proposes and demonstrates that there is a bidirectional relation between number and location. First, we will examine the impact of numerical magnitude on people's memory about location in study 1. Secondly, we will test whether location can bias people's numerical estimation in study 2.

STUDY 1: IMPACT OF NUMERICAL MAGNITUDE ON MEMORY

ABOUT LOCATON

The number-location association will be automatically activated when numbers are presented (Dehaene, Bossini and Giraux 1993). Research on spatial memory has shown that when participants can not clearly recall locations, they will use other source of information to help them recall (Huttenlocher, Hedges, Corrigan and Crawford 2004; Huttenlocher, Hedges and Duncan 1991). Accordingly, if people can not clearly recall the locations of numbers, the activated number-location association may serve as an additional source of information. As a result, recalled location of large number may be biased rightward whereas recalled location of small number may be biased leftward.

METHOD

Forty college students took part in this study in exchange for HK\$ 20. Participants firstly watched a slide show in which each number was shown for one second and followed by one second blank screen. The horizontal location of those numbers varied but the vertical location remained the same. After all stimuli (6 small numbers<1, 2, 3, 4, 5, 6>, 6 large numbers<999, 996, 997, 995, 998, 989>) were shown, participants saw each number again in the order they originally saw them, one at a time, at the center of the slide. Then, participants were asked to recall the location of each number by checking one of the fifteen boxes that located from left to the right on the screen.

RESULTS

The main dependent variable we used was the difference between the recalled location and original location. For both original location and recalled location, small code numbers represented locations near to the left side of the slide while large code numbers represented locations near to the right side. Therefore, we expect that for large numbers, the difference between recalled location and original location would be larger than 0; for small numbers, the difference would be smaller than 0.

The results showed a significant main effect of the category of stimulus ($F(1,80)=22.72$, $p<.001$). As expected, for large numbers, the difference ($M=1.85$) was significantly higher than zero ($t(40)=5.92$, $p<.001$); for small numbers, the difference ($M=-1.10$) was significantly lower than zero ($t(40)=-3.42$, $p<.001$). Therefore, our expectation got supported.

STUDY 2: THE EFFECT OF LOCATION ON NUMERICAL ESTIMATION

Perceptual symbols system theory suggests that people often behave like as though perceptual associations are literal (Barsalou 1999; Barsalou 2008). People's judgment and decision are consequently biased by the perceptual factors in those associations (Schuber 2005; Nel-

son and Simmons 2009). For example, because of the association between cardinal direction and vertical position—"North is up", people feel that heading north is going uphill, and hence expect that northbound travel(vs. southbound) will take longer time. Accordingly, we expect that people might treat the association between number and location literally. As a result, once the number-location association is activated, people's numerical estimation could be biased by location. Specifically, we assumed that a large (small) number will be more accessible in people's mind when they estimate the amount of products that are presented on the right (left) side of a screen.

METHOD

Eighty college students were told that we are interested in their memory ability and were asked to remember anything that appeared on the wall. On this pretense, participants were sequentially exposed to a pile of books and a pile of balls on the wall. The order of the two pictures was counterbalanced. Each picture was either displayed on the left or right side of the wall. Participants were given 1second to look at each picture. After that, they were asked to estimate the number of books and balls. As a manipulation check, they were also asked to indicate the location of each picture by circling "left" or "right".

RESULTS

98% of participants correctly recalled the locations of the pictures. The results of repeated measure ANOVA revealed a significant main effect of location on estimation (F (1, 78) = 7.20, p < .05). The estimated amount of objects was significantly higher when objects was presented on the right hand side (M=17.53) than when it was presented on the left hand side (M=14.84). This finding demonstrated that location could bias people's numerical estimation in an assimilation way.

This paper may contribute to extant literature in two different ways. First, it demonstrates an undocumented bidirectional relation between number and location. Second, much of extant literature only demonstrated that the number-location association could influence how fast or accurate a judgment was made. This research demonstrates that the number-location association can bias not only the process by which a judgment is made but also the judgment outcome itself.

When Under Cognitive Load, Extraverts Generate More False Memories but Introverts Generate Fewer False Memories

Daniel Rubin, CUNY Graduate Center, USA

Paul M. Connell, SUNY Stony Brook, USA

A considerable body of research has demonstrated that confabulations are relatively common with respect to memory for advertisements and consumption experiences (e.g., Bernstein & Loftus, 2009; Braun, 1999; Schlosser, 2006). Despite this attention, we still know very little about the intraindividual processes that lead to false memory formation. The purpose of this research was to explore the potential situational and dispositional boundary conditions for the formation of false memories.

The need for such a model has been suggested by prior false memory research, such as that of Schlosser (2006), who found that virtual object interactivity has the potential to increase accurate memory, while simultaneously increasing imagined attributes, or false memories. False memories of product attributes may lead to dissatisfaction as consumers may mistakenly expect product benefits despite the fact that they were never advertised. This research suggests that marketers should make an effort to better understand the conditions under which a false memory is most likely to occur, as false recall of product attributes can have a dramatic negative impact on customers' satisfaction levels. Studying false memories should be a priority when it is considered that they have actually been shown to impact ones' behavior. Bernstein and Loftus (2009) found that it was possible to convince people that as children a particular food had made them ill. The participants that adopted this false memory had altered food preferences and showed avoidance to the food used in the study. False memory research can

enhance the protection of consumers from ads with a greater likelihood of generating false memories as well as prevent misguided campaigns that will harm an organization by leading to customer dissatisfaction.

We predicted there to be an interaction between processing resource availability and an individual's level of extraversion on the generation of false memories. It was theorized that constraining processing resources during encoding would inhibit participants from mentally rehearsing the semantic associations between provided words. In terms of memory accuracy, we envisioned that this would result in a decided advantage for introverts who we believe normally rely on a rote memorization tactic. Extraverts on the other hand, we believe to be more conversation oriented, thus the connections between words or their semantic associations are focal to extraverts during the encoding of new information. Going under the assumption that introverts and extraverts use unique processes for memorization, we believe that extraverts use a conversation oriented encoding process that facilitates more accurate memory and encoding when processing resources are not constrained. The advantages of this process are however limited by a heavier reliance on cognitive resources and thus vanish when these resources are occupied by other tasks. We predicted that extraverts would show an increase in false memory formation under a cognitive load because they would be forced to rely upon a less resource intensive rote memorization process for which they are neither accustomed to, nor as adept at as introverts.

This experiment was conducted using 126 college undergraduates as participants. Processing resources were constrained by having an experimental group memorize a 7-digit number, while a control group was given a 2-digit number. Afterwards, participants were presented with six lists of words, each of which contained 15 terms that were conceptually linked (Deese, 1959; Roediger & McDermott, 1995). Participants were then asked to freely recall the terms immediately after viewing each individual list. A false memory was recorded if a non-given word was provided during free recall. After the memorization tasks were completed, participants completed the big-five personality inventory (Digman, 1990), which included items measuring extraversion, using a five-point Likert scale.

Analysis of the data revealed a significant 2-way interaction of extraversion and cognitive load on the formation of false memory, but not on correct recall. At a baseline level (i.e., with unconstrained processing resources), introverts generated more false memories than extraverts. When processing resources were constrained, this relationship is inverted, and extraverts generated significantly more false memories. Under a high cognitive load introverts had directionally fewer false memories, thought this reduction was only nearly significant. This suggests that introverts are more skillful rote memorizers, and that forcing them to rely on their natural process may improve memory accuracy in certain situations.

In summary, we believe that introverts tend to rely on rote memorization to encode new information and are thus less likely to mentally rehearse the semantic associations between words. In addition, we believe that extraverts generated significantly more false memories when processing resources were constrained because their natural conversation oriented memorization process, which focuses on the semantic associations between words, is inhibited. Because they are forced to use a process that they are not accustomed to during encoding they have greater difficulty source monitoring during recall. This explains the significant increase in false memory formation that we observe among extraverts in the high load condition. Additional studies are planned to further test this hypothesized psychological process driving the effect.

Understanding Sustainable Decision-Making of Young Consumers

Silke Speidel, University of Leipzig, Germany
Andre Marchand, Bauhaus-University of Weimar, Germany

Sustainable consumption is already a permanent element in the public debate and will become more important in the future (Sanne 2002), particularly when several exhaustible raw materials run out. Thus the competence of making the 'right' sustainable decisions might become one of the most important issues of future consumer generations. The most accepted model for operationalizing sustainability is currently the "triple bottom line", which postulates that sustainability is based on environmental, social and economic dimensions (Elkington 1998). However, existing empirical studies of sustainable consumption usually focus only one of the three aspects, like environmental aspects (Cornelissen et al. 2008), social aspects (Jackson 2008) or economic aspects (Kumar et al. 2011). When approached this way, it has not yet been sufficiently analyzed how the different and sometimes even conflicting aspects of sustainable decisions influence each other, which makes an integrative approach necessary. This study aims to understand how all three aspects of sustainability are taken into account when judging sustainable consuming decisions.

METHOD

A grounded theory approach (Corbin and Strauss 2008) was used for analysis and further data collection. Data was collected from high school students aged 16 to 18 from different high schools. This age group is old enough to make their own consumption decisions, but influenced by both their peer group and adults (parents, teacher etc.). These young consumers make interesting interviewees, as the idea of sustainability has been around ever since they have been able to make consumption decisions and they are closest to the future generations, whose rights sustainability acknowledges. The students were interviewed individually with a hypothetical decision situation concerning sustainable consumption and a set of predefined questions. The protagonist in the described situation desires a certain cell phone which to his/her knowledge has been or could have been produced in a problematic way. The problems addressed include child labor, working conditions in Least-Developed Countries, endangered species, and precarious working conditions in industrial nations. The situation was presented by orally explaining the circumstances of the decision situation and handing out cards with information the protagonist was said to possess. The word 'sustainable' was neither used in the description of the situation nor in the question, in order to avoid misunderstandings due to another concept of sustainability on the part of the interviewee. After the initial advice to the protagonist, for which the interviewees had to give reasons, they were asked about the assumed perspectives of different stakeholders mentioned on the cards, on hypothetical situations of every consumer acting the same way, and on possible solutions for the addressed problems.

PRELIMINARY RESULTS

Young consumers present themselves as perfectly willing to take environmental, social and economic issues into account when making consumption decisions as long as they can do so without noticeably modifying their patterns of consumption, especially if they perceive the modification as cutting back the standard of living to which they are accustomed. They display different ways of escaping a decision situation where their attitudes would possibly conflict with their preferred actions, such as reducing the problem on one particular product, breaking the situation down into one or more dilemmas, or arguing that they cannot make a difference anyway.

Although they get the information that every product of a certain kind comes with a particular (environmental, social, or economic) 'drawback' in the information cards, they try to solve the problem first by turning to another product of the same kind, thereby ignoring the information given. It seems that they expect to find a solution within consumption rather than in resisting a certain desire for consumption. When they are confronted again with the information that the particular 'drawback' exists for every product of that kind, they tend to break the more complex situation down into one or more dilemmas (e.g. protecting the environment vs. securing jobs), which often allows them to use one of the lines of argumentation to justify their preferred actions (e.g. buying a certain product). A young person's self-efficacy as a consumer in a certain situation might also influence the decision, as consumer behavior will only be adjusted according to what is perceived to be 'sustainable' if a person's actions are expected to make an ever so slight difference.

Furthermore, if sustainable development "seeks to meet the needs and aspirations of the present without compromising the ability to meet those of the future" (World Commission on Environment and Development 1987), a consumer's idea of man will influence what they think those "needs and aspirations" of the present and future generations are. What young consumers perceived as needs in industrial nations often differed from what they perceived as needs in Least-Developed Countries, e.g. they acknowledged that a consumer in an industrial nation has the need or at least the legitimate aspiration for a new cell phone, whereas they argued that consumers in Least-Developed Countries would not need a cell phone but food, concluding that (from their point of view) selling cell phones in Least-Developed Countries makes no sense.

CONCLUSIONS AND FUTURE RESEARCH

Since judging the sustainability of consuming decisions is challenging for consumers due to the possibly conflicting nature of the environmental, social and economic dimensions of sustainability, education for sustainable development should address this topic. Further data collection, e.g. in form of interviews with consumers who show sustainable consumption patterns in one area of life or the other, shall help to clarify the different levels of competence that consumers show when deciding about sustainable consumption. Based on the results from qualitative research, scales shall be developed to measure the complex competence of sustainable consumption in future analysis.

Which Rejection Makes Brand Yearning Stronger? The Impact of Consumer Exclusion, Brand Exclusion, and Ego-Defensive Goals on Brand Evaluations

Fang Wan, University of Manitoba, Canada
Namita Bhatnagar, University of Manitoba, Canada

One of the key strategies within niche branding involves the construction of perceived exclusivity and membership to desirable cliques through brand use (e.g., for *Harley-Davidson*). Mike Jeffries, the CEO of the fashion label *Abercrombie and Fitch* made comments that the retailer only hires and markets to cool, good-looking individuals, and that a lot of people don't, and cannot, belong to A&F (a likely reference to those that are unattractive, overweight, and therefore undesirable; Denizet-Lewis 2006). This is indicative of niche branding strategy at play. Though it has been found that exclusivity in brand membership engenders brand commitment and loyalty amongst *existing* consumers (McAlexander, Schouten, & Koenig 2002; Muniz & O'Guinn 2001), the impact on *future* consumers is not as clear—specifically, it is not well understood whether brand exclusivity would result in heightened desire or felt alienation within consumers desirous of joining a community of brand users. This is the central issue examined in our research.

Specifically, we study the direct and joint effects of two types of perceived exclusion on aspiring consumers' felt alienation and brand evaluations—i.e., (a) exclusion by a target brand (or its management team), and (b) exclusion by its existing consumers. Research in the areas of ostracism and scarcity effects provides evidence for dual effects of social exclusion—fortified yearning for group membership when ostracized (e.g., Williams, Cheung, & Choi 2000) and strengthened desire for products that are restricted in access (e.g., Cialdini 1993; Verhallen & Robben 1994) on the one hand, coupled with greater anti-social attitudes and aggressive behaviors toward those engaged in social ostracism on the other (e.g., Twenge et al. 2001; Gaertner & Iuzzini 2005).

We therefore started out by testing these two competing effects (positive vs. negative) of brand and co-consumer exclusion using a 2 (*co-consumer* exclusion vs. control) by 2 (*brand* exclusion vs. control) between-subjects experimental design in Study 1. Participants, recruited from a local university, were asked to imagine scenarios pertaining to their experiences at a hypothetical event organized by a network of prestigious university graduates. Consumer exclusion was manipulated by the treatment participants purportedly received at the networking event: in the co-consumer exclusion condition, participants were told that the other members snubbed and ignored them; in the control condition, no such information was provided. Brand exclusion was manipulated by the presence or absence of granted network membership after the event: in the brand exclusion condition, participants were told they were denied membership; in the control condition, they were granted membership to the network. Significant interaction effects of the manipulated variables on brand evaluations ($F(1,145) = 4.82$, p<.05) and felt alienation ($F(1,145) = 10.81$, p<.001) were found.

Planned contrasts revealed that brand exclusion (vs. control) lowers brand evaluations and intensifies felt alienation in the absence of co-consumer exclusion. However, where co-consumer exclusion does occur, brand exclusion has no significant effect. Additional contrasts revealed that with perceived brand exclusion, co-consumer exclusion (vs. control) positively affects brand evaluations but has no impact on felt alienation. Finally, felt alienation also mediated the relationship between the manipulated variables and brand evaluations. These findings of study 1 present a more complex picture of brand exclusion than previously hypothesized. Brand exclusion appears more detrimental to future consumers' brand evaluations than co-consumer exclusion (supporting a negative effect of social exclusion). The presence of both brand and co-consumer exclusion, however, makes brand evaluations more favorable (supporting a positive effect of social exclusion).

We conducted Study 2 to uncover moderators of the negative effects of brand exclusion. Specifically, we examined whether co-consumer inclusion (i.e., when future consumers feel included or welcomed by existing consumers) can counteract the negative effect of brand exclusion (vs. control). A 2 (brand control vs. brand exclusion) by 2 (consumer inclusion vs. consumer exclusion) between-subjects design was adopted. Findings suggest the negative effect of brand exclusion (vs. control) cannot be eliminated via co-consumer inclusion. Findings of Study 2 revealed the relative weight of brand vs. co-consumer exclusions in shaping consumers' brand experience. That is, brand exclusion is a diagnostic factor to evoke consumers' feelings of alienation. This negative brand experience is not affected by how co-consumers treat target consumers.

Study 3 was conducted to further delineate the underlying mechanism of the negative effect of brand exclusion on brand experience. We propose that brand exclusion (vs. co-consumer exclusion) can activate a self-defending goal, which leads to consumers' negative brand evaluations. We adopted self-affirmation procedure (Sherman 1988) to test this proposition. That is, when individuals are given positive feedbacks on a task, they would receive an ego boost. In this case, they will be less likely to engage in self defensive strategy when their self views are threatened. In our research context, we expect that consumers' self view is threatened more severely by brand exclusion (vs. co-consumer exclusion). Furthermore, when consumers receive an ego boost (vs. control), they will evaluate the brand less negatively even though a brand alienates consumers. Therefore, we further argue that consumers' self view mediates the relationship between brand alienation and brand evaluation. We conducted a 2 (brand exclusion, co-consumer exclusion) by 2 (ego-boost, control) between-subjects factorial design. ANOVA analyses yielded supportive findings.

We contribute to branding literature by examining a brand-exclusivity effect from the perspective of aspiring consumers (Kirmani, Sood, & Bridges 1999), and by providing evidence that brand exclusion may activate an ego-defensive goal which lower brand evaluations. We also look at the previously unexamined role of co-consumer exclusion in buffering negative brand exclusion effects.

What do single female baby boomers fear? Planning for their post-retirement housing

Foula Kopanidis, RMIT University, Australia
Linda Robinson, RMIT University, Australia
Mike Reid, RMIT University, Australia

The post-retirement housing market is expanding due to strong demand drivers including changing demographics such as greater longevity; universal access to healthcare; affluence within the population; and greater acceptance of alternative living arrangements (Beer, Faulkner and Gabriel, 2006). These trends are seen across Australia many industrialised nations including the United States of America, New Zealand, Italy, Japan, France and Canada experiencing similar patterns (Kim, Kim and Kim, 2003). For example, the number of Americans aged 65 and over is expected to increase from 35 million in 2000 to 40 million in 2010. As the baby boomer cohort matures and moves into retirement between 2011 and 2029, many will consider future accommodation options (Furlong, 2007).

As a viable and sustainable segment, baby boomers will become the largest driver of consumer demand for post retirement housing over the next four decades. Critical to marketers in developing strategies is understanding how baby boomers' will influence housing markets. However, while there has been a great deal of research examining post-retirement economic well-being among baby boomers (Sanders and Porterfield, 2010) few studies have explored the decision-making process related to post-retirement housing (Huang, 2011). In addition, there are still relatively few reviews published in major marketing journals about the effects of an aging baby boomer cohort on consumer decision making, public policy and marketing practice (see Yoon, Cole and Lee, 2009). Compounding this, few studies have considered two potentially important contributing factors of gender and marital status. According to U.S. Census data, the number of female householders has increased in recent decades from over five million in 1970 to 14 million in 2006 (U.S. Census Bureau 2006). Thus, with the proportion of female baby boomers entering retirement single, a reasonable question to ask is, how do these women plan for post-retirement housing, and what factors influence the decision making process in planning for a change in post-retirement housing?

This research employs the theory of planned behaviour (TPB) model to estimate the intention of single female baby boomers to change their housing situation post-retirement. In particular, we explore the impact of psychological barriers on retirement planning to generate a better understanding of decision making process for considering and planning for changes to housing post-retirement. The specific objectives of the study were to (a) use a modified TPB model to examine their attitudes and intentions on post-retirement housing decision making; and (b) identify the effects of psychological barriers on post-retirement housing decision making.

A total of 703 Australian single female baby boomers were surveyed regarding their attitudes and intentions in relation to their post-retirement housing. The questionnaire included measures of attitude towards housing change, social norms, perceived behavioural control, intention to change housing, advice seeking behaviour and general attitudes towards retirement as well as demographic items. All items included in the current investigation were derived from the TPB framework (Fishbein and Ajzen, 1975) and theoretical considerations regarding possible attitude and psychological barriers to retirement planning (Topa et al., 2009). Exploratory as well as confirmatory factor analyses were used to assess the reliability of all measures. The model was then tested using structural equation modelling analysis to estimate the effect of psychological barriers to retirement planning on intentions to change housing post-retirement and advice-seeking behaviour.

The results show that subjective norms (t=9.145, *p*<.01) and perceived behavioural control (t=10.738, *p*<.01) have significant direct effects on single female baby boomers intention to change housing post-retirement as well as advice-seeking behaviour (t=6.692, *p*<.01 and t=3.282, *p*<.01 respectively). The respondents' attitude towards this change (t=1.850, *p*<.1) and their general attitude towards retirement (t=2.428, *p*<.01) also both had significant effects on determining their intention. These findings are consistent with previous work on post-retirement housing (Huang, 2011). However, the absolute magnitude of the standardized path coefficients indicate that attitude towards a change in housing has the lowest direct effect on intention to change. The data revealed that the general attitude towards retirement *not* attitude towards a change in post-retirement housing was the salient factor in both intention to change housing post-retirement and advice-seeking behaviour of single female baby boomers. When the respondents attitude towards retirement revealed negative views to post-retirement planning, for example 'retirement is too far away to be bothered thinking about', there was a negative direct effect on both intention to change housing post-retirement as well as advice-seeking behaviour. Furthermore, this general attitude towards retirement completely mediates the relationship between perceived barriers to a change in post-retirement housing and both advice seeking and intention to change post-retirement housing. This suggests that behaviour-specific psychological barriers of single female baby boomers are not directly related to the actual intention to perform or the actual performance of that behaviour, such as retirement planning and related advice-seeking, but rather act through a general predisposition towards the larger object, in this case retirement.

In conclusion, this study suggests that for single female baby boomers, their general attitude towards retirement is a salient factor in the application of the TPB in the context of post-retirement housing decisions. Pertinent to achieving a greater understanding of how single female baby boomers are planning their post-retirement housing, is the examination of psychological barriers to retirement planning. This study provides insights into what is driving post-retirement housing planning, or lack therefore, in this cohort. Such information allows marketers and public policy makers to develop and communicate housing retirement planning products and services offerings specific to this demographic.

What's important depends upon how I see us:
The influence of self-construal on choice and advice-giving

Jason Stornelli, University of Michigan, USA
Richard Gonzalez, University of Michigan, USA
Carolyn Yoon, University of Michigan, USA

Consumers are often faced with the task of making recommendations about products and services to others; explosive growth in online reviews, brand communities, and social networks has made sharing recommendations more common than ever before. Yet, although much marketing research has examined choices for the self, we know relatively little about how individuals consider marketing features when choosing for others.

Research examining advice-giving shows that advisors use a weighting strategy that is more lexicographic, placing emphasis on one attribute when recommending jobs, courses and volunteering opportunities. Conversely, when choosing for the self, the difficulty of making tradeoffs and foregoing valued attributes leads to more equal weighting patterns (Kray & Gonzalez 1999; Kray 2000).

We broaden the scope of this framework in two ways. First, in contrast to Kray & Gonzalez, who explored decisions that are central to personal identity, we examine the model's effectiveness in a less identity-centric and broader product/service context. Additionally, we examine the role of self-construal – how the self is defined in relation to others – in this process. As recommendation networks become more global with the growth of online interaction, we need to study how culture impacts attribute weighting (Park 2008). Changes in self-construal generate two opposing hypotheses regarding attribute weighting for self-choices versus other-choices.

First, a self-other merging perspective (e.g. Aron et al. 1991) argues that collective self-construals promote a shared sense of resources, perspectives, and characteristics between the self and close others. This perspective suggests that self-other differences in attribute weights should be *attenuated* when the decision-maker operates under a collective (vs. independent) self-construal.

Conversely, the ability and motivation to engage in perspective-taking varies by culture, suggesting that collectivism may *enhance* differences in self-other attribute weighting structures. For instance, Cohen, Hoshino-Browne and Leung (2007; see also Wu & Keysar 2007) argue that Asian-Americans are more likely to use attention toward the background, habits, and feelings of others when understanding the world, compared to Euro-Americans who rely on egocentric projection. However, it remains unclear whether these results are driven by self-construal or other cultural norms, and if they would also apply to a choice context, particularly in light of research demonstrating that the links between agency, preferences, and choice are inconsistent across cultures (Savani, Markus & Conner 2010).

Thus, we predict that,

H1: *When making product/service choices, decision-makers are more likely to assign greater weight to one attribute when making a recommendation to others, compared to when they are making a choice for themselves.*

H2a: *This self-other difference will be attenuated when the decision-maker is operating under a collective self-construal due to self-other merging, or;*

H2b: *This self-other difference will be enhanced when the decision-maker is operating under a collective self-construal due to improved perspective-taking.*

METHOD

Two factors were varied between-subjects (n=91): self-construal [individual/collective] and choice target [self/other]. Participants began by completing two self-construal primes: pronoun-circling and Sumerian Warrior (Oyserman & Lee 2008; Gardner, Gabriel & Lee 1999). Respondents then read a scenario about choosing an apartment for themselves or recommending an apartment for a close friend of the same gender, and chose between two apartments described on three dimensions (rent, neighborhood, and in-unit laundry). The attribute structure allowed inference of the weighting strategy (Kray & Gonzalez 1999; Kray 2000). The *equal weighting* alternative was an apartment that maximized utility on two dimensions (the cost of rent and the washer/dryer), while the *lexicographic* alternative maximized utility on one dimension (the safety of the neighborhood). Thus, by observing the selection of the lexicographic alternative, we can infer that participants are giving greater weight to safety at the expense of the other two attributes. Conversely, the selection of the equal weighting alternative suggests participants maximize value on the greatest number of attributes.

RESULTS/DISCUSSION

Results support the perspective-taking hypothesis. A logistic regression yielded a significant omnibus interaction of self-construal and choice target: $Z = -1.99$, $p < 0.05$. More importantly, planned contrasts within each self-construal condition indicated that the choice target impacted choice patterns differentially. When respondents were primed with a collective self-construal, they preferred the lexicographic alternative when choosing for a friend, and the equal weighting alternative when choosing for themselves. This self-other difference in choice pattern was significant: $Z = 2.38$, $p < 0.05$. Conversely, there was no significant difference in self-other choices under an independent self-construal ($Z = -0.37$, $p = n.s.$). The equal weighting alternative was preferred for both self-choices and recommendations to others.

Two follow-up studies are underway. It is possible that, rather than differentially weighting attributes for self-versus-other choices, collectivist participants preferred lower rent for themselves and a safer neighborhood for a friend. Risk judgments are impacted by culture (e.g. Weber & Hsee 1998; Hsee & Weber 1999) and the judgment target (e.g. Raghubir & Menon 1998), so choice may have been influenced by the judged likelihood of one's ability to absorb financial obligations or of a dangerous event in the less-attractive neighborhood. Further, Luce (1999) argues that certain attributes, including safety, generate more loss aversion. Participants in the collective/self condition may be more attuned to this consideration and hesitant to recommend less-desirable neighborhoods. Thus, we employ a flipped attribute pattern, where the lexicographic apartment maximizes rent utility, and the equal weighting option maximizes utility from the neighborhood and washer/dryer. We measure risk perception, decision difficulty, and decision importance.

In a second follow-up, we change the attribute structure to infer weights differently. Participants choose between gyms that maximize one dimension (aesthetics or travel distance). When collective decision-makers give advice, we expect one option to garner a greater choice share because a disproportionate degree of weight is placed on the focal attribute. In contrast, both collective advisors and independent choosers/advisors should display choice shares closer to parity.

Additional follow-up studies are also in progress to explore whether the mechanism is affective or cognitive in nature.

This package provides an exciting advance in our understanding of the ways in which people weight attributes when choosing for another person, and begin to shed a brighter light on mechanisms underlying cultural differences in perspective-taking.

Effects of Legibility of Text in Product Descriptions on Price Perceptions

Rajneesh Suri, Drexel University, USA
Chiranjeev Kohli, Cal State Fullerton, USA
Dhruv Grewal, Babson College, USA
Shan Feng, Drexel University, USA

Marketing often needs to engage consumers and hold their attention in likable ways. It is not surprising then that retailers like Trader Joe's use creative point-of-sale materials with fancy calligraphy, a merchandising technique that not only provides product details but also capture consumers' attention by its uniqueness. Pieters and Wedel (2004) showed that advertisers aiming to maximize attention to their communications should consider devoting more space to its text, but also asserted that the extent to which such effects were caused by text layout (e.g., font type) was not well understood. The focus of the present study is whether typeface used to present product information affects attention to different text elements (price and product attributes).

Several recent studies provide evidence confirming that words are identified during reading by discriminating the underlying structure of their component letters. In particular, Sanocki (1987) showed that the visual cues readers use to derive the underlying structure of letters, and the rules they implement to achieve this, are adjusted according to the typeface in which text appears. Based on this research and evidence that individuals have limited visual attention (Wolfe, Cave and Franzel 1989), we predict that when typeface consumes greater cognitive resources, it results in increased attention to product details using that text at the expense of price information. Integrating this underlying process and the concept of working memory capacity (Hambrick and Engle 2002) and left-digit effect in number processing (Thomas and Morwitz 2005), we predict that consumers when processing product information presented in a harder to read typeface will pay greater attention to product attributes than if they were presented information in a relatively easy to read typeface. Because consumers' attentional resources are limited, increasing attention to an element in a communication maybe at the expense of other elements. Consequently recall of price information in more difficult to read typeface will be distorted and consumers will truncate numbers in a price (say $29.58) and recall a lower price (e.g., $20.08) than when price was presented in an easier to read typeface.

Pretests led to the selection of two typefaces that were either easy (Helvetica) or hard (Bradley) to read. Two studies then collected initial evidence for whether legibility of such typeface affected processing of attribute information and a distortion of price recall. In study 1, materials were presented on computer stations in a behavioral laboratory and participants (55 undergraduate students) were included in a lottery to stimulate their engagement with the task. The study was conducted as part of a larger study and the software randomly presented product information for two products using these two typefaces. At the conclusion of the study, participants completed a working memory task adapted from Hambrick and Engle (2002). Results revealed that participants committed fewer errors recognizing attributes when product descriptions were presented in the harder to read typeface. Furthermore, such a pattern of errors was explained by participants' working memory capacity; those with lower working memory capacity showed greater errors.

Though study 1 showed differences in the scrutiny of product attributes described in the two typefaces, the effects of this closer examination of attributes on recall of price information was not measured. Study 2 assessed both processing of product attributes, as well as price recall for the target product. Using the same typefaces as in study 1, four versions of the target description were created. These versions differed in whether product descriptions accompanied price in the same or a contrasting typeface. Similar to study 1, working memory capacity of participants (111 undergraduate students) was also measured. The results were interesting and revealed that the harder to read typeface resulted in a greater distortion of price recall, supporting not only a parallel visual search by consumers (Wolfe, Cave and Franzel 1989), but also left digit-effects on price recall. Furthermore, these main effects were qualified by a significant interaction effect of typeface and working memory capacity, with differences between the typefaces on price recall becoming non-significant for those with high working memory capacity. Consistent with study1, the harder to read typeface also increased accuracy of processing product attributes.

Though Nelson (1985) endorsed a complexity in advertising as it "slows down the reader making things more difficult to take in" (p. 115), others suggest that complexity hurts advertising because it makes people pay less attention to the brand (Pieters Wedel and Batra 2010). The initial evidence from this research shares kinship with the latter research and shows a superior effect of harder-to-read typeface on consumers' recognition of product attributes, but a weaker recall of the accompanying price. These results add not only to our understanding of how consumers conduct visual search, but also how consumers' attention to product descriptions compromises their attention to price.

The Neural Correlates of Buying: Implications for Marketing

Kristin Wiggs, University of Iowa, USA
Kanchna Ramchandran, University of Iowa, USA
Daniel Tranel, University of Iowa, USA
Levin Irwin, University of Iowa, USA

The emerging field of neuromarketing attempts to apply "neuroscientific methods to analyze and understand human behaviour in relation to markets and marketing exchanges"(Lee, Broderick, & Chamberlain, 2007). This field has touched on the brain systems associated with the processing of advertisements, as well as those associated with the predictability of choice, pleasure, and reward in the context of buying/ shopping (Lee et al., 2007). The current research expands on this through preliminary exploration of brain systems that may be associated with impulse buying, compulsive buying, and shopping ruminations. We hypothesized that the prefrontal cortex (PFC) and temporal (TL)/ parietal lobes (PL) (with projections from reward processing circuitry) would be differentially implicated in impulse buying, compulsive buying, and shopping ruminations. The medial prefrontal cortex has been previously implicated in collecting behaviors (Anderson, Damasio, & Damasio, 2005) and hence we hypothesized that compulsive buying behavior and excessive shopping ruminations may be associated with the PFC. Sections of the TL and PL have been associated with impulse control/temporal discounting since they receive projections from the subcortical reward processing circuitry, and we hypothesized that they would be associated with impulse buying (Raab, Elger, Neuner, & Weber, 2010; Richards, Zhang, Mitchell, & de Wit, 1999).

Utilizing the neuroscientific research approach of the lesion method, we recruited 36 participants (from the University of Iowa, Lesion Patient Registry) with single, stable, well-characterized brain lesions to the PFC *(N=10),* TL *(N=10),* PL *(N=4)* as target groups as well as the occipital lobe (OL) *(N=12),* as a brain damaged comparison group. These participants and their collaterals (a close relative), were administered a Shopping Behavior Questionnaire, which we created, based on other well validated questionnaires (Ridgway, Kukar-Kinney & Monroe, 2008) in order to assess the dimensions of impulse buying, compulsive buying, shopping ruminations and their life consequences. Each statement in the questionnaire was rated on two scales. The first scale was a Likert scale from 1 (strongly disagree) to 7 (strongly agree). The second scale was used to ascertain whether there was change in shopping behavior after the participant's brain lesion, ranging from a large decrease to large increase with an option of no change. Following these statements, a second section of the questionnaire assessed family history of compulsive/impulsive buying. In addition, usage, overall time, and access to the Internet and television were assessed. Transportation access and means (for shopping), as well as various financial questions (to ascertain income and financial control) were also asked. Only collaterals were asked if they had taken any steps or measures to curb the participant's spending. Twenty-three participants (63%) identified a collateral. Three participants were unable to respond via phone and data was solely collected from their collaterals. The research study was executed as phone based interviews, lasting approximately 15 minutes per participant/collateral.

Based on data drawn from participant self-ratings on the questionnaire, our preliminary analyses (ANOVA) have indicated that the PFC and the TL/PL are differentially implicated in buying behaviors. Not only the PFC (as we had hypothesized), but the TL and PL as well were associated with compulsive shopping behaviors, as the self-ratings ($p= 0.0256$*)* and change scores (after brain lesion) ($p=0.1179$) were significantly higher than the OL comparison group. In the case of impulse buying, however, only the TL and PL (as hypothesized) were implicated and the self-rating ($p=0.0232$) and change scores ($p= 0.0048$) were significantly higher than the OL and PFC groups. In the case of excessive shopping ruminations, the TL and PL groups were significantly higher in self-ratings ($p=0.0107$) and change scores ($p=0.1647$) than the PFC and OL groups. This is interesting since one would assume that the PFC, with its prior association with collecting behavior and compulsive shopping behavior (from our dataset), would also be associated with excessive shopping ruminations, but this was not the case in our dataset. This indicates that compulsive buying need not always be preceded or accompanied by perseverative cognitions or thoughts about shopping. Strong correlations existed between the PL/TL groups' excessive shopping ruminations and (a) lying about the time or money spent shopping to friends or family (.77), (b) having difficulty controlling the amount of time spent thinking about shopping (.72), and (c) having to obtain new lines of credit to increase or maintain shopping habits (.72).

Additionally, we also note that although a few individual participants did report decreases in buying behavior or ruminations after the onset of brain damage, no brain lesion group demonstrated a pattern of such decrease. While our target groups spent significantly less time on the Internet than the OL comparison group, t-tests revealed that there were no significant differences between our target and comparison groups in financial resources, financial control, or transportation access.

The brain lesions of a subset of these participants have been mapped. Thus, the next step in data analysis would be to map the region of maximum overlay within each target group to identify those regions within the PFC, TL and PL (for example, medial PFC, hippocampus, insula) that may shed more light on specific regions and how their explicit functions contribute to these buying behaviors.

Thus our data indicate that compulsive buying may be associated with both prefrontal and temporal and parietal lobes, while shopping ruminations and impulse buying are unique to only temporal and parietal lobes. These preliminary findings may have implications for the field of marketing in further delineating the neural substrates underlying buying behavior. Thus, consumers that impulsively shop need not

be compulsive shoppers and vice versa. Based on the nature of a product, particular shopping contexts, and susceptibility to advertisements, this distinction may be relevant to marketers.

The Influence of Goal Publicity on Goal-Consistent Behaviors

Yuchen Hung, National University of Singapore, Singapore
Xiuping Li, National University of Singapore, Singapore
Catherine Yeung, National University of Singapore, Singapore

People are encouraged to share with the world the goals they want to achieve. For example, World Wild Fund for Nature (WWF) encourages its supporters to "show off "commitments to a better environment by buying its logoed products. But how does publicizing one's goal affect one's subsequent behaviors? Several theory mechanisms predict that goal publicity motivates goal-consistent behaviors. First, people may do so because of social pressure. Nyer and Dellande (2010) show that weight losers in a weight management center achieved their stated targets when they posted their targets in bulletin. Second, goal publicity may increase goal-consistent behaviors because of an increase in intrinsic motivation. Publicizing one's opinion is shown to increase commitment to the stated position. This is because one attachments self to the public attitude so that one enacts one's belief (Ahluwalia, 2000). In fact, publicizing one's opinion is typically used as commitment manipulations (Nyer and Dellande, 2010). If so, one should attach a greater goal importance when the goal is public, and experience high motivation to carry out goal-consistent behaviors.

In addition, goal publicity may change self perception. Tice (1992) shows self presentation in public changes self concept. The reason is overt behaviors call the individuals' attention to certain aspects or potentialities of the self, which are then highly accessible and exert a powerful influence on subsequent self-assessment. Goal pursuers are typically associated with certain traits, and the associated traits may be incorporated to oneself concept due to goal publicity. For example, academic pursuers are associated with intelligence. Announcing an academic goal may lead one to see oneself as more intelligent. The change in self perception may self script associated with the goal highly accessible (Schlenker , Dlugolecki and Doherty, 1994), and increase goal enactment.

The above analyses suggest that when a goal becomes public, people are likely to internalize it and act upon it when opportunity arises. However, previous research has overlooked the distinctive values that goal achievement delivers. These values may fall into two categories, utilitarian- and symbolic-related. The distinction between utilitarian and symbolic values is well documented in consumer research. Researchers have shown that consumers consider purchasing decisions based on utilitarian values or symbolic values of products (Shavitt, 1990). Consumer needs are classified as functional needs or symbolic needs (Park, Jaworski and McInnis 1986). The functional needs are related to specific and practical problems, whereas symbolic needs are related to self image and social identification (Subodh Bhat, 1998). The distinctive values that one focuses on goal achievement predict different consequences of goal publicity. When symbolic value is highlighted, goal publicity communicates a desirable self image to others attainment. The communication of such a desirable self image may give a sense of temporary goal completion, thus decrease motivation for subsequent goal-consistent behaviors. In contrast, when utilitarian value is highlighted, the communication of a desirable self image should make one internalize the goal importance and motivate its enactment. Therefore, goal publicity should affect goal-consistent behaviors differently as a function of the values under consideration.

EXPERIMENTS & RESULTS

To test this hypothesis, we conducted a 2 (goal framing: symbolic vs. utilitarian) by 2 (publicizing: publicizing vs. not publicizing) between-subjects design in Experiment 1. The students were instructed to think of how academic success expressed who they were (vs. how academic success benefited them) in symbolic (vs. utilitarian) priming. Their answers were read by experimenter in the publicizing condition, but not read in the not publicizing condition. One week later, they were contacted via email and asked to report the time that they spent on studying in their own time in the past one week. The results were consistent with our hypothesis. The two-way interaction was significant (F $(1, 114) = 4.31$, $p = .04$). When symbolic values were considered, the studying time was significantly lower among students who publicized their goal than among those who did not publicize ($F (1,114) = 3.86$, $p = .05$). In contrast, when utilitarian values were considered, the studying time was not different between publicizing and not-publicizing conditions ($F (1, 114) = 1.09$, $p = .30$).

Experiment 2 examined a different goal, environmentally friendly. Similar to experiment 1, the participants were instructed to think of how being environmental expressed who they were (vs. how being environmental benefited them) in symbolic (vs. utilitarian) priming. Their answers were (not) read by experimenter in the (not) publicizing condition. Afterwards, they read an article from World Wild Fund for Nature

(WWF) on responsible consumption of seafood. The participants were instructed to read the article as they would read it in the newspaper and rate its overall persuasiveness. The article contained information on the ecological impact of overfishing and guideline of seafood consumption. The guideline categorized 18 fish into 3 consumption categories, which were "recommended", "think twice" or "avoid", according to the level of extinction. After reading the article, the participants were presented with a comprehension task, in which they identified the category to which the 18 fish belonged. Motivated individuals should exert more effort on goal-consistent information and remember the information to a better extent. Thus, the number of correct answers was indicative of their motivation of goal pursuit. The results showed that the two-way interaction of goal prime and publicizing was significant (F (1, 70) = 7.73, p= .007). The number of correct answers was lower in symbolic, publicizing condition than in symbolic, not publicizing (F (1, 70) = 4.83, p= .03), indicating publicizing symbolic goal decreased motivation. The reverse was found when participants considered the utilitarian value of environmental goal. Participants answered more answers correctly in the publicizing condition than in the not publicizing condition (F (1, 70) = 2.99, p= .09).

CONCLUSION

Past research has shown publicizing one's goal motivates people for goal achievement. Building on past research, the studies show that that goal publicity does not always increases goal-consistent behaviors. Goal publicity may decreases goal-consistent behaviors when the symbolic value of goal achievements was considered. In two experiments, we demonstrated divergent behavioral consequences of goal publicity when symbolic versus non-symbolic values were salient. The results showed that publicizing academic goal reduced time spent on studying, and publicizing environmental goal lowered attention paid to environmental information when symbolic value was highlighted. We established the contingency of goal publicity and its enactment.

Illusory Control as a Determinant of Ambiguity Seeking

Liang Song, National University of Singapore, Singapore
Yih Hwai Lee, National University of Singapore, Singapore

People generally tend to avoid taking risks with vaguely specified probabilities. This tendency, termed as *ambiguity aversion*, has been found robust in a variety of contexts, such as risky gambling, medical, or insurance decisions (Camerer and Weber 1992). Despite the robustness of ambiguity aversion, *ambiguity seeking* was also observed. Many theories have been put forward to explain what affected people's attitudes towards ambiguity, especially what might lead to ambiguity seeking (e.g., Heath and Tversky 1991; Kuhn 1997). The current research examined two new situational variables that contributed to ambiguity seeking, and pointed out a new psychological process.

Study 1 examined the effect of temporal distance on ambiguity seeking in gambling decisions. We propose that, when a gamble is played in distant future, as compared to near future, people may demonstrate greater ambiguity seeking. If illusory control is the underlying mechanism, ambiguity seeking should be reflected in terms of the judged winning likelihood. To test these hypotheses, we modified the classic Ellsberg's experimental paradigm (Ellsberg 1961) and asked participants to guess the color of a ball that would be drawn from some bottle(s) for a \$2 prize. Ambiguity was defined as uncertainty about a probability (Frisch and Baron 1988) and operationalized in many past research as a range of interval (e.g., Curley and Yates 1985; Kuhn 1997). Following this definition, participants in one condition (i.e. the condition with ambiguous probability) saw two bottles: one was described as containing 30 - 50% more white marbles than blue marbles, and the other 40% more blue marbles than white marbles. A die would be tossed to decide from which bottle the ball would be drawn. In comparison, participants in the other condition (e.g. the condition with precise probability) were presented with one bottle that was described as containing 50% white and 50% blue marbles. Temporal distance was manipulated by telling half of the participants that the ball would be drawn in 5 minutes and the other half of the participants that it would be drawn on the next day. Then they guessed the color and estimated their own probability of winning. Consistent with our hypothesis, the estimated winning likelihood was greater in response to the 1-day delay than to the 5-minute delay when the gamble was described ambiguously (0.58 vs. 0.47, *p* < .001); however, this tendency diminished greatly when the gamble was described precisely (0.53 vs. 0.51, *p* = .413).

Study 2 examined how having an option to select a product item from a chosen product influence ambiguity seeking. To illustrate, in the marketplace, consumers usually either get to select an item amongst similar SKU (e.g., picking up a box of vacuum cleaner amongst similar ones at the store floor) or have to rely on a store assistant to get an item for them (e.g., there is only 1 display item for each SKU on the store floor and the store assistant have to retrieve available stock from the store storage).We propose that consumers who are allowed to freely pick up a product from many others, as compared to those who are not allowed to do so, may demonstrate greater ambiguity-seeking towards product information that may be amenable to illusory control. We tested these hypotheses in a lab which simulated a marketplace setting. Participant entered a lab one at a time and was asked to make a choice between two brands of MP4 based on constructed product information. Ambiguity was manipulated by varying the "failure rate" product information. To explain, in one condition, failure rate of brand-B was given as range from 10-26%; in the other condition, failure rate of brand-B was given precisely as 18% (which was the center of 10-26%). Failure rate of brand-A was 22% in both conditions. Ratings for two other non-failure-rate attributes (e.g., sound quality) were also calibrated to make the two brands relatively comparable. To manipulate how participants pick up a product, in one condition, ten real items of each brand were displayed together on the table, and participants were allowed to pick up any item as their choice. In the other condition, only one item of each brand was displayed on the table, and participants were told that once they made a choice, the shop assistant (i.e. the experimenter) would get them another box of the same item from the storage (participants were told there are 10 "available stock" available). All participants then indicated their choice, relative preference (measured from 1-"definitely prefer brand-A" to 10-"definitely prefer brand-B") and estimated the failure rate of the product they would get. As predicted, allowing participants to pick up an item, compared to not allowing them to do so, led to a greater preference towards (and also greater choice over) brand-B when its failure rate was described ambiguously (6.58 vs. 5.09, *p* < .05), but not when it was described precisely (5.40 vs. 5.92, *p* = .49). More importantly, the estimated failure rate fully mediated the interactive

effect between probability format and way of choosing on consumers' preference judgments, supporting our argument about illusory control as the underlying mechanism.

Overall, this research adds to our understanding by revealing the underlying psychological causes of both ambiguity seeking behavior and illusory control perception.

You're Shady: The Effect of Pupil Obscuration on Consumers' Perceived Trust

Hamed Aghakhani, University of Manitoba, Canada
Kelley Main, University of Manitoba, Canada
Nick Turner, University of Manitoba, Canada

Research on eye contact has revealed that the most important cue in determining whether one is perceived as lying is a lack of eye contact (Sporer and Schwandt 2007). In contrast, direct eye contact results in greater perceived intimacy, attraction and trust (Burgoon et al. 1985) and greater perceptions of friendliness (Beebe 1974). While an averted eye gaze is believed to be a strong cue of deception, a prolonged gaze can be seen as threatening (Bayliss and Tipper 2006). However to date, the literature has focused only on comparisons of direct versus indirect eye contact with no consideration of eye contact with one's pupil obscured. The goal of the current research is to understand how the physical obscuration of a person's eyes (by wearing shaded or darkened glasses) affects others' perceptions of that person. In particular, we are interested in observing the effects of wearing shaded eyeglasses on other people's trust judgements of the wearer. Utilizing the theory of spontaneous trait transference (Winter and Uleman 1984) wherein people rely on automatically elicited inferences when making social judgments to interpret the behaviors of others, we expect that wearing shaded eyeglasses may result in the "shady" trait to transfer to the wearer, thereby reducing the previously demonstrated positive effects of direct eye contact. It is hypothesized that even when recipients are able to see the pupils of the person wearing shaded eyeglasses, some degree of distrust is expected based on the partial obscuration. We also propose that status of the person wearing the glasses moderates this effect. In particular, it is expected that wearing shady glasses does not affect those high in status and instead lower status individuals with shaded glasses are perceived as more distrusted. Two experiments examine these hypotheses.

EXPERIMENTS

Study 1 examined the main effect of pupil obscuration on perceived trust. This study was a 2 (participant gender: male vs. female) x 4(level of shade: clear, low, medium, full) x 2(model gender: male vs. female) plus 1(clear indirect eye gaze) between subjects design (N= 343). Participants were given a picture of a person with eyeglasses. The lenses of the glasses were tinted with computer software to vary from completely clear to fully shaded. Then participants asked to indicate their level of trust towards the target on seven items measuring trust that were mixed in with various other traits. The results revealed a main effect of model gender (M_{male}=2.99, M_{female}=3.22, $F(1,326)$=4.066 , p=.045) and a main effect of the level of shade (M_{clear}=3.40, $_{Mlow}$= 3.11, M_{med}= 2.62, M_{ful}=2.61 and $M_{indirect\ gaze}$=3.50, $F(4, 326)$=15.084, p=.000). These results reveal that people have less trust in a person wearing shaded eyeglasses even when there is a direct eye contact and the recipients are able to see the pupils of the communicator. The gender of the person wearing the glasses reveals that recipients have less trust in men as compared to women. Participants' gender had no effect. Post-hoc tests of the effects of different degrees of shading revealed that people have the highest trust in a person wearing clear eyeglasses and this trust decreases as the darkness of the lenses increases. The findings also show that even a picture with an indirect eye gaze with clear glasses had higher trust as compared with shaded glasses.

In experiment 2, we sought to extend the finding of the previous study by examining the status of the model as a potential moderator of recipient's perceived trust. In addition, we examined whether the model gender effect was a result of the attractiveness of the model. A 2(model gender: male vs. female) x 3(level of shade: low, medium, high) x 2(status: high vs. low) between subjects design (N= 236) was conducted. Status was manipulated through a paragraph that accompanied the photo indicating that the person featured in the photo did/did not win a prestigious award.

The results replicate the main effect of shade (p=.049) and model gender (M_{male}=3.908, M_{female}=4.259, p=.001) on perceived trust using the same items as Study 1. Results also indicate a significant two way interaction of shade and status ($F(2.224)$=2.43, p=.09) and a significant three way interaction of shade, model gender and status ($F(2,224)$= 4.69, p=.01). It is found that people have the least perceived trust in a lower status person who has shaded glasses (M=3.671) in comparison to those with low (M=4.20) or medium (M=4.12) shaded glasses. In contrast wearing shaded glasses does not affect perceived trust in a high status person. The results for model attractiveness showed no difference between the two models (p>.5).

GENERAL CONCLUSION

This research makes two major contributions to the field. First, in contradiction to results demonstrating that direct eye contact increases friendliness (Burgoon, Coker, and Coker 1986), this research found a boundary condition under which eye contact has no positive effect, specifically when there is a physical obscuration of the pupil. The second contribution of this research is the extension of the gazing literature above and beyond eye gaze or contact to demonstrate the importance of no barrier to one's pupils. The outcome of this research has direct implications for the marketing field, especially in a sales context. Many sales agents wear prescription photochromic glasses that will appear shaded depending on the time of day and lighting in the store. The current research suggests that this will lead to lower perceived trust in the agent, and perhaps may even influence evaluations of the store.

The Effects of Labeling on Prosocial Behavior

Zoe F. Rogers, Baruch College & The Graduate Center, CUNY, USA

Pragya Mathur, Baruch College, CUNY, USA

Labeling is a common persuasion tactic that involves suggesting to someone that they possess a specific attribute with the intention of influencing their behavior in ways corresponding to that attribute (Reingen & Bearden, 1983). For example, labeling an individual as a responsible voter can lead to increased voting behavior (Tybout & Yalch, 1980). In this investigation, we examine the impact of labeling on the effectiveness of charity appeals.

Most of the labeling literature in marketing involves positive labels (Moore, Bearden, & Teel, 1985), while few have considered negative labels, with the exception of Steele (1975) who found that negative (vs. positive) name-calling resulted in increased helping behavior. The potential effectiveness of negative labels can be understood in terms of the "shaken self" perspective (Gao, Wheeler, & Shiv, 2008), in which negative labels are understood as threatening a strongly held self-view, leading to behavior contrary to the label in attempts to restore confidence in this self-view.

The effectiveness of many persuasion techniques is often determined by the activation of an individual's persuasion knowledge, which is much more likely when an individual engages in thorough elaboration on the persuasion attempt (Friestad & Wright, 1994). Positive labeling is more effective when elaborative processing of the label is prevented (Cornelissen et al., 2007), while the impact of elaboration level on negative labels has not been examined.

Labeling is not only impacted by elaboration level, but also by content of the appeal, specifically whether it is self-focused (focused on the benefits to the self) or other-focused (focused on the benefits to others). This distinction corresponds to perceivers' underlying altruistic or egoistic motivations to engage in prosocial behavior (Wilson, 2000). Engaging in helping behavior for altruistic reasons is perceived as more appropriate behavior and serves as a norm to guide behavior in our society (White & Peloza, 2009).

Therefore, we hypothesized that in low elaboration conditions, those who are negatively labeled and who view the other-benefit appeal will have the highest giving intentions. Other-focused behavior is the *most* generous behavior people can display and is thus the most effective way in which to restore confidence in a "shaken" self-view. For those who are positively labeled, we did not expect any impact of the content of the appeal on giving intentions.

Study one was conducted using a 2 (valence of label: negative vs. positive) X 2 (accuracy motivation: high vs. low) X 2 (type of appeal: self vs. other) between-subjects design. First, respondents received the elaboration manipulation, which involved responding to two scenarios either with general opinions (low accuracy) or more thorough consideration (high accuracy), a manipulation used effectively by Agrawal & Maheswaran (2005). Participants then reported their opinions about different people, after which the computer "evaluated" the responses and provided (fictitious) feedback containing the (randomly assigned) "generous" or "not generous" label. This procedure has been shown by Strenta and Dejong (1981) to create convincing labels. Participants then viewed the appeal for "Hearing Loss Research" donations featuring either self-benefit or other-benefit ad copy. Participants evaluated the advertisement on several dimensions and indicated giving intentions.

A 2 X 2 X 2 ANOVA on label valence, accuracy motivation, and type of appeal revealed a significant three-way interaction ($F_{(1,177)}$ = 4.09, $p < .05$). In the low accuracy conditions, individuals who viewed the other-benefit appeal reported higher giving intentions when positively (vs. negatively) labeled (M = 4.71, M = 4.0; p = ns). In the high accuracy condition, individuals who viewed the self-benefit appeal reported higher giving intentions when positively (vs. negatively) labeled (M = 5.17, M = 4.36; p = ns). The results of this study indicate that when little elaboration occurred, those who were labeled as "generous" and viewed the other-benefit appeal responded with the highest giving intentions. When high elaboration occurred, those who were labeled as "generous" and viewed the self-benefit appeal responded with the highest giving intentions. These unexpected findings will be addressed in a future study.

A second study further examined negative labels using a different operationalization of elaboration, relevance of the appeal. When a message is self-relevant, an individual scrutinizes the message more thoroughly in order to judge the information more confidently (Maheswaran & Chaiken, 1991). When there is little relevance of the appeal, those who view the other-benefit (vs. self-benefit) appeal should be more willing to give, as these individuals are more likely to depend upon the "altruistic giving" norm discussed above to guide their behavior.

This study was conducted using a 2 (self-relevance: high vs. low) X 2 (type of appeal: self vs. other) between-subjects design. The procedure was the same as that of study 1, with two exceptions: (a) all participants were negatively labeled, and (b) participants viewed the appeal from the perspective of either someone who has never known anyone with hearing loss (low self-relevance) or someone who had a family member recently diagnosed with hearing loss (high self-relevance).

A 2 X 2 ANOVA on self-relevance and type of appeal revealed a significant interaction (F (1, 66) = 3.110, p =.05), as well as a main effect of the type of appeal ($M_{\text{Other-Benefit Appeal}}$ = 5.36 vs. $M_{\text{Self-Benefit Appeal}}$ = 4.70; p = .08). Decomposing the two-way interaction revealed that in the low-relevance condition, the individuals who viewed the other- (vs. self-) benefit appeal reported significantly higher giving intentions (M = 5.63, M = 4.25; p < .01). Additionally, respondents who viewed the self-benefit appeal reported significantly higher giving intentions in the high (vs. low) relevance condition (M = 5.19, M = 4.25; p = .05).

This research contributes to the labeling literature by comparing the relative effectiveness of positive and negative labels, as well as demonstrating the impact of content of the appeal on the effectiveness of labeling. Future research will further examine positive labels and their relationship with content of the appeal to better understand the findings of our first study. We will also consider cultural variables in order to examine the effectiveness of labels when used worldwide.

How Mindset Influences Consumer Decisions:
Investigating the Role of Mental Imagery and Affective Responses

Cheng Qiu, University of Hong Kong, China

Consumers may process incoming product information using different cognitive procedures. In some cases they may focus on abstract issues relating to values or end benefits (e.g., the effects brought by a product). In other cases they may focus on concrete aspects of the process (e.g., the process of consuming a product). The former can be referred to as an abstract mindset and the latter, a concrete mindset (Freitas, Gollwitzer, and Trope 2004). The activation of different mindsets may be influenced by individual difference such as age and culture (Hong and Lee 2010), psychological distance such as whether things happen in near or distant future (see Trope and Liberman 2010 for a review of construal level theory), and situational factors that induce a certain mindset temporarily (Escalas and Luce 2004; Torelli and Kaikati 2009).

Once a mindset is activated, it would have profound influence on people's responses. Previous research shows that an abstract mindset may shift people's focus to the desirable aspects whereas a concrete mindset may highlight feasibility concerns when people consider whether to carry out an activity (Eyal et al. 2004; Liberman and Trope 1998). While this finding bears important implications for many consumer decisions, there are also plenty of daily purchase or consumption decisions which involve few feasibility concerns. Under such situations, will mindsets still influence consumer decisions? Why or why not? This research is aimed to address these questions.

This research proposes that people in a concrete (vs. abstract) mindset are more interested in hedonic products when detailed product description is provided. This is because when consumers encounter such products, their focus on concrete processes and contextual information would facilitate the construction of vivid mental simulation of consuming the product, especially if there is sufficient product information that provides enough materials for mental simulation. When the consumption imagery becomes more accessible in memory, consumers have more favorable responses to the product (Petrova and Cialdini 2005). Moreover, such mental imagery may elicit positive affective responses (MacInnis and Price 1987), which also enhance consumer judgments. Therefore, we expect that a concrete (vs. abstract) mindset may lead

to greater intention to try products involving immediate, desirable experiences (e.g., nice fruit dessert) when detailed product information is provided (e.g., product picture). However, when product information is very limited, consumers may lack sufficient information for generating consumption imagery, regardless of their mindset. This would become a boundary condition where a concrete mindset may not enhance consumer judgments. Experiment 1 tested these hypotheses.

Experiment 1. This experiment adopted a 2 (mindset: concrete vs. abstract) x 2 (product information: picture vs. no-picture) between-subjects design. 110 participants were induced to be in a certain mindset by completing a task under the pretense of psychology research on actions and goals. In the abstract mindset condition, they were instructed to write about why they carry out several actions such as improving leadership skills, which shifted their focus to end benefits. Participants in the concrete mindset condition were instructed to write about how they carry out those actions, which shifted their focus to concrete processes (adapted from Freitas, Gollwitzer, and Trope 2004). Thereafter, they proceed to an ostensibly unrelated product survey in which they assessed several products. The target product was a fruit dessert. In the picture condition, participants saw a picture of a fruit dessert and indicated their interest in having it, whereas in the no-picture condition, participants were simply asked to indicate how interested they were in having a fruit dessert. The main dependent variable was measured on a seven-point scale ranging from "not interested at all (1)" to "very interested (7)". An ANOVA analysis reveals a main effect of product information (picture vs. no-picture; $F(1,106) = 18.92$, $p < .001$) and an interaction between product information and mindset ($F(1,106) = 6.27$, $p = .01$). Consistent with our prediction, when participants saw the product picture, they were more interested in trying the product if they were in a concrete mindset (M = 5.97) than if they were in an abstract mindset (M = 5.08; $F(1,106) = 4.31$, $p < .05$). However, when they did not see the product picture, the difference between concrete mindset condition (M = 3.89) and abstract mindset condition (M = 4.52; $F(1,106) = 2.14$, NS) diminished. Another set of planned comparisons show that when participants were in a concrete mindset, they were more interested in trying the product if they saw the product picture (M = 5.97) than if they did not (M = 3.89; $F(1,106) = 24.37$, $p < .001$); the difference diminished when participants were in an abstract mindset (5.08 vs. 4.52, $F(1,106) = 1.64$, NS). The findings provide preliminary support to our hypotheses.

Experiments are planned to further investigate the mechanism underlying the mindset effect. The next experiment would examine different types of hedonic products to improve generalizability, collect measures of imagery generation and affective responses to validate the mechanism, and study the possible moderating role of individual difference in imagery ability. A third experiment would examine the potential moderating role of the affective nature of consumption, which would help further pin down the mechanism. Note the fruit dessert studied in experiment 1 is desirable in terms of both consumption experience and end benefits. However, some products may bring desirable end benefits but entail negative consumption experience (e.g., using insect killer). If the proposed mindset effect is simply due to the accessibility of consumption imagery, a concrete (vs. abstract) mindset should be more likely to trigger mental imagery and lead to more favorable responses regardless of the affective nature of usage experience. However, if the affective responses elicited by the consumption imagery matter, a concrete (vs. abstract) mindset may result in greater interest/less interest in products involving pleasant/unpleasant usage experience.

To summarize, this research will complement previous research to offer a more comprehensive understanding of the mindset effect. The research will also investigate new mechanisms through which mindset may influence consumer judgments, namely, the generation of consumption mental imagery and the affective responses toward the mental imagery.

The Perception of lower and higher Price-Thresholds:
Implications from Consumer Neuroscience

Marc Linzmajer, Zeppelin University, Germany
Mirja Hubert, Zeppelin University, Germany
Marco Hubert, Zeppelin University, Germany
Peter Kenning, Zeppelin University, Germany

The investigation of optimal pricing has a long tradition in marketing and already yielded important contributions to our understanding of consumer behavior (Lowe and Alpert 2010; Mazumdar, Raj and Sinha 2005; Ofir 2004). Behavioral pricing research and theories (e.g., adaption-level theory, assimilation-contrast theory) have shown consumers to have lower and upper price-thresholds, represented by an inverted U-shaped price-acceptability-function (Helson 1964; Monroe 1973, 1990; Rao and Sieben 1992; Sherif and Hovland 1961; Winer 1988). Whereas prices below a lower price-threshold may signal suspect product quality, prices above an upper threshold may be considered as too expensive (Monroe 1973). The idea of lower and upper price-thresholds and, in between, an acceptable price range, are widely accepted and integrated in most theoretical accounts in pricing research (e.g., Kalwani and Yim 1992; Kalyanaram and Winer 1995, Lichtenstein, Bloch and Black 1988; Mazumdar and Jun 1992). Moreover, recent neuroscientific studies show the effect of different price levels on brain activation and decision-making (Knutson et al. 2007; Plassmann, O'Doherty and Rangel 2007).

However, the reason *why* consumers tend to have lower and upper price-thresholds and *how* the acceptable price range is processed in the consumers' brain remains mainly unclear. Against this background, we applied functional magnetic resonance imaging (fMRI) in order to investigate if there are neural activation patterns that correspond to a lower-, optimal-, and upper-price-threshold. Based on the theories we assumed, that people will not only accept prices from the optimal price range more often compared to prices below or above the price-thresholds, but that they will also exhibit different neural activation patterns during the perception of optimal versus low/high prices.

In a preliminary study, 127 participants were asked for their individual price-settings (too cheap, cheap, expensive or too expensive) for different variations of one FMCG. According to van Westendorp (1976) we extracted a lower- (.88 monetary units (MU) and upper price-threshold (.99 MU) as well as a (fictive) optimal price (.96 MU). In order to have more variance in the fMRI-study, we took the lower-price-threshold and subtracted 5%, 10%, and 25%. Accordingly we added 5%, 10% and 25% to the upper-price-threshold. Therefore we got a lower threshold-range from .66 to .84 MU, an optimal range from .88 to .96 MU and an upper threshold-range from 1.04 to 1.24 MU. In our fMRI-study, we measured the brain activity of 29 subjects (M_{age} =42.24 years; SD=4.22) during the perception of the price-product combinations extracted from our preliminary study. The task-design followed Knutson et al. (2007). Thus, we first showed participants a picture of a product (4 seconds), followed by the price information (4 seconds), and a decision-phase where they had to indicate their purchase intention (1="yes"/0="no"). In total, participants evaluated 90 product-price combinations. The study was executed on a 3T scanner (Magnetom Trio, SIEMENS). The data set consisted of 36 transversal slices of 3.6 mm thickness without a gap, FOV 230 mm x 230 mm, acquired matrix 64 x 64, that is, isotropic voxels with 3.6 mm edge length. Contrast parameters were TR=3000 ms, TE=50 ms, flip angle=90°. Within the group analysis a one-sample t-test was applied based on the individual contrasts of the lower price-thresholds versus the optimal prices as well as upper price-thresholds versus the optimal prices.

Preliminary results confirmed our assumption of an upper-price-threshold. Only 2.4% of prices within the upper-price-threshold-range were accepted by our participants compared to 31.5% accepted prices within the optimal range (χ^2 = 261, 277; p<.001). Also, the fMRI-data confirmed these results. The contrasting of high prices versus the optimal price range exhibited higher activity changes in the insula, the DLPFC (BA46), the superior frontal cortex (BA8), the anterior and posterior cingulate cortex (ACC/PCC). Activity in the insula has often been associated with the "price pain" and negative emotions (e.g., uncertainty, pain, anger) (Eisenberger and Lieberman, 2004; Knutson et al., 2007; Sanfey et al., 2003). Furthermore, our results indicate that the decision becomes more complex for prices above the upper-price-threshold, because the prefrontal areas (BA46, BA8) as well as the ACC/PCC are frequently associated with reflective processes, decision-making and conflict monitoring (Bechara 2005; Ridderinkhof et al. 2004; Sanfey et al. 2003; Volz, Schubotz and Cramon 2005) Additionally high prices led to higher activity changes in regions associated with memory retrieval and semantic/visual processing such as the hippocampus or the inferior frontal gyrus (BA 45) (Gabrieli, Poldrack and Desmond 1998; Squire 1992). However, our results did not confirm the assumption of a lower threshold. Prices below the lower-price-threshold-range were significantly more accepted (64. 8%) than prices within the optimal range (31.5 %) (χ^2 = 193,595; p<.001). Furthermore, prices below the lower-price-threshold did not lead to activity changes in regions associated with negative emotions such as the insula. Rather they lead higher activity changes in the middle temporal gyrus (BA 22), and the caudate nucleus. These results provide some evidence that lower prices are perceived as more rewarding than optimal prices (Delgado et al. 2003; Haruno and Kawato 2006). However, there is also no linear relationship between higher prices and activity changes in the insula. We only found higher activity changes in the insula for prices above the upper-price threshold. Contrasting the optimal price range versus the lower prices did not reveal activity changes in this brain region.

Our results provide some evidence and are in line with research on a revision of the inverted U-shaped price-acceptance-function. Based on the stimulus material from the FMCG-segment in this study, it might be that the price-quality relationship is stronger when higher-priced products are used (Völckner and Hofmann 2007). Therefore, a lower price threshold might come into play when the price-perceived quality relationship is stronger. But indeed, there already exists some theoretical evidence against a lower-price-threshold: first, economic theory presumes a decreasing demand function implying that, in general, consumers find lower price more acceptable (Monroe and Lee 1999). Second, observation of consumer behavior in the marketplace shows that some consumers actively seek out lower prices. In fact, the discount-retail formats addressing these needs are often very successful. Third, the commonly used direct-questioning-method (Monroe 1990) may be inherently biased, potentially directing consumers to indicate a lower price threshold when, in fact, it may not exist. The prevalent usage of this methodology in academic and applied research may have contributed to overlooking the possibility of the existence of only one threshold for some consumers or products.

The Effects of Mastery on Subjective Utility

Irene Scopelliti, Carnegie Mellon University, USA
George Loewenstein, Carnegie Mellon University, USA

Motivation to achieve and to improve skills is an important characteristic of mankind and a strong driver of behavior, even if it is not related to any immediate physical reward. Human beings engage and put enormous amounts of effort in a wide variety of activities just to prove themselves they are capable of doing them and of improving their performance. In such activities, the mastery of the task appears to be a reward in itself, since it reflects one's control over the environment (White 1959). Mastery motivation has been defined as a psychological

force (a disposition) that stimulates a person in a focused and persistent manner to attempt to master a skill or task that is at least moderately challenging for her (Morgan, Harmon, and Maslin-Cole 1990, 319).

Bentham (1781) included mastery, in the form of *pleasures of skill*, i.e., the pleasures derived by being good at an activity, in its original broad theory of utility. Mastery generates pleasure because it entails a sense of control over the environment, of goal achievement, and often a state of flow (Rozin 1999; Frijda 2002; Kubovy 1999; Csikszentmihalyi 1991). However, partly because of the difficulties encountered in formalizing its contribution to utility in decision theoretic terms (Loewenstein 1999), mastery has been overlooked even in the most recent refinements of utility theory. Nevertheless, the empirical observation that it is pleasurable to engage in an activity one is good at, no matter how useless it might be, while it is typically aversive to do something one is incompetent at, no matter how instrumental the activity (Loewenstein 1999), seems to legitimate the inclusion of this non-consumption form of utility within economic models.

In one experiment we manipulate mastery in mathematical problem solving (high vs. low) and assess its effects on persistence at (measured as the time spent and as the number of non-mandatory problems solved), and enjoyment (self-report measures) of the activity. In addition, we examine how the experience of high vs. low mastery affects the hypothetical choice between scenarios describing the two conditions (high-mastery with a low payoff and low-mastery with a high payoff). Subjects in the high-mastery condition (i.e., confronted with a set of mathematical problems that they can solve correctly almost in toto) spent more time, solved more problems and enjoyed more the activity than subjects in the low-mastery condition (i.e., confronted with a set mathematical problems of which they can solve correctly only a small fraction), despite in the latter condition they received a higher payoff per problem solved than in the former. However, results also show that these effects are not reflected in the hypothetical choice made by subjects between the two conditions: subjects that have experienced high mastery show a greater preference toward the low mastery condition (that gives a higher payoff) than subjects that have experienced low mastery, thus underestimating the impact of high mastery on their experienced utility compared to the pleasure of money. A reason could be that subjects in the high-mastery condition think of mastery as their natural state, and lack the ability to imagine how miserable low mastery would feel.

The results of this study provide initial insights on how mastery influences subjective utility by making a task being perceived as more enjoyable and by inducing subjects to work longer. From a social standpoint, it would be beneficial that people do something they master, since they would be more productive and happier than people that do something they are not good at. However, results also suggest that often people may choose activities they do not master because they give more weight to the materialistic utility of alternative options, disregarding non-consumption aspects of utility such as the pleasure of mastery.

Value Co-Creation in Subsistence Markets: An Empirical Study

Esi Abbam Elliot, University of Illinois at Chicago, USA
Benet DeBerry-Spence, University of Illinois at Chicago, USA

There is increasing interest in changing customers' role from passive adopters of product-services to equal partners in the process of adding value (Reichwald et al., 2003). One manifestation of this interest is value co-creation. Value co-creation has been defined as collaboration between a firm-provider and its customers to jointly create value (Vargo and Lusch, 2004, 2008; Prahalad and Ramaswami, 2004; Payne et al., 2007). Value is defined here as benefits eventually obtained by the customer through its involvement and assessment when using or consuming product-services (Holbrook and Batra, 1987). Recently, firm-providers such as Lego, Skype and E-bay, are engaging in value co-creation with their customers in the design and marketing of their products. Value co-creation activities are identified as a) collaboration, which refers to the firm relating to its customer as an equal and joint partner in the co-creation process (Lusch et al., 2007), b) dialogical interaction, which refers to interactivity, deep engagement, and the ability and willingness to act on both sides (Prahalad and Ramaswami, 2004) c) learning processes for both the firm-provider and the customer (Payne et al, 2008) and d) creative processes (e.g. Potts et al., 2008). Taken together, this body of work reveals the complexity and dynamism inherent to value co-creation.

Yet, existing research does not address a number of essential perspectives. First, value co-creation is a dyadic process, yet it has been studied primarily from the firm-provider's perspective; that is, most studies have focused on the customer's involvement in the firm's value creation. But what about the customer's perspective of the firm-provider's involvement in the customer's value creation? This perspective is important since value co-creation is a dyadic process and as such both the firm-providers' and the customers' viewpoints should be considered. Second, studies on value co-creation have been limited to business-to-consumer markets. Only recently has this work been extended to business-to-business markets (e.g., Ng et al., 2010). These studies, however, have mostly considered value co-creation between large firms.

How then is value co-created with micro-entrepreneurs (MEs), which form a large percentage of customers in many business markets? This consideration is important because value co-created with consumers or large firms may be different from value co-created with micro-entrepreneurs. Third, value co-creation has mostly been based on markets characterized by strong business infrastructures. A question that arises is: How does value co-creation occur between firm-providers and customers operating in markets characterized by weak business infrastructure (e.g., subsistence markets)? Business infrastructure significant impacts not only on how value is co-created, but also the type(s) of value that is co-created. For example whilst value for a business customer in a Western market might be convenience, value for the micro-entrepreneur in African markets might be an enhanced ability to leverage social networks.

In addition to these perspectives, studies on value co-creation have acknowledged the importance of socio-cultural factors (e.g. Penaloza and Venkatesh, 2006). Socio-cultural refers to traditional and social systems including values, norms and activities. With few exceptions (e.g. London, 2007; Simanas et al., 2008), however, theorizing has been limited to empirical studies based on Western markets, which have very different socio-cultural factors than most subsistence markets. Additionally, they have different environmental circumstances (i.e. environmental hostilities) from their Western counterparts. For example, subsistence markets, unlike more developed economies, have limited access to capital, technology, technical and managerial skills (Henriques and Herr, 2008). Arguably, it becomes obvious that incorporating non-Western markets is vital to gaining a global perspective and a more comprehensive understanding of value co-creation.

As such, the purpose of the dissertation is to address two critical research questions. First, how do firms (service providers) and micro-entrepreneur customers (customer-MEs) operating in subsistence markets engage in value co-creation? And what are the types of value they co-create? A subset question is how do socio-cultural and environmental factors impact the value co-creation process? An outcome of this research will be a working model of value co-creation. The context for this investigation is financial services firms and customer-MEs in Ghana, West Africa. Given that Ghana is ranked among the top ten reformers on the ease of doing business in Africa (World Bank report on Doing Business, 2007), it seems an ideal platform in which to investigate theories of value co-creation. Furthermore, due to the liberalized economy of Ghana, relationships between financial services firms and micro-enterprises are improving (Aryeetey, 2003). To address the research objectives, a qualitative approach, in the form of phenomenological interviews and observations will be used for the study. Phenomenological interviews are well suited for the study because they produce extraordinary depth and richness of data and enable the researcher to "understand phenomena from the perspective of those who experience it" (Cope, 2005, p.17). They also unveil the essence of participant experiences and uncover the reasons behind these experiences (Sanders, 1982).

Findings from this study will extend theories of value co-creation. Additionally, they will contribute to current research streams on creativity and learning and more specifically may be applied to theories of collateral learning (i.e. learning together to build the knowledge base of each partner) and relational-based creativity.

Time Pressure, Choice Overload and Well-Being Decision Deferral

Carlos Rossi, PPGA/EA/UFRGS, Brazil
Kenny Basso, PPGA/EA/UFRGS, Brazil
Amanda Lima, PPGA/EA/UFRGS, Brazil
Mariana Rosa, PPGA/EA/UFRGS, Brazil
Danielle Machado, PPGA/EA/UFRGS, Brazil

The studies about time, behavior and consumption are acquiring a growing importance on the scientific agenda, highlighting time pressure as the main subject (Dhar and Nowlis, 1999; Ackerman and Gross, 2003; Suri and Monroe, 2003; Lin *et al*., 2008). The pressure felt is linked to the perception of being unable to devote sufficient time to the chosen activities. The lack of time could affect the well-being choices, since the individual may postpone activities linked to well-being and the improvement of life quality because of the time pressure and busy life in big cities. Based on this, we develop our study within well-being choice context, verifying when time pressure and choice overload could affect well-being decision deferral.

By relating time pressure to deferral, Dhar and Nowlis (1999) found that deferral is lower when the individual feels time pressure, since the customers may change the way they process information. Consumers under time pressure use an effortless non-compensatory decision strategy (Dhar and Nowlis, 1999). The use of decision non-compensatory rules facilitates the choice, and decreases the likelihood of choice deferral (Payne *et al.*, 1988).

In addition, an aspect that may change the way that an individual makes a choice and may interfere in deferral decision is the complexity of decision making (Tversky and Shafir, 1992), in which the conflict between the alternatives can cause consumer deferral. With increasing complexity of the sets of alternatives the individuals may choose to defer the decision to a future moment (Jessup *et al.,* 2009), or not choose to prevent a possible negative outcome (Anderson, 2003). Then, in a well-being context, under time pressure, individuals exposed to a larger choice set will postpone the decision. We predict, based on a prospect theory (Kahneman and Tversky, 1979), that the perceived losses in the larger set will be greater than those of the smaller set, and therefore the likelihood of choice deferral will be higher to individuals under time pressure and larger choice set. We assume that choice overload will moderate the effect of time pressure on choice deferral.

To test this, the experimental design was a 2 (with or without time pressure) by 2 (two or six alternatives in the choice set) between subjects, with 153 undergraduate students (57.5% female, age average of 26).

Before showing the scenario, we instigated the participants to think about his/her daily routine. In the scenario, participants received information about a research presented by a fictitious European health magazine, which praised the benefits of therapy for well-being. Then a program developed by the government that offered free treatment service to the population was presented. To participate in this program, it was necessary to choose the therapist. If the participant did not make his/her choice among the therapists, then he/she could choose to defer. In the time pressure conditions we show time count decreasing and inform a time limit to take a decision. To manipulate choice overload, we presented two or six therapists to each participant.

Checking the manipulations, the increase of the number of therapists increases the difficulty to make a decision (M_2=2.22, M_6=2.86, F=25.09, df=1, p<.01), and under time pressure condition the pressure felt by subjects was higher ($M_{no\text{-}time}$=2.13, $M_{time\text{-}pressure}$=3.17, F=37.64, df=1, p<.01).

Our analysis indicates a significant interaction between time pressure and number of alternatives (Wald $\chi^2(1)$=4.15, p<.05). In the two alternatives set, we found that participants were more likely to defer without time pressure (35.3%) than with time pressure (17.2%, $\chi^2(1)$=10.25, p<.01), which confirms the results found by Dhar and Nowlis (1999). However, under time pressure subjects in the six alternatives condition (40.5%) choose deferral more than subjects in the two alternatives (17.2%, $\chi^2(1)$=12.57, p<.01), which confirms our assumption that choice overload moderates the effect of time pressure on deferral. In addition, there are no differences in the amount of deferral between six alternative set without time pressure (35.3%) and six alternative set with time pressure (40.5%, $\chi^2(1)$=.21, p=.64).

Although time pressure reduces the focus on negative information, diminishing the choice deferral, the increase of the quantity of alternatives in the choice set may be linked to the increase of the feeling of loss, since more alternatives represent more chances to make the wrong choice. The interaction between time pressure and choice overload evidences that the perceived losses suppress the effect of time pressure on choice deferral, since the more evident the losses the higher the risk associated to the choice, which is why the individual chooses to defer. The risk in this study was associated to the commitment to the experimental public health program and the time spent to participate. This result integrates the field of research suggested by Scheibehenne *et al.* (2010), and supports the assumption that time pressure interacts with a number of alternatives causing choice deferral.

We suppose that the type of information active in the subject, may reduce the risk in the decision. The information active before the decision drives the choice (deferral or not) since the information is congruent with the decision to be made (Laran, 2010). Based on this, we consider that our scenario may induce the individual to reflect about self-controlled past decisions (e.g. work), which could enable him/her to take an indulgent decision (Laran, 2010) in the experiment, choosing deferral under time pressure and with six alternatives. Therefore, we suggest to follow this study with the manipulation of the type of information prime in the subject, expecting that no differences will be found between two and six alternatives under time pressure.

Additionally, the type of decision (in this case, the opportunity to choose a therapist) may influence the interaction between time pressure and choice overload, and then have an impact on the choice deferral. So, a hedonic set choice may be more attractive and the effects of time pressure suppress the effects of choice overload, while an instrumental one may be more influenced by the choice overload effects. Hence we suggest that future studies manipulate the type of decision and the type of product or service involved in the choice set.

Images of Attractive Women Make Young Females Behave Virtuously

Xiuping Li, National University of Singapore, Singapore

Meng Zhang, Chinese University of Hong Kong, China

Images of sexy women are ubiquitous in daily life. Prior research has focused on the negative effect of these stimuli on other women. For example, women engaging in upward social comparison with images of physically more attractive women might demonstrate a lower level of self-satisfaction and a higher rate of self-destructive behavior, such as an eating disorder (Grogan, 2008; Cattarin et al. 2000). In this paper, we test how such kinds of stimuli would affect females' social interaction. Drawing on prior research which shows that the positive relationship between physical attractiveness and social popularity is a strong and internalized belief for women (Brouwers, 1990; Diener, Wolsic, and Fujita 1995), we propose that exposure to pictures of attractive women leads other women to behave more pro-socially in unrelated tasks. This might occur for two reasons. First, when physical attractiveness, as a source of gaining favorable social impressions and acceptance by others, is under threat from the sight of images of ideally-shaped women, other women may become more motivated to gain such favorable impressions by engaging in desirable behavior. This is consistent with the view of self-affirmation theory (Liu and Steele, 1986), which proposes that when one's integrity or adequacy is being challenged, one will strive to "protect" it by employing other means of achieving integrity or adequacy. Second, the presence of attractive women may prime a motivation to gain social popularity due to the strong association between the two concepts for females. We investigated our predictions in three experiments.

EXPERIMENT 1: GREEN PRODUCT CHOICE

All participants were college female students aged from 18 to 24 recruited from a large university in Asia. Experiment 1 (N = 87) examined participants' choices of green products. Participants were randomly assigned to three conditions (sexy women, landscape, and baseline). In the first two conditions, they were asked to select the best picture out of eight that they thought fit for the cover of either a *fashion* magazine (sexy women condition) or a *travel* magazine (landscape condition). All participants were then asked to indicate their preference of battery brand from a choice of two. Brand A was described as "lasting for longer hours" and brand B as "being the most environmentally friendly." The prices were the same. As predicted, participants in the attractive women condition were more likely to select brand B (53%) than those in the other two conditions (16% for baseline and 28% for landscape condition, χ^2 (1, N = 87) = 9.17, $p < .01$). The other two conditions did not differ (χ^2 (1, N = 57) = 1.20, $p = .27$).

EXPERIMENT 2: PROSOCIAL BEHAVIOR

Experiment 2 (N = 132) examined whether the changes in women's preference for green products were merely driven by viewing "human pictures", which could have heighted concern about social values. We included a condition in which some participants viewed pictures of average-looking women. The participants were randomly assigned into three picture conditions. The conditions of attractive women and landscapes employed the same set of pictures as in experiment 1, while in the average-looking women condition, participants were asked to select a picture of an average-looking woman to appear on the cover of a *life* magazine. Pretesting showed that the pictures of average-looking women were evaluated as less attractive than those of sexy women (N = 60; $p < .001$).

Afterwards, participants were asked to play nine decomposed games in which they needed to allocate points between themselves and a stranger. These games are a widely used technique for measuring social value orientation (Van Lange et al.1997). Based on the established criteria, participants were categorized as *pro-socials* if they chose six or more "pro-social options" (maximizing a stranger's welfare). As predicted, after viewing pictures of landscapes or average-looking women, 26% and 30% of the participants were *prosocials* ($p = .69$). However, after viewing pictures of attractive women, the percentage of *prosocials* significantly increased to 51% (χ^2s > 4.13, ps < .05).

EXPERIMENT 3: ADVERTISEMENT COPY AND PURCHASE INTENTION

Experiment 3 (N=105) had a 2 (pictures: attractive women or landscapes) × 2 (ad frame: self-benefit or other-benefit) between-subject design. After selecting the picture, participants viewed an advertisement for a new vacuum cleaner. The two advertisement frames differed only in the taglines. In the *self-benefit* condition, the tagline read "Great News for Your Ears," whereas in the *other-benefit* condition, it read "Great News for Your Neighbor's Ears." The participants were asked to indicate their intention to buy this product if they were shopping for a new vacuum cleaner on a scale ranging from 1 (not likely at all) to 7 (very likely).

As predicted, an interaction was observed ($F(1, 101) = 5.75$, $p < .05$). After viewing the pictures of landscapes, the participants indicated a higher intention to buy when the advertisement emphasized benefit to the self rather than others ($M = 5.28$ vs. 4.23; $F(1, 101) = 8.23$, $p < .01$). However, after viewing pictures of attractive women, participants' preference for the other-benefit advertisement increased; there were no differences between the two advertisement conditions ($M = 5.20$ vs. 5.42; $p = .59$).

Taken together, the results of three experiments support our prediction that exposure to pictures of attractive women as those portrayed in mass media will enhance other women's pro-social behavior in unrelated tasks. These results are interesting and worth future investigation. For instance, responses of women from different demographic groups should be explored.

My Heart Longs for More: The Role of Emotions in Assortment Size Preferences

Yangjie Gu, London Business School, UK
Aylin Aydinli, London Business School, UK

Past research has documented the factors that influence consumer choice among assortments, such as the decision flexibility (McAlister and Pessemier 1982), the probability of a match between consumers' preferences and the available alternatives (Lancaster 1990), availability of ideal point (Chernev 2003), the anticipated cognitive effort in making a choice (Huffman and Kahn 1998) and the nature of decision process (Chernev 2006). This research has mainly focused on the cognitive processes used in the construction of assortment size preferences.

In this paper, we investigate the role of emotions in influencing consumers' assortment-size preferences. In particular, we explore whether decisions based on affective versus cognitive processes may influence preferences for assortment size. Prior research has shown that emotional system is holistic (Epstein 1994). Accordingly, we argue that while evaluating the assortment, people who engage in such holistic processing may focus more on judging the overall features of the choice set. Research has shown that individuals who perform global evaluations favour high variety (Ratner, Kahn and Kahnman 1999). Compared to smaller assortments, larger assortments may therefore provide greater "fit" to the desire for more variety. Hence, we argue that people who make feeling-based choices would be more satisfied with a large assortment than a small assortment.

In contrast, people who are more likely to engage in cognitive processing may experience less "fit" from the large assortment compared to people who engage in affective processing. As a consequence, the difference in preference for large versus smaller assortment is mitigated when people are making reason-based choices. The predicted effect of different types of processing strategies on preference for large assortments versus smaller assortments was tested in three studies by using both individual difference measure and indirect manipulation of likelihood of reliance on feelings.

In study 1, we provided participants a scenario where they were asked to consider purchasing a DVD at an entertainment store that either provided a selection of 24 movies (small-set condition) or a selection of 60 movies (large-set condition). We measured (1) their satisfaction with the assortment and (2) their dispositional tendency to rely on their feelings as opposed to their reason and logic by using the 10-item version of the Rational-Experiential Inventory (Epstein et al. 1996). As hypothesized, for participants who are inclined to adopt affective thinking styles, those in the large-set condition were more satisfied with their assortment than those in the small-set condition. Conversely, this difference in satisfaction was not significant for those who adopted cognitive processing.

Study 2 was designed to replicate the effect found in Study 1 by manipulating the degree of reliance on affective processing. This study was a 2 (assortments size: small vs. large) x 2 (cognitive load: high vs. low) between-subjects design. We provided participants a scenario in which they were asked to select a coffee for their friend from either a selection of 12 options (small-set condition) or a selection of 36 options (large-set condition). In order to induce different degrees of reliance on affective system, we used the cognitive load manipulation (Shiv and Fedorikhin 1999), where participants were asked to memorize either a 2-digit code (low-load condition), or a 10-digit code (high-load condition) and to reproduce the code at the end of the study. Prior research has demonstrated that choice under cognitive load limits cognitive capacity, thus generating a greater degree of reliance on affective system than choice under low cognitive load (Lieberman et al. 2002). Accordingly, we predicted that participants who memorized 10-digit (vs. 2-digit) code are likely to rely more on their affective system while making decisions. Consistent with our hypothesis, when their cognitive capacities were constrained and therefore had to rely on affective system, participants in the large-set condition were more satisfied with the selection of coffees than those in the small-set condition. However, this difference in satisfaction was not significant for low-load participants who relied on affective system less.

Study 3 was designed in order to test the underlying mechanism, as well as to replicate the effect demonstrated in Study 1 and Study 2. This study was a 2 (assortments size: small vs. large) x 2 (cognitive load: high vs. low) between-subjects design. Similar to Study 2, reliance on feelings was operationalized by manipulating participants' cognitive capacities. Participants were asked to select a snack for their friend either from a selection of 36 snacks (large-set condition) or a selection of 12 snacks (small-set condition). At the end of the study, participants answered some questions about (1) their satisfaction with the assortments they were given; and (2) desire for variety. Replicating the previous findings, the results showed that high-load participants who were confronted with large assortments were more satisfied with their snack selection than those who were confronted with smaller assortments. Mediation analysis showed that the desire for variety mediates the effect of the choice-set size on satisfaction with the selection, in the context of making either feeling-based or reason-based choices.

To summarize, we found that the reliance on affective processes boosts individuals' preference for larger assortments as opposed to smaller assortments. However, this difference in preferences is mitigated when individuals rely on cognitive processes. Study 1 and Study

2 have demonstrated the main effect. Study 3 has provided the process evidence: A large assortment provides a better "fit" to the desire for variety seeking that is triggered by the emotional processing, thereby inducing greater satisfaction, compared to a smaller assortment.

Dispositional Greed: Scale Development and Validation

Goedele Krekels, Department of Marketing, Ghent University, Belgium
Mario Pandelaere, Department of Marketing, Ghent University, Belgium
Bert Weijters, Department of Marketing & Sales, Vlerick Leuven Gent Management School

BACKGROUND AND PURPOSE

Greed is often invoked as an explanation for non-cooperative behavior in economic games (Stanley & Ume, 1998), as a driving force in resource exploitation (Ludwig et al, 1993) and is considered as intrinsic in a materialistic lifestyle (Belk, 1985). Despite this view of greed as a fundamental motive, no empirical research has been conducted to investigate causes and consequences of greed. Related to this, it is not clear why people differ in how greedy they are. To investigate these issues, a measure for dispositional greed - or greed as an individual behavior caused by internal characteristics - is develop to investigate the extent to which various factors covary with greed.

We first engaged in a thorough review of the philosophical and psychological literature concerning greed and conducted focus group research to identify different associations with 'greed' that may serve as the foundation for the development and individual difference measure of greed. In a second step an initial item pool of 60 items was generated based on theoretical assumptions, on operationalizations of theoretically related constructs in previous studies, like materialism (Richins and Dawson, 1992), envy (Belk, 1995) and greed avoidance (Lee and Ashton, 2004), and on population sampling, thus enhancing face validity. Furthermore, the response format was determined based on response tendencies and social desirability literature. The item pool and response format were both judged by laypersons for face and content validity, and the response format was assessed by a measurement expert. Moreover, the scale items and question wording were checked by a professional copy editor to ensure wording clarity, wording redundancy and correct meaning of the items. This resulted in an initial item pool of 60 questions attributed to five latent dimensions, of which three were highly related. These dimensions were: wanting more than is merely needed; insatiability; joy and pleasure from owning much; greed for status, wealth and power; and the use of ethically questionable methods to gain more.

METHOD

Pilot testing was used as an item-trimming procedure and to obtain initial estimates of reliability and validity. Given that the scale will be administered to further samples for refinement, a pilot study can reduce the number of items that do not meet certain psychometric criteria in an initial pool to a more manageable number. Also, items can be assessed initially for internal consistency, means, variances, average inter-item correlation and factor structure. Therefore, as part of a bigger questionnaire, the greed scale was administered among 400 Caucasian Americans (200 males, M age = 44.5, SD = 12.4).

RESULTS

An exploratory factor analysis was conducted for trimming and retaining items for the final scale. This EFA was used to reveal items that load poorly in terms of magnitude on an intended factor or load highly on more than one factor. The useful sample of this pilot study was 318. Factor interpretation took all items into account with loadings greater than 0.35. The requirements for the measures of sampling adequacy were met: KMO was 0.884 and Bartlett's Test of Sphericity was highly significant at p < 0.001. Items which violated the criteria of anti-image correlations greater than 0.5, high inter-item correlations through item-wording redundancy, high cross loadings on different factors or low factor loadings were eliminated from the factor solution. The cumulative percentage of total variance explained by the final factor solution was 63%. Three factors were retained: insatiability, materialistic greed and unethical greed, measured by 10, 15 and 7 items respectively and with Cronbach's Alphas of 0.89, 0.83 and 0.78, respectively.

On this refined item pool, an initial confirmatory factor analysis was conducted. Bearing in mind that more studies have to be executed before finalizing the scale, an initial test of internal consistency and validity was deemed useful as a detection of initial items that may threaten the dimensionality of the scale. The factor structure derived from the EFA and from theory showed a manageable initial fit. After deletion of items with highly correlated residual errors or low squared multiple correlations the model had a decent fit: the χ^2/Df ratio was 1.997, the Goodness-of-fit index was 0.89, the Non Normed Fit Index was 0.96 and the Standardized RMR was 0.056. The Root Mean Square Approximation was only 0.059 but the threshold of 0.05 fell within the 90% confidence interval and had an upper confidence interval limit of 0.067. Discriminant analysis showed that all three greed constructs were significantly different and they had adequate composite reliability indices: 0.84 (insatiability, 7 items), 0.87 (materialistic greed, 10 items) and 0.79 (unethical greed, 5 items), respectively.

RELEVANCE

This model still has to be tested profoundly through further studies on several samples of relevant populations and additional item analysis and estimates of validity across studies have to be executed. Nonetheless, this initial study shows that this scale should be reliable and valid. Next the scale will be used to gain insight in greed. First, more research will be executed investigating what it means to be greedy, why people differ in how greedy they are, and how the concept of greed is linked to other psychological traits such as materialism, egoism and individualism. Second, when we have a better understanding of the effects and motives for greed, experiments will be set up to gain further insight into the nature of greed and to see how greed affects economic decisions. Specifically we will explore whether greed necessarily leads to uncooperative decision making in economic games, and if so, how these effects differ from those due to (anticipated) envy.

Why Does Guilt Lead to Self-punishment?
A Deterrence Account

Liang Song, National University of Singapore, Singapore
Xiuping Li, National University of Singapore, Singapore
Gita Venkataramani Johar, Columbia University, USA

The self-punishment triggered by the feeling of guilt has been documented in the literature. For example, it has been found that participants who cheated in an earlier task tended to impose a higher intensity of electronic shock to themselves later in an unrelated task (Wallington 1973). Similarly, Nelissen and Zeelenberg (2009) manipulated guilt via fairness concern and found that people in the guilt condition tended to allocate more penalty points to themselves later on. However, seeking unpleasant experience voluntarily seems to contradict with the hedonistic assumptions (e.g., seeking pleasure but avoiding pain), and such a behavior has been explained with the motivation to reduce guilt feelings via self-punishment. In other words, it has been suggested that people carry out the "eye for an eye" philosophy even for their own wrongdoings and want to balance out the wrong for which they felt responsible by punishing themselves. Self-punishment thus is predicted to restore moral balance and resolve the negative experience of guilt (Lindsay-Hartz, De Rivera, and Mascolo 1995). This view focuses on the affect-regulatory function of self-punishment.

However, we propose that people can have the intention to "prolong" their negative experience via self-punishment to protect the goal that they have failed (which elicits guilt). This view focuses on the strategic motivational function of guilt and is referred to as the "deterrence" account.

The position that self-punishment is viewed as a motivational device for future successes is consistent with the "feeling-is-for-doing" approach (Zeelenberg and Pieters 2006). According to this approach, emotion facilitates behavior that is aimed to address the concern reflected in an emotion. As guilt, a self-conscious emotion, arises when one's behavior violates norms or goals that guide our behavior, it will be associated with an unsatisfied goal when such as an emotion is experienced (e.g., Berndsen et al. 2004). In most situations, people do not have opportunities to satisfy the goal. Alternatively, they might be in a mind of seeking ways to "protect" the failed goals by strategically choosing to stay in negative states. We argue that self-punishment may occur as a way to make the failed goal more likely to be achieved in the future.

If as we argue that self-punishment (e.g., forgoing pleasure experience) is a strategic behavior to protect one's goal, those who experience guilt should be more likely to demonstrate a tendency to engage in self-punishing behavior when and only when participants are mo-

tivated to achieve the failed goal. Thus, we will find more self-punishing behavior when participants are persistent with their goals (Study 1), when the failed goal is more accessible in their mind when they make decisions (Study 2), or when they believe that self-punishment is useful in achieving their goals (Study 3).

In study 1, goal persistence was primed with a "sentence unscrambling task", and guilt was elicited with a recall task. All participants recalled an experience where they did not spend their own money prudently and felt responsible for their decisions. After that, self-punishment was assessed with a "news reading task" where participants chose one piece of news among two: one about a baby who died because of child abuse, the other about how to take an enjoyable vacation. As predicted, when experiencing guilt, participants who were persistent with their goals were more likely to pick up the sad news than participants who were less persistent with their goals (72.2% vs. 38.9%, $p < .05$).

Study 2 extended the findings of Study 1 in three aspects. First, a different goal violation scenario was employed to elicit guilt: failure in academic performance. Second, rather than goal persistence, participants' chronic achievement motivation was measured and used as the moderator (Hart and Albarracín 2009). Third, self-punishment was measured more directly. Participants indicated the amount of penalty they wanted to allocate to themselves for giving a wrong guess. Supporting the "deterrence" account, guilty participants allocated significantly more penalty points to themselves than did non-guilty participants only when chronic achievement motivation was high (2.81 vs. 1.45, $p = .001$), but not when it was low (1.24 vs. 1.59, $p = .373$).

Study 3 further supported the "deterrence" account by showing the moderating role of individual beliefs regarding whether self-punishment is a good way for goal achievement. It found that participants were more willing to forgo pleasant experiences in response to guilt (than non-guilt) only when they regarded self-punishment as useful in achieving their goals. Belief regarding the instrumentality of self-punishment was assessed with 3 items (e.g., "Self-punishment for one's goal failure makes one remember the failed goal better"; Cronbach's $\alpha = 0.77$). Guilt was manipulated as in study 2, and self-punishment was assessed with two scenario questions (e.g. forgoing a coupon of dinning at a five-star restaurant, accepting a concert ticket from a close friend). Results hold for both combined and separate responses.

Overall, this research added to the growing body of research on self-conscious emotions by looking at the strategic motivational function of guilt.

Individualism, Collectivism, and Goal-Oriented Saving

Zhenfeng Ma, University of Ontario Institute of Technology, Canada
Terry Wu, University of Ontario Institute of Technology, Canada
Zhiyong Yang, University of Texas, USA
Tamotsu Nakamura, Kobe University, Japan

Domestic savings rate in the United States is persistently lower than that in some East Asian countries such as Japan. The United States and East Asia also differ markedly on an important cultural dimension, namely individualism (vs. collectivism). The United States is characterized by higher individualism and lower collectivism than are East Asian countries (Hofstede 1980). It may be tempting to posit that individualism is associated with lower propensity to save than is collectivism. In this research, we show that chronically salient or situationally primed individualism is actually associated with a higher propensity for goal-oriented saving than is collectivism, provided that the saving is for self-enhancing rather than self-indulging purposes.

Hypotheses. People often save money for a specific purpose. We recognize two distinct types of saving in terms of their purposes. The first type involves saving for self-enhancement, such as saving for a better education or career. The other type relates to saving for self-indulgence, such as saving for a vacation or a luxury car. The dichotomy between the self-enhancing and self-indulging goals is akin to the dichotomy between virtues and vices (Dhar and Wertenbroch 2000).

We expect that people high in individualist value (the "individualists") have a higher propensity to save for self-enhancing purposes than do those high in collectivist value ("collectivists"). Such differential propensity to save for self-enhancement can be explained by the difference in self-orientation associated with the individualists versus the collectivists. The individualists define the self as an autonomous entity separated from others, whereas the collectivists view the self as part of a social network and connected with others (Markus and Kitayama 1991). Because of their orientation toward the self, the individualists will attach more importance to goals that hold high stakes for self-enhancement (Markus and Kitayama 1991). Consequently, the individualists will be motivated to save for self-enhancing goals, especially when saving is the only means for achieving such goals. By contrast, the collectivists insist on self-others connection and show pervasive attentiveness to the relevant others. Research has shown that the perception of an extended social network can serve as a psychological "cush-

ion" against financial risks (but not other types of risks such as physical risks) (Hsee and Weber 1999; Mandel 2003). Because of this cushion effect, the collectivists will be more tolerant of financial uncertainties and consequently are less motivated to save for personally significant goals compared with the individualists. However, the individualists and the collectivists will not differ in their propensity to save for self-indulging purposes. This is because self-indulgence is not more pertinent to the goal orientation of the individualists versus the collectivists and is thus unlike to induce differential propensity to save between the individualists and the collectivists.

H1*: The individualists have a higher propensity to save for self-enhancing purposes than do the collectivists, whereas the individualists and the collectivists do not differ in their propensity to save for self-indulging purposes.*

People often need to resist myopic temptations to prematurely dip into their savings in order to fulfill their savings plan. Because the individualists have a strong motivation to fulfill their savings plan for self-enhancing purposes, they will be less likely to yield to myopic temptations when following through such a plan than will the collectivists. However, the individualists and the collectivists will not differ in their ability to resist myopic temptations when saving for self-indulging purposes, because the motivation to save for such purposes does not differ between the two groups of individuals in the first place.

H2*: The individualists have a higher propensity to resist myopic temptations than do the collectivists when saving for self-enhancing purposes; the individualists and the collectivists do not differ in their propensity to resist myopic temptations when saving for self-indulging purposes.*

METHODS AND RESULTS

The hypotheses were tested through three experiments, in which individualism (collectivism) was manipulated through either situational prime or culture. In experiment 1, we manipulated individualism (vs. collectivism) through situational prime. The experiment features a 2 (prime: individualism vs. collectivism) × 2 (purpose of saving: self-enhancing vs. self-indulging) design. Participants were 190 undergraduate students in a Canadian university. We first primed individualist or collectivist values using a scenario about a tennis match (Aaker and Lee 2001). Participants then imagined a scenario in which they made decisions on how much to save out of a fixed amount of personal income for an anticipated job transition (self-enhancement) or for a vacation (self-indulgence). Consistent with hypothesis 1, the individualists saved more than the collectivists for job transition ($p < .05$), whereas the collectivists saved directionally more than the individualists for a vacation. The same findings were replicated in experiment 2, using different prime for individualism (collectivism) (Trafimow, Triandis, and Goto 1991) and different stimuli for purpose of saving (education vs. vacation).

Experiment 3 is a cross-country study, which features a 2 (country: US vs. Japan) × 2 (purpose of saving: self-enhancing vs. self-indulging) design. Participants were 300 undergraduate students from a US university and 300 undergraduate students from a Japanese university. Purpose of saving was manipulated as previously. After indicating the amount of savings, participants imagined a scenario in which their most favourite musician has come to town to stage a live concert. Temptation for immediate gratification was measured in terms of the amount of money they would spend out of their savings to buy a concert ticket. Consistent with hypothesis 1, the US participants reported a higher savings rate than did their Japanese counterparts for job transition ($p < .05$), but the two groups did not differ in their savings for the vacation. Furthermore, the US participants showed a higher tendency to resist myopic temptation than did the Japanese participants when saving for self-enhancing purposes, as indicated by the lower amount of money they spent on the concert ticket ($p < .05$). However, the tendency to resist temptation did not differ between the US and the Japanese participants when saving for a vacation. Thus, hypothesis 2 was supported.

DISCUSSION

Our findings show that individualism (vs. collectivism) promotes goal-oriented saving behavior, provided that the saving is for self-enhancing purposes. So far, we have focused on decision contexts where the saving is for relatively short-term goals and saving is the only means of achieving the goals. In the next step, we will investigate whether the individualists' relatively high propensity to save for self-enhancement will persist when alternative means for obtaining financial resources (e.g., borrowing) is available, or when the saving is for long-term goals.

Social Stratification and Luxury Consumption Value:
Classifying Complaint Types of Korean Luxury Consumers

Su Yeon Kim, Yonsei University, South Korea
Ae-Ran Koh, Yonsei University, South Korea

This study was conducted in reference to two intertwining socio-cultural phenomena in Korea; (a) various and stratified motivational values of luxury clothing consumptions and (b) diversified types of post-purchase complaints against luxury clothing. Consumers' high/low levels of cultural and economic capitals were applied as the major determinants of perceived luxury consumption value. Since there have been limited studies regarding distinguishing complaint types based on consumer's economic & cultural class, this study might present a widen approach to conceptualize social value-oriented complaining types.

Complaint types of Korean consumers are various due to the different values they impose on luxury, and after all, due to the disparity of culture they are involved. The nation could not have had long-lasting dominant culture since 1910. After undergoing Japanese occupations and Korean War, there had been sudden social change through democratic labor movements. The rapid economic development gave rise to the sudden wealth, and barriers to the excess of luxury fashion products have been lowered due to the increase of wealth-creation opportunities in a variety of social statuses.

Social stratification refers to the prevailing structure of inequality within a society, and the relationship between social class and consumption value is the subject of a debate in sociological literature. In Bourdieu(1986)'s point of view, the arrogation of distinction showing off economic power and cultural distancing is actively used by dominant social classes as a means of symbolically demonstrating their superiority. Luxury clothing functions as code allowing for social distinctions and individual's ability to determine the fashion reflects their capitals. This study adopts the two conceptual forms of capitals, economic & cultural, to analyze the antecedent factors of luxury consumers' complaining propensity.

The major purpose of this qualitative study is to develop a conceptual framework of categorizing the complaint types of economically and culturally stratified Korean luxury consumers. To allocate individual consumers by stratus, the researcher originated 2X2 matrix utilizing the distinctive 2 levels of economic and cultural capitals that Bourdieu (1986) articulated as the major basis of social classes. Thus, divided 4 social groups are characterized as luxury clothing consumers (1) with higher level of economic and cultural capitals, (2) with higher economic capital but lower cultural capital, (3) with lower economic capital but higher cultural capital, and (4) with lower economic and cultural capitals.

Additional purpose of this ethnographic research is to establish 'capital scales' to measure high/low levels of economic and cultural capitals in Korean society. The standards for high/low levels of economic capital will be partially set up by the monthly income figures of the affluent and the middle-income classes released by The Korea National Statistical Office (2009) imposing the lower limit of $9,023 for group 1 and 2, $3,176 for group 3 and 4. Origin of wealth and means of wealth accumulation will be further investigated through in-depth interviews, by checking if they inherited a fortune or earned sudden money.

The high/low levels of cultural capital will be established through observing respondents' embodied state of cultural capital, i.e., opinion, attitude, tone of voice, typical body- movements, taste in culture (food, clothing, music, painting, exhibition, social activities), and mannerism. Bourdieu(1986)'s concept of legitimate cultural taste, e.g., frequency of attending culture exhibition, activities, and purchasing objectified state of cultural goods, is to be modified to fit Korean cultural contexts.

This study used grounded theory methodology to explore Korean luxury consumers' hidden and fundamental complaining intentions, which were constructed by socially symbolic luxury consumption values based on the hierarchically divided social contexts. Respondents of this study are Korean luxury clothing complainers who are clearly identified as each of the 4 class groups. Since this research is in the working paper stage, up to the present, 24 cases were interviewed using a snow-ball sampling. Observations and in-depth interviews were carried out during four months from March, 2010 to June, 2011.

The classified 4 groups were named as (1) 'high class elite', (2) 'parvenus' (3) 'low income cultural elite', and (4) 'low class luxury seeker'. Luxury consumption values for each group were characterized as (1) 'individuality': seeking differentiated clothing for individual distinction, (2) 'conspicuousness': having preference on well-recognized luxury brands, (3) 'hedonism': exploring various taste-suiting clothing for self-satisfaction, and (4) 'conformity': causing excessive consumption to meet ideal group norms. These 4 types of luxury consumption value distinctively influenced each group's complaint motivations respectively, such as (1) uniqueness of design, special services, (2) social recognitions, (3) design-related dissatisfaction, (4) exchange, refunds, and compensations. Complaint types of 4 groups were determined by their motivations, and classified as (1) expressing their opinion mildly on their ways to shop (2) direct aggressive voice complaint (3) complaint with preparations, taking plans to do actions, (4) website posting, negative word of mouth, and sabotage.

Group 1 with high cultural capitals chose to complain mildly, and they could successfully communicate their dissatisfactions. Whereas, group 2 with less cultural capital, with poorly restrained manners in complaining, failed delivering what she demanded but expressing her anger. Both group 1 and 3, with high cultural capital asked for unique and better design. While group 1 complained based on their beliefs regarding the brand's artistic accomplishment, group 3 required compensations in return to their design-related dissatisfactions. Group 3's demands for the financial compensations were due to their lower level of economic capitals which leads to their high sensitiveness on price.

The level of economic capitals, however, was not the direct indicator of the level of price consciousness. Group 2, who accumulated sudden wealth and spend far more money on luxury clothing than other groups, seemed even more price sensitive than the other groups with less economic capitals, and group 4, who perceived relatively lower subjective value of money, refused to voice out. Instead, Group 1,2, and 3, who held relatively higher capitals than group 4 tended to exhibit greater self-confidence, and they were more willing to take risks and had positive attitude toward complaining.

INTRODUCTION AND CONCEPTUAL FRAMEWORK

New product concepts are often the result of combining features of two or more existing product concepts into one product. In most combinations one of the parent products can be considered the 'base' to which another product or part of another product (e.g., a single feature) is added. The present research examines new products where a single new feature is added to a base product. Building on Gill (2008) we propose that the fit between a given base product and the newly added feature can be better or worse, depending on consumers' consumption goals. Consumption goals are defined as benefits that consumers seek in a consumption context (Gill 2008; Huffman and Houston 1993). They may differ according to dimensions such as (1) hedonic–utilitarian (i.e., whether a product offers experiential or functional benefits) and (2) feature relatedness (i.e., whether or not a new feature offers benefits related to a product's core). While the effect of fit between the hedonic versus utilitarian consumption goals of the base and the added new feature has been examined previously (e.g., Gill 2008), we investigate the role of feature relatedness in determining the value of new product concepts.

Gill (2008) showed that the nature of the fit in the hedonic versus utilitarian consumption goals of the base and the new feature can have a differential effect on overall incremental product value. Specifically that for products with a utilitarian base, adding an incongruent hedonic feature improved overall product value perceptions more than adding a congruent utilitarian feature. In contrast, for products with a hedonic base, adding an incongruent utilitarian feature improved overall product value much less than adding a congruent hedonic feature. In other words, fit/congruence of consumption goals of the added feature is more valuable for a hedonic base product, but incongruence is more valuable for a utilitarian base product.

In the present research we investigate the second aspect of fit of consumption goals: namely, the extent to which the added new feature is *related* vs. *unrelated* to the base product's core functionality. Consumption goals are *related* when a newly added feature enhances the core benefits in the base product (e.g., an improved battery increases the talk time on a cell phone). Consumption goals are *unrelated* when the new feature does not influence the core benefits in the base (e.g., a scratch-resistant screen does not affect the talk time of a cell phone). We propose that increases in product value of a base with an added new feature can be explained more accurately by also accounting for the effect of feature relatedness in addition to the fit on hedonic/utilitarian goals. More specifically, we predict that adding a new feature that is related to the core benefits of the base product will increase overall incremental value more than adding a new feature that is unrelated. Additionally, we expect that feature relatedness would explain changes in incremental value over and above those based on the fit between the hedonic versus utilitarian consumption goals of the new feature and the base.

METHOD AND RESULTS

We tested our predictions in a 2 (type of base: hedonic vs. utilitarian) x 2 (type of new feature: hedonic vs. utilitarian) x 2 (new feature relatedness: related vs. unrelated) factorial design. Two hundred and ninety-eight students from a mid-sized University participated in the experiments. All stimuli were pretested in order to match them as closely as possible with the proposed factor levels. In each condition participants read a scenario in which a new feature was added to either a hedonic base (mp3 player) or a utilitarian base (business smartphone). The newly added feature was either hedonic or utilitarian and (in addition) either related or unrelated to the product core feature/functionality. Overall incremental value (OIV) and incremental willingness to spend money (IWTSM) served as our main dependent variables (both measured on 7-point bipolar scales). The data was analyzed by means of two factorial ANOVAs for each dependent variable. We found a significant main effect of feature relatedness for both OIV, $F(1, 290) = 6.00$, $p = .02$, $\eta_p^2 = .02$, and IWTSM, $F(1, 291) = 4.94$, $p = .03$, $\eta_p^2 = .02$. That is, related new features increased both OIV and IWTSM more compared to unrelated features. In addition, we obtained a significant

main effect of type of new feature (hedonic/utilitarian) for OIV, $F (1, 290) = 4.33$, $p = .04$, $\eta_p^2 = .02$, but not for IWTSM, $F (1, 291) = .95$, $p = .33$. OIV increased more when a hedonic (vs. utilitarian) new feature was added, however there were no differences in terms of IWTSM. Interestingly, there was a significant interaction for OIV between feature relatedness and type of base product, $F (1, 290) = 8.85$, $p < .01$, $\eta_p^2 = .03$, and between feature relatedness and type of new feature, $F (1, 290) = 6.78$, $p = .01$, $\eta_p^2 = .02$. The first interaction showed that related new features (vs. unrelated ones) improved OIV for the hedonic but not for the utilitarian base product. The second interaction showed that relatedness improved OIV when the added new feature was utilitarian but not so when it was hedonic (for hedonic features the OIV remained high irrespective of relatedness).

CONCLUSIONS

Our results show that both related (as opposed to unrelated) and hedonic (as opposed to utilitarian) new features contribute to overall incremental product value. From a company's perspective, adding a new feature that is utilitarian (as opposed to hedonic) is least advantageous. However, if a new utilitarian feature is added, it should be related to a product's core feature/functionality. In short: hedonic-new features lead to an increase in product value, even when unrelated; however, utilitarian new features must always be related to yield a similar increase in product value.

When Would Extroversion in Me Come Out?
Personality Paradox in Different Contexts

Alisara Charinsarn, JDBA Program, Thammasat University, Thailand
Kritsadarat Wattanasuwan, Thammasat University, Thailand

Why some quiet people become sociable when they are in the online social network? Why some shy people become talkative when they are with close friends and family? If this is the case, these personality traits such as being introvert or extrovert are not intrinsic, sustainable, over time, and across different situations like what the traditional personality trait theory stated. How could this be possible?

The situation affects how people behave (Belk 1975). The big five personality can be variant across situations (Fennis et al. 2005). People can have multiple self-concepts across time (Kelly and Rodriguez 2006).

The Interactional Personality model (Lewin 1935) believes that the personality or the behavior we can observe is a result of the interaction between the person him/herself and the situation. This is in line with what Wattanasuwan and Elliott (1999) explain that the life history of a person and the social situation together form a meaning of a person's experience (Wattanasuwan and Elliott 1999). Zayas et al. (2002) mentioned that "human behaviors commonly attributed to the individual are inseparable from the context in which they occur: Some behaviors may not be meaningful or even observable without placing individuals within contexts, particularly those that involve interpersonal relations" (Zayas et al. 2002) (p.852).

One important and interesting aspect is that the other person we interact with is a type of situation (Zayas et al., 2002). Goffmann wrote that people change in the society because of the presence of another person (Goffman 1956).

In this paper, we focus on the introvert/extrovert personality paradox when interacting with different situations.

Introvert is defined as "reserved, quiet, shy, and distant" (Karkoulian et al. 2009)(p.74). Manning and Ray (1993) did a research on shyness and proposed that shyness is situational. It can be activated or deactivated by situation (Manning and Ray 1993).

Extrovert is defined as associable, active, talkative, person-oriented, optimistic, fun-loving and affectionate (McCrae and Costa 1987). Interestingly, prior research found that there is an association between the latent trait and extroversion (Maij-de Meij et al. 2005).

We believe that the latent extrovert trait will become dominant when a person perceives that the situation is secure, that is, when it is lack of 'perceived subjective discomfort (arises from interacting with the situation)'.

'Subjective discomfort' is a type of 'interaction anxiety' or 'contingent interaction' (Pilkonis, 1977). In other words, whether this discomfort will occur or not depends on the situation. Pilkonis (1977) explained that people speak less and try to avoid the situation when they feel anxious about the interaction.

'Fear of negative evaluation' is a kind of subjective discomfort (Pilkonis 1977) which is in line with Shepperd and Arkin (1990) that how an anxious person present him/herself is not to seek approval, but to 'avoid disapproval' (Shepperd and Arkin 1990).

People who are generally shy or introvert might lack of trust in the social interaction, and therefore, perceive the subjective risk more than extrovert people (Manning and Ray 1993). It is possible that introvert could have higher subjective risk and is more selective in whom to reveal information (Maij-de Meij et al. 2005). When people perceive that the subjective risk is higher, they are less likely to reveal information (Omarzu 2000).

The online environment is a great example of reduced subjective discomfort because it is lack of physical presence, it facilitates the sense of control, and it can be anonymous.

An introvert likes to reflect and think on one's own rather than talking and thinking with the group. Being online, one does not have to immediately respond to other person on the spot like in face-to-face context (McKenna and Bargh 2000), and therefore feels more control.

The virtual world makes it possible for people to be anonymous. When one is anonymous, one is de-individualized. As a result, the influence of self decrease while the influence of the context increase (Johnson and Downing 1979). People do not have to confine themselves

in the boundary of their real life such as their family, their responsibility, or even their self (Haraway 1991; Haraway 1997). Young et al. mentioned that anonymity helps shy people to feel safe and secure in the social interaction (Chak and Leung 2004), and therefore a comfortable arena for them to express.

Online environment is found to reduce social anxiety (McKenna and Bargh 2000). Those who are shy or have anxiety find internet an outlet that they can express, which they cannot do so in the offline world (Tosun and Lajunen 2009). The online context is an alternative playground which is like a laboratory which one can try out different personality without any risk (McKenna and Bargh 2000; Turkle 1995).

We employ the interpretive approach using both offline ethnography and online netnography. This method allows us to investigate the complex nature of human beings. The contrast online/offline context is selected as the site of study to explore the paradox personality.

Our initial findings suggested that there is dynamism between the virtual and the real world. An introvert student at school becomes extrovert in the online game. Likewise, a quiet office worker becomes an opinion leader in a political chat room.

Personality paradox is found when looking across different contexts. We seek to further explore how the online and offline world shape this personality contradiction.

Great Expectations and Charity: Studying the Effect of Unexpected Schemas on Charitable Behavior

Geetanjali Saluja, HKUST, Hong Kong
Rod Duclos, HKUST, Hong Kong

Whereas the last decade has seen more extreme adverse meteorological conditions than any comparable period before, scientists predict this trend will only worsen in years to come due to global warming. Hence, as the frequency and severity of natural disasters striking the planet are expected to rise (e.g., earthquakes, tsunamis, floods, etc), nonprofit organizations will have no choice but to increasingly turn to

the more fortunate among us to plea for help. And with the proliferation of causes, charities face today fierce competition. Indeed, in the US alone, thousands of charitable organizations are officially registered with the Internal Revenue Service (IRS) and actively vying for donors and resources. Critical for these organizations, then, is to understand *why* and *how* consumers decide to help others. The present research attempts to address this question by examining the influence of embodied cognitions (i.e., ideas, thoughts, concepts shaped by aspects of the body) on prosocial behavior. So doing, we also examine the impact of unexpected environmental influences on charitableness.

Lakoff and Johnson (1999) have proposed that concrete experiences (e.g., temperature) ground abstract concepts (e.g., affection). A study by Zhong et al. (2008) has shown that social exclusion can induce an experience of psychological coldness. Ijzerman et al. (2009) have also explored the effects of temperature on perception of social proximity. Hence, drawing on the above, we propose that feeling warm (cold) may foster (impede) one's charitable orientation.

Design & procedures. To test this proposition, we randomly assigned 94 students from a large East Asian university to one of four conditions. To manipulate body temperature, we asked participants to drink (under the pretence of a taste-test) either hot, cold, cool (i.e., room temperature) or no (i.e., control) tea before completing a series of manipulation checks. Among other things, these checks prompted participants to rate their respective beverage in terms of taste, smell, and temperature. Next, in a seemingly unrelated survey administered on behalf of the Facilities Management Office (FMO), we asked participants of all four conditions to estimate the temperature of the room in which they were as well as how hot/cold and how comfortable they felt. Lastly to control for any potential mood effect, we asked participants to complete the PANAS scales, an exhaustive measure of affect/emotions by Watson et al. (1988).

To assess charitableness, we asked participants to review an appeal from "Global Relief", an alleged charity collecting money to help the victims of a recent earthquake that struck China's Sichuan province. Vivid in nature, the advertisement featured death toll statistics (e.g., "over 100,000 killed and 1 million others homeless"), a description of the victims' needs (e.g., "food and medicine for vulnerable children and devastated families"), and the pictures of suffering victims underneath the text. The ad concluded by asking participants to visit the charity's website to make a donation.

Results. An analysis of variance and follow-up contrast analyses on our manipulation checks suggest that our manipulation was unequally successful. Indeed, whereas participants in the hot tea condition did report feeling warmer than their counterparts in the cool, cold, and control conditions, the latter three conditions did not differ from one another. Hence, participants in the cold tea condition did not feel any colder than subjects in the cool and control conditions.

Pertaining to our hypothesis, we found that participants in the cool condition (M = $155) pledged donating strikingly more than their counterparts in the hot (M = $74), cold (M = $106), and control (M = $69) conditions (F (3, 90) = 4.061, p = .009). Follow-up contrast analyses further confirmed that the latter three groups did not differ from one another.

These results are quite surprising. Indeed, whereas we expected participants in the hot tea condition to donate most, we found instead that these participants donated neither more nor less than subjects in the cold and control conditions. Rather, subjects in the cool-tea condition exhibited the most generosity toward victims of the Sichuan earthquake.

To make sense of these surprising yet very significant results, we took a closer look at our manipulation checks and proceeded by elimination. One at a time, we examined whether body temperature (i.e., how cold/hot I feel), liking of the beverage's taste, liking of the beverage's smell, personal comfort, or affect (i.e., PANAS scores) could account for our findings. Unfortunately, none of these factors provided a viable explanation.

Discussion. Drinking cool tea (as opposed to hot, cold, or no tea at all) led our participants to subsequently donate strikingly more in favor of earthquake victims. Contrary to what one might expect, this boost in charitableness cannot be readily explained by subjective feelings of body warmth or overall enjoyment of the beverage. To understand this puzzling phenomenon, follow-up experiments are now investigating the role that schemas and expectations might have played in our findings. Tea is traditionally served hot or cold/iced. Few would indeed make/ buy hot or cold tea to let it sit until it reaches room temperature before drinking it. From this simple observation, we derived the hypothesis that schema-inconsistent experiences might subsequently foster a sense of openness in consumers. Greater openness, in turn, might give way to greater empathy, compassion, and charitableness. Preliminary results from follow-up experiments seem to support this view.

This paper highlights the importance of understanding various cognitive constructs and processes, and the possible effect of these processes on charitable behavior. To our knowledge, this paper is one of the first to explore the link between schema-based expectations and prosocial behavior. Hence, for its potential contributions to both theory and practice, we believe this poster would be of interest to a wide audience at ACR.

Less is More: Positional Concerns are stronger in Inevaluable Domains

Tess Bogaerts, Ghent University, Belgium
Mario Pandelaere, Ghent University, Belgium

Positional concern is the extent to which one is concerned about one's status or position in one's reference group. To measure positional concerns, Solnick and Hemenway (1998) developed the Positional Concern Questionnaire (PCQ), in which respondents have to indicate for a number of domains which of two outcomes they would prefer. One of the options is always superior from an absolute point of view but inferior from a relative point of view (e.g. working in a company in which one earns USD 50,000 but others earn USD 60,000). The second option is superior from a relative point of view but inferior from an absolute point of view (e.g. working in a company in which one earns USD 40,000 but others earn USD 30,000). As people become more concerned about their position, they are more likely to choose the second option in which one is the better off in *relative* terms. A number of studies indicate that positional concern may vary across domains (Solnick & Hemenway, 1998, 2005). We propose that the domain differences in positional concern are due to differences in the inherent evaluability of the domains involved.

Inherent evaluability refers to whether people have an innate reference system to assess the value of an outcome (Hsee & Zhang, 2010). For instance, if people take a sip from a cup of coffee, they know immediately whether or not it is too hot because people have an innate reference system to evaluate temperature. Temperature is therefore an inherently evaluable quantity (Hsee & Zhang, 2010). In contrast, a woman who receives a diamond engagement ring may want to compare her ring to that of her friends in order to assess the love of her future spouse. Diamond value is an inherently inevaluable quantity (Hsee & Zhang, 2010) as people cannot judge how valuable a diamond is without an external reference system. We suggest that relative position is more important for inherently inevaluable domains.

The PCQ was developed to measure differences between *people* in positional concern. While some people routinely care about their position, others do not. Correspondingly, the former exhibit positional concern in a host of domains, the latter do not. The (in)evaluability framework not only allows predicting for which domains people are more likely to display positional concern, but also when people are more likely to differ from one another. We expect that most people do not care for relative position for inherently evaluable domains. So, the impact of individual differences on positional concerns should be moderated by the evaluability of the domain involved.

To test this idea, we focused on an individual difference variable that may be associated with positional concern, namely envy. Considering that envy entails a negative feeling that is triggered when others do better than oneself, envy-prone people should not want others to outperform them. In the PCQ, envy should thus be associated with the tendency to prefer a positional outcome over an absolute one.

In a first study, 400 US citizens participated in an online study in return for a participation fee. First, we used the PCQ to measure concerns regarding relative standing. To measure envy, we administered a 7-point scale (1 = strongly disagree, 7 = strongly agree) which contained 9 items (α = .61) based on the envy dimension from Belk's materialism scale (Belk, 1985; Ger & Belk, 1995). Finally, we used the AB identification survey developed by Hsee and Yang (in press) to identify whether a given domain is inherently evaluable (type A) or inherently inevaluable (type B).

To test whether domain evaluability and envy predict positional concern, we ran a multilevel logistic regression with choice of relative option as binary dependent variable. The inverse relationship between positional concerns and domain evaluability was clearly significant (B = -1.620, SD = .156, p < .001). The more a domain is inherently inevaluable, the more people prefer to be better off from a relative point of view. Moreover, results revealed a significant main effect of envy (B = .156, SD = .064, p = .014) and a significant interaction effect between envy and domain evaluability (B = -.612, SD = .205, p = .003) on positional concerns. Consistent with the hypothesis, we found that positional concerns are stronger in inherently inevaluable domains, and even more so for envy-prone people.

In a second study, we investigated what happens if people have a third option in the PCQ, in which everyone in society is equal (e.g. working in a company in which one earns USD 50,000 and others also earn USD 50,000). Another 400 US citizens participated in this second online study in return for a participation fee. Afterwards, we ran a multilevel regression with positional concern as ordinal dependent variable. Consistent with the first study, we found a significant inverse relationship between domain evaluability and the tendency to choose a positional outcome (B = -1.750, SD = .153, p < .001). Choosing the positional outcome over an absolute or an equal one is more likely if one is envious (B = .489; SD = 0,120; p < .001), envy especially predicts positional choosing in inherently inevaluable domains (B = -.463; SD = 0,184; p = .012). Taken together, we found that domain evaluability is a strong predictor of people's tendency to choose a positional outcome, and moderates the impact of individual differences in envy on positional concern.

The contribution of this article is threefold. First, it provides an explanation of the difference in positional concern across domains. Second, it shows that the (in)evaluability framework could be applied to choices people make. Third, this research contributes to a better understanding of positional concern on both an individual level and domain specific level. Consistent with an interactionist point of view, this article shows that dispositions interact with situations to shape behavior. To arrive at an even better understanding of positional concerns, additional research is being conducted to investigate the effect of domain evaluability and other dispositions on people's inclination to choose a positional outcome.

On the Question of Altruism vs. Self-Interest in Ethical Consumption, And On Why This Question Might Not Really Matter

Joachim Scholz, Queen's University, Canada
Jay M. Handelman, Queen's University, Canada

Do consumers consume ethically because they truly care for the well-being of others or out of more selfishly oriented desires to be perceived in a favorable light? Previous research has pointed towards the predominance of identity projects in anti-consumption practices (Cherrier 2009). For example, consumers boycott companies to express their individuality and for moral self-realization (Kozinets and Handelman 1998), and consumer activists construct morally superior identities (Kozinets and Handelman 2004). In these accounts, ethical behavior is presented as rooted in self-interested concerns of self-transformation or the creation of hero identities (Cherrier 2009).

Other investigations have explored self-scarifying caring dimension of consumption (Thompson 1996) and how sharing has a component of care for others (Belk 2010). Research on citizen consumerism has extended these caring orientations into non-family contexts without exploring in detail the interplay between self-interested desires for favorable identities and desires to benefit the well-being of distant others (McGinnis and Gentry 2009).

When does caring for others become self-serving through establishing a caring identity? We suggest that questions like this, which call for the disentanglement of altruistic and selfish motives, are ill-posed, since they are based on the assumption that each individual is a separated entity apart from other people (Gergen 2009). While this understanding is certainly dominant in contemporary Western culture, an alternative view of the self that is based on the assumption that everyone is connected to everyone and everything else (Capra 1996) has become more influential over recent years due to a growing awareness of the interconnections in our physical world (e.g., ecological systems, social networks; Rifkin 2009)

Rather than continuing the quest of disentangling "true altruism" from "self-interest" and the related quest of drawing boundaries between self-interest and caring for others, we argue that our understanding of ethical consumerism would be advanced by taking into account different perspectives of the self and how relationships between self and others are conceptualized (i.e., separated self vs. interconnected self). Specifically, the purpose of our research is to expose beliefs of interconnectedness in consumer activists' narratives and to explore how this worldview allows consumers to care for the wellbeing of others.

We conducted a netnography of various webpages associated with the Transition Movement (TM). Four major webpages that serve as global info and discussion hubs of the TM served as our main data source.

We found the beliefs of *interconnectedness* to be a hotly debated issue within the TM. Those who subscribed to these beliefs frequently rejected the atomistic view of individuals (e.g., "a shift in consciousness" that "gives the lie to old-paradigm notions of the isolated, competitive self") and instead saw their own well-being as dependent on and "inseparable from the well being of all the people, plants, and creatures that we affect and that affect us". Furthermore, we registered a second theme of *individual empowerment*. Based on beliefs that the current state of the world is an outcome of the cascading effects of interconnected relationships and choices, members of the TM located responsibility for the world as well as the power to change the world in everyone's personal reach (e.g., "taking responsibility for our individual power to create the world"). Such localization of responsibility was connected with an awareness to avoid vilifying others (e.g., corporations or mainstream consumers) as 'evil', in part out of a realization that the world can be changed on the level of positive, individual connections among individuals.

Our findings contribute to the ethical consumption literature by questioning the core assumptions of separated individuals when analyzing why and how people engage in caring consumption. But more broadly, our study complements and extends recent explorations of the relational self (e.g., Epp and Price 2008) by addressing the question to "what extent the self is best conceptualized as extended [...] versus part of an organic unity with others and the environment" (Belk 2010, p. 728). As we demonstrate in this research, some consumers indeed adopt the latter perspective, which has implications for why they care for others, how they relate their caring consumption to their self-interest, and how they attempt to create social change. Last, our finding that members of the TM transcend dualistic notions of 'good' versus 'evil' point towards the possibility that such dualisms may be only a structural feature of identity construction (Luedicke, Thompson, and Giesler 2010) if the self is conceptualized as separated from others, but less so when people adopt an understanding of the self as being interconnected with other people and with the natural world at large.

Artistic Stylistic Properties of Fashion Luxury Advertisements

Jennifer Zarzosa, New Mexico State University, USA
Cuauhtemoc Luna-Nevarez, New Mexico State University, USA

Visual consumption is a critical attribute of the experience economy. The visual past is critical as it influences a vocabulary of representation. Traditions of art history inform how consumers relate to the visual world, affecting advertising imagery and creative techniques (Schroeder 2002). Through sophisticated visual rhetoric, advertising images become part of a convention-based symbolic system (Scott 1994). Cultural knowledge allows for a learned system of pictorial conventions. Thus, a symbol theory of pictures is needed for complex visual consumption (McCracken 1987). Furthermore, the theory of visual literacy proposes analogical representation does not need obvious visual similarity between the image and what the image is about. Additionally, the lack of explicitness of visual syntax allows advertisers to convey persuasive messages (Messaris 1998).

Fashion photography has shifted stylistically since the 1960s due to cultural and historical changes. Specifically, style was reinterpreted in terms of the new economy. Fashion photography featured the liberated woman in many distinct images: the working girl who replaced couture with prêt-à-porter and the active girl who favored active wear to formal wear. The new rather than the well-made became preferred, thus, making innovation rather than quality signifiers of style (Bruzzi and Gibson 2000). With this change, the "look" of style, its vocabulary, its iconography, were reversed; low became high.

Fashion photography creates a historical document that captures a given period. It is a vehicle for circulating new patterns of consumption tied to evolving notions of the self. Early fashion photography created a visual fantasy to which women could aspire, and which fashion photography still pursues. Only after the art movements of surrealism, realism, and modernism was the fantasy notion challenged. Modernism influenced fashion photography with graphic and geometric styles while surrealism inspired dream-like images. Realism inspired a less formal approach where models were depicted in movement. Brutal realism portrayed images of melancholy and anxiety, using images that resembled snapshots with a glamorous setting. The School of London Style stripped the fantasies of the fashion industry and presented the reality of everyday life in a defiant anti-glamour style (Bruzzi and Gibson 2000).

The purpose of this study is to identify artistic stylistic properties of fashion luxury advertisements. The dimensions of style can be examined to evaluate brand identity-related styles by using four perceptual dimensions: complexity, representation, movement, and potency (Schmitt and Simonson 1997). The dimension of complexity places style on a continuum from simple to complex. Minimalism, on one end of the spectrum, strives for simplicity of structure and form while ornamentalism possesses complexity and multiple meanings. Representation explores the depiction of reality on a continuum of realism to abstraction. Realism is the depiction of the world of objects and human beings. Conversely, abstraction does not represent any objects in the contemporary real world. Movement is placed on a continuum from dynamic to static. The style dimension of potency refers to whether an identity comes across as loud and strong, or soft and weak.

Coherent themes provide mental anchors and reference points that are a crucial to aesthetics. The thematic stylistic property of prototypicality is the degree to which an object is representative of a category. In most cases, consumers respond more favorably to objects that are highly prototypical as they are more familiar. However, some consumers prefer novelty as seen in non- prototypical images (Veryzer and Hutchinson 1998). The postmodern thematic elements of pastiche and hyper-reality are also investigated. Pastiche refers to irony, parody, and imitation. Hyper-reality involves the loss of a sense of authenticity and the becoming real of what was originally a simulation (Brown 1995).

An exploratory content analysis approach was used to reveal how stylistic properties evolve. A pretest of eight hundred and twelve fashion luxury advertisements that advertise apparel and leather goods and accessories were sampled. *Vogue* magazine was selected as it offers high fashion accessibility while reaching one out of ten American women. September and February issues were chosen which aligns with the fall and spring collections. The sample captured ads from1995 to 2000 and 2005 to 2010 in order to compare two decades. Forty fashion luxury brands were selected from the luxury fashion brands index (Okonkwo 2007). Two students coded the fashion luxury advertisements and a coding book was included with detailed instructions and visual examples of each variable along with the code sheet.

Fashion luxury advertisements during 1995-2000 exhibited the following perceptual dimensions of style: minimalism (85%), realism (91%), static movement (86%), and soft and weak potency (86%). Interestingly, advertisements during 2005- 2010 also featured the same dimensions of style: minimalism (53%), realism (84%), static movement (76%), and soft and weak potency (68%). Currently, the artistic stylistic properties support a traditional classical visual style, which is characterized by simplicity, realism, static movement, and lack of color. However, there is an increasing trend towards the ornamental, abstract, dynamic, and loud and strong styles. The postmodern thematic stylistic properties of hyper-reality and pastiche respectively increased 30% and 10%. During 1995- 2000, 63% of ads had no or low prototypicality while 39% had no or low prototypicality during 2005-2010. Although, there was a decrease, there are still a considerable number of ads that lack prototypicality suggesting the social construct of fashion luxury is evolving as it is based on historical and cultural conditions influenced by the broad cultural production system of artistic movements. There are parallels between the artistic movements and advertising. Consumers view advertisements as a cultural text with distinct cultural codes of branding, therefore, advertisers need to understand the meaning based representation system in order to create powerful campaigns.

The study is designed to contribute to the literature in multiple ways. First, the study examines the social and cultural antecedents for contemporary visual culture. Secondly, the study illustrates a negotiated concept of luxury that is culturally derived. Thirdly, the study identifies visual creative techniques and execution tactics. The objective is to show a sociohistoric pattern of visual consumption influenced by the social structure of artistic movements, which shapes consumption choices and behaviors.

When the Same Objects Mean Completely Different Things That Unite Us All

Joachim Scholz, Queen's University, Canada
Jay M. Handelman, Queen's University, Canada

The role of special objects in the construction of identities is one of the most central concepts in consumer research (Arnould and Thompson 2005). While previous research has focused on the relations between special possessions and either individual identities (Kleine, Kleine, and Allen 1995) or collective identities (Belk 1992), more recent research stresses the importance of considering objects through the lens of dynamic interplays between individual, relational, and collective identities. For example, Epp and Price (2008) assert (but do not empirically test) that a single activity that is symbolic for a collective identity (e.g., family) can incorporate a diversity of meanings to the individual members of the collective. Going beyond the context of family identities, the purpose of the current research is to empirically explore how special objects help consumers to negotiate tensions that may arise when they seek affiliation in a consumption community and strive to maintain their autonomous identities at the same time.

We examine this question through ethnographic research of the engineering student community at our university. This community resembles more typical consumption communities in that a variety of special objects, most notably a jacket called the "Golden Party Armor" (GPA), are central to this community. Over the last two years, we have visited various community events and have been exposed to many GPAs during our daily commute over campus. In addition to observational research, we conducted on-site and in-depth interviews with several members of the community.

We find that students use the GPA to negotiate individual and collective identities. Four interrelated themes emerged through interpretive analysis. *(1) GPA as a community symbol*: The GPA is heavily invested with shared meanings, and wearing the GPA enables students to be a part of the community. On a more collective level, wearing the GPA also sets the engineering community apart from other faculties and thereby provides collective identities for our informants. *(2) Imbuing individualized meanings:* Our informants achieve individuality within their community through physically altering their jacket. Almost all jackets we observed over the last two years have physical alterations in forms of color, bars, and badges. The combination of such additions make each jacket unique. On a more psychological level, we also found our interview partners to achieve individuality within their community by using their jacket as a "scrapbook" to collect individualizing memories and experiences. Through its inclusion in core community events (e.g., slamming the jacket, dyeing the jacket purple, kicking the jacket over the campus, and having cars rolling over the jacket), each jacket becomes a transcript of ones own personal history with the community. *(3) Standing out without falling outside:* All GPAs have certain features (e.g., the university crest) that reaffirm the communal character of the jacket. Beyond this, community members adhere to firm rules and norms how to individualize their jackets (e.g., which and where badges can be added). In our fieldwork, we hardly ever came across jackets that break with these codes. Even more surprising, we found that some interview partners did not bother to sew on all the badges they had, even if these badges represented important achievements within their community. We interpret such foregone opportunities to highlight individual uniqueness as attempts to emphasize the shared meaning of the jacket for the sake of safeguarding one's communal identity. (*4) Enabling individualization through enacting community:* It is interesting to note that opportunities to individualize one's GPA are provided through community traditions. For example, dyeing one's jacket purple offers opportunities for individualized experiences (e.g., the act of purpling, or how the purple color fades away) while at the same time the shared rituals reaffirms the community and increases the communal character of the jacket. This link between individuality and community is apparent in how students connect their enactment of a community ritual (i.e., either "kicking home" their jacket as a first year student or interfering with such efforts as an upper year student) with both notions of experiencing community and collecting unique experiences.

In sum, our study demonstrates how community members embed individualized meanings into a shared community symbol while emphasizing and reaffirming – not sacrificing – its shared meanings. In other words, the 'same object', by becoming a 'completely different thing' in everybody's own mind, allows community members to feel like individuals, but by being still the 'same object' it also 'unites' these individuals in a community.

We believe that these findings advance our understanding of the meaning of objects and of the nature of object-person relationships. Specifically, we point out how objects can take on different meanings at any singular moment in time (Epp and Price 2010) and how objects allow consumers to negotiate conflicts that can arise from an interplay of various levels of identities (Epp and Price 2008). Previous research exploring multiple layers of meanings emphasizes the relative freedom consumers enjoy in constructing individualized meanings (Hirschman 2001), but also that some meanings are institutionalized as a shared "canon" (Kozinets 2001). However, this research does not pay attention to the interplay between individual and collective identities and therefore curtails our understanding of the dynamic nature of subject-object relationships: By only adopting an individual identity perspective, one fails to recognize how shared meanings are preserved and becomes prone to misinterpret members' safeguarding activities as sign domination (Murray 2002). On the other hand, by only adopting a communal

identity perspective, one easily neglects the individualized meanings of symbols in favor of their shared core meanings (Belk and Costa 1998). Recognizing the interplay between being an individual and being a community member allows for a much more dynamic and holistic understanding of special objects.

This Time (Again) Consumption May Not Unite Us

Cagri Yalkin, King's College, UK
Sinasi Ozgur Mumcu, Galatasaray University, Turkey

This paper aims to explore the ideological and social tensions that soap operas exported by a developing country engenders in other developing countries, and hence to extend the resistance literature in marketing as suggested by Izberk-Bilgin (2010) through the use of qualitative research.   In-depth interviews with international relations experts and media professionals as well collated material from the press provided preliminary insights and clarified the context, as explained below. Izberk-Bilgin (2010) pointed out the need to expand the geographical boundaries of research on resistance beyond the Western world. While she suggested studying the tensions and reactions to Western goods in developing countries as a starting point, this study will examine the tensions created by and reactions to (immaterial) goods originating from developing countries in developing countries, extending Thompson and Arsel's (2004) local-local work. Although a number of scholars have studied the tensions in developing countries by exploring consumer desire for Western products (e.g. Belk 1988; Eckhardt and Houston 2002; Ger, Belk, and Lascu 1993), the reactions to goods exported by one developing country to another have not been studied within the resistance literature in marketing.

Thompson and Arsel (2004) develop the notion of hegemonic brandscape which is "a cultural system of servicescapes that are linked together and structured by discursive, symbolic, and competitive relationships to a dominant experiential brand" (p.632). They use this notion to study how Starbucks structures local coffee shops and the anti-Starbucks discourse. Similarly, it is suggested here, based on the interviews with international relations experts and media practitioners, and on material in the media, that a hegemonic cultural goods space exists which consists of production and consumptionscapes that are structured around relationships to soap operas exported from a dominant country. The dominant country in this study is Turkey, for reasons explained below.

Ahmet Davutoglu (2001), in his 2001 book *Strategic Depth* (SD), argues that geographic depth transcends the artificial breakdown of ancient ties in the Middle East. SD aims, for example, to reunite Urfa(Turkey) and Aleppo(Syria), or the whole Mesopotamia which disintegrated after the collapse of the Ottoman Empire. SD claims that this reunification does not have any irredentist or imperial agenda and that Turkey's relations with former Ottoman regions are reminiscent of Japan's influence over Eastern Pacific region (Davutoglu 2001). This tightening of relationships comes with the baggage of spreading Turkey's cultural and economic influence over Ottoman cultural sphere (countries formerly included in the Empire territory), as is also acknowledged by Davutoglu (2001). One of the hallmarks of this cultural influence has been that of exporting the currently very popular Turkish soap operas (such as Gumus, known as *Noor*) to other countries in this sphere.

Within these hegemonic production and consumptionscapes, there are different discourses that are produced by both the consumers in the host countries (e.g. Syria, Egypt, etc.) and the guest country (Turkey), as is gathered from the preliminary interviews and the media (e.g. Apikian 2010, Bilbassy-Charters 2010): *"The (Anonymous) Media Group is good at this, since they are the producer company. They get their share of success… always running pieces about how people in those countries buy licensed t-shirts of the series, how the royal family there is friendly with the actors"* (interview, news editor in a national Turkish TV channel, 37, male). Further complicating the terrain are competing constructions in the media. In addition, there are competing discourses around how these TV series are received, consumed, and resisted in the host countries. What can be classified as the celebratory approach to this import/export of soap operas lies within the market-bound perspective of resistance (e.g. Firat and Venkatesh 1995). Some (Baraka 2009, Gokcek 2010) suggest that the popularity of the soaps is

drawing the Arabic and Turkish people together after years of mutually held prejudice. The non-celebratory approach, provided by interviews with two editors form the media and two international relations experts, however still market-bound, resonates with Marx's (1844/1973) and Horkheimer and Adorno's (1944/2000) views on resistance which are centered around the concepts of enslavement, cultural imperialism (Tomlinson 2002), hegemony, and at times, misogyny.

Davutoglu (2001) suggests that the Western civilisation no longer has the monopoly over humanity's accumulation of experience. SD asserts that in order to contribute to that accumulation of experience, Turkey, as the centre of the last non-Western civilisation basin, can use its Islamic-Ottoman legacy to influence the interaction of civilisations (Davutoglu 2001) and give the Western civilisation an opportunity to cope with cultural plurality (Davutoglu 2002). By presenting Turkey as the centre of the last non-Western basin, SD is rooting Turkey as the potentially hegemonic party which is also accentuated by the Ottoman rule's heritage. It is suggested here that Turkey emerges as the hegemonic power both because of this conceptualisation and is perceived as such by some accounts (Buccianti 2010), therefore casting the import of its immaterial cultural goods as hegemonic, if not culturally imperial. How consumers in both the host countries and Turkey perceive and negotiate the export of these goods is the ultimate concern of this paper.

Just as Thompson and Arsel (2004) report different manifestations of the desire to experience the local, it is expected that consumers will have built more than one discourse about the hegemonic cultural presence of Turkish soap operas. Do the consumption of soap operas challenge the practices in the host countries as is suggested by some accounts (i.e. the values communicated through the television series challenging religious values and norms) or structure the reactions of local media production companies (Sakr 2007, Baraka 2009, Thompson and Arsel 2004)? What form of resistance is practiced by different agents such as those that view the series as *'wicked and evil'* (see Hammond 2009) or by left-wingers who perceive the phenomenon as *"politically insignificant markers of the relationship between Turkey and Arabs"* (interview, international relations expert, 30, female, Egyptian)? It is suggested here that opinions of the consumers of these soap operas be consulted to better understand the "…issues of national sovereignty, preservation of national idiosyncrasies, and authenticity and ownership of cultural products… [that] may arise in cross-cultural examinations… revealing previously unexplored motivations and forms of resistance" (Izberk-Bilgin 2010, p.316).

Consumers' Commitment to Spend

Chrissy Mitakakis, Baruch College, USA
Keith Wilcox, Babson College, USA
Lauren Block, Baruch College, USA

In Western culture and society, emphasis has been placed on necessities, which are considered moral and ethical obligations, and are generally more important in the hierarchy of needs (Kivetz and Simonson 2002). As a result, much prior research has documented the lower status of luxuries and indulgences (as compared to necessities) and has found that individuals tend to select necessities over indulgences (i.e., saving for college over going on a cruise; Kivetz and Simonson 2002; Maslow 1970). Furthermore, research has also found that in order to avoid the mental angst and guilt most often associated with the consumption of indulgences, consumers utilize various justifying mechanisms to rationalize spending on indulgences.

Although previous research has shown that people use precommitments or effort in order to justify the consumption of an indulgence, most of this research has focused on people's commitment to consume a single indulgence. Alternatively, the current research examines the question of whether individuals can commit to the act of spending, such that they continue to spend until an initial indulgence goal has been satisfied. Thus, we propose that the commitment to spend on an indulgence activate individuals' indulgence goals. We do not expect these effects to occur when individuals initially commit to a necessity, nor when a subsequent item that is presented to individuals whose indulgence goal has been activated is non-indulgent.

We test these predictions in a series of experimental studies. For our first study, we sought to examine whether individuals do indeed have a commitment to spend. Participants were given a hypothetical scenario where they had seen an advertisement in the newspaper for a particular product. We provided participants with a picture and description of this product, for which half were told it was an indulgent item (sunglasses) while the other half were told it was a necessity item (laptop). All participants were told that they had committed to purchasing this product, which cost $499, upon seeing the advertisement. Participants were then told that upon arriving at the store, they found out that the item was discounted by $50. Next, participants encountered a second item, which was either an indulgent item (scarf) or a necessity (flashdrive). They proceeded to answer a series of questions, including how likely they would be to purchase this second product and several self-report measures. In addition, we measured reward-seeking tendencies using the behavioral approach system subscale in order to assess whether our proposed effect might be stronger for individuals with particularly strong reward-seeking tendencies (Carver and White 1990). Results support our hypotheses; participants who were told that they had committed to spending on an indulgent first product were more likely to buy the second product when it was an indulgent product than when it was a necessity product. Furthermore, we did not find a greater likelihood of purchase of a second item, regardless of its type, when participants initially committed to spending on a necessity product. Importantly, we also found a significant three-way interaction of first product, second product, and BAS reward responsiveness, such that effects were especially pronounced for individuals who had relatively high reward-seeking tendencies.

In our second study (currently underway), we seek to generalize the findings from Study 1, as well as provide stronger evidence for individuals' commitment to spend. Similar to our previous study, we gave participants a hypothetical shopping scenario which included either a necessity or indulgent product. Importantly, we told participants that once they arrived at the store to purchase this item, they found out it was out of stock. Participants were then told about a second product that they could purchase instead, which was varied to be either an indulgent item or a necessity, and asked about their likelihood of purchasing this second item. We reason that participants who are firstly presented with an indulgent item will commit to spending, such that they will therefore be more likely to purchase the subsequent item when it is an indulgent item rather than a necessity. We do not, however, expect individuals to be very likely to purchase the second item when it is a necessity, nor when they were initially committed to spending on a necessity item (regardless of the second item type).

Finally, in our third study, we will examine whether the nature of our effect is in fact driven by an indulgence goal. If so, then we expect to see our effect moderated when individuals are given other, different category opportunities to satisfy an activated indulgence goal. We will provide participants with a hypothetical shopping scenario similar to the one in our previous two studies. We will tell participants that they have committed to spending on an initial product (i.e., either an indulgent or necessity product), and then inform them that the product is out of stock. Next, we will present participants with an allegedly separate study, in which they will be given a choice task that will include a series of dessert options ranging in indulgence. We expect that participants who were initially committed to spend yet denied the opportunity to purchase an indulgent product to be more likely to choose the most indulgent dessert than those who initially committed to spending on a necessity product.

In conclusion, our research finds initial evidence for individuals' commitment to spend. Interestingly, we do not find this effect to hold when individuals initially commit to spending on a necessity, therefore providing initial evidence that an indulgence goal may be driving individuals' commitment to spend. Our results can have important implications for consumers' behavior with regard to their commitment to spend. In particular, our findings may lend insight into particular situations that consumers often encounter during the consumption of indulgences (i.e., discounts), and specifically the consequences these situations can have on consumer behavior leading to overspending and debt. Therefore, future research may find it worthwhile to explore how consumers' commitment to spend can be prevented or lessened through alternate means (i.e., fulfilling the indulgence goal through non-monetary ways).

Objectification and Consumer Choice

Chrissy Mitakakis, Baruch College, USA
Sankar Sen, Baruch College, USA
Stephen Gould, Baruch College, USA

Prior research has examined the effects of media on people's attitudes and behaviors. In particular, researchers have found that one of the most prominently imposed values and beliefs from the media has been the objectified view of the human body (Monro and Huon 2005). Such research has mainly focused on the negative consequences that often result from the exposure to stereotypical and objectified cultural standards, and has found that the internalization of these pervasive social standards can lead to adverse effects in many domains of endeavor (Stice et al. 1994). For example, researchers have found that the constant exposure to objectification has been associated with severe, long-lasting consequences such as depression, sexual dysfunction, and eating disorders. In addition, because Western media emphasizes objectified views of the female "ideal" much more than that of the male, the effects of objectification are often especially dire for females compared to those for males.

As a result, many researchers have attempted to understand females' process of internalization of objectification, and have come up with empirically validated theoretical accounts and explanations. One such construct, termed objectification theory, posits that in Western society, the female body is regarded as a sexual object that is to be looked at and evaluated (Fissel and Lafreniere 2006; Fredrickson and Roberts 1997; Moradi, Dirks, and Matteson 2005). According to this theory, the female body is "treated as a body (or collection of body parts) valued predominantly for its use (or consumption) by others," (Frederickson and Roberts 1997, 174). Consequently, females come to internalize this "observer" position of themselves, and therefore view their bodies as objects for visual inspection and evaluation, in a process termed self-objectification (Calogero 2004; Fiissel and Lafreniere 2006). In addition to the long-term effects often produced by objectification, self-objectification has also been associated with more immediate consequences, such as the decline of peak motivational states and flow experiences because of the conditioned responses of shame when failing to meet societally constructed ideals. Additionally, these feelings of shame have also been shown to lead to momentary decreases in cognitive ability (Fredrickson and Roberts 1997; Moradi et al. 2005).

Given the potential of self-objectification to cause immediate, negative consequences for females, it can be argued that objectification can affect decision processes. Research in behavioral decision making suggests that consumer preferences are not always defined, but are instead constructed during a choice task (Novemsky et al. 2007). Oftentimes, consumers base their decisions on the apparent ease or difficulty surrounding the choice. While this subjective experience of ease or difficulty can be the result of the choice process itself, it can also be an outcome of external circumstances that are unrelated to the choice (Novemsky et al. 2007). Regardless of the source of difficulty, however, consumers often attempt to reduce the resulting feelings of discomfort and conflict through the choice process itself, by choosing a cognitively easier, more easily defensible compromise option. The current research proposes that the momentary experience of self-objectification will act as a source of difficulty for females during the choice process. This, in turn, will lead to an increase in the choice of the compromise option among females (but not males).

In our first study, we examined the proposed effect of objectification on female consumers' choice through a hypothetical shopping scenario. We gave all participants a word scramble task, which has been utilized in prior objectification research (Roberts and Gettman 2004), in which they had to rearrange four out of five words to form a coherent sentence,. Half of the participants received all neutral words (i.e., "sat to they town drove"), while the other half received words relating to objectification (i.e., "was hear unshapely she really"). After the word scramble task, participants were told to imagine that they were shopping for a camera. Following our manipulation, participants were given a choice set of three cameras varying in dimensions and price (Novemsky et al. 2007), and asked to carefully examine the options and select one.

Results confirm our hypothesis. We found a main effect of condition ($F(1, 268) = 9.30$, $p < .01$), such that choice of a compromise option was greater for the objectification condition ($M = 36\%$) than for the control condition ($M = 17\%$). In addition, results also demonstrate a significant main effect of gender ($F(1, 268) = 13.47$, $p < .01$), as choice for the compromise option was greater for females ($M = 34\%$) than for males ($M = 15\%$). Further analyses also indicate a significant condition by gender interaction ($F(1,268) = 4.19$, $p<.05$). Planned follow-up contrasts showed a significant effect for female participants in the objectification condition, as these participants choose the compromise option more than females in the control condition ($M = 47\%$ versus $M = 21\%$; $F(1, 268) = 16.00$, $p < .01$). Furthermore, we also found that females in the objectification condition chose the compromise option more than males in the objectification condition ($M = 47\%$ versus 7%; $F(1, 268) = 16.47$, $p<.01$). Based on our findings, Study 2 (currently in progress) examines the effect of objectification on consumer choice in greater detail, by attempting to determine the underlying process (i.e., the nature of the proposed difficulty during choice) that may be driving the effects we observed in Study 1.

Our research contributes to the literature by examining the effect of a rather common phenomenon on consumer choice. This paper demonstrates that objectification can lead to choice of a compromise option for those most vulnerable to its consequences, namely, females. In addition, given that we did not find any effect of objectification on males' choice process, we argue that the effects of objectification are much more pronounced for females because of the implications of the female gender role in society. Thus, we offer new insight about the effect of objectification within the choice domain. Future research might also examine whether the effects of objectification on choice might vary for different types of products.

A Test of Universality of the Relationship between Self-Construal and Impulsive Consumption: the case of Russia

Alexander Jakubanecs, Institute for Research in Economics and Business, Norway
Olga Patosha, State University Higher School of Economics, Russia

Impulsive consumption plays an important role in consumer behavior being a major driver of sales across many industries (Vohs and Faber 2007). Furthermore, research has shown effects of the cultural dimension of self-construal type on impulsiveness (Zhang and Shrum 2009; Chen et al. 2005). However, since the connection between self-construal and impulsive consumption has been investigated primarily within and between the North American and a number of Asian cultures e.g. (Chen et al. 2005; Zhang and Shrum 2009) the question remains whether the connection is universal. Russia particularly presents an interesting subject of research since impulsiveness as well as recklessness has often been mentioned as Russian cultural traits both by Western and Russian researchers (Dicks 1952; Inkeles, Hanfmann et al. 1961; Peabody, Shmelev et al. 1994; Peabody and Shmelyov 1996). At the same time, Russia historically has had a collectivist societal structure (Miller 1960; Toltz 2001) and is often classified as collectivist in the extant research (Hofstede 1991). Thus, we may expect to find a different relationship between self-construal and impulsiveness in the Russian context. This research has important implications for cross-cultural research in impulsive consumption and universality of consumer behavior theories.

SELF-CONSTRUAL AND IMPULSIVE CONSUMPTION

Independent self-construal implies loose connection to other members of society while interdependent implies close connection (Triandis 1995). Impulsiveness is usually defined as greater accessibility of hedonic compared to self-regulation goals (Shiv and Fedorikhin 1999). Cross-cultural differences in impulsive consumption have been documented with independent self-construal positively influencing impulsive consumption and consumer impatience and interdependent negatively both on individual and inter-cultural levels (Chen et al. 2005; Trafimow et al. 1991). Furthermore, peer presence can be expected to enhance chronic cultural patterns (Zajonc 1965).

RUSSIAN CULTURAL TRAITS

Extant research on Russian culture has shown it to be considerably less developed in capacity for self-regulation that is very typical of other Northern peoples (Dicks 1952; Inkeles et al. 1961). This characteristic has been documented both through qualitative research e.g. (Inkeles et al. 1961) and through self-ratings (Peabody and Shmelyov 1996). Self-ratings have shown Russians to be considerably more impulsive, reckless and rash compared to a range of other cultures e.g. American, German, British and Japanese (Peabody et al. 1994; Peabody and Shmelyov 1996). Traditionally experiencing these tendencies, albeit evaluated negatively by the members of the culture, has been socially acceptable and not associated with guilt or remorse after the experience.

HYPOTHESES

Weakly developed self-regulation and thus impulsiveness are widely spread syndromes in the Russian culture that are socially acceptable (Dicks 1952; Peabody and Shmelyov 1996). Therefore we postulate that peer presence may increase impulsiveness in both self-construals, albeit in different ways. Independents will be concerned with their unique identity which can be also expressed through impulsive consumption. This predisposition can be enhanced by peer presence. Thus, the interaction of independent self-construal with peer presence will be manifested in attitudes towards impulsive consumption.

Group norms are important for interdependents (Triandis 1995). However, since impulsive behavior and consumption in Russia are socially acceptable, although not necessarily encouraged, we should not see the interaction of interdependent self-construal with peer presence on the attitudes. Yet, as interdependent self-construal is chronic in the Russian culture and impulsiveness is a cultural syndrome, we should observe this interaction on the level of internal state, i.e. level of impulsiveness. Thus,

H1: There will be positive effects of peer presence on consumption attitudes for independent self-construal.

H2: There will be positive effects of peer presence on state of impulsiveness for interdependent self-construal, but not on consumption attitudes.

Further, impulsiveness is such a central cultural trait that it should be less subject to variations in value orientations (e.g. unique identity vs. group norms). Thus, it will be less dependent on the type of primed self-construal. Therefore:

H3: The main effect of self-construal on impulsive consumption will be insignificant.

Since both impulsiveness and recklessness are chronic cultural traits we expect impulsiveness and risk preferences to be interrelated and both to influence impulsive consumption. Therefore, the effects of impulsiveness on consumption are likely to be moderated by risk preferences.

METHODOLOGY

The study built on the methodology by Zhang and Shrum (2009). In both the pretest and the main study participants were undergraduate students of Moscow's Higher School of Economics. 90% were ethnic Russians. A pretest to elicit impulsiveness of several consumption scenarios has been conducted (N=107). The main study was run using the alcohol consumption scenario, 2(type of primed self-construal) X 2(peer presence)(N=118). The scenario focused on going to a café to have an alcoholic drink. Peer presence was manipulated by referring to going on one's own vs. going with friends. Consumption attitudes were measured by three items: good/bad, positive/negative, like/dislike. Self-construal cognitions were measured by 6-item scale (Hamilton and Biehal 2005), impulsiveness by 10-item scale (Puri 1996), risk preferences by 12-item scale (Weber et al. 2002) and affect by 10-item scale (Pham et al. 2001). All items were measured by 7-point Likert scales.

RESULTS

Manipulation of self-construal was significant (F(1,117=10.68,p<0.001). The 2x2 interaction was significant for immediate alcohol consumption attitudes (F(1,117=4.18,p<0.01). In support of H1 there was a positive effect of interaction of peer presence with independent self-construal on consumption (M=4.37 vs. M=3.23 (no peer presence); t(59)=2.37,p<0.03). The interaction with interdependent self-construal was insignificant (M=3.60 vs. M=3.43 (no peer presence);t(55)=0.33,p=.74).

The 2x2 interaction was significant for state of impulsiveness (F(1,117=2.18,p<0.09). There was only a tendency of a positive interaction of peer presence with interdependent self-construal on impulsiveness (M=-0.10 vs. M=0.43;t(55)=-1.01,p=0.32) (the smaller value means stronger impulsiveness). Thus, H2 receives only mixed support. No interaction was shown for independent self-construal (M=-.57 vs. M=-.60,t(59)=.09,p=.93).

The main effect of self-construal on consumption attitude was insignificant (F<1) in support of H3.

Regressions confirmed H3. Effect of impulsiveness on consumption was positive (β=-.248,p<.01), its effect on risk preferences was also positive (β=-.227,p<.02). When both impulsiveness and risk preferences were included in the regression on consumption, both were significant (β=-.164,p<.07; β=.354,p<.001).The effect of impulsiveness was significantly reduced, which implies moderating effect of risk attitudes. General affect, alcohol knowledge, experience and gender were not significantly related to the variables in the study. The effect of 2x2 manipulations on risk preferences was insignificant contrary to extant research (Hamilton and Biehal 2005).

CONCLUSIONS

Our findings indicate results partially diverging from extant research e.g.(Chen et al. 2005; Zhang and Shrum 2009). Priming self-construal does not enhance or suppress impulsive consumption in the Russian context, contrary to the literature. According to extant research self-regulation is relatively weakly developed among Russians (Peabody and Shmelyov 1996). Priming self-construal does not appear to change these entrenched predispositions. Interdependent self-construal which is chronic (Dicks 1952) for Russians does not significantly interact with peer presence, both for impulsiveness and consumption attitudes. However, there are tendencies for positive effects which can become significant with other scenarios of impulsive consumption.

At the other hand, we see positive effects of the peer condition for independent self-construal on impulsive consumption which suggest potential universality of this relationship. Furthermore, priming self-construal does not change risk preferences which also deviates from the existing research (Hamilton and Biehal 2005). Risk preferences are closely related to impulsiveness which is different from other research (Zhang and Shrum 2009), but in line with the literature on the Russian culture.

The results have to be confirmed by further tests on other types of impulsive consumption before being conclusive. However, the findings point to possible cultural specificity of the relationship between self-construal and impulsive consumption. Majority of fundamental consumer behavior theories have been tested primarily in North America and parts of Asia. Our results warrant caution in generalizing established theories to other parts of the world, particularly to nations characterized by potentially culture-specific traits.

Like 'Em or Leave 'Em: Prior Beliefs and Correspondent Inferences Spark Endorser Effectiveness

Sommer Kapitan, University of Texas at San Antonio, USA
David H. Silvera, University of Texas at San Antonio, USA
Maria L. Cronley, Miami Univeristy, USA

Does a celebrity endorser's reputation precede him or her into the endorsement context? Since the advancement of source attractiveness and credibility models (McGuire 1969, Miller 1970), the literature has questioned whether the use of a famous face in advertising buys lasting attention and access to consumers. Existing models indicate that a match-up between endorser and product features is necessary (Kahle and Homer 1985), and that advertisers must weigh meanings the endorser brings to the product (McCracken 1989). Yet if reputation and image factor into the endorsement context, how do consumers' prior beliefs about an endorser impact endorser effectiveness?

We suggest that, depending on personal inclinations to engage with a message, prior beliefs about an endorser become a processing filter for messages. What happens when consumers are triggered to think carefully about product endorsers? The default tendency is for observers to make correspondent inferences (Gilbert and Malone 1995) that endorsers promote products because they like, value, and actually use the product. We propose that attributions are a key mechanism for endorser effectiveness, and that they can lead to source effectiveness via shallow or deep processing. Mehta (1994) argues that advertising responses to celebrities are only found in shallow processing encounters. Her study finds that consumers viewing celebrity-endorsed commercials generate thoughts about the source that cannibalize thoughts about the product or brand, yet still lead to positive evaluations (Mehta 1994). Kang and Herr (2006), however, argue that source information is also encoded as product arguments. We suggest that endorser characteristics always impact persuasion, but that the influence of the endorser is either direct—via simple reliance on source characteristics and shallow processing—or indirect, as a result of deep processing and a preferential search for information that supports consumers' prior beliefs about the celebrity.

Under shallow processing, research suggests that correspondence bias should occur. This is positive for celebrity endorsers, since a default correspondent inference is that celebrities promote products because they truly believe in the products. Yet this finding has only been demonstrated with positive or neutral endorsers (i.e., Cronley, Kardes, Goddard and Houghton 1999). For disliked endorsers, consistent with existing research on source effects, the endorser takes on the role of a product argument. In this way, prior beliefs about a celebrity endorser spur properly motivated consumers to engage more deeply with the message. We expect resulting inferences about the endorser to turn on the valence of those prior beliefs.

Our goal was to understand how endorser likeability cues processing when consumers face environmental stimuli and are motivated to engage with promotional messaging. We hypothesize that non-motivated consumers will process likeability as a heuristic, but that motivated individuals will use prior beliefs about an endorser as a deep processing cue when situational information is made salient. 127 participants viewed one of two advertisements for sunglasses. The advertisements were identical aside from featuring two different celebrity endorsers. The endorsers were closely matched on demographic characteristics and pre-tested as high (rapper and actor Will Smith) and low likeability (rapper Kanye West). Similar to previous research, (Cronley et al. 1999; Silvera and Austad 2004), we also provided information about whether the endorser was paid or not for his endorsement. After viewing the ad and receiving payment information, participants completed measures of correspondent inferences about the endorser's true liking for the product and their attitudes toward the product, the advertisement, and the endorser, then completed the Need for Cognitive Closure scale (NFCC; Webster and Kruglanski 1994) to capture their motivation to engage with the advertising message. The final design was thus 2 (likeability: liked vs. disliked) x 2 (fee: paid vs. unpaid) x 2 (NFCC; high or low). Confirming our pre-test results, Will Smith was viewed as significantly more likeable than Kanye West, indicating that the likeability manipulation was successful.

A 3-way (likeability x fee x NFCC) ANOVA predicting correspondent inferences indicated significant main effects such that both unpaid and likeable endorsers produced stronger correspondent inferences, in addition to a marginally significant 3-way interaction between pay, likeability, and NFCC ($F(1,126) = 3.20$, $p < .08$). To further explore this interaction, 2-way (NFCC x likeability) ANOVAs were conducted

separately for paid and unpaid endorsers. In the unpaid condition, results indicated a simple source effect—stronger correspondent inferences were made about the likeable than the unlikeable endorser ($F(1,55)=4.33$, $p<.05$), with no main effect or interactions with NFCC (F's<1). In the paid condition, a similar main effect for likeability was observed ($F(1,64)=7.25$, $p<.01$), but this main effect was qualified by a likeability by NFCC interaction ($F(1,64) =10.03$, $p<.005$). Further breaking down this interaction indicated that likeability had no impact on correspondent inferences for high NFCC participants ($F<1$), but that likeability increased correspondent inferences for low NFCC participants ($F(1,33)=19.44$, $p<.001$).

These results suggest that two distinct evaluation processes operate depending on information about payment of the endorser. When participants received salient payment information, they appear to have engaged in simple source-based processing—they trusted the likeable endorser more, and this was not moderated by their motivation to process information carefully (i.e., NFCC). When participants were told that the endorser was unpaid, their reasoning process appears to be more complex—unmotivated (high NFCC) participants showed no source effects, but highly motivated (low NFCC) participants showed the strongest source effects of any group. This suggests that low NFCC participants engaged in a deeper processing in which they accessed their pre-existing attitudes toward the endorser and used them to guide processing of ad-related information.

Why do we care about correspondent inference processes? In the present study, correspondent inferences were significantly correlated with attitudes toward both the advertisement ($r(127) = .41$, $p < .001$) and the product ($r(127) = .45$, $p < .001$). The role of prior beliefs, when cued by environmental information such as an endorser's salary, thus can have an important impact on evaluations of both promotion and product. In short, reputation impacts endorsed advertising via both heuristic and systematic thought processing.

What You Smell Affects What You Like
How Incidental Scents Can Affect Product Preference By Eliciting Emotion

Elise Riker, Arizona State University, USA
Andrea Morales, Arizona State University, USA
Stephen Nowlis, Washington University in St. Louis, USA

The sense of smell is commonly overlooked amid the five senses, but recently the human nose has been getting popular press on its unexpected emotional power and connection with memories. How might this power be harnessed in the marketplace? We propose that the scent-evoked emotions and memories affect consumers' choices, making a particular subset of products and services more attractive in subsequent decisions.

Scents associated with emotional experiences can evoke the same emotion by its mere presence. Past research has shown that the scent of eugenol, associated with dental procedures, induces fear for those who fear the dentist (Robin et al., 1998). It is interesting that the scent alone, independent of other dentist-related cues, is sufficient to elicit a strong negative emotion, but only for those with painful associated memories. Beyond eliciting associations, smell has the power to reactivate the original emotional experience.

Several reasons have been suggested for this connection between scent and emotion. First, the two areas of the brain that respond to and evaluate odors, the amygdala and the orbitofrontal cortex, are also closely connected to processing of emotion in the brain (Hamman, 2003). The olfactory system's close synaptic distance connects easily and quickly with emotional context, requiring little cognitive mediation (Bone and Ellen, 1999). Emotions and scents can thus be encoded without conscious effort. Additionally, scents generally have less interference than do other stimuli (Herz, 2004), due, in part, to the immense number of differentiated smells. With over 10,000 scents, a unique scent may be encountered and encoded with a distinct emotional experience.

Past research on ambient scent suggests that congruency, or correspondence among store elements, increases evaluations (Mitchell et al., 1995, Spangenberg et al., 2005). However, prior work has focused on the semantic match, rather than the match between consumers' specific

emotional states and product evaluations (for an exception, see Griskevicius et al., 2010). We focus on the emotional congruency of the scent and product choices, based on product-in-use and associated memories.

Specifically, we propose that a scent-induced discrete emotion will increase attraction to products that 'match' with that emotion, or to those products that enable consumers to carry out the action tendencies evoked by that emotion. In this study, we investigate a light, sweet smell that is unique to baby products (lotions, shampoos, etc.), and propose that this scent will induce nurturant love via consumers' associations with caring for helpless infants. 'Nurturant love' is defined as feelings of love and concern for another's well-being, particularly of kin, and compassion toward those that are dependent (Griskevicius et al., 2010). We hypothesize that these feelings will increase the evaluations of family-focused products and services, cute products, and services that involve the vulnerable or express compassion. In contrast, a general positive affect induced by a pleasant scent should increase evaluations of all products across categories, as seen in past research (Chebat and Michon 2003).

Study 1 consists of two parts. In the first part, we exposed participants to either the target scent or the control scent under the guise of a new product evaluation. Participants evaluated a product sample on a variety of dimensions, with the product scent evaluated last. Participants completed part 2 of the experiment as an ostensibly unrelated study on general product and service evaluations, including emotionally-congruent products (e.g. grape tomatoes, baby carrots, nurturing cat food, Goldfish crackers, Cracker Barrel dinner, and Disneyland vacation) and emotionally-incongruent products in similar product categories (e.g. beefsteak tomato, Quilted Northern toilet paper, Brawny paper towels, RA Sushi dinner, Vegas vacation, rat trap). Participants then reported their emotional state during the study.

Results showed that the baby scent increased evaluations of the nurturant-love-congruent products as compared to the control scent (4.84 versus 4.32), and this difference was significant ($F(1,40) = 4.56$, $p = .035$). To ensure that the baby smell did not increase evaluations across the board, emotionally-incongruent products were selected that were similar in product categories or kinds to the emotionally-congruent products, but were purposely not consistent with actions associated with the emotion (i.e., not family-friendly or cute). A comparative index showed no significant differences ($F(1,40) = .58$, $p = .48$), although the control condition produced directionally higher index evaluations (4.60 versus 4.78). This indicates that the baby scent did not increase general product evaluations, but selectively enhanced evaluations for emotionally-congruent products.

Subject's emotional states support our explanation of the role of emotions. We expected that the 'baby' scented shampoo would evoke feelings of nurturing, love, and compassion, while the control scented shampoo was expected to evoke general positive affect without activating specific emotions. Using self-reports of love and compassion as a proxy for nurturant love, we found stronger emotions reported in the baby condition (6.18) than the control condition (4.93) and this difference was marginally significant ($F(1,40) = 4.56$ $p = .073$). There were no significant differences for general positive emotions (i.e., good, happy, and positive), indicating that the scents produced comparable generally positive feelings.

Study 1 also eliminated familiarity and liking of the scents as potential explanations; no significant differences were found on either measure. To further validate the results, Study 2 addressed other possible emotions or associations that could be elicited by the scent, such as romantic love or priming 'baby' in general, resulting in increased preference for romantic or baby related products respectively. Neither product types were found to be affected by the target scent. Study 3 addressed the role of scent identification in eliciting the desired emotions. Because scents can be ambiguous and difficult to interpret when unidentified (Herz, 2003), we wanted to see what differences resulted from upfront identification of the scent as 'baby' or left as a general personal care product scent.

By connecting recent findings on emotions in psychology with sensory marketing, this research demonstrates that an incidentally encountered olfactory cue can increase perceptions of emotionally-congruent offerings. Scents created as part of a branding identity become entangled with the emotional memories that consumers create as they use the brand, and thus the scent activates that powerful emotional connection.

A Subtle Sense of Specialness Triggers Feelings of Uniqueness

Jiska Eelen, KULeuven, Belgium
Kobe Millet, VU Amsterdam, Netherlands
Luk Warlop, KULeuven, Belgium, Norwegian School of Management, Norway

Would you feel awkward and uncomfortable or rather special and intrigued when you do not feel your usual self? Gao, Wheeler and Shiv (2009) have suggested that unfamiliar actions may shake one's self and lower self-confidence. Also, research about familiarity would suggest that unfamiliar stimuli are not fluently processed and hence disliked (Winkielman et al. 2003). Yet we propose that people may actually like what is unknown and different, and that doing something unfamiliar can activate the goal to stand out of the clutter. Recent research by Wood (2010) points in this direction. Wood found that people who experienced life changes were more likely to be attracted to new or unfamiliar options. Of interest to our research, Maimaran and Wheeler revealed that exposure to novel visual arrays of geometrical shapes made people choose more unique products (2008). We predict that performing an unfamiliar action will result in a similar effect, namely trigger a goal to be unique and make people choose more unique products. Also we predict that this effect will be moderated by initial feelings of uniqueness. For consumers who have a chronic need for expressing uniqueness, we expect our manipulation to have no effect. Momentary affective states can have an impact on judgments, but when people are made aware of the source they correct for it (Pham 1998; Schwarz and Clore 1983). In line with affect-as-information theory, we predict that unfamiliar actions need to be subtle in order to impact behavior. In three studies we find evidence for these hypotheses.

In Study 1, right-handers performed a task with their dominant right hand (i.e., usual) or nondominant left hand (i.e., unusual). After several filler tasks, participants filled in the consumers' need for uniqueness scale (Tian, Bearden, and Hunter 2001) on a 5-point Likert scale. A one-way ANOVA with hand used as the independent variable and need for uniqueness (Cronbach's alpha = .94) as the dependent variable was marginally significant ($F(1,68) = 3.53$, $p = .06$). There was a tendency for participants who used their left hand to score higher on need for uniqueness ($M = 2.66$) than participants who used their right hand during the choice task ($M = 2.39$).

One way for consumers to communicate their uniqueness through the choices they make, is by buying scarce products (Lynn and Harris 1997). In Study 2 we made participants (all right-handers) choose between four different boxes of chocolates of which one was labeled as "limited edition". First they performed a computer task with their left (unusual) or right (usual) hand. In a logistic regression with choice (0 = not unique, 1 = unique) as a dependent variable, and hand used (left vs. right) as a discrete between-subjects variable and NFU as a continuous between-subjects variable, we found a significant two-way interaction ($\chi^2(1, N = 99) = 4.16$, $p = .04$). Doing the usual task, low NFU participants ($M_{NFU} - 1SD$) seemed less likely to choose the unique product ($\hat{P} = .19$) than high NFU participants ($M_{NFU} + 1SD$, $\hat{P} = .42$) ($\beta = .73$, $\chi^2(1, N = 99) = 3.28$, $p = .07$). Doing the unusual task, NFU was not significant, but the probability to choose the scarce product for low NFU participants increased from 19% (usual task) to 49% ($\chi^2(1, N = 99) = 4.16$, $p = .04$). Also this chance was not different from high NFU participants who did the usual task ($\hat{P} = .42$, $\beta = .43$, $\chi^2(1, N = 99) = .24$, $p = .63$).

In our third study we generalized our findings to a different unfamiliar task (i.e., performing a task with a new technological device, namely a touch screen). In a control condition participants performed a computer task with the mouse, whereas in the "unusual" conditions participants had to touch the screen to indicate their choices. In the explicitly unusual condition we drew people's attention to the specialness of the task. Our dependent measure was the extent to which people chose different travel destinations than a majority of students of whom they saw the choices while responding to the survey. In the implicitly unusual condition, participants preferred unique travel destinations more ($M = 3.94$, $SE = .19$) than in the control condition ($M = 3.25$, $SE = .19$, $t(79) = 2.53$, $p = .01$), and in the explicitly unusual condition ($M = 3.38$, $SE = .19$, $t(79) = 2$, $p < .05$). There were no differences between the control condition and the explicitly special condition ($t(79) = .50$, $p = .62$).

Our research shows that doing unfamiliar tasks boosts people to stand out of the clutter. Performing a task with the nondominant hand made people feel more unique and choose products that are scarce in the marketplace. We demonstrated that a subtle situational cue boosted people's goal to be unique to the level of people who have this goal chronically activated. Using a new technological device led people to prefer more unique travel destinations. When people's attention was drawn to the task specialness, it no longer affected behavior. Perceptions of difficulty did not affect our results. Neither did self-esteem or self-awareness mediate our findings. This suggests that encountering an unfamiliar situation does not always lower people's self-views, as suggested by Gao et al (2009). Rather it may induce an open mind-set and break habitual behavioral patterns and promote novel options (Wood 2010). Future research should investigate whether unusual situational cues affect decision making processes more broadly. As suggested above, it is possible that unfamiliar situations make people more open-minded. As such, unfamiliar situations may also induce higher levels of variety-seeking, or even creativity. Our research may have considerable practical implications. If change is not always disliked, then shopping aisles for instance, may be reorganized once in a while to break consumers' habitual shopping patterns. Also websites may be visited more thoroughly when updated from time to time. However it remains an open question how subtle changes should be and whether too obvious changes result in opposite patterns of choice.

Shifting Away From Discomfort: Managing Difficult Decisions Through Reconstruals

Stephanie M. Carpenter, University of Michigan, USA
J. Frank Yates, University of Michigan, USA
Stephanie D. Preston, University of Michigan, USA
Lydia Chen, University of Michigan, USA

Research on pre-decisional coherence shifting (Simon, Krawezyk, & Holyoak, 2004; see also pre-decisional distortion; Russo, Meloy, & Medvec, 1998) indicates that changes in the desirability and importance of choice alternative features begins prior to making a choice, rather than following the choice. Proposed mechanisms for why coherence shifting occurs, however, have been limited. Evidence suggests that difficult decisions that are likely to create cognitive dissonance (see Cooper, 2007, for a review) are associated with a heightened arousal state or a feeling of discomfort (Croyle & Cooper, 1983). This research sought to determine whether feature conflict arising from lacking a clearly dominant option produces a feeling of discomfort, which, in turn, produces a motivating need or desire to reduce this discomfort. We propose that coherence shifting reduces decision conflict, which reduces discomfort.

In the present study, we predicted that coherence shifting would resolve feelings of discomfort that are experienced when an individual must make a difficult choice between two competing alternatives, each of which includes both positive and negative attributes. We hypothesized that those individuals who coherence shift more would feel less physiological arousal and would self-report the decision as being less difficult.

To test these hypotheses, 59 university undergraduates participated individually in a computerized study using an established coherence shift paradigm (Simon et al., 2004) and physiological measures. One method for measuring physiological arousal is the skin conductance response (SCR), which is measured by attaching electrodes to the palm of the hand to detect slight changes in skin perspiration that reflect sympathetic activation. A seminal study on cognitive dissonance and skin conductance response (Croyle & Cooper, 1983) indicated that cognitive dissonance increased SCR, and that resolving cognitive dissonance weakened the high arousal state. In our study, individuals were informed that they would be participating in a physiological study on decision making, and skin conductance response electrodes were attached to the palm of each participant's non-dominant hand. Participants were randomly assigned to either a control condition, which served to replicate previous evidence of coherence shifting (Simon et al., 2004), or a justification condition, where participants were asked to imagine that eventually they would be justifying their decision to a close other. The justification condition was added to ensure that participants would take the decision task seriously, and also to determine if there were effects of being asked to imagine justifying the decision to a close other (Lerner & Tetlock, 1999). All participants rated the desirability of a number of possible job attributes, and then weighted how important these attributes were in an average decision context. Participants were then shown the attributes of two possible job offers that varied on the dimensions of commute time, salary, office space, and vacation package. After viewing the job offers, participants rated the desirability of the attributes and weighted attribute importance a second time. Participants then indicated their choice leaning. An interim task was given prior to participants making their final choice, followed by a third rating of attribute desirability and weighted importance.

Results indicated that the justification condition did not interact significantly with the final choices or degree of coherence shifting, and justification condition effects were not included in subsequent analyses on coherence shifting. Participants in the control condition, however, had higher overall SCR across the study blocks ($p<.05$) than those in the imagined justification condition. This plausibly occurred because individuals who are not prompted to justify their choices are less successful at reducing discomfort. Such an explanation is consistent with research on accountability that suggests when people know they will be held accountable for their decisions, they make decisions that they expect will meet the approval of those to whom they are accountable. This process is thought to reduce the cognitive effort necessary for making complex decisions or difficult tradeoffs (see Lerner & Tetlock, 1999, for a review).

In the studies conducted by Simon et al. (2004), coherence shifting was measured as a change in the attribute desirability and importance ratings at each time point to be consistent with the preferred option that was eventually chosen. We replicated these general findings that individuals shift their desirability and importance ratings toward their final choice leanings. Analyses were conducted by dividing participants into three groups based on the degree of coherence shifting, with the dependent variables representing SCR during the maximal decision window of 2000ms–3000ms. Results indicated that participants with high levels of coherence shifting on importance weightings also had significantly lower SCR ($p<.05$) across study blocks. Coherence shifting on the importance weightings was also negatively correlated with the perceived difficulty of the decision ($r=-.262$, $p=.045$), indicating that those who coherence shifted more perceived the decision as less difficult. Correlations between desirability and importance also increased over time ($p<.05$) such that participants' evaluations on the two dimensions became more consistent with each attribute re-rating. Analyses were next conducted to measure coherence shifting with respect to the specific attributes. These revealed that participants who changed their importance weights the most also had significantly lower SCR ($p<.05$) across blocks, and that degree of coherence shifting with respect to the job offer attributes correlated significantly with decision dif-

ficulty for both the desirability ratings (r=-.36, p=.005) and the importance weightings (r=-.53, p<.05). These results were consistent with our predictions that participants who coherence shift more resolve feelings of discomfort and perceived decision difficulty that arise from not having a dominant choice option.

These data provide initial evidence for our proposed model of feature conflict leading to feelings of discomfort, which some individuals resolve through the use of pre-decisional coherence shifting. Additional research is being conducted to further establish the proposed causal sequencing. In the present study, those who coherence shifted less exhibited higher physiological arousal, while those who coherence shifted more exhibited lower physiological arousal. These findings shed light on the basic mechanisms underlying decision making and have implications for how consumers make decisions in difficult decision contexts when there is no objectively correct choice.

Too Much Information?
How Expertise Disclosures Affect the Persuasiveness of Online Consumer Reviews

Soyean (Julia) Kim, Boston University, USA
Barbara Bickart, Boston University, USA
Frederic Brunel, Boston University, USA

Online word-of-mouth (WOM) via consumer-generated product reviews has a significant impact on consumers' purchase decisions (e.g., Chevalier and Mayzlin 2006; Godes and Mayzlin 2004). In this context, information exchange is typically among strangers, and readers can learn about reviewers only through reviewers' own disclosure of their identity, expertise, and product involvement. Thus, source-related disclosures function as one cue through which readers can evaluate the usefulness of the review and thus, the persuasiveness of the message.

Identity-related disclosures can be important determinants of the persuasiveness of a review (e.g., Forman, Ghose, and Wisenfeld 2008; Naylor, Lamberton, and Norton 2011). Our research builds on this earlier work by focusing on the effect of expertise-related disclosures on the persuasiveness of an online review. Specifically, we test the hypothesis that in some situations, too many expertise-related disclosures can reduce the persuasive impact of a message.

LITERATURE

Recent research has focused on the role of identity-related disclosures on the persuasive impact of an online consumer review. For example, Forman et al. (2008) found a positive relationship between the presence of identity-related information in a review and product sales. Naylor et al. (2011) demonstrated that when limited or ambiguous identity-related information is provided in a review, consumers automatically infer that the reviewer has preferences similar to their own. Thus, a review with no identity-related information is often as persuasive as one that includes similar identity information.

Both of these papers focus on identity-related disclosures, such as age, gender or geography. Our research focuses on disclosures related to reviewer expertise. In general, we expect that expertise-related disclosures will increase perceptions of source credibility and thus the persuasiveness of the review (e.g., McGuire 1969). While expertise-related disclosures should increase perceptions of source credibility, expertise disclosures could also reduce perceptions of similarity between the source and the message recipient. Thus, we expect that the impact of the number of expertise-related disclosures on persuasion will depend on the consumers' level of product category knowledge. Specifically, for high knowledge consumers, the number of expertise-related disclosures in a review will increase source credibility and judgments about the evaluated product will be assimilated toward the evaluation provided in the review. On the other hand, for low knowledge consumers, high levels of expertise-related disclosure may reduce perceptions of similarity. If the message recipient infers that he/she is different than the message source, then they may use the review information as a standard of comparison or anchor, in which case the product evaluation would be contrasted from the evaluation provided in the review. Thus, a review containing more expertise-related disclosures will be less persuasive for low product knowledge consumers.

METHOD

To test these hypotheses, we conducted an experiment where the number of expertise-related disclosures and level of expertise represented by these disclosures were manipulated, and participants' self-reported product category knowledge was measured. Undergraduate students (n = 176) participated for course credit. Participants read three online reviews about a specific pair of running shoes. A photo of the shoes was provided, followed by the reviews. The first two reviews were seen by all participants. These reviews were mixed, mentioning some positive and some negative features of the shoes and included a rating of three out of five stars. These reviews did not include any disclosures or identification information about the reviewers.

The third review was favorable, mentioning all positive attributes and a rating of five out of five stars. The structure of this review varied across participants. Specifically, we varied the number of disclosures included in the review (one vs. three) and the level of expertise

suggested by the disclosures (expert vs. novice). We used a pre-test to select three novice (e.g., "I am a new runner") and three expert (e.g., "I am a lifelong runner") disclosures. In the high disclosure condition, the review included either three novice or three expert disclosures, while in the low disclosure condition only one novice or expert disclosure was included, and we counterbalanced across the three disclosures in each group.

After reading the target review, we measured brand attitudes. We then measured participant's perceived similarity to the target reviewer, and perceptions of this reviewer's expertise and trustworthiness. The analyses below are based on the top and bottom 40% of respondents on the product category knowledge measure.

RESULTS AND DISCUSSION

Our predictions suggest a three-way interaction between number of disclosures, expertise of the disclosures and participants' product category knowledge. This interaction is significant ($F1,128 = 6.20$, $p < .01$). For participants *low* in product category knowledge, when the reviewer makes only one disclosure, brand attitudes do not differ by the expertise of that disclosure ($p > .29$). Consistent with our predictions, when the reviewer makes three disclosures, brand attitudes are higher when these disclosures indicate that the reviewer is a novice ($M = 3.44$) versus an expert ($M = 2.95$), $F1,128 = 3.76$, $p < .055$. In contrast, for participants *high* in product category knowledge, one disclosure has more influence on brand attitudes than does three disclosures. Specifically, brand attitudes are more favorable when the reviewer makes one novice disclosure ($M = 3.31$) versus one expert disclosure ($M = 2.87$), $F1,128 = 2.75$, $p < .10$. When the review includes three disclosures, brand attitudes do not vary by the expertise of the disclosure (p > .39). The participant's perceived similarity to the reviewer mediates these results.

These findings suggest that for lower knowledge consumers, source similarity has a larger effect on the persuasive impact of a message than that of source expertise, and that more disclosures allow low knowledge consumers to identify similar reviewers. High knowledge consumers seem to infer that a source is similar when disclosures are limited, and appear to discount reviews as the number of disclosures increases, regardless of the expertise suggested by those disclosures. In other words, for both low knowledge and high knowledge consumers, increasing the number of expertise-related disclosures can reduce the persuasive impact of a review.

That tastes awful, unless I hear it tastes good – The impact of informational social influence on conflicting evaluations

Andrew Bryant, The George Washington University, USA
Kashef Majid, The George Washington University, USA
Vanessa Perry, The George Washington University, USA

In today's marketplace consumers are becoming increasingly reliant on the judgments of others in order to form their subject evaluations. For example, when determining if a movie is good or bad the consumer can view the ratings given by other users, or when sampling a new drink the consumer recalls that in a national taste test nine out of 10 consumers preferred the drink over the current market leader. Instances such as these are but a few examples where the prior judgments made by an anonymous group of consumers can exert a powerful effect on the judgment of the target.

Deutsch and Gerard (1955, 629) conceptualize this effect as information social influence where the individual "accepts information obtained from another as evidence about reality." The term should not be confused with a normative social influence that refers to "an influence to conform to the positive expectations of another" (Deutsch and Gerard 1955, 629). Under informational influence the individual has no pressure to conform while under the normative influence the individual's judgments are motivated by a desire to conform to the judgments of others. The present paper focuses on the impact that informational influence can have on the judgments of consumers. Specifically, whether the impact of informational social influence can increase how a poor product is evaluated or decrease how a good product is evaluated.

Prior work has done well to demonstrate that a positive informational social influence can positively impact the evaluations consumers have (Cohen and Golden 1972) and a negative influence can have the reverse effect (Pincus and Waters 1977). However, what is less clear is the interplay between the type of informational social influence and the quality of the product. Specifically, what impact does a positive (negative) informational influence effect have on a poor (good) quality product? Furthermore, the presence of competing signals, a positive informational influence and one's own subjective taste can create a state of dissonance (Festinger 1957). In order to move away from this state of dissonance, consumers often attempt to resolve this conflict through further evaluation (Sengupta and Johar 2001). Therefore, it is

likely that when consumers are faced with competing information they will be more likely to want to try the product again to move away from their state of dissonance.

Using an experimental methodology we tested whether a positive or negative informational social influence would either enhance or decrease the perceptions of sweet (or bitter) tasting drink. A total of 105 undergraduate students from a large Mid-Atlantic private university participated in the study in exchange for bonus course credit. Participants were divided into one of six cells for our 2 (sweet tasting vs. bitter tasting) x 3 (positive vs. negative information social influence vs. no informational influence) between subjects design.

An unsweetened guava juice concentrate was mixed according to the directions and the flavor was either enhanced using a sweetener (sweet) or made to taste worse using lemon juice (bitter). A pre-test found that the sweeter drink was rated as more pleasant than the bitter drink (M_{Sweet} = 4.22 vs. M_{Bitter} = 2.94, $F(1, 40)$ = 11.22, $p < .01$). Participants in the study were randomly divided into one of the six cells and told that they would be sampling a new type of drink. The drink was given to participants in a clear plastic cup with no markings. Before sampling the juice, the participants' attention was directed to a whiteboard that contained previous students' flavor ratings of the drink displayed in a stem and leaf style tick mark chart similar to the manipulation used by Cohen and Golden (1972). The tick marks were skewed to the top of the whiteboard under the positive informational influence condition and then inverted under the negative informational social influence condition.

Each participant was given approximately four ounces of the juice mixture and asked to fill out a questionnaire. Two seven point measures; Pleasant (*anchored by Unpleasant to Pleasant*) and Willingness to Try Again (*anchored by Never to Very Likely*) were used as the main dependent variables of interest. Once the study was over, participants were debriefed as to the true nature of the experiment and asked not to discuss the study with anyone.

Results were analyzed using an Analysis of Variance (ANOVA). Participants who received the sweet tasting juice were not impacted by the informational social influence effects; however, those that received the bitter tasting juice were significantly impacted by the social influence manipulation. Those who tasted the bitter juice and viewed the ratings given by others felt the pleasantness of the drink was significantly higher than those who were making their judgments without any social influence effects ($M_{Information\_Positive}$ = 4.10 vs. $M_{No\_Information}$ = 2.94, $F(1, 37)$ = 12.25, $p < .01$). This finding indicates that the positive informational influence effect can increase the evaluation of a poor product. Furthermore, the in-congruency between the positive informational influence and the bitter tasting drink caused consumers to want to try the drink again ($M_{Information\_Positive}$ = 4.10 vs. $M_{No\_Information}$ = 2.61, $F(1, 37, p < .001)$ which indicates that not only can informational social influence impact subjective consumer evaluations but it may also impact repeat behaviors.

Our study explores the interplay between informational social influence and evaluations of products. Our results suggest that an unpleasant product can be given a more favorable evaluation if consumers are made aware that other consumers had previously evaluated the product favorably. We also provide an avenue for further investigation by identifying the impact that conflicting signals can have on future intentions. In summary, we question the familiar adage, if everybody did it would you?

The Price of Love: the Gifting Behaviors of Insecure Lovers

Weixing Ma, University of Houston, USA

Love is in the giver, not the gift. (William Sloan Coffin)

In the romantic dyad relationship, to love and to be loved may not always strike the perfect balance. If a person is more in love with or more devoted to his or her lover, he or she may feel insecure in the relationship. Purchasing and giving gifts to one's romantic partner is one of the most important and common ways to show one's love and nurture the intimate relationship. The average American spent about $100 on Valentine's Day in recent years, which was equivalent to almost one third of their entire Christmas shopping spending (Paul 2009). While the early research generally regard gift giving as an economic exchange process based on reciprocity motivation (e.g., Mauss 1925; Sherry 1983), Belk and Coon (1993) turned to the romantic love model within the agapic love paradigm to explain lovers' gifting behaviors, and found it to be a necessary addition to the economic exchange model. Nevertheless, they still viewed gift giving as an instrumental act designed to accomplish a goal such as gaining the recipient's love (Belk and Coon 1993). Particularly in an unbalanced romantic dyad, the motivation of an insecure lover trying to gain more "love" and secure feelings, may be manifested by the way he or she gives gifts for his or her beloved one.

In Sherry (1983)'s influential study of consumer gift giving in anthropological perspective, gift-giving is viewed as a continuous cycle of reciprocities. One important factor that is associated with satisfaction in a relationship is the reward level of the resources exchanged in the relationship (cf. Sprecher 1998).Notably, gift giving is a way of reinforcing relationships that are highly valued but insecure such as the kinship ties weakened by distance (Caplow 1982). In the romantic relationship, gifts are used to enhance self-attractiveness and self-esteem

(Mick and DeMoss 1990) or express feelings of love towards one's significant other (Cheal 1987). Research on dating gift giving shows that such gifts can also serve as a diagnostic cue for people to assess the intensity of a partner's love (Belk and Cook 1991). These instrumentalities of gift-giving naturally lead us to ask when and how people may develop different gifting strategies. Initial evidence has shown that gift giving patterns do evolve along different stages of a romantic relationship, e.g. often starting from the "gift-showering" at the early stage to "becoming unnecessary" at the mature stage (Joy 2001).

Existing literature has primarily focused on the desired recipients' influence as the origin of gift givers' gifting behaviors. For example, Otnes et al. (1993) integrated the study of recipient influences within the research on gift-selection behavior and explored how givers themselves actually view recipients and then examine how these perceptions influence actual gift-selection practices. Similarly, Ruth et al. (1999) investigated how the recipient's perceptions of the existing relationship, the gift, and his or her emotional reactions converge to affect relationship realignment. In this research, we propose a different perspective to consider givers' motivation of gaining feelings of security as the origin of their gifting behaviors. More specifically, we propose that the need to feel secure in the relationship will influence (1) how often an insecure lover gives gifts to his or her lover, (2) what kind of gifts he or she is inclined to purchase, and (3) how much is his or her willingness to pay for the chosen gift.

We first conducted an exploratory study to probe the gifting behaviors of lovers. Semi-structured interviews with 18 subjects who were in romantic relationship uncovered the following gifting patterns: (1) people tended to spend more time and effort in gift giving during courtship; what's more, they tended to focus on more hedonic items as their gift choice; (2) once the relationship settled down, people tended to reduce gift-giving to only occasion based (e.g. birthday) and holiday based gifting, and they tended to choose more functional or utilitarian items as gifts; (3) gifting was one of the most common means to please one's romantic partner; (4) when people felt less secure in the relationship, they thought of purchasing a gift more often, and they indeed did so. These findings support that in general, the power structure of a romantic relationship influences people's gifting behaviors.

We also conducted an experiment to investigate whether level of felt security in a romantic relationship has impact on people's choice of gift items. We randomly primed subjects (N=125) using scrambled sentence task with either feeling secure or feeling insecure in a relationship. Subsequently, the subjects primed as feeling insecure were more likely to select hedonic or discretionary items from the given list of gift choices compared to the subjects primed as secure (budget was controlled for; 85.6% vs. 57%, p<.01). Additionally, we plan to conduct a second experiment to test the difference in the willingness-to-pay for a desired gift item when subjects are subliminally primed with either feeling secure or insecure.

Meanwhile, a 3-month event-contingent diary study (N=38) is under way (confidentiality was assured through study's administrative procedure). Each time a subject gives a gift to his or her romantic partner, (s)he is instructed to record the experience following an agenda of topics specified in the journal kit as well as filling out a set of scale items adapted from the Relationship Assessment Scale (RAS, Hendrick 1988), the commitment scale (Lund 1985) and Braiker and Kelley (1979)'s love scale. This longitudinal study aims to gather further evidence of how level of felt security influences a lover's gifting behaviors along the evolving relationship.

We aim to contribute to the literature by demonstrating that in a romantic dyad relationship, an insecure lover is more likely to engage in more frequent gift giving to his or her beloved one, is more likely to select hedonic or discretionary items as gift choice, and is willing to pay more for a desired gift item. We also identify managerial and public policy implications that stem from these findings.

Do I Listen to You When You are Not Like Me?
The Effects of Priming Self Construal on the Influence of Others

Mina Kwon, University of Illinois, USA
Rashmi Adaval, HKUST, Hong Kong

Consumers are constantly exposed to ads where a similar or dissimilar source advocates the use of a product. People spontaneously compare themselves with these spokespersons and assimilate when they think of similarities or contrast away from them when they think of dissimilarities (Mussweiler 2003). Yet, the conditions in which these comparisons occur are unclear.

Research on source similarity presents mixed evidence with some suggesting that similarity can increase persuasion (Brock 1965; Woodside and Davenport 1974) and other work showing that this is not always the case (Leavitt and Kaigler-Evans 1975). Such discrepancies imply that the same source could have different effects depending on the recipients' frame of mind. We propose that self construal might be a critical factor that has been ignored.

Self construal pertains to how one sees oneself in relation to others; either independent of them or interdependent on them (Triandis 1989; Hofstede 1980). Although these differences might be chronic, self construal can also be primed (Brewer and Gardner 1996; Oyserman, Sorensen, Bergen, and Chen 2009). We suggest that one's self construal can influence whether people see themselves in relation to the source or not and this plays a role in how the message from the source is processed and the impact it has.

When a communication is presented, participants who have an interdependent self construal are more likely to assess if they are similar to the source or not. In contrast, participants who have an independent self construal might be more likely to see themselves as independent of any person or group. Thus, they may not engage in this assessment. We conducted two experiments to examine the effect of self construal on how much one takes into account information provided by similar or dissimilar others.

96 participants participated in Study 1. First, participants' self construal was manipulated by asking them to circle the pronouns "I" or "we" (Brewer and Gardner 1996). Then, as part of a different task, each participant read two product testimonials. Both came from the same source; a student with a gender neutral name who belonged to either their home university (similar source) or from a different university (dissimilar source). The two testimonials described the spokesperson's reactions to products that were either favorable or unfavorable. Participants then indicated how good the product was and indicated how similar they felt to the source (Aron, Aron, and Smolan 1992).

As expected, participants who were primed with "I" indicated that they felt further apart from the spokesperson (M = 3.13) whereas those who were primed with "we" reported feeling closer to the spokesperson (M = 3.68), $F_{dir}(1, 92) = 2.74$, p < .05.

Results suggest that when participants are primed with "I", the effect of product information (favorable vs. unfavorable) on participants' judgments does not depend on source similarity (M_{diff} = 3.32 vs. 3.39 for similar and dissimilar source), F < 1. However, when participants are primed with "we" the impact of product information on these judgments is greater when it comes from a source that is similar to them (M_{diff} = 4.17) than when it comes from a source that is dissimilar to them (M_{diff} = 2.25), $F(1, 48) = 4.90$, p < .05. This difference in means is confirmed by a marginally significant 3-way interaction involving the three variables, $F(1, 92) = 2.63$, (p = .10).

Although Study 1 shows that self construal determines the extent to which one takes into account information provided by the source, it is unclear if cognitive procedures activated by other tasks can override such effects. Experiment 2, investigates this issue.

Study 2 employed a 2x2x2x2 between subject design with procedures similar to Study 1, but with an additional comparison prime in the beginning. First, 208 participants were given a word task in which they were asked to compare pairs of objects (e.g., dog and cat) and asked to rate either how dissimilar or how similar they are (Xu and Wyer 2008). Then, participants were primed to think of themselves as independent or interdependent (using the "I" or "we" pronoun circling task). They then evaluated a testimonial from a similar or dissimilar source. The source described the product as having favorable or unfavorable features. Participants were then asked to indicate how good the product was and how persuaded they were by the message. They also indicated how similar they felt to the spokesperson.

Participants primed to think about similarities reported that they felt the spokesperson was more similar to them (M = 5.93) than those who were primed to think about differences (M = 5.03), $F_{dir}(1,191) = 7.26$, p <.01. Participants who were given product information from a similar spokesperson rated this person as more similar to them (M = 5.80) than those who were told that this information came from a dissimilar source (M = 5.18), $F_{dir}(1.191) = 3.42$, p < .05.

Consistent with study 1, the effect of product information on judgments was the same for participants with an independent self construal and source similarity did not matter. The additional task to induce a cognitive procedure to think about commonalities and differences had no effect on these participants (F < 1). In contrast, this task had an effect on participants primed with an interdependent self construal. The effect of product information on judgments was stronger when participants were thinking of commonalities rather than differences and was independent of source similarity. Thus, participants who had an interdependent self construal attempted to see commonalities and differences between themselves and the source if the prior task activated these procedures overriding the effects of source similarity. A three-way interaction of self-construal, commonality and difference prime and product information $F(1, 200) = 4.05$, p < .05 that was not contingent on where the source came from (F < 1) confirmed this pattern.

This research suggests that consideration of self construal might help clarify ambiguities in previous research findings on the effects of source similarity.

Shaping Product Perceptions

Tanuka Ghoshal, Indian School of Business, India
Peter Boatwright, Carnegie Mellon University, USA

Academic researchers reiterate the importance of product design and aesthetics as an opportunity for differential advantage in the marketplace (Creusen and Schoormans 2005, Bloch 1995). There has been a recent upsurge in academic interest in product design aesthetics, and some of this work includes studying how aesthetic stimuli are processed (Reimann et al 2010), how aesthetics impact perceived functionality (Hoegg, Alba and Dahl 2010) etc. In the current research we attempt to isolate and investigate the impact of product shape, arguably a more subtle component of product design. We firstly investigate whether people have preferences for certain kinds of shapes for different types of products for which shape is not related to product functionality. We then try to establish whether there is transference of the positive attitude towards aesthetically appealing shapes to perceived functional and/or hedonic benefits of the product. We finally investigate how product shape influences perceptions, and whether the influence of shape occurs at a conscious or non-conscious level.

Preference for specific shapes. Given that a vast majority of products and packages in the marketplace are rectangular (Raghubir and Greenleaf 2006) a question that naturally arises is whether consumers in general prefer products with angular shapes as opposed to curvaceous shapes, despite evidence from psychology that people tend to prefer curved objects to angular objects (Bar and Neta 2005). Photographs of various common hedonic (examples: car, mp3 player) as well as utilitarian products (examples: teapot, external hard drive, sports bottle) that are typically available in both curvilinear and angular forms, were converted into outline diagrams using a software so that there were no obvious differences in design other than the outer shape of the products. These line drawings were evaluated by subjects, as part of a "Product Prototype Evaluation study". The angular and curvilinear versions of each product were pretested to be equivalent on prototypicality (Reber, Schwarz and Winkielman 2004). We find that across the range of products we tested, the curvilinear form is preferred over the angular by a vast majority of respondents. "Visual pleasure" is the most common spontaneous reason provided for the preference, and in an upcoming study, response times will be measured to see whether higher perceptual fluency for curvilinear shapes drives this preference (Reber, Schwarz and Winkielman 2004).

Shape and perceived functionality. There is a fair amount of research evidencing that shape of a container can impact perceived quantity perceptions and consumption (Raghubir and Greenleaf 2006, Yang and Raghubir 2005, Wansink and Ittersum 2005), but the specific role of aesthetically pleasing shape(s) in influencing product perceptions has received limited attention. We study whether superior functional and/or hedonic benefits are attributed to aesthetically preferred shapes, for products where shape should not be associated with functionality. We have evidence that visually appealing shapes are associated with perceived superior functional benefits (example: a curvilinear car is perceived to be more fuel-efficient than a more angular (boxy) car, a curvilinear external hard drive is perceived to have more capacity than an angular shaped one), and/or perceived superior hedonic benefits (example: curvilinear teapot perceived to be "better suited for party"). This will be further explored with a larger range of utilitarian and hedonic products.

The nonconscious role of shape. In a third study we set out to investigate whether the influence of product shape may be at a less conscious level than we imagine. We showed subjects two prototype products belonging to the same category, one curvilinear in shape and the other angular. The products shared one common attribute specification, were individually superior to the other product on a second attribute, and were individually inferior on a third attribute. (The latter two attributes were pretested to be equally important). A control group evaluated the same pair of products with the same attribute specifications but without any pictures (no difference on visual appeal). Subjects were asked to evaluate the importance of the three given attributes for the purchase decision-making process for that category. The hypothesis was that the attribute on which the aesthetically appealing shaped (curvilinear) product is superior would be deemed to be of higher importance as compared to the control group. We find preliminary support for our hypothesis in several product categories, and are currently working on generalizing these results to different kinds of product categories.

In summary, in this research we investigate in what manner product shape impacts decision-making, and whether apart from conscious visual aesthetic preferences, there are nonconscious impacts of aesthetically pleasing shapes on perceived functionality, or whether there is nonconscious rationalization of visual pleasure by awarding higher importance to other functional aspects.

The Relationship between Brand Personality and Self Construal

Jenny Jiao, University of Iowa, USA
Irwin Levin, University of Iowa, USA

This paper examines the sincere and exciting dimensions of brand personality and individual differences which prior work on consumer-brand relationship has overlooked. The aim of this research is to provide insight in the previously stated question about consumer–brand relationships. The major question is how individual difference affects consumer-brand relationships by attaching to different kinds of brand personalities. This research examines the extent to which Aaker's (1997) structure of personality attributes is associated with individual difference (either independent or interdependent individual).

This study defines brand personality as the set of human personality traits that are both relevant and associated with brands (Aaker, 1997). Thus it includes such characteristics as gender, age, socioeconomic class and human personality traits as warmth, concern and sentimentality (Aaker, 1996). For example, Coca Cola is classic but Pepsi is young; Victoria's Secret tends to be feminine and sexy in comparison to Jockey; Disney tents to be young and fun when compared to Yellow Stone National Park.

Brand personality is a vehicle for the consumer to express different aspects of self (Aaker 1997; Belk 1988; Escalas and Bettman 2005; Johar, Sengupta, and Aaker 2005). Previous research suggested that a person's personality could influence consumer behavior, and consumer's personality traits could influence their shopping styles or strategies (Horton 1979). Furthermore, researchers have suggested that brand personality could help differentiate brands (e.g., Crask and Laskey 1990), identify personal meaning for the consumer and to determine brand equity (Aaker 1991). But little research is known about how individual difference influences consumer-brand relationship by attaching to different kinds of brand personalities. This study tries to fill up the gap between individual difference and brand personality.

This study will focus on capturing *exciting and sincere* brand personalities. Among Aaker's five dimensions of Brand Personality Scale, exciting and sincere brand personalities appear to capture much of the variance in personality ratings of brands (Aaker, 1997). Exciting and sincere brand personalities are particularly important because they map onto the key three ideals that Fletcher et al. (1999) note as being important in interpersonal relationships: warmth, vitality, and status (Swaminathan& Stilley, 2009). *Exciting* brand personalities try to achieve differentiation through unique and irrelevant advertising (e.g., Dr. Pepper and BMW). *Sincere* brand personalities have been pursued by companies which wish to build a warmer, trustful and responsible brand image (e.g., Coca-cola and Ford).

Independent individuals regard themselves as independent from others in order to express their unique attributes (Johnson, 1985; Marsella et al., 1985), this view of the self derives from the belief that each person's configuration of internal attributes are whole and unique (Johnson, 1985). *Interdependent individuals* view the relationship between the self and others features the person not as separate from the social context; they view themselves as part a group. Individuals with an interdependent self-construal are motivated to find a way to "fit in with relevant others, fulfill and create obligation", and in general to become part of various interpersonal relationships (Markus and Kitayama, 1991).

Consumers are known to form a strong relationship with their brands to express their identities (Escalas & Bettman, 2005; Reed, 2004). Therefore, we hypothesize that individuals would have different motivations to be attached to a certain brand. An independent individual should be motivated by an exciting brand that allow expression of his important self-defining, and validate his inner attributes. In contrast, an interdependent individual should be motivated to those actions that enhance or foster one's relatedness or connection to others, maintain harmony with social context and adjust oneself to the social group. Sincere brands fit interdependent individuals' needs by allowing one to be connected to the social context and convey a sense of belonging.

Across two studies we test the overall hypothesis that consumers with an independent self construal are more likely to have a higher brand attachment and brand attitude toward exciting brands than sincere brands. We also tested how brand information type influences the consumer brand relationship.

In study 1, 119 participants were randomly assigned to one of two conditions in a 2 (brand personality: sincere vs. exciting). Instead of manipulating self construal, we used Singels' (1994) Independent Self-Construal scale to measure independent and interdependent self construal. Participants were asked to view a Win detergent ad which manipulated the brand personality and provide their reactions to it. We chose Win detergent because based on the pretest, it is not a very exiting or sincere brand, and participants have a very low familiarity with

win detergent. Brand personality was manipulated via taglines and brand elements and pictures to convey either a sincere or an exciting brand personality.

The pretest confirmed that participants who *were exposed* to the exciting ad rated the brand as significantly more exciting than sincere (*Mexciting= 3.89, Msincere=3.09; t=* -2.58, p<0.005).

The result showed that generally the exciting brands are rated higher than the sincere brands on consumer-brand relationship *(Mexciting= 2.86, Msincere=2.44;* t=-2.20, p<0.015), that's because our participants are undergraduate students who are their age of 20s. 2 (brand personality: exciting brand vs. sincere brand) * 2 (individual difference: independent individual vs. interdependent individual) ANOVA revealed a significant interaction between brand personality and self construal (F (1, 116) =3.89, p<0.02). As we predicted, an independent self prefers the exciting brands than the sincere brands.

However, this consumer-brand relationship might change depending on the advertising's type. Study 2 examined the commercial information type and brand personality because we are also interested in examining how the commercial information type influences consumer brand relationship. 183 participants were randomly assigned to one of the following 4 conditions: 2 (Brand personality: sincere vs. exciting) *2 (Commercial information type: attractive vs. professional). Brand personality was manipulated as the same way in study 1, commercial information type was manipulated by conveying difference source of information providers and information contents. For example, in the attractive information condition, the Win detergent information was provided by a Mom from Iowa City, starting with "I saw Tim Gunn endorse this product on a talk show. I bought and tried; now I love it;" but in the professional condition, the information was provided by an expert, starting with "The new product, is 100% biodegradable, and doesn't contain brighteners, phosphates, or dyes." The resulted showed a significant two-way interaction between brand personality and information (F(1, 170) =4.62, p<0.005) , which means consumers have a higher brand attitude toward a sincere brand if the product information is framed in an attractive way than professional way.

This prediction is consistent with self-congruity theory (e.g., Sirgy 1982), which suggests that consumers feel more connected, and are more likely to purchase brands whose personality matches consumers' self-concept. This study tries to demonstrate that distinct views of the self will lead to different consumer-brand relationship with exciting and sincere brands. It has important implications for companies who wish to build a strong relationship with consumers, the independent individuals prefer the exciting brands but the interdependent individuals prefer the sincere brands. We also showed this consumer-brand relationship might change depending on the advertising's type. Future research could focus on investigating whether there are any circumstances under which consumers are more likely to choose brands that mismatch their self-concept. Furthermore, it would be interesting to investigate whether self-construal moderates how consumers respond to transgressions from exciting vs. sincere brands (e.g., Aaker, Fournier and Brasel 2004)

Uh-Oh, This Might Hurt Our Bottom Line: Consumer and Company Reactions to Product Harm Crises

R. Justin Goss, University of Texas at San Antonio, USA
David H. Silvera, University of Texas at San Antonio, USA
Daniel Laufer, Yeshiva University, USA
Kate Gillespie, University of Texas at Austin, USA
Ashley Arsena, University of Texas at San Antonio, USA

Product harm crises, "discrete, well publicized occurrences wherein products are found to be defective or dangerous" (Siomkos and Kurzbard 1994), can cause damage to both the financials and reputation of a company. Research suggests that an important determinant of the amount of damage the company incurs is the degree to which consumers blame the company for the crisis. Blame attributions for product-harm crises can have a variety of negative consequences for the company, including reduced consumer satisfaction with the product, increased consumer complaints, and desire for refunds. These findings suggest that blame attributed to a company in association with a product-harm crisis will negatively affect attitudes toward the brand, purchase intentions, and recommendations relative to the company's products. The current research attempts to identify factors that can potentially influence blame attributions by observers of a product-harm crisis. Specifically, we investigated the roles severity of the crisis, familiarity of the involved brand, post-crisis company reactions, and personal vulnerability of observers of the product-harm crisis have in determining blame attributions.

Much of our understanding of the mechanisms underlying blame attributions comes from social psychology; in particular, social psychology research related to the defensive attribution hypothesis offers some potential insights into these mechanisms. The defensive attribution hypothesis posits that when an incident results in a more severe outcome and/or observers feel more personal vulnerability in relation to that incident, more blame will be attributed to a potentially responsible party (Shaver 1970). Further, outcome severity is an important feature of product failures and product-harm crises in marketing contexts. For example, minor product defects have a small effect on consumers, whereas major defects (e.g., contaminated drinks or cars that tend to roll over on turns) can lead to catastrophe. The present research examines the applicability of the defensive attribution framework to product harm crises, and also adds several variables that the marketing literature suggests might moderate blame to the company, most notably familiarity of the brand involved in the crisis and the content of the company's public response to the crisis. In three studies, participants read a product harm scenario in which the severity of the product harm crisis was manipulated, after which participants were asked to make a series of judgments in relation to the product harm crisis including the amount of blame attributed to the company, personal vulnerability, severity of the crisis, future purchase intentions, and attitudes toward the company involved.

The three experiments used similar methods. Participants were asked to read a fictitious newspaper article about a product harm crisis. Severity of the crisis (Experiments 1-3) and familiarity of the involved brand (Experiment 2) were manipulated using different versions of the article. In Experiment 3, participants were also presented with a press release that manipulated the company's reaction to the crisis. Subsequent to the manipulations, participants were asked to respond to measures assessing blame, feelings of vulnerability, and perceived severity.

Experiment 1 developed a preliminary model testing the impact of severity and other relevant variables on blame attributions in a product-harm crisis about tires. Results showed that blame to the company is positively related to both severity of the product harm crisis and participants' feelings of personal vulnerability in relation to the product-harm crisis. Further, instead of personal vulnerability predicting blame to the company directly, personal vulnerability only influenced blame indirectly through its relation with perceived severity. Blame to the company was also negatively related to attitudes toward the brand, which were in turn related to purchase and recommendation intentions.

Experiment 2 tested the interaction between brand familiarity and severity. For the low severity crisis, brand familiarity had no impact on blame to the company; for the high severity crisis, participants ascribed significantly more blame to the company when the brand was unfamiliar than when the brand was familiar. These results indicate that familiar brands are more resistant to the negative effects of a product harm crisis than unfamiliar brands.

Experiment 3 investigated how an unfamiliar brand can similarly protect itself against negative effects of product harm crises based on the company's media response to the crisis. Analyses revealed a significant 2 (severity: low vs. high) x 4 (press release: no press release vs. apology vs. accepting responsibility vs. blaming the victim) ANOVA interaction predicting blame to the company involved in the product harm crisis. Specifically, compared to the no press release control condition, (a) a company apology resulted in increased blame to the company regardless of the severity of the crisis, (b) the company taking responsibility for the crisis and promising to fix the problem resulted in less blame for a low severity crisis but more blame for a high severity crisis, and (c) blaming the victims in the crisis resulted in decreased blame to the company regardless of the severity of the crisis. The reduction in blame to the company, when the company blamed victims, was larger for a low severity than for a high severity crisis. These results suggest that the best way for an unknown company to avoid blame is to use media communications to try to deflect blame to victims of the product-harm crisis. This might be something of a catch-22 situation, however, as it seems unlikely that consumers who were harmed in the crisis will respond favorably to such a media policy.

Across three experiments, results indicated that blame to the company was positively related to feelings of personal vulnerability and the severity of the crisis, familiar brands are more resistant to the negative effects of a product harm crisis, and companies that respond by shifting the blame to the victim of a product harm crisis are most able to keep their reputations intact. Future studies aim to investigate potential moderators and outcomes of the victim-blaming strategy and the impact public interest groups and legislative changes have on blame attributions after a product harm crisis.

Effects of Green Products on Price Perceptions

R. Justin Goss, University of Texas at San Antonio, USA
David H. Silvera, University of Texas at San Antonio, USA
Daniel Laufer, Yeshiva University, USA
Kate Gillespie, University of Texas at Austin, USA
Ashley Arsena, University of Texas at San Antonio, USA

Desire to buy green products, although far from being a fad, has not always resulted in product purchase. For instance, sale of hybrid cars, long considered as fuel efficient and green, only accounted for 3.5 percent of the cars sold in the US market in 2010 (www.hybridcars.com). Similarly, in the American cleaning products segment, though companies such as Seventh Generation and San Francisco's Method Products have been making natural cleaning products for years, their combined sales amount to only 1% (Information Resources Inc.). Highlighting this as a worldwide trend, Mckinsey and Company's global poll reported that only 33% of those surveyed had bought a green product during the previous year even though 87% expressed strong interest in purchasing green products (Bonnini and Oppenheim 2008). A goal of this research is to explore this lack of 'interest-to-sales' conversion in green products.

Price is often cited as one of the inhibitors of green product purchase (Ewing 2009) although some consumer surveys point to consumer willingness to pay a premium for the same (Environmental Leader 2007). This raises an interesting question pertaining to how consumers may trade-off green aspects of a product when assessing its price (Bonnini and Oppenheim 2008). Specifically, we begin by asking if consumers expect to pay relatively higher price for green products.

Furthermore, companies often try to get around the cost of developing completely green products by joining the green bandwagon by promoting traditional offerings in their lineup as somewhat or partially green alternatives (e.g., Toshiba's A600 laptops running on low voltage; HP desktop PCs featuring AMD's 'Cool 'n' Quiet' processors). In the recent past only few companies worked on plans to increase their offerings of completely green products (e.g. Toyota Prius). A second issue, then, is to understand if consumers process price information differently for complete and partially green products. Finally, given the gap between interest and actual purchase, will consumers' motivation to purchase a product differentially influence the way they process such higher prices when products under consideration area) completely green products and b)with few green attributes (i.e. partially green)?

Though past research on information processing proposes that consumers are cognitive misers (Shugan 1980), the idea also embodies that efficient information processors must strike a balance between minimizing their processing efforts and maximizing their judgmental confidence. Maheswaran and Chaiken (1991) proposed the *sufficiency principle* which suggests that consumers cannot be completely confident that their judgments are correct and can only hope to achieve some level of confidence (sufficiency threshold), which is benchmarked against their desired level of confidence. Based on this principle consumers would step up their efforts to systematically process information when less effortful heuristic mode confers insufficient judgment confidence; a discrepancy in product attribute information would encourage consumers to scrutinize the given information. Integrating these conclusions with research on consumers' use of price as a dual cue to infer quality (Miyazaki, Grewal and Goodstein 2005) and assess monetary sacrifice (Monroe 2003), we predict that participants who are motivated to process information will use a relatively high price of a green product, irrespective of whether it is completely or partially green to conclude that it requires a high monetary sacrifice. In low motivation conditions, a completely green product would be processed heuristically and its high price will be used more to infer that it is of high quality. More importantly, we predict that despite low motivation to process information, a partially green product at a high price will be processed systematically, and its price will lead to perceptions of a high monetary sacrifice.

A series of three studies examined this issue. In Study 1, using semantic association task and implicit association test (Greenwald, Nosek and Banaji 2003), we confirmed differences in associations between products described as completely and partially green. In study 2, participants were first provided with a description of a green product and an average price (P) for a similar conventional product. Participants then indicated their willingness to pay (WTP) for the green product. Three products, tote bag, metallic water bottle and jump drive, were randomly presented to the participants. The results revealed a significant price appreciation [(WTP- P) / P; 28% - 177%] for the green products over their conventional counterparts affirming the perceived expensiveness of such products.

Study 3 tested our predictions by examining how a relatively expensive ($399.99) environmentally friendly printer described as either completely green (all green attributes) or partially green (one green attribute) will be perceived by participants with different processing goals towards its purchase (low vs. high motivation). The results revealed that in high motivation conditions, printers were perceived high on monetary sacrifice irrespective of the number of green attributes associated with them. Also in low motivation conditions, the printer was perceived less expensive when it was described as completely green. More interesting was the result that in low motivation conditions, description for the partially green printer was processed systematically and it was perceived expensive compared to the completely green printer.

Overall, the results seem to suggest that consumers with no assigned purchasing goals were willing to pay more for a green versus a comparable conventional product. Assigning purchase responsibility for a product enhanced attention to its price and the evaluation of its monetary sacrifice was not impacted by the number of green attributes used to describe that product. In low motivation conditions, participants relied less on price to assess monetary sacrifice but more to infer product quality when its description was dominated by green attributes. However inconsistency between its high price and a few green attributes, i.e., partially green product, resulted in a heightened attention to price which was then used to infer that the product required a high monetary sacrifice. Hence, though green products are perceived as expensive (DeBare 2008), the results suggest that "greenness" of a product is a cue which when diluted, as in case of partially green products, may reduce consumers' willingness to pay high prices.

Loyalty Can Engender Blind Acceptance:
Brand Identification and Brand Identity Fit in Co-branding

Na Xiao, University of Winnipeg, Canada
Fang Wan, University of Manitoba, Canada

Brand identity is considered to be one of the most important drivers of a successful brand. Emerging research defines brand identity as a cultural meaning system that resonates with target consumers' lifestyles, dreams, and goals (Thompson, Rindfleisch, and Arsel, 2006). Brands with strong identities make it easier for consumers to identify with, to internalize brand values, and therefore foster a strong bonding between consumers and brands (de Chernatony 1999, 2006). As a result, brands can eventually become important means, tools and symbols for consumers to employ to express values and identities, or become an extended part of consumers themselves (Mittal, 2006; Fournier, 1995).

Existing research has explored how brand concept fit and product category fit can affect the success of brand alliances. Therefore, attitude will be more positive when brand concept fit or product category fit than misfit (e.g., Aaker and Keller 1990; Park et al. 1991; Simonin and Ruth 1998) whereas "brand identity fit" is rarely examined in this context. We argue that brand identity is an important dimension to gauge the fit between brand partners other than brand concept (Park et al. 1991; Simonin and Ruth 1998). Brand identity is the cultural meaning system co-created, shared and perceived by consumers whereas brand concept is brand meaning engineered and crafted by corporations. Therefore, our focal concern is how brand identity fit between brand partners affects the success of their alliance and how identification with a focal brand moderates the effect of brand identity fit on attitude toward brand alliance. Specifically, we address 1) how the fit or misfit of the brand identities of two partners affect consumers' attitude towards the brand alliance and 2) how loyal consumers of the focal brand reconcile with the misfit with co-brand, if there is any. This research addresses these issues in a co-branding context where two parent brands are aligned to create a single product or service.

To address these research questions, we tested how identification with a focal brand moderates the impact of brand identity fit on the attitude toward brand alliance and found that consumers with high identification with a focal brand tend to tolerate brand identity misfit in a brand alliance (Study 1). We employed qualitative depth interviews and identified two coping strategies loyal consumers of original brand employ to reconcile with the misfit between the original brand and the co-brand (Study 2). Lastly, we examined the effect of different coping strategies on loyal consumers' attitude towards the brand alliance (Study 3).

Study 1. Study 1 was designed to test how identification with a focal brand moderates the relationship between brand identity fit and attitude towards the brand alliance and loyalty of the target brand. We first conducted a pretest to identify brand alliance pairs which have either a high or low identity fit. In a pretest of 30 participants, Apple had the highest rating on the dimension of anti-status quo and rebellious (M=4.00) among all selected brands. Among the brand partners, Intel had significantly lower rating on this dimension (M=2.73, p<.05) and Nintendo had similar rating compared to Apple (M=3.98, p>.05). In addition, the perceived fit between Apple and Intel is lower than between Apple and Nintendo (4 vs. 4.78, p<.05). Therefore, we selected Apple and Intel alliance as the brand alliance with low brand identity fit and Apple and Nintendo as high brand identity fit.

In the study, eighty four Apple users were asked to indicate their identification with Apple brand on 5 items (Bhattacharya et al., 1995). Next, they read a fictitious press release announcing the collaboration of Apple and Intel (or Nintendo). They were asked to rate the identity fit between the two brands, their attitudes of the brand alliance. Regression of identification (a continuous variable) and identity fit (high vs. low) on the attitude toward brand alliance was significant (beta =.43, p<.05). We found that when consumers have strongly identified themselves with Apple brand, their attitude toward brand alliance is not affected by whether brand partner is a fit or misfit with Apple brand (M=5.45 vs. 4.98, F<1). However, when consumers have low identification with Apple brand, they evaluated low fit pair (Apple+Intel) more favorably than high fit pair (Apple+Nintendo) (M=5.93 vs. 4.72, $F_{(1, 80)}$=6.86, p<.05). Our post-hoc study discovered that consumers highly identifying themselves with Apple demonstrated a halo effect. In other words, their emotional bonding with Apple carried over to its brand partners regardless of their fit, therefore they do not discriminate brand alliance with low brand identity fit. In contrast, with low identification with Apple brand, consumers' attitude toward brand alliance is driven by the functional benefit of the partner. In this case, Intel made the computer run faster whereas consumers did not know in what way Nintendo could benefit Apple, therefore, they rated brand alliance more positively in a brand identity misfit condition.

Study 2. Study 2 set out to understand the halo effect uncovered in Study 1. That is, when a brand partner has a low brand identity fit with the focal brand, how do loyal consumers reconcile with the misfit and evaluate the brand alliance positively? Depth interviews (one to two hours) with six Apple loyal Mac users (basic themes can present themselves within six interviews, Guest et al., 2006) were conducted. Through thematic analysis, we found that informants felt that Apple's brand identity was impaired because Intel had been mainly associated with PCs. This indicates that loyal Apple brand users in Study 1 recognized the identity misfit between Apple and Intel but they were just tolerant of the misfit. In addition, we uncovered two coping strategies informants employed to buttress their support of Apple brand vis-à-vis the misfit co-branding efforts: "decoupling" (as in Ahluwalia, 2000, subjectively and blatantly dismiss the negative impact of Intel on Apple brand) and "biased assimilation" (subjectively boost evaluation of Intel so that it can be assimilated into positive associations of Apple brand).

Taking findings of Study 1 and Study 2 together, we propose that when brand identity fit is low, *decoupling* is more effective than *biased assimilation* at defending, or maintaining the positive attitudes of the brand alliance. However, when brand identity fit is high, coping strategies may not affect brand alliance evaluation because both the positive association with the original brand and the brand identity fit can drive up the evaluation of the brand alliance. We tested this proposition in Study 3.

Study 3. A 2 (coping strategy: decoupling vs. biased assimilation) by 2 (fit: low vs. high, measured factor) between-subject design was adopted. Eighty six Apple users participated in the study. They read a "new product release" announcing the brand alliance between Apple and Intel and then were provided with comments by online consumers on the brand alliance (coping strategies were manipulated by whether comments from peer consumers demonstrate decoupling or biased assimilation strategies). Then subjects responded to a survey measuring their attitude toward the brand alliance and the perceived fit between Apple and Intel (7 items, adapted from Taylor and Bearden 2002). Regression yielded a significant interaction between coping strategies and fit on attitude towards the brand alliance (beta=-.42, *p*<.05). To extrapolate the interaction, we classified perceived fit into low and high groups based on median split. Our propositions were confirmed that when the perceived fit was low, attitude towards brand alliance was more positive when a decoupling strategy (vs. biased assimilation) was activated (M=5.08 v.s. 4.22; F(1,41)= .66, p<.05). However, when the perceived fit was high, coping strategy had no impact ($M_{decoupling}$=5.19 vs. M_{biased}=5.47, F(1,39)= .17, p>.05).

This research discovered that whether brand identity fit/misfit affects attitudes towards brand alliances depends on how consumers identify themselves with the focal brand. Specifically, loyal consumers are tolerant of brand identity misfit in brand alliance due to the halo effect and due to the biased assimilation strategy (vs. decoupling) they adopt to maintain their loyalty. However, for consumers with low brand identification, brand identity fit is not a diagnostic cue for their evaluation of the brand alliance as they do not really understand the nuanced meaning of the focal brand and can accidentally favor brand alliance with brand identity misfit.

Picture Yourself…: The Effect of Personal Imagery on Pragmatic / Ideal Trade-offs

MengHsien (Jenny) Lin, Iowa State University, USA
Laura Smarandescu, Iowa State University, USA

In order to understand consumers' judgments and preferences researchers must first determine what inputs are attended externally or retrieved from memory and understand how these inputs are weighted in decision outcomes. Construal-level theory provides a theoretical framework that explains how psychological distance alters the mental representation of these inputs and the weights that are attributed to "high-level" and "low-level" criteria.

THEORETICAL BACKGROUND

Liberman and Trope (1998) first introduced construal level–theory (CLT) to explain how temporal distance affects the mental representations individuals have for events. CLT suggests that individuals use concrete, low-level construals to represent near events, and abstract, high-level construals to represent temporally distant events. Liberman and Trope (1998) suggest that a high construal level activation is linked with a subordinate purpose, the "why" of the activity, such as getting a good education, whereas in a low construal level activation, the focus is placed on "how" to do the activity, such as reading a textbook.

So far the notion of psychological distance has been explored in relation to spatial distance (i.e., spatially close vs. far), social distance (i.e., self vs. others), or in relation to an event's probability of occurrence (i.e., frequent vs. less frequent). Fujita et al. (2006) show that people who believed that characters in a film were spatially distant used more abstract language in describing the events in the movie. In a social distance domain, a higher level of dissimilarity is considered to be a higher construal level (Liviatan et al. 2008), as individuals view distant others at a more abstract level than similar others. Research that looked at how individuals perceive events with different occurrence likelihood shows that events with a lower occurrence probability are perceived at a greater psychological distance than events that have a higher probability of occurring (Chandran and Menon 2004).

A form of psychological distance that has been examined less in relation to consumer decisions and behavior is related to the notion of personal perspective and self-imagery. Bem (1972) suggests that perspective affects individuals' attributions of cause for a behavior. Observers tend to understand an actor's behavior as a function of the actor's disposition, where visual focus is on the actor. In comparison, actors tend to understand their own behavior as a function of the situation, where the situation is focal for the actor (Jones and Nisbett 1971; Storms 1973). People use visual perspective to picture past events, with effects on emotions, self-judgment and behavior (Ashworth and van Boven 2007; McIsaac and Eich 2002; Robinson and Swanson 1993). Libby et al. (2007) found that people who pictured themselves voting in a third-person perspective not only adopted a stronger mindset before voting, but they were significantly more likely to vote in the election. The present research investigates the effects of psychological distance in the form of personal perspective on individual preference judgments. Hence, we investigate how taking a first vs. third person personal perspective may highlight different aspects of options and influence preference for pragmatic and ideal considerations.

Consistent with previous studies on personal perspective (Libby et al. 2007; Libby and Eibach 2002), we conceptualize that a first-person mental perspective would be represented at a lower construal level. We hypothesize that individuals taking a first person perspective will make preference judgments based on more concrete and pragmatic reasons. In comparison, individuals primed with a third person mindset may construe the same activity at a more abstract higher construal level. Hence, we propose that purchase decisions made under this context would be based on more idealistic rather than pragmatic reasoning.

This paper is organized as follows. Study 1 examines how perceived psychological distance cued by a personal perspective manipulation affects how individuals weigh pragmatic and ideal dimensions in choice. Study 2 investigates the moderating effect of individual differences in self-orientation (i.e., pragmatic vs. value orientation).

Study 1

Sixty-three undergraduate students participated in a consumer preference study. The study design was a 2 (personal perspective: first, third) × 1 between subjects design. Following the personal perspective manipulation, individuals were presented with a consumer choice scenario. The choice task presented two types of light bulbs, one described with ideal attributes (e.g., energy savings, recyclable) and the other with pragmatic attributes (e.g., lifespan, natural light). Individuals primed with a third person mindset were more likely to choose the light bulb described with ideal features (63%), consistent with a mindset favoring more abstract, higher construal level features. Individuals who were primed with a first person mindset favored the option described with more pragmatic considerations (61%), a marginally significant relationship ($c^2_{(1, 63)} = 3.57$, $p = .059$).

Study 2

Study 2 was a 2 (personal perspective: first, third) × 2 (self-orientation: pragmatic/ ideal based on a median split) between subjects design. Individuals were randomly assigned to one of the two personal perspective conditions, indicated their preference between two banks (Bank A: pragmatic attributes vs. Bank B: ideal/ value attributes), and rated their self-orientation using a 4-item scale (Liberman and Trope

1998). The preference judgment was concerned with the strength of preference for bank A vs. bank B. The analysis revealed a significant interaction between personal perspective and self-orientation on preference for a bank ($\beta = .416$, t (53)= 2.22; $p < .05$). In a third person perspective, and when the individual was more idealistic than pragmatic, preference for bank B increased by .41.

CONCLUSION

Through two studies we show that predictions of CLT theory are supported in the personal perspective domain. As hypothesized, a first person perspective is associated with less perceived psychological distance, more concrete judgments, and greater weight attributed to pragmatic considerations. On the other hand, individuals primed with a third person mindset make judgments based on more abstract and idealistic attributes. This present study contributes and extends previous findings on construal level theory and suggests a causal role of mental imagery in determining future purchase behavior.

Temporal Distance and the Endowment Effect

Dongwoo Ko, University of Iowa, USA
William Hedgcock, University of Iowa, USA
Catherine Cole, University of Iowa, USA

Research on the endowment effect has identified factors which enhance or mitigate the effect such as duration of ownership (Strahilevitz and Loewenstin, 1998), and information processing differences between sellers and buyers (Nayakankuppam and Misha, 2005). But these studies have primarily involved immediate transactions between sellers and buyers. An interesting question emerges about whether the endowment effect will be observed for temporally distant transactions. The main purpose of my research is to examine how the temporal distance of transactions influences customers' evaluations of products by comparing buyers' willingness to pay and sellers' willingness to accept in the present and in the future.

THEORETICAL FRAMEWORK

The mechanisms underlying the endowment effect and temporal construal level theory (Liberman & Trope, 1998) suggest different underlying processes for temporally different transactions. Prior studies have found buyers and sellers have different cognitive perspectives during transactions. Sellersfocus on their products while buyers focus on their money. These different cognitive perspectives induce price gaps between sellers and buyers and increase loss aversion. However, if events are in the far distance, sellers' and buyers' cognitive perspectives may change. When sellers conduct transactions in the present, they think about the feasibility of the transaction. Sellers may describe actions and transactions in terms of how they will attach a value to the product. However, if the transaction is in the future, the primary purpose of the transaction will be weighted relatively more than the subordinate feature of the action. For sellers, the main purpose of the transaction will be obtaining money, whereas for buyers the main purpose will be to acquire the product. Thus, aspects of the "why" identification will lead

sellers and buyers to change their cognitive perspectives, which will decrease the endowment effect. The willingness to accept will decrease because the sellers' cognitive perspective will move from the product to money; in contrast, willingness to pay will increase because buyers will give more weight to the products when the transaction is expected in the far future. Specified hypothesis are as follows:

H1. As temporal psychological distance increases, the price difference between sellers and buyers will decrease.

H1a. When a transaction is temporally distant, buyers will be willing to pay a higher price than when a transaction is temporally close.

H1b. When a transaction is temporally distant, sellers will be willing to accept a lower price than when a transaction is temporally close.

H2. Temporal distance will affect sellers and buyers' cognitive perspectives

H2a. When a transaction is temporally distant, sellers' cognitive perspective will be more on the cash than product. Whereas when a transaction is temporally near, sellers' cognitive perspective will be more on the product than cash.

H2b. When a transaction is temporally distant, buyers' cognitive perspective will be more on the product than cash. Whereas when a transaction is temporally near, buyers' cognitive perspective will be more on the cash than product.

STUDY 1

The main objective of this experiment is to examine whether temporal distance affects people's willingness to pay and accept. In the experiment, subjects were divided into two groups—sellers and buyers—as well as into two different situations involving near and distant transactions, resulting in a 2 (buyers vs. sellers) x 2 (near distance vs. far distance) between subjects design. The participants were 74 undergraduate marketing students. The experiments were conducted via a paper and pencil survey. As subjects sat down, they found a pen which they used throughout the study. Participants were told the research was part of a new product development study. Participants were randomly assigned to the buyer or seller roles by a coin toss. Temporal distance was manipulated by giving two different transaction situations: today and a month from today. Respondents were asked what price they would pay or what price they would accept (depending on their role). The 2(role) X 2(time) between subject ANOVA on price revealed a significant main effect for role ($F(1, 65)= 7.873, <.007$) and a significant two way interaction effect between role and temporal distance ($F(1, 65) =5.710, <.020$). The interaction was significant because the price gap between sellers and buyers in the present (seller - buyer : 1.69 -.998) was greater than the same price gap in the future (seller - buyer: 1.535- 1.2974). As temporal distance increases, buyers' willingness to pay increased ($t=-1.748, <.09$) and sellers' willingness to accept decreased ($t=2.204, <.051$), consistent with H1.

In order to examine the underlying process, respondents' thought listings were analyzed using the Standardized median rank difference (SMRD) between money and pen. SMRD is defined as $2(MRP-MRM)/n$ where MRP = median rank of product thought type in a participant's sequence, MRM = median rank of money thought type in a participant's sequence, and n=total number of thoughts in respondents' sequence (Johnson et al., 2006). Analysis yields the variable, "thought type", which approaches 1 if subjects give more value to the product and approaches -1 if subjects give more value to the money.

A 2 (role) X 2 (time) between subjects ANOVA on thought type revealed the only significant factor was the two way interaction between role and time ($F(1, 65) = 7.547, <.008$). This occurred because under near transaction condition, sellers thought more about products, while buyers thought more about money (0.7086, -.4792). On the other hands, when the transaction was expected in the future, sellers gave more value on money than product, while buyers gave value more on product than money (-.3033, .2474). This is consistent with H2.

We believe this is the first study that demonstrates the endowment effect changes depending on whether transactions are temporally near or distant. We show the cognitive focus of sellers and buyers changes as transaction distance changes. These results raise interesting questions about whether construal level influences customers' willingness to pay and sellers' willingness to accept without temporal distance manipulation. We are currently running studies to see whether alternative construal level manipulations influence the endowment effect.

The Two-Sided Mirror: How Correcting For Diagnosticity Impacts Social Comparisons With Advertisement Models

Abigail Schneider, University of Colorado, USA
Susan Jung Grant, University of Colorado, USA

The impact of featuring idealized models versus realistic depictions of people in advertisements has been a topic of much debate in both the consumer literature (Richins 1991; Smeesters, Mussweiler, and Mandel 2010) and society (www.campaignforrealbeauty.com). Much of this research has focused on the detrimental effects of idealized images on satisfaction with the self (Richins 1991), on resulting distortions of body image (Rothblum 1990), or on the diminished judgment of the attractiveness of others (Kenrick and Gutierres 1980).

As a stand against the adverse effects of idealized models, Dove launched its Campaign for Real Beauty in 2004, casting women of all shapes and sizes in its advertising. Yet, the actual effect of these "real" women models on women's self-esteem is debatable. For instance, Smeesters et al. (2010) find that "real beauty" advertising may not enhance consumers' self-esteem, suggesting that the potential persuasive impact of Dove's ads may be limited.

Our research seeks to extend this work and address when "real beauty" ads are effective in evoking social comparison that leads to enhanced perceptions of attractiveness (contrast) or average perceptions of attractiveness (assimilation). We then explore the role of a more diagnostic standard of comparison in women's assessments of their own attractiveness when exposed to ads featuring idealized models versus everyday people.

We report findings from a study in which women rate themselves as being less attractive after seeing advertisements featuring idealized models but rate themselves as being more attractive after exposure to advertisements featuring more realistic images of everyday women. We then reverse this effect and suggest that it is moderated through assessments of diagnosticity for social comparison.

The literature suggests that an assimilation-contrast framework is relevant to self-assessments of attractiveness. Richins (1991) suggests that consumers viewing an advertisement spontaneously engage in social comparison (Festinger 1954; Gilbert, Giesler, and Morris 1995) and relate to the model by assimilating to the model's level of attractiveness or contrasting away. With assimilation, the model's attractiveness becomes incorporated into the consumer's self-perception. With contrast, the model's attractiveness becomes a standard against which a comparison is made. People may also correct for such judgments (DeCoster and Claypool 2004) and, thereby, "mentally undo" assimilation or contrast. However, because the diagnosticity of the comparison, or the appropriateness of the target as an object of comparison, is only considered after the comparison is made (Gilbert et al. 1995), it is possible for people to make nondiagnostic comparisons that they then correct (Gilbert et al. 1995, p. 227). One way of "mentally undoing" the comparison is to consider the diagnosticity of the comparison standard and to re-evaluate based on a more diagnostic source.

We conducted a 2 (advertising: model vs. real people) x 2 (referent group: non-salient peers vs. salient peers) factorial design. Participants were 102 female undergraduate students from a large Western US university who participated in exchange for partial course credit.

Upon entering the lab, participants were told that they would be completing separate studies related to college female undergraduates' opinions about health and beauty advertisements and about a potential dating service that would be piloted on campus. Participants received a booklet containing six ads, three of which were ads featuring either models or real people and three of which were filler ads showing only products. Participants first wrote a few sentences about their initial reactions to the ads and then rated the ads on various dimensions (e.g. "How much do you like this advertisement?" "How attractive do you think the featured model is?").

Students then read about a dating service that would ostensibly target the college market and hence sought feedback from college students. Afterwards, they rated their own attractiveness, as well as the attractiveness of the typical female on their campus. The order of rating constituted the manipulation of referent group salience. In the non-salient referent condition participants rated their own attractiveness first. In the salient-referent condition, participants rated the attractiveness of the typical female undergraduate before rating their own attractiveness.

A two-way ANOVA revealed a significant interaction between advertising type and referent-group salience on ratings of self-attractiveness $(F(1,98)=16.12, p<.0001)$. When assessing themselves without a referent group, participants felt less attractive when they viewed model ads (M=4.96) than when they viewed real people ads (M=5.44). This effect was reversed when participants assessed their own attractiveness with a referent group (after being asked about the typical female undergraduate student). Participants judged themselves as less attractive when they viewed real people ads (M =4.63) than when they viewed model ads (M=5.52). Planned contrasts showed that all four pairwise comparisons are significant (all Fs>4.00; all ps<.05).

In summary, when people rate their own attractiveness first, they demonstrate a contrast effect when viewing real and ideal models; however, when they rate their peers' attractiveness first, they demonstrate an assimilation effect with the real and ideal models. We theorize that the introduction of a diagnostic referent group, such as other female undergraduates, influences correction. Thus, when participants saw model ads and were then reminded of the typical undergraduate, the contrast effect was deemed to be extreme, not diagnostic. When correcting for the influence of a non-diagnostic comparison, participants could still justify elevated self-attractiveness ratings. Alternatively, when participants saw real people ads and were then reminded of the typical undergraduate, the comparison was deemed to be appropriate and diagnostic. When taking into account a diagnostic comparison, participants had no justification for inflating judgments of their own attractiveness and thus, ratings were lower.

We propose a second study to explore this explanation. Because correcting for diagnosticity requires cognitive resources (Gilbert et al. 1995), we expect that those who rate others' attractiveness first but are under cognitive load will demonstrate a contrast effect similar to the one observed for those who rate themselves first; however, those who rate others first but are not under cognitive load will continue to demonstrate assimilation. Thus, we propose a 2 (advertising: model vs. real people) x 2 (referent group: non-salient peers vs. salient peers) x 2 (cognitive resources: load vs. no load) factorial design.

Is Older Wiser?
Effects of Expertise and Aging on Experiential Learning

Ashley Goerke, Temple University, USA
Eric Eisenstein, Temple University, USA
Ayalla Ruvio, Temple University, USA

Consumers often need to learn the relationship between an unobservable outcome of interest and observable attributes. For example, antique shoppers appraise items; used car buyers must learn how car attributes affect price; gift-givers must learn the preferences of those to whom they give gifts; and in general, consumers constantly make decisions that are based on their predictions of quality, price, value, and liking. In this research, we investigate the costs and benefits of having developed expertise, both recently (based on training) and over a lifetime of consumer learning and decision making (for products that are highly familiar), and we compare the costs and benefits of expertise against the greater processing speed of more youthful subjects.

Prior research has presented a mixed view of expertise, with some researchers demonstrating costs of expertise (Camerer & Johnson, 1991; Wood & Lynch, 2002) and others showing benefits (Alba & Hutchinson, 1987; Hutchinson & Eisenstein, 2008; Meyer, 1987). As a general rule, people develop expertise from their repeated experiences in markets. Based on this, we posit that a lifetime of encountering products, developing fair market price and quality judgments about these products, and filing away this information for use at a later date, could be categorized as a form of experiential learning (EL) expertise, which increases with age.

Consumers often use previously paid or encountered prices as a reference for the evaluation of price expectations when dealing with frequently purchased goods (Kalyanaram & Winer, 1995). However, developing price referents is increasingly more complicated in situations where consumers have little or no previous experience with the product or product category. Price predictions for novel products that are associated with multi-attribute learning tasks have shown to produce generally conservative, implicit, rules associated with each attribute in just a few trials (Shirai & Meyer, 1997). However, as previously alluded to, the overall level of respondent accuracy in these trials is poor. While most consumer learning research focuses on conditions under which learning is inhibited (Howard & Howard, 2001; Wood & Lynch, 2002), and circumstances under which learning can be improved (Huffman & Houston, 1993; West, 1996), it has generally failed to address the inhibitory or enhancing conditions in an experiential context. In response, this study aims to bring these learning strategies, more recently identified in the consumer learning literature, into the EL paradigm in order to improve respondent performance on price and preference prediction tasks.

Consumer Learning and Age.

This study takes a unique interest into the differences in learning performance between senior citizens and their Generation Y counterparts. The U.S. Administration on Aging estimates that by the year 2030 the number of Americans over the age of 65 will more than double, to nearly 72 million people. Acknowledging the senior market's power due to high proportions of discretionary income and increased leisure time, and compounding this with the impending exponential growth the market is about to endure, it is critical to gain insight into the differences in how this consumer group learns about products.

Studies have suggested that experience feeds into knowledge, and that older adults may use non-traditional cognitive skills when performing difficult tasks (Baltes et al. 1995; Hedden, Lautenschlager, & Park, 2005). In contrast, much of the geriatric literature has demonstrated a cognitive decline associated with age (Hedden & Gabrieli, 2004) including reductions in processing speed and the ability to encode information into short term memory (Craik, 1994). These deficits lend themselves to the prediction that performance on EL tasks will decrease with age due to seniors' decreased ability to quickly process the information, identify and remember patterns and relationships, and ultimately encode the recognized associations into short term memory to serve as a reference point throughout the task. Considering the substantial support for either prediction, proposition 1 serves as an exploratory inquisition:

> **Proposition 1:** Evidence for the increase in EL expertise will be supported by senior respondents outperforming undergraduate respondents on price prediction tasks, holding the environment constant.

The Advantage of Environmental Cueing.

While several cognitive psychology studies have shown the advantage of prior knowledge on subsequent learning (Alba & Hutchinson, 1987), recent consumer research has shown some evidence in dispute of this claim (Wood & Lynch, 2002). Given the poor performance of experts when an environmental change was not cued, the authors posited a lack of motivation at the point of information encoding as the cause of inferior learning. As this motivation was adjusted using an environmental cue, experts paid more attention and performed better on the learning task than their novice counterparts (Wood & Lynch, 2002). This research focuses on whether cueing environmental change in an experiential context, will improve the respondents' performance on the multi-attribute learning task across generations.

Proposition 2: The existence of a cue about a change in relationships between attributes will increase respondents' rate of EL, in comparison to before the cued environmental change.

Goal Oriented Learning and the Impact of Emotion.

Consumers direct their information acquisition toward goal-relevant feature information, therefore retaining more information associated with their purchase goal and ignoring the goal irrelevant information (Huffman & Houston, 1993). Older consumers focus more attention on, and retain more information from, emotionally charged information (Levanthal, 1990). This is empirically attributed to the relatively stable condition of the emotional processing centers of the brain throughout later life (Hedden & Gabrieli, 2004). This literature suggests that introducing goal directedness to the EL paradigm should increase performance across both groups, and additionally, the use of an emotionally charged goal may further increase the performance of senior citizens on the learning task.

Proposition 3: The introduction of goal directedness to the learning task, will increase performance when predictive attributes are goal relevant.

Proposition 4: The introduction of an emotionally charged goal will increase senior's performance on the learning task to a greater degree than their generation Y counterparts, when predictive attributes are goal relevant.

Study design is complete and analysis of preliminary results should commence shortly.

Price Comparisons as Information about Personal Competence and Relational Value: The Influence on Perceived Fairness

Lindsay McShane, Queens University, Canada
Laurence Ashworth, Queens University, Canada

It is not uncommon for consumers to pay different prices for the same product (Elmaghraby and Keskinocak 2003). Fairness research, however, indicates that not all of these price discrepancies are equally unfair. Work based on equity theory finds that price unfairness is affected by consumers' perceptions of their inputs (Darke and Dahl 2003). Other research shows that fairness is affected by perceptions of the firms' role in causing the unfairness (e.g. motive, intent, responsibility) (Campbell 1999; Vaidyanathan and Aggarwal 2003). Largely absent, however, is consideration of the self-threatening nature of unfair treatment. We suggest that one reason why unfavorable price discrepancies are considered so unfair is because they can threaten aspects of consumers' self-concept. We examine the role of two types of self-threat that we think are important in (un)fairness judgments: threats to personal competence and threats to relational value.

People want to be seen as competent and valued (Jones and Pittman 1982). Such characteristics are important to individuals' self-concepts, and are often treated as components of self-esteem (Heatherton and Polivy 1991). Some have even argued that being valued by others is the *function* of self-esteem (Leary et al. 1995). We suggest that, in some cases, paying more than someone else for the same product threatens one or both of these components of self-concept. To the extent that a price inequity conveys threatening information about consumers' competence and/or relational value, we expect consumers to perceive the situation as more unfair. We examine the influence of these self-threats on fairness judgments in Study 1. In Study 2, we focus more specifically on the different sources of threats to relational value and their influence on fairness judgments.

Unfair treatment is often facilitated by consumers' credulity or naivety. We argue that these situations are likely to be particularly threatening because they undermine consumers' perceptions of personal competence. We test whether threats to personal competence influence consumer reactions to price discrepancies by varying the extent to which consumers had a choice in the purchase. When consumers have little choice, price discrepancies should have fewer implications for their competence, and therefore, we argue, be perceived as less unfair.

Price inequities can be threatening for other reasons too. Specifically, they may suggest that the consumer is not valued by their relational partners. In Study 1, we look at situations where the threat to relational value stems from what it implies about the consumer's relationship with the firm. We expect price inequities to be threatening to the extent that they communicate to the consumer that the firm does not value them. We expect price inequities to communicate this information when the firm is perceived to have deliberately charged the consumer the higher price. When the firm is not held responsible for the discrepancy, implications for the firm's opinion of the consumer should be reduced, and therefore have a diminished impact on fairness.

STUDY 1

Study 1 consisted of a 2 (Deliberate: yes, no) x 2(Choice: yes, no) experiment. In the Deliberate conditions, we manipulated whether the other consumer's lower price was the result of a deliberate action taken by the seller. In the Choice conditions we varied whether the consumer had a choice in whether to engage in the exchange.

Primary analysis revealed a main effect of Deliberate on perceived fairness and perceived relational value (Fs(1,112)=40.72 and 54.48, ps<.001 and <.001). Consumers perceived the situation as significantly more unfair and felt less valued when the seller's actions were deliberate (Ms=2.78 vs. 4.51 and Ms=3.81 vs. 5.46: note that in the lower numbers indicate more unfair and less valued). A Sobel test of the indirect path from deliberate to fairness via perceived relational value was significant ($z = 4.32, p < .001$), consistent with mediation.

The ANOVA also showed the predicted two-way interaction (F (1, 112) =3.84, p=0.05). Follow-up analyses showed that in the Deliberate condition, consumers perceived the situation as significantly less unfair and felt less incompetent when they had no choice in whether to engage in the exchange (Ms=3.39 vs. 2.15 and Ms=3.71 vs. 3.02, Fs(1,112)=9.84 and 6.55 and ps <.01 and <.05). The results of a Sobel test of the indirect path from Choice to fairness via perceived competence supported the prediction that threats to personal competence exacerbate perceived unfairness ($z = 2.21, p < .05$).

STUDY 2

Study 1 focuses on threats to relational value that stem from what the price inequity implies about the consumer's standing with the firm. Price inequities, however, may threaten the consumer's perceived relational value with regards to other relationships as well, such as friendships. The purpose of Study 2 was to investigate the influence of these threats. We predicted that threats to one's relational value in relationships external to the consumer-seller relationship would exacerbate unfairness perceptions only when the other consumer's lower price was not attributable to a mistake made by the seller.

To test these ideas we ran a 2 (Mistake: yes, no) x 2(Seller Selection: Friend, Target Consumer) experiment. Participants read that they paid $30 more than another consumer for the same product at a different online retailer. In the Mistake conditions, we varied whether the other consumer's lower price the result of a mistake made by he seller or not. For Seller Selection, we varied whether the consumer selected the online retailer or whether it was recommended by a friend. We predicted that when the price inequity was not the result of a mistake, participants would perceive the situation as particularly unfair when the seller was recommended by a friend. Here, the risk that the consumer's friend may knowingly have led the consumer to overpay may be taken by the consumer as evidence that their friend does not value their relationship. We expect this threat to relational value to exacerbate perceived unfairness.

Consistent with Study 1, an ANOVA revealed a main effect of Mistake on perceived fairness and perceived relational value (Fs(1,67)=8.82 and 9.58, ps<.01 an d <.01). Consumers perceived the situation as significantly more unfair and felt less valued when the seller's actions were not a mistake (Ms=4.19 vs. 5.14 and Ms=3.67 vs. 4.26). A Sobel test of the indirect path from mistake to fairness via perceived relational value supported the predicted mediation ($z = 2.67, p < .01$).

Follow-up analyses showed that in the Mistake condition, consumers perceived the situation as significantly more unfair and felt less valued when the seller was recommended by their friend rather than self-selected (*M*s=3.69 vs. 4.69 and *M*s=3.36 vs. 3.97, *F*s(1,67)=4.88 and 4.93 and *p*s <.01 and <.05). A Sobel test of the indirect path from Seller Selection to fairness supported the predicted mediation of perceived relational value (*z* = 2.04, *p* < .05). The results suggest that, in certain cases, external threats to relational value (i.e., those based on relationships other than the consumer's relationship with the firm) may also exacerbate perceived unfairness.

DISCUSSION

Given the negative consequences of perceived unfairness, it is important to understand why price discrepancies across consumers vary in the extent to which they are deemed unfair. This research suggests price inequities are perceived as unfair to the extent that they threaten important aspects of the self. Importantly, we identify two different self-threats, threats to personal competence and threats to relational value, that exacerbate perceived unfairness.

Does a Product Category Have a Motivational Orientation? Effects on Health Message Efficacy

Adilson Borges, Reims Management School, France
Pierrick Gomez, Reims Management School, France

Designing effective health message is important for health policy makers (Keller and Lehmann, 2008). Extant research shows that regulatory focus is a strong determinant of health message efficacy. Regulatory focus theory postulates that goal-pursuit strategies will result in fit when these strategies match the individual or situational regulatory orientation (Higgins 1998). For instance, pursuing a goal through carefully avoiding losses, highlighting safety and security will "feels right" for prevention oriented individuals, while pursuing a goal through searching for gains and avoid missing gains will match promotion oriented individuals

The persuasive power of regulatory fit results from the sense of having done the right thing – it "feels right" and a heightened motivation (Camacho, Higgins, and Luger 2003; Higgins 2002, Aaker and Lee, 2006). Thus, under prevention orientation consumers are more sensitive to health problems than under promotion orientation. Loss framed-messages are also more convincing when prevention focus is activated whereas gain-framed messages are more convincing under promotion focus (Aaker and Lee, 2004). Keller (2006) has shown that health messages are more efficient when the perceived easiness of the advocated health behavior is paired with promotion focus and when the response effectiveness is paired with prevention focus.

Regulatory fit has mainly been sustained throughout two paths (Lee and Higgins 2009). The first is when the goal pursuit strategy fits with the individual regulatory orientation. For example, subjects took an experiment where they have to choose between a pen and a coffee mug. Prevention oriented subjects using a safety strategy declared higher willingness to pay for the mug than subjects that used an eager strategy. The results were reversed for promotion subjects (Higgins et al. 2003). The second is when the message regulatory focus fits with the characteristics of the persuasion appeal. For instance, promotion oriented adolescents declare lower smoking intentions to gain (vs. non-gains) messages whereas prevention oriented subjects were more persuaded by messages stressing potential losses (instead of no-losses) (Zhao and Pechmann 2007).

We proposed that regulatory fit may be sustained trough a third path. Indeed, we suggest that product category can trigger regulatory focus (i.e, product category motivational orientation), which could create a fit with the message orientation. Past research seems to imply that a product category could prime regulatory focus. For instance, people carrying out a decision-making task related to stock market shares (a product associated with the idea of maximizing gains) tend to use a promotion strategy in a subsequent unrelated task, whereas those carrying out a decision-making task related to saving plans (a product associated with the idea of avoiding losses) have a greater tendency to use prevention strategies (Zhou and Pham, 2004). Extant research has shown that products are highly connected to the goals they serve and product categories have a motivational component (Dhar and Wertenbroch, 2000). Product category is also preferably associated to delayed or immediate gratification (Wertenbroch, 1998). In three studies, we show that product category motivational orientation and message regulatory focus interact to determine health message efficacy.

A first pre-test shows the priming effect of product category. 41 participants were randomly assigned to a category goal orientation (prevention vs. promotion). Following Aaker and Lee (2004) we use orange juice and a sunscreen cream as respectively a promotion and a prevention category. To prime regulatory focus, respondents imagined that they have to buy this product. Subjects are then asked to indicate

three best strategies to face an exam (Zhou and Pham, 2004). Six strategies were presented (3 prevention and 3 promotion strategies). The results show that subjects declare more promotion (prevention) strategies after seeing the promotion (prevention) category.

The study 1 tests the persuasive effects of the fit between product category motivational orientation and the health outcome frame. Thus, we expect that an individual exposed to a prevention category should be more convinced by a prevention message whereas an individual exposed to a promotion category should be more convinced by a promotion message.

Using the same categories from the pre-test, we develop an advertising that frame the product benefits either as a health gain (promotion frame) or health loss (prevention frame). 136 participants took part in a 2 (product category: prevention vs. promotion) by 2 (message frame: gain vs. avoiding loss) between subjects design. The results show that promotion (prevention) categories increase the attitude toward the product and the purchase intention when the message frame is gain (avoiding loss).

The study 2 tests different product categories and identifies ad credibility as a mediator. We randomly selected 3 categories identified on a previous qualitative study as promotion oriented (orange juice, chocolate and yogurt) and 3 prevention oriented (sunscreen, insurance and elliptical trainer). 260 subjects told they would buy promotion categories more due to the pleasure the product provides than for the problems the product avoid. The results are reversed for prevention categories. Subjects then look at an advertising following the same structure of the study 1. The results show the same pattern as study 1. Promotion (prevention) categories increase the attitude toward the product and the purchase intention when the message frame is gain (avoiding loss). These results stand even when the subject's regulatory orientation is controlled for. Moreover, ad credibility fully mediated the fit effects on intentions.

This research shows that the product category creates fit with the message frame independently of the perceiver regulatory orientation. Product categories are used to achieve goals, and these goals become strongly associated with the category itself. The product category itself is enough to elicit the goal orientation (prevention or promotion), and the use of the right category creates fit with the message frame, increasing product evaluation trough ad credibility.

Fair for You and Indulgent For Me:
Product Positioning and Consumer Intentions Toward Ethical Products

Katherine White, University of Calgary, Canada
Rhiannon MacDonnell, University of Calgary, Canada
John Ellard, University of Calgary, Canada

Although the marketing literature has begun to examine the implications of justice perceptions related to *one's own* consumption experiences, less attention has been given to consumer attitudes and behaviors related to *justice received by others*. Notably, recent research has suggested that while consumers are increasingly interested in ethical, socially conscious product options (Trudel and Cotte 2009), product ethicality does not invariably lead to a positive consumer response (Luchs et al. 2010). This work suggests that the way in which the product is positioned—as an indulgence or a necessity—can influence consumer concerns for justice for others. This, in turn, can influence willingness to purchase products with ethical attributes (e.g., fair trade products).

Fair trade is a social movement that aims to set fair prices for products, alleviate poverty, and assist producers marginalized by the traditional economic model (Pelsmacker and Janssens 2007). Of particular interest from a marketing perspective is research showing that consumers are increasingly interested in ethical options such as fair trade products (Nicholls and Opal 2005). However, consumers often do not actually support fair trade options when given the opportunity to do so (Auger and Devinny 2007). Recent research finds that one reason for this is because it is not clear whether such options will resolve the observed injustice (White, MacDonnell, and Ellard 2011). Such uncertainty about the ability to resolve injustice via purchases can ironically lead to decreased support for fair trade options when communicated need on the part of producers is very high (as opposed to low). We build on this past work to examine two key variables that will influence consumer fair trade intentions, even when marketers communicate high need circumstances (i.e., very dire and unjust circumstances for producers).

First, we propose that *indulgences* increase sensitivity towards justice for others, leading consumers to favor fair trade options. We define indulgences are products "adding to pleasure or comfort but not absolutely necessary" (Hagtvedt and Patrick 2009). In this context, considering an indulgence is predicted to heighten sensitivity to justice for others for two reasons: 1) the unjust fate of the producer is highlighted (i.e., high need communications about fair trade) and 2) the privileged, and hence "undeserved" fate of the consumer is salient (i.e., consumer is considering an indulgence). Thus, indulgent products may lead the consumer to be particularly sensitive to injustice for others. Second, we examine the moderating role of individual differences in sensitivity to injustice—belief in a just world (BJW; Lipkus 1991). High BJW individuals are particularly sensitive to injustice (Rubin and Peplau 1973). Importantly, when the opportunity to help is available, those high in BJW are particularly likely to assist victims (Miller 1977). We propose that when sensitivity to injustice is most heighted—the product is an indulgence and BJW is high—Consumers will be most moved to help by purchasing fair trade.

In study 1, we test the assertion that, in the fair trade context, indulgences lead to more of a concern for justice for others. Fifty-eight undergraduates read background information to familiarize them with fair trade and to communicate high need (unfair circumstances for producers; White et al. 2011). They then read a scenario asking them to imagine a purchase of the "Dagoba" snack bar, made with fair trade cocoa. The bar was described as either an *indulgence* or a *necessity*. Participants then completed items to assess concern for justice for others and the extent to which they were focused on their own needs. As expected, participants reported greater concern for justice for others when they considering an indulgence ($M = 4.94$), rather than a necessity ($M = 3.64$; $p < .01$). Further, they were more focused on the self when the product was a necessity ($p < .01$).

In study 2, we suggest that because indulgences are particularly likely to activate justice concerns (study 1) and those high in BJW are most sensitive to injustice (Rubin and Peplau 1973), when the product is positioned as an indulgence and BJW is high, people will be most responsive to fair trade options. Further, we examine whether concern for justice for others mediates the effects. Consumers ($n = 147$) at a local market read the background information and the product manipulation (study 1). They then completed a purchase intentions measure regarding the Dagoba bar ($a = .88$). They also completed items to assess concern for justice for others ($a = .92$), general efficacy ($a = .74$), and BJW ($a = .92$; Lipkus 1991).

Regression analysis using product type, BJW, and the interaction as predictors of purchase intentions, revealed the predicted interaction ($p < .02$). Simple slopes analysis showed that when the product was an indulgence those higher in BJW reported stronger purchase intentions than those lower in BJW ($t = 2.55$, $p < .02$). However, when the product was a necessity no differences as a function of BJW emerged ($p < .40$). Bootstrapping analysis showed that justice concerns for others mediated the effects (CI: .0083-.2362), but general efficacy did not (CI: .0994-.0946).

The results demonstrate that product type can influence justice concern for others. Although intuition might suggest that indulgences would relate to a focus on the self, in study 1, consumers were more concerned about justice for others (and less focused on the self) when the product was an indulgence versus a necessity. In study 2, when the product was an indulgence, higher BJW related to more positive purchase intentions towards a fair trade product. When the product was a necessity, consumers did not demonstrate differential purchase intentions as a function of BJW. Thus, when justice concerns are heightened (the product is an indulgence and BJW is high), consumers are most likely to support fair trade products. The results further suggest that justice concerns for others are driving responses, rather than more general efficacy effects. We also make a unique contribution to the marketing and justice literatures by examining how responsiveness to the plight of others is influenced by circumstances shaping one's own deserving.

My picture, my product: Does co-creation of a usage experience lead to positive consumer outcomes?

Shanker Krishnan, Indiana University, USA
Arun Lakshmanan, SUNY Buffalo, USA
Lura Forcum, Indiana University, USA

Many modern products engage consumers as co-creators in the exchange process (Vargo and Lusch 2004) rather than being passive recipients of product benefits. One of the dominant findings from this literature is that customer co-creation often correlates with consumer elaboration (Moreau and Herd 2010). Such elaboration could take the form of visual imagery, narrative transportation or cognitive elaboration (e.g., Green and Brock 2000; Schlosser 2003; Unnava, Agrawal and Haugtvedt 1996).

Co-creation engages the consumer in an active role with the end product often a result of consumer action. For example, many websites allow consumers to manipulate and design various fashion accessories by uploading their own pictures, versus seeing images of others (from ads, catalogs). Major retailers (Wal-Mart, Carrefour) are also considering the use of virtual mirrors that allow consumers to design a specific look for some products (e.g., cosmetics). In such situations, consumers are visually transporting themselves into product use with the attendant elaboration and visual imagery. Whether such transportation (versus cognitive elaboration) moderates the effects of image use is an issue that is worthy of investigation.

A laboratory based study was conducted using a commercial online service aimed at making collages using digital pictures. The primary consumption task was the formation of collages from a set of photographs to design a vacation. Image type was manipulated by providing participants product images, product images with people, or product images with self-images. For this last condition, as the user provides images, involvement should increase. Yet, a greater degree of physical activity should lead to a stronger focus on the task and thus, attitude formation may be impeded (versus the passive conditions where the user does not provide any images). Further, when transportation imagery is engaged via a second manipulation, participants in the self-image conditions should face greater interruption to the imagery generation process (due to the necessity to perform operations upon the website/images). This interruption of the mental transportation process should lead to poorer attitudes for this group when transportation is engaged (versus not). Thus, narrative transportation should interact with the type of imagery in predicting attitudes. This hypothesis was tested using the method described below.

One hundred and sixty two undergraduate marketing students at a large Midwestern university completed the study. The experiment followed a 2 (elaboration: transportation imagery vs. cognitive) by 3 (image type) between-subjects factorial design. Each participant was provided with a fictitious spring-break travel planning scenario in which they were either asked to immerse themselves and imagine their prospective holiday vividly (transportation imagery group) or plan for their holiday as comprehensively as possible (cognitive elaboration group). Subsequently, participants were directed via the computer's web-browser to one of three versions of the website. One-third of the participants (product image) were shown a screen with 36 images of a beach vacation. A second group (product image with people) was shown 36 images of beach vacations with people in them. The third (product image with self-images) group was asked to upload up to six images of their choice from personal online accounts and their screen showed these six images along with 30 images from the experimental website.

Subjects in all conditions were simply instructed to "make a collage" depicting their ideal vacation. This collage was subsequently saved yielding a unique participant-specific collage image. Time-stamped user information was collected unobtrusively on the experimental website and logged for process analysis. Subsequently, the website directed them to the online survey containing other measures. Cognitive response protocols were also collected toward the end of the session.

The primary dependent measures for this study were attitude towards the website and vacation purchase likelihood. A two-way ANCOVA with elaboration (transportation imagery vs. cognitive) and image type (product image, product image with people, and product image with self-images) as predictors, and overall attitude toward the website as the criterion variable revealed a significant main effect for the photo condition ($F(2,148) = 4.2$; $p < .02$). This effect was qualified by a two-way interaction with the elaboration factor ($F(2,148) = 4.92$; $p < .01$). Planned contrasts revealed that within the self-image condition the transportation imagery group had *lower* attitudes compared to the cognitive elaboration group ($M_{imagery} = 17.52$, $M_{cognitive} = 15$; $t = 2.44$, $p < .02$), with other within-group comparisons not statistically significant ($ps > .2$). This finding supports our hypothesis.

Consistent with this finding, a two-way ANCOVA on participants' purchase likelihood for the vacation also revealed a main effect for the photo condition ($F(2,148) = 3.29$; $p < .04$) as well as a significant two-way interaction ($F(2,148) = 3.06$; $p < .05$). Planned contrasts revealed that within the self-image condition the imagery group had lower purchase likelihoods compared to the cognitive elaboration group ($M_{imagery} = 3.84$, $M_{cognitive} = 4.78$; $t = 2.1$, $p < .04$), with other within-group comparisons not significant ($ps > .2$). This finding also supports our core hypothesis.

Study 1 presents initial evidence that the combination of narrative transportation and self-selected images can interfere with the formation of product attitudes and willingness to buy.

We intend to continue to our investigation with two additional studies which will also be presented at ACR, should this paper be accepted.

Study 2 will involve evaluating the output of the creative process and investigating process explanations for our counter-intuitive findings. We plan on rating collages on a variety of dimensions, including creativity, overall aesthetic value, and characteristics related to the photographs chosen in the subject-selected image condition. Study 3 will explore whether varying degrees of involvement in the collage-creation process affect attitude toward the site and willingness to purchase.

Say No More!
Experiential Consumption and the Spoiler Effect of Positive Word of Mouth

Kendra Hart, Ivey Business School, University of Western Ontario, Canada
Mirand R. Goode, Ivey Business School, University of Western Ontario, Canada
Matthew Thomson, Ivey Business School, University of Western Ontario, Canada

People seek WOM from a trusted source as a way to anticipate and explore consumption choices (Frenzen and Davis 1990; Smith, Menon, and Sivakumar 2005). Yet, people also engage in storytelling, a form of WOM, as a way to savor prior hedonic experiences, such as vacations or other special events**.** We propose that this latter post-consumption communication can negatively impact consumers who are in the pre-consumption stage of a similar hedonic experience. We suggest that WOM in the form of storytelling can interrupt a receiver's pre-consumption fantasy, discouraging future consumption and altering choice. Specifically, receiving information about a hedonic experience from a trusted source is likely to lead to a sense of experiential demystification resulting in reduced motivation to pursue that experience.

PRE-CONSUMPTION FANTASIES AND DEMYSTIFICATION

Consumption experiences include three distinct phases: A pre-consumption phase characterized by information search and consumption fantasies; the actual consumption phase; and a post-consumption phase characterized by consumption memories and reminiscing. Pre-consumption pleasure can stem from forecasting the details of an experience and enjoying the emotional response in prospect. However, there is also utility in the curiosity and suspense that may arise prior to engaging in an experience (Knobloch-Westerwick and Keplinger 2006). Uncertainty in how an experience may unfold, followed by the thrill of discovery during an actual experience, is a hedonic reward (Quinn 2003) – one which we argue can be weakened through experiential demystification.

People in the pre-consumption phase, anticipating a consumption experience, seek WOM from a trusted source as a way to explore consumption choices. People in the post-consumption phase are often eager to share their memories. Exposure to a sender's recounting of a consumption experience demystifies speculation surrounding the receiver's impending experience. Demystification is a process that clarifies the previously uncertain and vague. We propose that this demystification of an upcoming experience serves as a story spoiler, satiating curiosity, and constraining the receiver's ability to imagine the many ways in which an experience may unfold.

To investigate the effect of demystification on consumer choice, we explore how WOM from a friend versus stranger weakens desire for a consumption experience. Individuals associate and bond with those who have similar values, tastes, and attitudes (McPherson, Smith-Lovin, and Cook 2001). We suggest this greater similarity between friends increases trust, resulting in increased demystification via smoother acceptance of the details communicated by a friend. This leads to a demotivating effect, characterized by a decreased sense of specialness surrounding the impending experience and reduced interest in pursuing the experience.

METHOD AND FINDINGS

Participants (n = 144) were asked to select one of five consumption experiences (e.g., white water rafting, hot air balloon ride) that they would like to try if given a free ticket. Next, participants were directed to envision the experience and asked to write a paragraph recording the details and expectations for their chosen experience. After a filler task, participants were randomly assigned to one of two WOM conditions, where they read a description of the selected experience and were asked to imagine that it was provided by either a friend or stranger. Participants responded to a series of scale measures to assess their expectations for the experience, as well as measures related to demystification, desire to pursue the selected experience and individual trait measures.

A series of ANOVAs, controlling for individual need for uniqueness, showed that participants exposed to WOM from a stranger estimated a greater expectation of being able to "make the experience their own" had a "greater sense of wonder" about the experience than those exposed to WOM from a friend. Participants in the friend condition reported that they expected the experience to be *more boring* and *less adventurous* than those in the stranger condition. Further, particpants in the friend condition reported that the experience would be less "special" (meaningful, special, extraordinary); and more "ordinary" (familiar, typical, run-of-the-mill). Taken together, these measures provide evidence for demystification. Interestingly, a set of contamination-like indicators emerged suggesting that the upcoming experience seemed more "tainted" (devalued, spoiled, tainted) in the friend (versus stranger) condition.

As anticipated, the WOM source (friend vs. stranger) significantly influenced participants' desire to try their selected experience. Participants who received WOM from a friend (versus stranger) were significantly more willing to switch their selected experience for an alternate option. It is important to note that these findings are not a result of altered or disconfirmed expectations for a future event. We measured the degree to which respondents thought the WOM matched their own expectations, and found that most respondents believed the WOM was highly consistent with their own expectations.

DISCUSSION

These results contribute to the extant literature on WOM, suggesting that positive WOM can have a negative impact on consumer evaluations and choice. Additionally, this research introduces the idea of demystification, an idea which has not previously been applied to experiential consumption. This initial study suggests that WOM may demystify an impending experience, and reduce consumer motivation. The effect of demystification on notions of meaningfulness and the ordinary in experiential consumption are consistent with previous research on the pleasure paradox (Wilson et al. 2005).

However, one interesting line in these results is the evaluation of an experience being "tainted" after WOM exposure. Indicators such as "tainted", "spoiled" and "polluted" suggest a contamination-like effect that begs further exploration. Physical objects touched by others leads to consumer disgust and perceived contamination, rendering the touched object impure (Argo, Dahl, and Morales 2006). We consider that perhaps, analogously, *conceptual contamination* is driven by consumer demystification, when the open-ended *idea* of potential consumption is sullied by details of another's actual consumption. Specifically, we question if conceptual contamination stems from demystification and a loss of wonderment about the impending experience, leaving the receiver feeling that the experience will be more spoiled, impure, mundane, and less his own. In essence, the impending consumption experience is contaminated for the receiver. Additional studies are underway to address the dimensions of this possible contamination.

The Effects of Dissociative Segment Adoption of Brand Extensions on the Evaluation of the Parent Brand

Claudio Alvarez, Boston University, USA
Remi Trudel, Boston University, USA

Brand extensions play a critical role in corporate growth strategies because they bring new sources of revenue while minimizing brand development investments. This revenue growth can be achieved by extending the brand to new customers (e.g., Porsche Panamera, Bic surfboards) or through more conservative moves within the customer base (e.g., Clorox's home cleaning products). A major concern when branching out into new customer segments is the potential negative impact on the image of the original brand, particularly when these new customers are perceived to belong to an outgroup by current customers. After all, brand managers try to maximize revenues from brand extensions without exposing the current customer and revenue base to significant risks. Despite its relevance to managers, the effect that venturing into new segments has on existing customers has been largely overlooked in the brand extension literature. The present study aims to fill this gap by investigating the potential negative effects of extending the brand into new customer segments to the parent brand.

Consumer research has provided compelling evidence for the impact of reference groups on brand evaluation. Escalas and Bettman (2005) proposed that reference groups can be an important source of brand associations, and showed that the association of a brand with a group that consumers belong to (an ingroup) leads to higher self-brand connection whereas the association with an outgroup lowers self-brand connection. White and Dahl (2007) also demonstrated that consumers tend to avoid brands associated with dissociative reference groups, not only in terms of self-brand connection but also in product evaluation and product choice tasks. In a longitudinal field study conducted by Berger and Heath (2008), students that had bought Livestrong wristbands stopped using them after they were adopted by "geek" students. Mere extension of this line of research would lead us to predict that the negative affect derived from the adoption of a brand extension by a dissociative segment (*versus* an ingroup) can transfer to the parent brand, resulting in more negative attitudes and purchase intentions.

However, the effect of reference groups is expected to vary depending on the perceived fit of the parent brand with the extension product category. Perceived fit impacts the affect transfer from the brand extension to the parent brand, as has been extensively demonstrated in experimental manipulations of brand extension failure (see Keller and Sood 2003 for a review). When the performance of the brand extension contradicts expectations derived from the parent brand, dilution effects are more likely to happen when the extension has high fit with the parent brand. In other words, brands can be largely immune from being contaminated by far extensions. We make the novel prediction that perceived fit will moderate the effect of dissociative segment adoption, so that a brand extension adoption by a dissociative segment (*versus* an ingroup) will negatively impact the parent brand when product category similarity is high, but will not have an impact when similarity is low.

To test these hypotheses, we randomly assigned 238 undergraduate students to six experimental conditions in a 2 (fit: high, low) x 3 (reference group: no information, ingroup, dissociative segment) between-subjects design. Through a series of four pretests, we defined (1)

the parent brand to be American Eagle, which was familiar, moderately liked, and perceived as being characteristic of our student population (i.e., an ingroup brand); (2) the brand extensions to be backpack (high fit) and bicycle (low fit); and (3) reference group characterizations to be "men and women between 18-35 years old from middle and upper socioeconomic classes that are pursuing an undergraduate degree" (ingroup) and "men and women between 40-60 years old from a lower socioeconomic class and less than high school education" (dissociative segment).

After a brief introduction, participants were asked to imagine that American Eagle had launched a new backpack (high fit) or bicycle (low fit), and that this brand extension was being used by the ingroup or dissociative segment (no information about user profile was given in the control conditions). They were then asked about their attitudes toward the American Eagle brand and how likely they were to buy an American Eagle t-shirt, which is one of the current products sold by this brand; men and women received almost identical pictures of a white t-shirt with the American Eagle logo.

The expected two-way interaction was confirmed both for brand attitudes and likelihood of purchase. Specifically, the use of American Eagle backpacks (high fit) by a dissociative segment resulted in lower attitudes toward the parent brand and lower likelihood of purchasing American Eagle t-shirts relative to the ingroup condition. On the other hand, the use of American Eagle bicycles (low fit) by a dissociative segment did not impact attitudes toward the parent brand and resulted in even higher likelihood or purchasing an American Eagle t-shirt than the ingroup condition.

The results of this first study provide preliminary support for our hypotheses. They demonstrate that the negative affect derived from the usage of a brand extension by a dissociative segment may transfer to the parent brand when there is high fit between the parent brand and the brand extension product category. They also provide an important boundary condition for the effect of reference groups on brands, since no dilution effects emerged in low fit conditions. The implications to managers are mildly optimistic. On the one hand, managers who use brand extension as a mechanism to increase consumption within the current target market should be more careful about not extending into too dissimilar product categories. But on the other hand, if the main objective is to bring new customers to the parent brand franchise, dissimilar brand extensions may be a viable alternative (Milberg, Sinn and Goodstein 2010) that generates lower dilution risks than similar brand extensions.

Understanding Design Elements in Bundles

Deny Belisle, Concordia University, Canada
H. Onur Bodur, Concordia University, Canada

Bundling strategy is widely used in today products and services markets. It refers to the selling of two or more products/services together at a single price (Stremersch and Tellis 2002). Past research suggests that the contingency level among bundled products (i.e., their complementarity, substitutability or independence) influences consumers' evaluation of the offer. On the one hand, products complementarity appears as an essential condition to building successful bundles (Guiltinan 1987). On the other hand, products substitutability is viewed as detrimental to bundle value (Venkatesh and Kamakura 2003). Despite the wide array of bundles offered in the marketplace, it is unknown whether contextual information provided with the offer such as price and image presentation formats can influence bundle attractiveness, by either highlighting products' complementarity or reducing their perceived substitutability.

Past work highlighted consumers' use of contextual information when evaluating bundles. Different contextual cues, such as the set of alternatives considered as well as their presentation format, can be used as a means to simplify information processing (e.g., Simonson and Tversky 1992). In line with this literature, we examine the influence of adopting a mixed-joint pricing strategy where the reduction is assigned to the total price of the bundle (Guiltinan 1987; Yadav and Monroe 1993) versus a mixed-leader strategy, where price reduction is applied to one of the bundled items only, on bundle attractiveness across contingency levels. We also investigate whether presenting the products under the same or in separate images affects consumers' perceived attractiveness of bundles of complements.

It is proposed here that using a mixed-joint pricing strategy is likely to emphasize complementarity among items, which essence is the joint use of products. It should therefore yield to a higher bundle attractiveness perception for bundles of complements as compared to a mixed-leader strategy. On the other hand, mixed-leader pricing strategy is expected to be beneficial to bundles of substitutes. Coherent with Blattberg and Wisniewski's (1989) findings, a mixed-leader strategy is expected to increase dissimilarity between substitutable products. Applying a reduction on only one product in a bundle composed of two equally-priced products makes the prices of these products different. As a result, products' similarity is reduced, therefore leading to a higher assessment of bundle attractiveness than when a mixed-joint strategy is adopted. Finally, these pricing strategies are not expected to differently influence the assessment of bundles of independent products.

To test our predictions, a first study was developed using a 2 (pricing strategy: mixed-joint (MJ) vs. mixed-leader (ML)) × 3 (contingency levels: complements, substitutes, independent products) between-subjects design. Three bundles of two equally-priced products differing in terms of contingency levels were chosen based on a pretest. The primary product of this triplet was identical across the three combinations. Three different add-on products determined bundles' contingency level. Each of the 150 participants evaluated one bundle offer, which was briefly presented with a picture of the products. An identical price reduction amount was applied to each bundle. However, the price reduction was presented either in a mixed-joint or in a mixed-leader format. Bundle description was immediately followed by 7-point scales measuring transaction value, willingness to buy, and discount attractiveness.

A MANOVA with transaction value, willingness to buy, and deal attractiveness as dependent variables revealed a significant multivariate interaction between price bundling strategy and products' contingency level ($F_{6, 276} = 4.81$, p <.01). Items' preference and price consciousness did not have a significant influence on the dependent variables.

As expected, higher perceived transaction value ($M_{MJ} = 5.33$ vs. $M_{ML} = 4.45$; $F_{(1,46)} = 7.00$, p = .01), willingness to buy ($M_{MJ} = 5.16$ vs. $M_{ML} = 3.86$; $F_{(1,46)} = 12.02$, p < .01), and deal attractiveness ($M_{MJ} = 5.04$ vs. $M_{ML} = 4.24$; $F_{(1,46)} = 3.65$, p = .06) were reported for the bundle of complements when the identical price reduction amount was presented under a mixed-joint than under a mixed-leader format. Similarly, for the bundle of substitutes, higher perceived transaction value ($M_{MJ} = 4.21$ vs. $M_{ML} = 5.03$; $F_{(1,45)} = 4.16$, p < .05), willingness to buy ($M_{MJ} = 3.75$ vs. $M_{ML} = 4.68$; $F_{(1,45)} = 4.24$, p < .05), and deal attractiveness ($M_{MJ} = 3.33$ vs. $M_{ML} = 5.32$; $F_{(1,45)} = 23.99$, p < .01) were reported when the price reduction was presented under a mixed-leader than under a mixed-joint format. Finally, as expected, no significant difference between the two strategies was found for the bundle of independent products. These results support our predictions and suggest that price bundling strategy effectiveness depends on bundled products contingency level.

In study 2, we extend these context effects to the visual presentation of the bundle itself. Based on Fishbach and Zhang (2008), we expect that presenting products under the same image enhances their perceived complementarity more than presenting them under separate images. Therefore, presenting bundled products under a same image format is expected to lead to higher bundle perceived attractiveness than presenting products under a separate images format.

Fourty-two participants evaluated a bundle offer of complementary products presented in a mixed-joint format along with an illustration of the products that are either presented in the same photo or in two separate photos. As expected, higher perceived transaction value ($M_{SI} = 4.48$ vs. $M_{DI} = 3.68$; $F_{(1,40)} = 3.89$, p = .05), willingness to buy ($M_{SI} = 3.91$ vs. $M_{DI} = 2.93$; $F_{(1,40)} = 4.11$, p < .05), and deal attractiveness ($M_{SI} = 4.57$ vs. $M_{DI} = 3.71$; $F_{(1,40)} = 4.20$, p < .05) were found when the bundle offer was presented under a same image than a separate images format

This research provides evidence that perceived attractiveness of a bundle can be positively affected by contextual information present in the bundle offer. This is, to our knowledge, the first research that examines the impact of products' contingency level on price framing effect in a bundling context. Our results suggest that the superiority of a mixed-joint or mixed-leader strategy is contingent upon bundle composition. In addition, this research innovates by demonstrating that contextual information, not related to price (i.e., image presentation format), can also influence bundle perceived attractiveness.

Perceived Difficulty of Manufacturing the Extension and Extension Evaluation: Do Perceptions of Complementarity and Substitutability Matter?

Vishal Bindroo, Indiana University South Bend, USA
Rajani Ganesh Pillai, North Dakota State University, USA

Brand extension – using an established brand name to enter a different product class – is frequently used by marketers to enter new categories (Aaker and Keller 1990). A good proportion of research in brand extension has focused on understanding the factors that influence consumers' attitude towards the extension product, including the perceived fit of the extension with the parent brand (Aaker and Keller 1990; Mao and Krishnan 2006). Mariadoss et al. (2010) note that despite the advances made in understanding influences on the attitudes towards the extension, a primary focus in extant research has been on the characteristics of the parent brand. In this research we extend the work of Mariadoss et al. (2010) to investigate two important characteristics of extension brands that may influence the relationship between

perceived difficulty of manufacturing the extension and attitude towards the extension product: the perception of extension as complement of or substitute to the parent brand.

Perceived difficulty of manufacturing the extension (the difficulty of designing or making products in the extension category) has been shown to impact the evaluation of extension product (Aaker and Keller 1990). Mriadoss et al. (2010) investigated the often conflicting findings in literature (e.g. Aaker and Keller 1990; Bottomley and Holden 2001) to show that the relationship between perceived difficulty of manufacturing the extension and extension evaluation is not simple and linear as was often proposed, but instead is complex and non-linear. Additionally, they have called to investigate other inconsistent relationships in brand extension research. We heed this call by demonstrating that perceived complementarity and perceived substitutability of the extension product moderate the curvilinear relationship between perceived difficulty of manufacturing the extension and extension evaluation.

Perceived complementarity is defined as the extent to which the extended brand is jointly consumed with the parent brand to satisfy a specific need and perceived substitutability is defined as the extent to which the extended brand is perceived to be a substitute of the parent brand (Aaker and Keller 1990). We argue that both perceived complementarity and perceived substitutability moderate the curvilinear relationship between perceived difficulty of manufacturing the extension and evaluation of the extended product. We draw upon the literature in holistic versus analytical thinking (e.g. Monga and John 2007; Nisbett et al. 2001) to suggest that perceived complementarity of the extension product will induce consumers to use holistic thinking that encourages reliance on the context, complementarity of use, and relationships among objects to evaluate the extension (thinking style that is not primarily focused on evaluation of attributes). Further, complementarity itself becomes an additional cue in holistic thinking, aiding the evaluation of relatively less difficult to make extension that has fewer differentiating attributes. This leads to decrease in evaluation difficulty, which in turn, results in higher attitudes towards the extension. When the extension is considered to be extremely difficult to make, complementarity does not help as an additional cue in holistic thinking. It makes the evaluation of extension more difficult since the presence of so many attributes may in fact hinder successful evaluation of the extension in a holistic manner. This increase in evaluation difficulty will lead to lower attitudes towards the extension.

Unlike, complementarity, perceived substitutability will induce analytic thinking that is characterized by focus on evaluation of attributes (thinking style that is not focused on relationships and context, but rather on evaluation of attributes). Substitutable products that share several common and allignable attributes make such multiattribute evaluations more effortful and difficult, especially when there are fewer differentiating attributes as with trivial extensions. This increase in evaluation difficulty will lead to lower attitudes towards the extension. When the extension product is perceived to be extremely difficult to make, whereas, too many differentiating attributes are available for evaluation, doing so becomes even more difficult (Payne, Bettman, and Johnson 1993).

EMPIRICAL STUDY

We tested our predictions using a comprehensive database assembled by Bottomley and Holden (2001), which contains consumer perceptions of different brands and their extensions obtained from university students. In all, the comprehensive datatbase contained a total of 10,689 observations pooled from six separate data sets. The observations were generated by 9-18 evaluations of extensions per participant, as minimum of three parent brands and three brand extensions per brand were used in all the studies (cf. Mariadoss et al. 2010). All the variables in the study were measured. Perceived difficulty of manufacturing the extension (one 7-point item) and evaluation of extension (two 7-point items) was operationalized similar to Mariadoss et al. (2010). In addition, perceived complementarity and perceived substitutability were measured by one 7-point item each. Finally control variables like parent brand quality, and transferability of parent brand to extension were also measured consistent with Bottomley and Holden (2001). To control for within-respondent correlations, we estimated a mixed model as suggested by Echambadi et al. (2006) and Mariadoss et al. (2010). Results indicate support to our hypotheses that as perceived difficulty of manufacturing the extension increases, perceived complementarity significantly strengthens the relationship between perceived difficulty and extension evaluation (β =0.007 , $p<.05$), whereas at extremely high levels of perceived difficulty, the relationship is significantly weakened (β= -0.005 , $p< .01$). Perceived substitutability weakened the relationship between perceived difficulty and extension evaluation when extension was relatively less difficult to make (β= -0.01, $p<.05$), whereas in case of extremely difficult to make extensions (β=0.001 , $p=NS$), we did not find statistical support. Thus, our predictions were largely supported, although results were clearer for complementary extensions.

DISCUSSION

This paper investigates an important research question as to whether perceived complementarity and perceived substitutability influence the relationship between perceived difficulty of manufacturing the extension and extension evaluation. We make theoretical contributions and attempt to resolve several inconsistent findings in the area of brand extension research. Further, the research has implications for managers who plan to leverage the equity of existing brand by introducing extensions that are either complements or substitutes of the parent brand. We show that complementarity helps in some cases but substitutability hurts the extension evaluation.

Poseurs: Understanding When Product Use is Perceived as Impression Management

Ethan Pancer, Queens University, Canada
Laurence Ashworth, Queens University, Canada

People frequently make inferences of consumers' personalities based on the products they use. The identity-signaling literature has largely assumed that observers interpret an identity signal as intended; e.g. if you ride a Harley, you are seen as rebellious. Along with emerging research (e.g. Ferraro, Kirmani, and Matherly 2010), we question this assumption and ask: What causes observers to think that a consumer is *intentionally* trying to create a certain impression? What is the effect of such motive judgments?

We know that "our possessions are a major contributor to and reflection of our identities" (Belk 1988, p. 139). This perspective has recently evolved into the identity-signaling literature, where researchers have demonstrated empirically that consumers use products to construct and express desired identities to others (e.g. Berger and Heath 2007; Escalas and Bettman 2005). In fact, we are pretty good at predicting what people will be like based on the products they use. People are able to 'read' elements of others (identities and other preferences) based on their possessions (e.g Belk, Bahn, and Mayer 1982; Gosling et al. 2002). Observers are able to form remarkably accurate impressions based on the belongings of others, even based on minimal information (Funder 2001; Gosling et al. 2002). These findings are certainly consistent with the idea that using trait-laden products allows the consumer to absorb and embody their symbolic values. So if we, as observers in the general public, believe that "you are what you eat / wear / use / consume," why would one ever believe this is not the case?

Another research stream questions the connection between a person and their products as solely identity expression. Impression management (IM) has been the subject of extensive research in both consumer behavior and social psychology (Schlenker and Weigold 1992; Leary 1995; White and Dahl 2007). This literature suggests that consumption may not always be motivated by identity expression, but is sometimes based on strategically influencing the opinions of others. Consumers have been shown to avoid products linked to dissociative reference groups (White and Dahl 2006; 2007), choose higher quality products in presence of others (Argo et al. 2005), and not use coupons to avoid looking cheap (Ashworth et al. 2005). Nevertheless, while people may able to 'read' people from their possessions, little attention has been paid to the ability to understand the intentionality and motives underlying behavior. Anecdotal evidence suggests that we do have the ability to make attributions about others as poseurs. Our research begins to examine the conditions where we question why people are using certain products, which instead, can lead to the inference that they are attempting to manipulate the image they create.

At the heart of the inference of an IM attempt is the idea that the observer believes the target is deliberately using a product in order to create a particular look. We believe that questions surrounding the target's motives for their appearance (of which an attempt to impression manage might be one) are initially inspired by product usage that cannot be explained by the situation. Observers are motivated to explain product usage when the product is seen as obviously not needed for the situation. This can be conceptualized as a product-situation discrepancy, where the central function of their product cannot be tied to elements of the situation i.e., wearing sunglasses when it is dark; using a scarf when it is warm. In these cases, the product use is seen as a little odd, not fitting with the norms of the particular situation. This discrepancy leads the researchers to the question: Which environmental cues are more suggestive of a motive of impression management versus something else?

Without other cues regarding the functional reasons for product use, observers are likely to use visible and salient cues in the environment that observers can use to deal with a product-situation discrepancy. The primary cue that is suggestive of an impression management motive is the perceived impact the image is having on others. One cause of impact is the overall positivity and extent of the impression, referred to forward as efficaciousness or efficacy of their look. If we believe that the product is responsible for making the target look good, we are likely to infer that they selected these products to create this impression.

278 university students responded to our 2 (Legitimacy of Product Use: Low vs. High) X 2 (Attractiveness of Product: Ugly vs. Attractive) X 2 (Brand Prominence: Logo Present vs. Logo Absent) between-subjects factorial design for course credit. Participants were shown an image of an individual wearing a scarf either indoors or outside, manipulating the legitimacy of scarf use. The scarf shown was either ugly or attractive (pre-tested earlier). Also, consistent with research on brand prominence (Han et al. 2010, Berger & Ward 2010), we manipulated the presence or absence of a Burberry logo.

As predicted, there was a significant interaction between legitimacy of product use and attractiveness of the product on the attribution of IM motive ($F(1,269) = 8.30$, $p < .01$). The target was perceived as significantly more motivated by IM concerns when they wore an attractive scarf inside (M = 4.51) compared with an ugly scarf inside (M = 3.97). When outside, a legitimate context for product use, inferences of IM motive attenuated. Interestingly, the presence of a large brand logo (M = 4.39) on the scarf was only marginally significant compared with the no logo condition (M = 4.15) ($F(1,269) = 3.26$, $p = .072$). This suggests that environmental cues and the efficaciousness of product use may be cues that are more suggestive of motive inferences than brand prominence. This research begins to examine the environmental cues which are suggestive of a motive of impression management. Although the target may have an appropriate functional reason for using a product in a certain context, observers may perceive a discrepancy between cues, which can ultimately lead to unintended outcomes. Future research will test cues beyond attractiveness that are suggestive of this motive as well as additional observer-related moderating variables.

Word-of-Mouth vs. Number-of-Mouth and the (Mis)Communication of Preferences

Samuel Bond, Georgia Tech, USA
Stephen Xihao He, Georgia Tech, USA
Talya Miron-Shatz, University of Pennsylvania, Ono Academic College, USA

Mirroring recent growth in social networks and consumer-generated content, word-of-mouth (WOM) research has regained attention in marketing theory and practice. Among various purposes served by consumer WOM, one important function is to communicate speakers' evaluations of goods or services, and this advisory role of WOM is perhaps most clearly illustrated by online product reviews. A burgeoning literature has explored the content of these communication efforts and their relation to audience inferences, persuasion, and firm performance (Chevalier and Mayzlin 2006; Weiss, Lurie, and MacInnis 2008; Schellekens, Verlegh, and Smidts 2010). In contrast, we focus on the ability of consumer WOM to perform its basic communication function. This issue is important to consumers and marketers alike, as more accurate WOM not only benefits consumer decision processing, outcomes, and satisfaction, but also enables more efficient use of WOM as a communications and feedback tool.

Consumers exchange WOM in a variety of forms varying in richness and complexity. We focus on two distinctive forms that represent opposite extremes: attribute ratings and commentary. For example, when sharing our opinions about a product online (e.g., a hotel stay), some forums allow open-ended discussion of anything deemed relevant (e.g., a description of our experience), while other forums restrict communication to ratings of specific features (e.g., cleanliness, location). Each format has distinct advantages for communicating one's opinion. Attributes are concise and easily understood; to the extent that relevant attributes are included, this format is consistent with multi-attribute utility models (Holbrook and Havlena 1988), enabling recipients to 'calculate' a sender's opinion. Commentaries are not conducive to such mental calculation and the process of verbally transcribing one's opinions is inherently noisy. However, commentary provides a far richer context offering its own advantages (e.g., West, Huber, and Min 2004; Escalas 2007). Commentaries allow speakers to express not only 'pros and cons', but also the idiosyncratic importance of those pros and cons to that speaker. In addition, commentaries aggregate components of a consumption experience to convey an overall impression, while attributes artificially separate the experience in a manner that may exaggerate single positive or negative aspects (Thaler 1985). Importantly, both these advantages are compounded for very positive or negative experiences, which often result from extreme performance on a few important dimensions. Therefore, building on prior evidence that narratives elicit stronger affective reactions (Adaval and Wyer 1998), we suggest that commentary is particularly suited to transmission of highly valenced opinions, so that any advantage of attributes over commentary in communicating evaluations will be attenuated when those evaluations are extreme.

Utilizing actual consumer reviews from a popular travel website, Study 1 examined individuals' ability to predict the hotel evaluations of reviewers. Twenty five reviews (each from a different hotel) were selected from the website using a stratified random sampling procedure. Undergraduate participants (N=109) were assigned to one of three conditions: participants in the *commentary* condition were given the body of review text to read; participants in the *attribute* condition were given the reviewers' rating of specific attributes (e.g., "service = 3/5"), and participants in the *combination* condition were given both forms of content together. Participants read reviews for five different hotels, one at a time. After reading each review, they were asked to estimate what overall rating the reviewer gave for the hotel (on a 5-pt. scale).

Communication error was calculated by taking the absolute deviation between a participant's estimate and the reviewer's overall rating. In support of our hypotheses, analysis revealed a significant interaction between information type and evaluation extremity. For hotels rated far from the mean, commentary and combination were more effective than attributes; for medium-rated hotels, attributes were more effective.

A follow-up analysis explored how the effectiveness of commentaries related to their linguistic content. Each of the 25 commentaries was analyzed using the Linguistic Inquiry and Word Count tool (Pennebaker, Booth, and Francis 2001), which categorizes words from a target script into over 70 linguistic or psychological categories. Descriptive analyses yielded interesting insights (e.g., positive emotional content greatly outnumbered negative content - Liu 2006)' surprisingly, longer reviews did not enhance communication (c.f. Mudambi and Schuff 2010). Words describing cognitive processes accounted for fully 16% of review content, and greater use of these words was a significant predictor of communication error. Moreover, cognitive process content was found to partially mediate the effect of extremity, supporting the notion that the idiosyncratic theorizing inherent to neutral evaluations is partly responsible for their greater communication error.

A defining property of WOM communication is its ability to be absorbed and retransmitted along a 'chain' of communicators. Building on the first study, we suggest that the disadvantages of commentary-based WOM make it especially unsuited to accurate retransmission. In particular, if the likelihood of commentary elements being retransmitted depends solely on their vividness than their representativeness, certain valuable elements will be "lost" as the chain progresses. Study 2 explored the implications of this property for communication effectiveness by adopting a 'telephone-game' framework (Bartlett 1932; Brown and Reingen 1987). After a screening process, one hotel review was selected from those used in Study 1. Undergraduate students (n=135) were divided into 45 different 'chains' of three participants apiece. The first member of each chain was given the original hotel review in one of three formats (*commentary*, *attributes*, or a *combination*), along with the reviewer's overall evaluation. After completing a short filler task, they were then asked to both reproduce the original review to the best of their ability and recall the evaluation. The next member in each chain was provided the first member's reproduced WOM, without any evaluation, and then (after a delay) asked to both reproduce it themselves and estimate the original evaluation. This process was repeated for the third member of the chain.

Decay of information was captured by the absolute difference between the original reviewer's evaluation and the estimates of each member along the chain. Analysis of decay revealed an interaction between stage and information type. Follow-up analyses showed that for *commentary* and *combination* conditions, the accuracy of review estimates fell sharply from stage-1 to stage-2, and continued to decline at stage-3. In contrast, decay in the *attribute* condition was negligible across the sequence. Examination of the reproductions themselves revealed an explanation in keeping with our arguments. Although the original evaluation was positive (4/5), reproductions in the *commentary* condition contained a disproportionate level of content that was vivid but negative (and therefore unrepresentative); in the *attribute* conditions this was not the case.

Taken together, our results provide insights regarding the utility of consumer WOM for performing a basic but critical function: communicating the speaker's preference. As such, this research represents an initial foray into a topic of growing importance to the field of consumer behavior. In addition, our findings have important implications for marketers interested in utilizing WOM to inform or influence consumer learning, choice, and satisfaction.

The Dark Side of Social Consumption:
Behavioral Addiction in the WoW Online Brand Community

Darrell Bartholomew, Oklahoma State University, USA
Marlys Mason, Oklahoma State University, USA

Past literature has revealed a dark side to consumption in terms of compulsive behaviors and addictions (Hirschman 1992; O'Guinn and Faber 1989). Such adverse consumption has typically been examined in contexts involving products with addictive physical attributes (e.g., tobacco, drugs) or in contexts where compulsive tendencies arise due to the pleasurable engagement derived from the consumption (e.g., gambling, excessive shopping, binge eating). In today's high-tech world, an excessive use of technology has prompted questions about whether some behaviors (e.g., excessive texting, online gaming) may also exhibit compulsive patterns.

Research in brand communities has also alluded to a potential dark, compulsive side that may result for some participants. Schouten and colleagues (2007 p. 366) note that, "there may be a fine line between the well-being of transcendence (flow) and the dangers of addictive escapism… it appears that one person's path to bliss may be another person's road to ruin." Virtual brand communities may pose one such threat for heightened addiction due to transcendent nature of technology and immersion in the virtual/online (rather than tangible/physical) realm.

The purpose of this research is to explore the merging of technology, transcendence, and community in heightening the potential for compulsive consumption. We examine this phenomena in the context of online gaming. Drawing upon the addiction literature and through a lens of social learning, we explore the nature and potential for compulsive consumption in the online brand community of the World of Warcraft (WoW). Using a netnographic approach (Kozinets 2006), we examine a popular blog set up for current and former gamers of WoW. This blog contains more than 2,000 anonymous entries posted over a four year period. WoW was the chosen context because it is estimated that as many as 40% of WOW players are addicted (Ahn 2007).

CONCEPTUAL BACKGROUND

Compulsive consumption is defined as, "…a response to an uncontrollable drive or desire to obtain, use, or experience a feeling, substance, or activity that leads an individual to repetitively engage in behavior that will ultimately cause harm to the individual and/or to others" (O'Guinn and Faber 1989, p. 148). Compulsive consumers may be aware of the harmful personal consequences, but are driven and 'lose control' by the psychological fulfillment derived from the consumption. Similarly, addiction is viewed as a psychological or physical dependence on something (Herie 2007), with behavioral addictions involving "an impulse-control disorder that does not involve an intoxicant" (Young 1998). Compulsive, addictive consumption may be especially difficult to break if it involves social identification with other product users/community members. For example, smoking and drinking are embedded in the norms and socialization of some groups, and ending the substance use would involve renegotiating group inclusion. New forms of consumption and community affiliation which is co-constructed through technology may be particularly prone to such behavioral addictions.

ANALYSIS

The goal of our analysis was twofold: 1) to identify how online gaming attributes and communities may contribute to the potential for compulsive behavior, and 2) to explore the nature of harmful outcomes (if any) may be occurring. Transcendent consumer experiences (TCE; Schouten et al 2007) and social learning theory are used to guide the analysis. TCE are defined as "peak" and "flow" experiences in a consumption context (Schouten, McAlexander and Koenig 2007) where individuals feel more active, alert, happy, and become highly focused and immersed in the activity. TCE can be enhanced by both the social aspect of the community and attributes of the product. Social learning (Bandura 1977) and its processes of 1) attention, 2) retention, 3) motor reproduction, and 4) motivation can shed light on how transcendent elements may built into online gaming. Table 1 highlights our findings within this framework. Table 2 then presents emergent themes in the blogs of harmful consequences stemming from compulsive involvement in the online brand community.

Attention in Game Environment Game play is joined, game always active (real-time) leading to immersion. High quality graphics, sound and 3-D stimulate sensory engagement Game world is continuous (can never be fully explored) Game advancement is never-ending (goals/ rewards always changing)	**Retention through TCE** Entering game, escapism. Enjoyment through anticipation and play Rewards in power/skill increases Attainment of high levels form of peak experience Achieving state of TCE increasingly important
Avatar Modeling Active character performing acts Customizable character reflect ideal self Race, gender uninhibited Rewards for violent acts is acceptable norm	**Social Motivation** Socialization part of game structure Team efforts to achieve game goals Game activities are socially structured Norms jointly enforced company and group Characters are part of a group identity that allows for group inclusion Stories are shared in game that motivate continuation with storyline. Tools given for documentation (record videos) and sharing game themes with others.

Table 1. Social Learning Theory Applied to Video Games

Based on these	Expressions of Harm	Consequences of Harm
Behavioral Harm	Sleep deprivation Eating deprivation Eye strain No desire to leave the game Physical aggression towards others Verbal aggression towards others Depression Trying to quit Absenteeism Neglecting school work/attendance Preoccupation with the game and virtual world	Neglect of housekeeping Poor health Poor eyesight Homebound by choice Physical abuse, violent acts w/ weapon Verbal abuse Suicide Inability to quit Loss of Jobs Lower grades, drop out of school Retaking classes Inability to concentrate on other tasks and tangible world
Social Harm	Neglecting relationships outside of game and virtual community Lying about playing Socializing in the game	Loss of relationships, divorce Child neglect Loss of Trust Loss of social activities outside game

Table 2. Signs of Addictive Gaming Behavior.

Our initial coding suggests that addictive patterns are occurring that harm both the community member and others. Our findings can be used can shed light on the harm that may be caused by some forms of brand communities and technology. We hope these insights foster new ways for envisioning and transforming emerging societal problems related to gaming and behavioral addiction that have not been addressed by the industry or the government.

The Role of Self-Regulatory Focus, Self-View, and Benefit Focus in Attitudes Toward Organic Brands

Ioannis Kareklas, Washington State University, USA
Jeffrey Carlson, University of Connecticut, USA

The organic food segment has experienced considerable growth over the past two decades (Organic 2010). According to the Organic Trade Association (2010), U.S. sales of organic food and beverages have grown from $1 billion in 1990 to $24.8 billion in 2009. Extant research suggests two main attitudinal and behavioral influences of organic food consumption: 1) concern for one's health (e.g., Chen 2009) and, 2) concern for the environment (e.g., Squires et al. 2001; Wandel and Bugge 1997). However, despite these influences, Hughner et al. (2007) observe that the majority of organic researchers have focused mostly on the demographic differences of consumers, at the expense of important behavioral influences (e.g., attitudes, goals, etc.). Hence, the purpose of this study is to understand how a consumer's attitudinal preferences toward organic food intersect with organic food labels in impacting consumers' organic food attitudes. Given the relative importance of the concern for one's own health and concern for the environment in regards to organic food, we test how the manipulation of such factors can interact and subsequently affect consumers' attitudes toward an organic brand.

THEORETICAL BACKGROUND

The theoretical foundations for this study stems from two areas. First, is that the view of self intersects and in influenced by broad society (see Fiske et al. 1998 for a review). This often results in an independent focus (e.g., unique individual characteristics, concern for one's health) or interdependent focus (e.g., one's self defined by others, a focus on greater good for society, etc.). The second conceptual foundation is regulatory focus theory (Higgins 1997). Aaker and Lee (2001) show promotion-focused message are more persuasive on individuals with an active, independent self-view. However, prevention-focused messages are more persuasive if an individual has an active, interdependent self-view. Given that a focus on one's self or for the environment drives organic food attitudes and purchase intention, we study how prevention and promotion-framed food messages intersect with one's active self-view. Based on Aaker and Lee's (2001) findings, one can expect promotion-framed messages to more effective with an active, independent self-view and a prevention-framed message to more effective with an active, interdependent self-view. Our study addresses how this process is impacted by the focus of the organic food labels, whether they highlights personal health benefits versus environmental benefits (a common practice in organic food labeling).

METHOD

We examined evaluations of an organic brand of milk called Farmer's Cow. While this is an existing brand sold in Connecticut, it was presented to participants at a large west coast university as "a new brand of organic milk," produced by a group of six local dairy farms, that is now available in their local grocery stores. We used a 2 (self-view prime: independent or interdependent) x 2 (benefit type: promotion or prevention) x 2 (benefit focus: personal health benefits or environmental benefits) between-subject design.

Existing research has shown that self-view and regulatory focus can be activated using a situational prime (Aaker and Williams 1998). The situational prime we used to activate the desired self-view was manipulated by using a picture focusing on an individual or group of people, accompanied by text. Regulatory-focus was manipulated through differences in text (e.g., a prevention message emphasized the presence or absence of negatives). Finally, benefit focus was manipulated by exposing half the participants to messages that focused on the environment versus a focus on personal health). All manipulations scored in the expected direction on manipulation check questions. Our dependent variable, attitude toward the brand, was measured using three seven-point scale items ($\alpha = .93$).

RESULTS

Results show a significant three-way interaction (F (1, 188) = 8.53, p = .004) between the factors. If the focus in on environment (F (1, 101) = 5.70, p = .019), a promotion-farmed message (M = 5.63, SD = 1.06) is more persuasive than a prevention-framed message (M = 5.32, SD = 1.17) with an active independent self-view. However, a prevention-farmed message (M = 5.58, SD = .70) is more persuasive than a promotion-framed message (M = 4.89, SD = 1.13) with an active interdependent self-view. If the focus in on personal-health (F (1, 85) = 4.01, p = .049), a prevention-farmed message (M = 5.54, SD = 1.10) is more persuasive than a promotion-framed message (M = 5.03, SD = 1.16) with an active independent self-view. However, a promotion-farmed message (M = 5.69, SD = .88) is more persuasive than a promotion-framed message (M = 5.59, SD = 1.49) with an active interdependent self-view.

DISCUSSION AND FUTURE RESEARCH

The results of this study make several theoretical and practical contributions. First, it extends previous works on self-view and regulatory focus and shows that promotion-framed messages are not always most persuasive with an independent self-view (or that prevention-framed message are not always most persuasive with an interdependent self-view). In other words, "I" do not always seek pleasure and "we" do not always avoid pains. Specifically, if an organic food message focuses on the environment, then "I" avoid pain and "We" seek pleasure. We do find, though, that Aaker and Lee's original finding does apply to messages that focus on personal health. This finding underscores

that in an organic food context, a focus on personal health versus environmental health is important. In our next study, we are exploring the mechanism that helps explain these results. Second, we believe the results of this study can inform practitioners in the design of better organic food messages (e.g., labels). Finally, consumers' can also better understand the often overlooked forces that impact their daily purchase attitudes and decisions.

Is Negative Brand Publicity Always Damaging? The Moderating Role of Power

David Norton, University of South Carolina, USA
Alokparna Monga, University of South Carolina, USA
William Bearden, University of South Carolina, USA

As consumers have increasing access to multiple sources for product information (e.g., blogs, television, news outlets, etc.), the ability to manage negative publicity becomes increasingly difficult. Prior research has demonstrated that consumers place more weight on negative than positive information in forming judgments (Eagly and Chaiken, 1993) showing that negative publicity can cause substantial harm. For example, the recent events surrounding British Petroleum's oil spill in the Gulf of Mexico have led to detrimental effects on the brand.

We know that negative publicity can be damaging for brands ((Menon et al. 1999; Tybout et al. 1981). Surprisingly, little research has focused on characteristics of the message recipients and how they might influence responses to negative publicity (Ahluwalia, Unnava and Burnkrant, 2000; Monga and John, 2008). In this vein, we examine the effect of consumers' power on responses to negative publicity. Power is an important characteristic to study, as it is ubiquitous and highly malleable. In many instances throughout our daily life, we may be shifting between a high power (e.g., meeting with a subordinate) and a low power (e.g., meeting with a boss) mindset. Aside from these situational variations, power is also conceptualized as an individual difference which varies across consumers (Anderson and Galinsky, 2006).

In this research, we suggest that high power individuals are less likely to be affected by negative publicity than low power individuals. Galinsky et al. (2008) find that high power people possess more freedom from influence of external forces compared to low power people. High power people are less influenced and constrained by salient information in the environment, because power increases sensitivity to internal states and increases confidence in one's own thoughts (Brinol et al., 2007). This sensitivity to internal states suggests that high power individuals may rely more on their own thoughts about the brand and are less likely to be influenced by negative publicity information, compared to low power individuals. Thus, upon exposure to negative publicity, brand evaluations of high power individuals would be more favorable than those of low power individuals.

In study 1, we test our hypothesis using a power manipulation (Galinksy et al., 2008) in a 2 Power: High, Low) x 2 (Stimuli: negative information, control) between subjects design. In the high power condition, participants wrote about a situation in which he/she controlled the ability of another person or persons to get something they wanted. In the low power condition, participants wrote about a situation in which another person controlled the ability of the participant to get something he/she wanted. Next, participants in the negative information condition were exposed to a press release stating that BMW was experiencing manufacturing problems on their new line of cars. Participants in the control condition (who served as a baseline) were not exposed to the press release. Subsequently, participants rated the BMW brand on attitude and belief scales. As expected, when exposed to the negative information, participants in the high power condition rated the brand more favorably than participants in the low power condition. In contrast, there were no differences between low and high power participants in the control condition. Further, high power participants also weighted the negative information less heavily than did low power participants.

In study 2, we examine the role of source credibility (Brinol et al., 2004). We anticipate that when negative information originates from a less credible source, high power individuals would be less susceptible to the negative publicity than low power individuals (as in our prior study). However, for a more credible source, which is likely to be a more powerful source, we expect that high power individuals would be more likely to attend to the negative publicity and their brand evaluations would decrease. As a result, differences in brand evaluations between low power and high power individuals would dissipate.

In study 2, participants were exposed to the same power manipulation as in study 1. The source of the press release was indicated as either a highly credible source (*The Wall Street Journal*) or a significantly less credible source (*The National Enquirer*). Participants in this condition were not exposed to the negative publicity. Thus, we used a 2 (Power: High, Low) x 3 (Source Credibility: High, Low, Control) between subjects design. Our results show a significant interaction between power and credibility on brand evaluations, such that in the low credibility condition high power individuals evaluate the brand higher (and weight the negative information less heavily) than low power individuals. However, this difference dissipated in the high credibility condition. Further, no differences emerged in the control condition.

In study 3 we examine the role of thought confidence (Petty et al. 2002). High power people tend to be more confident in their own thoughts and consequently place less weight on external information. If we boost the confidence of low power individuals before they are exposed to negative information, we expect that they would be less likely to rely on external information in brand evaluations. Consequently, we expect their brand evaluations of low power individuals would rise to the level of the high power individuals, thus eliminating the difference.

In study 3 participants were exposed to a confidence priming task, such that people in the high confidence condition wrote about a time they felt confident in their abilities and individuals in the low confidence condition wrote about a time they were skeptical or less confident of their abilities. Power was measured using the Sense of Power (SOP) scale (Anderson and Berdahl 2002). Thus, we used a 2 (Power: High, Low) x 3 (Confidence: High, Low, Control) between subjects design. Our results show a significant interaction between power and confidence, such that in the low confidence condition high power individuals evaluate the brand higher (and weight the negative information less heavily) than low power individuals. However, this difference dissipates in the high confidence condition, with evaluations of low power individuals rising to the level of the high power individuals. Further, no differences emerged in the control condition.

The findings in our paper contribute to the negative publicity literature and to the largely understudied area of consumer power. Prior research shows that negative publicity can adversely affect the brand. We show that this effect is more likely to happen for low power than high power consumers, except when the source of the negative information is highly credible or when the consumer's confidence is high.

Can Colors Make Me Happy? The Effect Of Color On Mood: A Meta-Analysis

Jamie Hyodo, Pennsylvania State University, USA

Being visually-oriented creatures, color is a pervasive and encompassing feature of our visual environment. There is not a single physical thing that cannot be described by its color. Furthermore, colors have long been understood to be used as judgement criteria. Some of these judgements are widely agreed upon, such as a blue sky being a source of pleasure, but many more are personal judgements, such as favorite colors, or reactions to clothing. In these personal contexts, colors are seen to have the power to alter the meaning and value of an object.

Colors can also add meaning to objects or environments via association. For example, red is often considered a color of aggression or anger due to it also being the color of blood (Grossman 1999). These meanings may vary by culture; for example, white symbolizes mourning or death in many East Asian cultures (Ricks 1983), but happiness or purity in Australia, New Zealand, and the USA (Neal et al 2002).

Despite the potential impact of color in an exchange environment, many practitioners spend very little time or effort deciding on color. Those that do spend time making color decisions may be skewed by personal biases or weigh the aesthetic value disproportionately when compared to potential symbolism inferences.

While some researchers measure the direct effect of color on purchasing behavior (Bellizzi & Hite, 1992), many more follow the belief that the effect of color on behavior is mediated by mood. Specifically, there is a growing body of research which recognizes the effects of warm and cool colors on a range of pleasure and arousal constructs (Cheng, Wu, & Yen, 2009). This literature, however, has not been comprehensively evaluated to this point, and many of the findings have been widely varying in effect size and even effect direction in some cases. Therefore, a meta-analysis, a systematic statistical tool, will be used to quantitatively synthesize these diverse findings.

The primary purpose of this meta-analysis is to analyse the color-mood relationship, with the understanding that consumer mood can have a significant impact on behaviour. Drawing on the collective efforts of many researchers in their individual studies of color and affect, I conduct two meta-analyses, analyzing the overall effects of warm versus cool colors on both arousal and pleasure.

Following a review of the relevant literature, I will aggregate the findings of past publications in order to determine the overall effect of warm versus cool colors on the pleasure and arousal constructs. I will also use the statistical power of the combined vast quantity of data to explore the possibility of a series of moderating variables in the color-mood relationship. Finally, I will address future research needs in this area.

LITERATURE REVIEW

Research on color is part of the study of 'atmospherics.' The field of atmospherics came about as a result of earlier psychology work in the field of environmental behaviour. Environment-behavioral theory suggests that individuals interact with the environment around them, resulting in certain responses and behaviors (Lewin, 1951).

Kotler (1973) examined environmental psychology through a marketing lens when he examined the idea of the physical environment as an important part of the total consumption package. He believed that the atmosphere of a purchase environment had an effect on purchase intentions, and identified an initial set of variables which affect the perceived quality of a business atmosphere. These variables were termed 'atmospherics' (Kotler, 1973). While the concept of atmosphere had been recognized as important in service and entertainment industries, this had not been considered as a valuable feature for most other consumption and exchange environments.

Research on the influence of atmospheric variables built off of this early work to currently encompass five categories: external variables, general interior variables, layout and design variables, point-of-purchase and decoration variables, and human variables (Turley & Milliman, 2000). A prominent feature that is relevant across all five categories is color.

Color

Color is an ever-present characteristic of products as well as less intrusive elements of the exchange environment, such as lighting, decorations, themes, signage, and walls. Most consumers have a 'favorite' color and are subconsciously attracted or repelled from spaces or objects as a result of the color of these spaces and objects. Colors have also been classified as warm and cool. The descriptor 'warm' is colloquial, but is generally accepted to include the colors red, yellow, and to a lesser extent, orange. Red is the 'warmest' color. Color can be measured by wavelength within the electromagnetic spectrum, and within the visible spectrum (400-700 nm), red has the longest wavelength of any color (650 nm) (Kusterer, 2007). The descriptor 'cool' is also colloquial, and is generally accepted to include the colors blue and green. Blue is the 'coolest' color, and generally considered to be opposite to red. Blue has one of the shortest wavelengths (475 nm) (Kusterer, 2007).

While it is not wholly certain why different colors have effects on behavior, one area of research that may help to explain these effects is associative learning (Grossman & Wisenblit, 1999). This theory indicates that consumers learn color preferences for particular products or settings as a result of associations that have been formulated through their experiences (Grossman & Wisenblit, 1999). Researchers have suggested that color associations may have been formulated early in human history when man associated dark blue with night, and therefore passivity, and bright yellow with sunlight and arousal (Luscher & Scott, 1969).

While the underlying theory is not entirely certain *why* consumers react differently to different colors, much research has examined *what* various color effects may be across various contexts. Color has been studied for its effects on purchase behavior (Bellizzi & Hite, 1992), affect, (Bellizzi, Crowley, & Hasty, 1983; Bellizzi & Hite, 1992; Chebat & Morrin, 2007; Cheng et al., 2009; Countryman & Jang, 2006) and behavioral change (Etter, Cucherat, & Perneger, 2002; Garrett & Brooks, 1987). It is possible that color's relationship with affect may supersede or mediate these more specific relationships.

Affective responses to color stimuli

As can be seen above, the impact of color on affect has been one of the most widely studied areas of color research. Affective responses consist of two dimensions: arousal and pleasure (Lin, 2010). Arousal is a basic, subjective state, ranging from sleep to frantic excitement (Berlyne, 1960), while pleasure refers to the degree to which a person feels good, joyful, happy, or satisfied in the situation (Donovan & Rossiter, 1982). A recent study found that across many measures of mood, these two factors, pleasure and arousal, accounted for 80% of measured variance (Cheng et al., 2009).

Mehrabian and Russell (1973, p. 315) identified arousal-seeking tendency (AST) as "an individual's preference for an environment that is closely related to his preferred arousal level; some persons characteristically prefer calm settings, whereas others actively seek to increase their arousal by selecting novel, complex, or unpredictable settings". If different colors affect arousal and pleasure, AST may explain why affective responses to colors are not perfectly universal, and may also help explain the existence of demographic-based moderating variables on color-affect relationships.

Researchers generally agree that cool colors (such as blue) are more strongly associated with pleasure than warm colors (such as red) (e.g. Babin, Hardesty, & Suter, 2003; Bellizzi et al., 1983; Bellizzi & Hite, 1992; Moore, Stammerjohan, & Coulter, 2005), and that warm colors are more strongly associated with arousal than cool colors (e.g. Bellizzi et al., 1983; Cheng et al., 2009; Moore et al., 2005). This is because of widespread acceptance of both Bellizzi's (1983) seminal findings on the topic, and the evolutionary theory outlined above. Consquently, I hypothesize that:

H₁: Cool colors lead to affective pleasure responses more strongly than the warm colors.

H₂: Warm colors lead to affective arousal responses more strongly than the cool colors.

However, not all studies support these hypotheses. Some studies findings are counter to H₁ (e.g. Chebat & Morrin, 2007; Cheng et al., 2009), while others have findings counter to H₂ (e.g. Babin, Hardesty, & Suter, 2003; Bellizzi & Hite, 1992; Yildirim, Akalin-Baskaya, & Hidayetoglu, 2007). Therefore, potential demographic moderators such as culture, gender, and study date will be explored. Drawing on associative learning theory, it is plausible to assume that individuals of different cultural backgrounds would have different color associations. Male and female children are also often surrounded by male- or female-specific colors of toys and clothing, which may also produce different associations across gender. It is also possible that as popular media changes across time, different generations will have grown up with different color associations. Finally, it is possible that these varied findings are a result of study design differences, therefore moderators such as colors used and manipulation strength will also be examined.

METHOD

Meta-analysis is a transparent, systematic review of currently existing research which uses statistical analysis to synthesize previous quantitative results from a series of studies which employ similar variables. This synthesized data is used to determine the nature of a particular relationship between variables and will usually be drawn from studies with similar hypotheses. The goal of a meta-analysis is to understand the results of any study in the context of all the other studies by examining consistency of effect size, whether this effect size is robust across studies and, if not, to quantify the extent of the variance and consider implications (Borenstein et. al, 2009). A meta-analysis is an appropriate tool to employ here, as all studies included are experimental and quantitative in nature and examine similar independent variables (warm versus cool color stimuli) and similar dependent variables (various measures of pleasure and arousal). Furthermore, all studies examine similar theoretical constructs and as such can be compared conceptually.

In conducting this meta-analysis, I follow the steps outlined in Borenstein et. al's *Introduction to Meta-Analysis*. An initial search of Scholars Portal for 'color' OR 'colour' and 'meta-analysis' indicated that a meta-analysis on this paper's topic had not been conducted. I then conducted a literature review and selected articles for inclusion based upon pre-determined meta-analysis criteria (for criteria, see Appendix A). An initial literature search was conducted using Scholars Portal, using the terms 'color' and 'colour' as present in peer-reviewed journal articles and conference papers. Follow-up searches in the PsycINFO and Web of Science databases and reverse-tracing of reference searches were subsequently conducted. In all, these searches resulted in 16 articles which examined how colors pertain to mood or affect behavior. No other meta-analysis was found, and four authors were emailed requesting further data, one of whom provided it. As a result of these searches, seven articles were found which were included in the meta-analysis. A summary of the data in these studies can be found in Appendix B.

A comparison of mean differences was used as the standard comparison effect size for this analysis. Effect size calculations were conducted using Formula 1 from Table B10 of Lipsey and Wilson's *Practical Meta-Analysis* (2001):

Formula 1: $$ES_{sm} = \frac{\bar{X}_1 - \bar{X}_2}{s_{pooled}}$$

$$s_{pooled} = \sqrt{\frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{n_1 + n_2 - 2}}$$

While some studies provided means and standard deviations for relevant condition groups, other studies' data was presented in the form of multi-way ANOVA F-values or independent t-values. Authors of papers which reported multi-way F-values were contacted to request condition group means and standard deviations. For the studies which reported independent t-values, a mean differences effect size was calculated using either formula 2 from Table B10 for different sample sizes:

Formula 2: $$ES_{sm} = t\sqrt{\frac{n_1 + n_2}{n_1 n_2}}$$

or formula 3 from Table B10 in the case of equal sample sizes (when sample sizes were not given, equal sample sizes were assumed):

Formula 3: $$ES_{sm} = \frac{2t}{\sqrt{N}}$$

These effect sizes were then corrected for unreliability:

Formula 4: $$ES' = \frac{ES_{sm}}{\sqrt{r_{yy}}}$$

I then weighted each individual effect size for relative sample size:

Formula 5: $$w_{sm} = \frac{2n_{G1}n_{G2}(n_{G1} + n_{G2})}{2(n_{G1} + n_{G2})^2 + n_{G1}n_{G2}ES_{sm}^2}$$

A weighted mean effect size was calculated for both pleasure and arousal conditions, and Z-scores were calculated for these to determine significance.

Q was calculated for both pleasure and arousal analyses to determine heterogeneity of true study effects.

Formula 5: $$Q = \sum_{i=1}^{k} W_i Y_i^2 - \frac{\left(\sum_{i=1}^{k} W_i Y_i\right)^2}{\sum_{i=1}^{k} W_i}$$

These Qs were then compared to the degrees of freedom:

$$df = k - 1,$$ where k is the number of studies, where k is the number of studies

I have not gained the necessary data to accurately include two key study results: the Moore et al. and Middelstadt studies. The Moore et al. study used a two-way ANOVA and provided F-values. These values were used as an approximation of a one-way ANOVA. The Middelstadt study was not included in the analysis.

RESULTS

The results of the two meta-analyses incorporate over 1,000 participants each (pleasure: 1,601; arousal: 1,607). As Table 1 (calculations in Tables 2, 3) indicates, color does indeed have an effect on consumer mood as measured by pleasure. As expected, blue is seen to be more strongly associated with pleasure responses than red (Z=3.325, p<.001). Thus, H_1 was supported with an effect size of 0.168. Unexpectedly, H_2 was not supported, with an overall insignificant effect of color on mood. Arousal was still reviewed in the moderator analysis, in order to determine whether H_2 holds under select boundary conditions.

Q, a measure of chi-square distribution, was used to test for heterogeneity of data. Upon comparison of each Q to each meta-analysis' degrees of freedom, Q far exceeded the degrees of freedom for both the arousal and pleasure meta-analyses ($Q_{Arousal}$-$df_{Arousal}$ = 22.705; $Q_{Pleasure}$-$df_{Pleasure}$ = 43.167). This excess variation indicates differences in the true effect from study to study.

Table 1 - Results

	Pleasure		*Arousal*	
Mean effect size (ES')	0.168		0.075	
Effect direction	C > W		C > W	
Z on mean effect size	3.325		1.476	
Confidence interval	0.069	0.267	-0.174	0.024
Q	28.705		49.167	
d.f.	6		6	

In an attempt to resolve the differences shown by Q, potential moderators of culture, color selection, gender, publication date, and manipulation strength were investigated (see Appendices C and D for moderator coding).

MODERATORS

For each moderator, the set of studies was divided into sub-samples according to my coding of each in Appendix D. For each sub-sample, an overall weighted mean was calculated, as well as a Z-score and Q comparison.

Table 4 - Moderator Results

	Pleasure				Arousal			
	Result direction	Mean effect size	Untransformed mean effect size	Z on mean effect size	Result direction	Mean effect size	Untransformed mean effect size	Z on mean effect size
Sample Nationality								
North American	C > W	0.21	0.21	3.27	C > W	0.01	0.01	0.17
Non-North American	C > W	0.10	0.10	1.23	C > W	0.18	0.17	2.16
Color Treatment Condition								
Blue/red only	C > W	0.00	0.00	0.02	W > C	0.27	0.27	2.78

Publication Date								
Pre-1995	C > W	0.41	0.39	2.96	W > C	0.16	0.16	1.14
Post-1995	C > W	0.13	0.13	2.42	C > W	0.11	0.11	2.02
Manipulation Strength								
Strong manipulation	C > W	0.19	0.19	3.24	C > W	0.13	0.13	2.23
Subtle manipulation	C > W	0.10	0.10	1.10	W > C	0.07	0.07	0.76

Culture

Color associations vary by culture (Aslam, 2006). As such, it is possible that color manipulations which are tested on non-North American participants may produce unexpected results.

Arousal: Exploring different levels of arousal by culture revealed a very interesting difference in results. The North American sample showed no relationship between color and arousal, while the non-North American sample showed a significant effect size (ES = 0.18, Z = 2.16) in favor of cool colors being more arousing than warm colors, counter to H_2.

Pleasure: The North American sub-sample showed a mean effect size of 0.21 in favor of cool colors leading to greater pleasure than warm colors, while the non-North American sub-sample showed an insignificant effect .

Colors

Red and blue are considered opposite colors (Bellizzi & Hite, 1992). The original studies upon which my hypotheses were based drew their conclusions based largely on a comparison of red versus blue manipulations. The examination of warm versus cool colors, however, possibly 'blurs' this contrast, resulting in weaker effect sizes. Another possibility is that red and blue specifically have associative properties which lead to pleasure and arousal effects, while other warm and cool colors do not share these associations. As such, the first moderator sub-segment was limited to studies which exclusively used red versus blue, while the second sub-segment included all other studies.

Arousal: Studies using red versus blue manipulations showed a significant mean effect size of 0.27 (Z=2.78) in favor of red more strongly associating with arousal than blue. Studies using other warm versus cool comparisons, however, showed a significant mean effect size of 0.20 (Z=3.41) in favor of *cool colors* being more strongly associated with arousal than warm colors. This would appear to indicate that a) effect sizes are greater when comparing more extremely opposite warm and cool colors and b) other warm (cool) colors do not elicit arousal (disinterest) in the same way that red (blue) do.

Pleasure: Studies using red versus blue manipulations showed insignificant results. A more significant finding was that other warm versus cool color manipulations supported H_1 with an effect size of 0.23 (Z=3.88). Thus, while H_2 may not hold across the full spectrum of cool and warm colors, H_1 received some support from the warm/cool sub-sample.

Gender

As seen in Appendix D, some of the studies employed female-only participant groups. In one case, this was because the authors believed that the majority of shopping/purchase decisions were made by women (Bellizzi et al, 1983). It is possible that women differ from men in some cognitive or associative manner which affects their perception or interpretation of environmental colors.

Arousal: No significant results were found for either sub-sample of arousal measures when split by gender.

Pleasure: When split by sample gender, H_1 is seen to hold true across both sub-samples with significance. A point of interest here is the effect size for each sub-sample. For the mixed gender sub-sample, cool colors were weakly associated with pleasure at an effect size of 0.13 (Z=2.28). For the female-only sub-sample, cool colors were more strongly associated with pleasure at a medium-strength effect size of 0.34 (Z=2.42). This effect size is almost three times the mixed gender sub-sample, which might indicate that women find cool colors more pleasing than men.

Publication Date

Kreitler (Kreitler & Kreitler, 1974) notes that color associations change over time, sometimes in as little as a few years. Some studies included are over twenty years old. As such, it is possible that warm/cool color associations have shifted since then. A cut-off date of 1995 was selected due to its tangency to one of the greatest recent culturally impactful process, the widespread acceptance of the internet. It is possible that as a result of various tasks and media being replaced by the internet, traditional associations have also changed.

Arousal: When split into pre- and post-1995 sub-samples, the data reveal an interesting change of direction in effect. Pre-1995 data show that warm colors are more strongly associated with arousal at an effect size of 0.16, without significance (Z=1.14). Post-1995 data show a dramatic shift, to cool colors being more strongly associated with arousal at an effect size of 0.11 (Z=2.02). This might indicate that a shift in underlying population color associations occurred during the mid-1990s or has been consistently shifting since that time.

Pleasure: Similarly interesting results were seen when comparing pre- and post-1995 sub-sample data for pleasure. Pre-1995 sub-samples showed a mean effect size of 0.41 (Z=2.96), while post-1995 sub-samples showed a mean effect size of 0.13 (Z=2.42). While the direction of the effect (that cool colors are more strongly associated with pleasure) held true across both sub-samples, the degradation of the strength of the effect also serves to support the possibility of a shift in color effects in or since the 1990s.

Manipulation Strength

Manipulation strength is defined here as the extent to which a participant's full visual perception is impacted by a color manipulation. Manipulations such as wall color changes or entire background color tinting are considered strong, while manipulations which impact less than half of the visual environment, such as décor or wall panels, are considered subtle.

Arousal: When comparing strong versus subtle manipulation sub-samples, the strong manipulation sub-sample shows a mean effect size of 0.13 (Z=2.23). This effect runs counter to H_2, however, as its direction shows that cool colors elicit greater arousal than warm colors. The subtle manipulation sub-sample was in the opposite direction, but without significance. This seems to indicate that the extent to which a certain color scheme is used to elicit consumer arousal is important, as subtle color schemes do not induce arousal effects.

Pleasure: For pleasure, similar findings are noted. Both sub-samples indicate that cool colors more strongly lead to pleasure, with the strong manipulation having an effect size of 0.19 (Z=3.24) and the subtle manipulation having an insignificant effect size of 0.10 (Z=1.10). Both of these sub-samples support H_1. These results appear to indicate that manipulation strength is a moderator to the color-pleasure relationship, with environments requiring a dominant color to elicit a mood effect.

DISCUSSION

This meta-analysis examined two previously widely accepted beliefs: that cool environmental colors elicit a greater sense of pleasure and that warm colors elicit a greater sense of excitement or arousal. Based on the results of this meta-analysis, the first of these beliefs (H_1) is seen to be of weak-moderate effect size with significance (ES = 0.17, Z = 3.325), while the second (H_2) is shown to be not significant.

Thus, while managers have been employing warm colors in an effort to gain consumer attention, this actually may not be effective, possibly as a result of changing color associations in the general population. H_1 shows a fairly robust relationship, however, indicating that managers should feel comfortable in creating store environments which are dominated by cool colors, as these environments will likely be perceived as pleasurable by consumers.

Impact of Potential Moderators

The exploration of potential moderators led to discovery of various boundary conditions and findings that were not initially obvious.

An analysis of sample cultures led to interesting, if not entirely unexpected, results. North Americans were found to elicit pleasure from cool-color environments, while non-North Americans were found to not be significantly impacted in terms of pleasure. Non-North Americans were found to be excited by cool colors, however, while North-Americans' arousal was not significantly impacted. This finding serves to strengthen the possibility that colors' meanings are derived through association, as different cultures place different symbolic meaning on different cultures. It also serves as a reminder that it is unsafe to generalize results from a North American sample pool to an international context.

When colour manipulations were examined, red was seen to be more strongly associated with arousal than blue, while other cool colors were seen to be more arousing than other warm colors, though with a slightly weaker effect size. These results would support the idea that red is the most arousing color, but not necessarily as a result of being the warmest color. Red may simply be considered arousing as a result of red-specific color associations. While cool colors were seen to be more pleasing than warm colors, however, the color blue itself was not seen to be more pleasing than the color red. This finding also serves to show that cool and warm colors do not have universal effects, but rather it is possible that individual colors each have their own effect.

The most significant implication of gender as a moderator was that women appear to elicit more pleasure from cool colors than men. With a medium strength effect size, this finding has strong implications for businesses with a female-skewed clientele.

Analysis of study age showed that there have been changes in color effects on mood since initial color-mood studies began in the 1980s. Once-assumed relationships (that warm colors are arousing and that cool colors are pleasing) have shifted and weakened since this time, perhaps as a result of greater access to color stimuli via the internet and other forms of media. Whether or not this is leading to new color associations, or simply a diminishing of color associations, is yet to be determined.

Examination of the dominance or strength of a color stimulus produced did provided very clear results. Stronger manipulations lead to stronger effects, for both pleasure and arousal, while subtle manipulations were not seen to have any significant effect. It would appear safe to state that colors do not have impact on consumer mood unless they are presented in a dominant and perhaps overwhelming fashion. There are so many color cues surrounding modern consumers that it is unlikely that colors will even be noted unless they are made obvious to the senses.

Overall, only three conditions presented by moderator analysis supported H_2: exclusive blue/red comparison, studies conducted prior to 1995, and subtle manipulations (and only one of these conditions had significance). It appears safe to say there is not a strong enough relationship between color and arousal to be overly useful in an exchange context. When examining color's effects on pleasure, however, H_1 is seen to be robust across all but two scenarios: when examining cultures outside of North America and when exclusively comparing blue to red. This would seem to indicate that planning for environments to have cool color schemes comes at little risk.

Strengths and Weaknesses

This study employed statistical analysis to evaluate the effect of color on mood on a larger scale than has been done before. In combining the results of past studies, I was able to work with a much larger sample size, which was much more representative of the consumer spectrum than any single previous study was able to do.

This study contributes to the marketing literature by evaluating previously unexplored moderators of the color-mood relationship of gender, study age, and manipulation strength. Furthermore, it provides actionable recommendations for marketing managers regarding atmosphere design and reactions to expect from specific customer groups that are exposed to significant degrees of warm or cool colors.

Despite these contributions, this study has some notable weaknesses. Firstly, with only seven studies comprising the meta-analysis, it was not possible to examine potential interaction effects of moderators to isolate more exact boundary conditions. Also, and potentially more significantly, one of the studies is currently included in the meta-analysis on the assumption that its 2-way ANOVA F-values are equivalent to what a one-way ANOVA would result in. This study, while providing results in-line with many other studies, may be skewing results.

Directions for Future Research

Future color-mood research is needed to further explore the culture moderator – thus study showed that North Americans differ in their reactions to environmental color from non-North Americans, but this finding could be expanded by research that investigates different cultures within North America as well as more specific non-North American cultures.

The longitudinal change in color effects is one that is of great interest. Further development of the theory behind this change and monitoring of the color-pleasure/arousal relationship correlations is necessary to determine whether or not this effect is still shifting or if more recent studies have identified a 'stabilized' effect. Finally, further experiments are needed to determine the true extent of cool versus warm effects, especially regarding whether they hold across warm colors other than red. Further notable holes encountered during the process of creating this meta-analysis include examination of color hues, blended colors, and text color effects.

CONCLUSION

This meta-analysis has reaffirmed the belief that cool environmental colors can increase consumer pleasure, while rejecting the hypothesis that warm colors lead to greater excitement/arousal. The beliefs that cool colors increase pleasure and warm colors increase arousal were firmly entrenched in the color literature prior to this meta-analysis, with authors of studies which produced findings counter to these discount-

ing their findings or indicating that their findings were outside of the true relationship boundary conditions. This meta-analysis showed that the color-arousal link is questionable, at least when considering warm versus cool colors, while also showing that the color-pleasure link, while different across conditions, is one which is robust and significant. This study also revealed a trend of shifting color effects over time. This finding bears potential significance and requires further investigation. Overall, while it is seen that colors do have an effect on mood, this effect varies by context and subject. Further, the extent and direction of these effects may also vary. Strong understanding of the extent of color effects in specific contexts, however, will undeniably be of aid to marketers operating in exchange environments.

Appendix A – Meta-Analysis Study Inclusion Criteria

Studies included in this meta-analysis were limited to those that:
- employed an experimental or quasi-experimental design
- examined different color treatment conditions (warm versus cool colors)
- measured effect of treatment conditions on mood in some manner which included measures or factors representing arousal or pleasure constructs, or constructs which could act as proxies for pleasure or arousal
- provided statistical findings
- were available via either database searches or requests from researchers
- were written or translated to English for publication

Variety Leads to Satiety: Varied Meal Composition Leads to Greater Satiety

Aner Tal, Cornell University, USA
Brian Wansink, Cornell University, USA
Michael Giblin, State University of New York at Buffalo

Variety-seeking has been extensively studied in consumer research. Many studies have documented consumers showing a preference for variety for its own sake, leading researchers to treat variety as a drive (Faison 1977, Goukens et al. 2007, McAlister 1982, Menon and Kahn 1995). The drive towards variety might stem from seeking optimum stimulation-level (Menon & Kahn 1995, Raju 1980) or from attempts to fulfill self-presentation or identity needs, making the consumer appear more interesting to her fellows (Ariely & Levav 2000, Ariely & Norton 2009).

Variety-seeking tends to guide consumer choice to such extent that at times, consumers select less-preferred products that they may in fact enjoy less for the sake of variety (Ariely & Levav 2000, Ratner et al. 1999). This may potentially lead to suboptimal choices, particularly when selecting products for future consumption (Simonson 2000, 2002).

Though less attention has been given to the effects of variety once already present within purchases, the presence of variety within meals has been shown to have specifically detrimental effects on quantity people eat, leading people to eat more when offered variety than they would without variety (Raynor and Wing 2006, Wansink 2004).

Tough it may indeed lead people to eat more, due to reduced habituation and a satisfaction of the variety-seeking urge in more varied meals, it may also potentially increase satiety regardless of the amount eaten. Below, we explain the reasoning for this hypothesis.

HABITUATION, ATTENTION AND ENCODING

A considerable portion of day-to-day eating behavior tends to be mindless (Wansink 2004). Consumers can drift through a meal without registering how much they ate, relying on cues to retrospectively infer how much they've eaten (Wansink 2006).

Variety within a meal might call more attention to the meal, leading consumers to register the quantity eaten to greater extent. Generally, consumers tend to remember particular moments within experience, with "segment" endings being recorded to greater extent than other parts (Ariely and Carmon 2000, Baumgartner et al. 1997, Kahenman 2000, Schrieber and Kahneman 2000). Accordingly, when experiences are "broken" into segments, consumers process events differently, with different segments that would normally be neglected influencing evaluation. This leads segmented experiences to be evaluated differently than non-segmented experiences. (Ariely and Zauberman 2003, Nelson et al. 2009).

Relevant to our case, segmenting snacking into particular portions can alter the manner people register their meal and consequently affect when consumers think they're full (Geier, Wansink and Rozin 2011). The more segmented an experience is, the more consumers can register its discrete parts, leading them to remember eating more than they would given unsegmented experience.

Satiety is determined by a combination of physical and psychological cues (Wansink 2006). In determining how full they are, consumers rely not only on internal cues, but also on their judgment of how much they've eaten, often driven by external cues (Wansink et al. 2005, Wansink and Payne 2007). If ttention is aroused at "segmentation points" during consumption, when consumers shift from one type of food to another, consumers may be more sensitive to their physiological level of satiey. No less importantly, they may register what they eat to greater extent, leading to a memory-induced inference of quantity eaten, which would in turn result in a greater *psychologically-driven* sense of satiety.

STUDY

The study aimed to examine whether variety in a meal led to greater satiety in a naturalistic snacking situation. To this end, participants (*N*=106) were given snacks while completing unrelated questionnaires and allowed to snack as much as they wanted. Participants were ran-

domly assigned to one of five conditions, with three conditions offering a single snack: cheese, chocolate kisses, or crackers, and two conditions offering snack combinations: cheese+chocolate or cheese+crackers.

Participants reported their satiety on a 3-item scale, the items of which were averaged to create each person's fullness score. Each person answered the 3-item scale before and after snacking. A person's level of satiety was her fullness score after snacking, and her fullness score after snacking.

Results. Participants in combo conditions reported being more full (1.63 increase in fullness from time 0) than did participants in the non-combo condition (.83). However, combo participants also ate more, in accordance with prior findings (Wansink 2004). To test whether variety led to increased satiety even controlling for quantity eaten, we ran a model of satiety as a function of being in a combo condition, with the amounts eaten of each snack as covariates. Adjusted means were virtually identical as non-adjusted means, with higher lsmeans for combo participants (1.66) than for non-combo participants (.79). Being in a combo condition had a significant effect on satiety controlling for quantity of food eaten: $F(1,60)=6.62$, $p=.01$.

Discussion. The current study provides an initial demonstration that eating a combination of foods, rather than one type of food, leads to greater satiety, controlling for quantity eaten. However, in the current study quantity eaten was controlled statistically, rather than experimentally. A planned follow-up study will control for quantity of food, providing participants with similar size/weight snacks of two types, either on their own (non-combo) or in combination (combo). We predict a similar finding to that in the current study, with higher satiety for people who received a combo snack.

Further followup studies will aim to get a better idea regarding the causes of enhanced satiety given variety. Specifically, we believe increased attention and encoding during the meal may underlie the effects of variety on satiation. Passage from one food item to the next may supply an attentional cue that leads to increased encoding of foods eaten during the meal. This may later serve to psychologically cue consumers that they've eaten more, leading to greater reported satiety.

Regulatory Fit, Attitudes, and Loyalty: The Interactive Effect of Chronic and Situational Regulatory Focus

Meltem Tugut, Saint Louis University, USA
Mark J. Arnold, Saint Louis University, USA
Rajani Ganesh-Pillai, North Dakota State University, USA

This research proposes that fit between consumers' chronic and situational regulatory focus enhances their evaluations of and loyalty intentions toward the promoted product. Two experiments were conducted to test the proposed regulatory fit effects in the context of a loyalty program and a favorable restaurant dining experience. Findings from both studies confirm the interactive effect of chronic and situational regulatory focus on attitudes and loyalty intentions of prevention-focused consumers.

Regulatory focus theory (Higgins 1997) posits that individuals differ in how they approach pleasure and avoid pain. These differences are manifested in two distinct regulatory orientations which govern how people pursue goals: promotion focus and prevention focus (Higgins 1997). Both self-regulation systems can be a chronic predisposition of individuals or can be situationally induced (Aaker and Lee 2001; Higgins et al. 2001; Semin et al. 2005). Promotion-focused individuals are sensitive to the presence and absence of positive outcomes (gains and non-gains), are approach motivated, and are oriented to the pursuit of accomplishment, advancement, and growth (Camacho, Higgins, and Lugar 2003; Higgins et al. 1994). On the other hand, prevention-focused people are concerned with the presence and absence of negative outcomes (losses and non-losses), are avoidance motivated, and emphasize protection, safety, and responsibility (Higgins, Shah, and Friedman 1997; Shah, Higgins, and Friedman 1998).

Central to the current research is the notion of regulatory fit. People experience regulatory fit when their strategies for goal pursuit match their regulatory orientation (Higgins 2006; Lee and Higgins 2009). Accordingly, regulatory fit has been shown to make individuals "feel right" about their actions and intensify their motivational strength during goal pursuit (Higgins 2000). In contrast, when people adopt strategies that conflict with their regulatory focus, they exhibit reduced motivation due to the resulting regulatory nonfit state (Hong and Lee 2008). These subjective experiences then transfer to individuals' subsequent evaluations of attitude objects.

Consistent with Higgins (2000) claim that regulatory fit can be applied to a broad range of orientations and goal pursuit means, extant research offers different conceptualizations and operationalizations of the phenomenon. For instance, promotion-focused consumers are more persuaded when they encounter messages emphasizing eagerness (vs. vigilance) appeals, whereas the reverse occurs for prevention-focused consumers (Keller 2006). Lee and Aaker (2004) found that individuals evaluate promotion-focused information presented in a gain frame and prevention-focused information presented in a loss frame more favorably. Similarly, promotion-focused consumers are willing to pay more for a product when they base their evaluations on feelings (vs. reasons), whereas the reverse is observed for prevention-focused consumers (Avnet and Higgins 2003). Other regulatory fit studies have reported that promotion vs. prevention focus is associated with distant vs. proximal temporal perspective (Mogilner, Aaker, and Pennington 2008), abstract vs. concrete mental representations (Lee, Keller, and Sternthal 2010) and search strategies (Pham and Chang 2010), and dejection vs. agitation emotions (Lee, Aaker, and Gardner 2000).

Above all, Haws, Dholakia, and Bearden (2010) recently called for further research examining the potential interaction between individuals' chronic and situational regulatory focus. The present research highlights this relatively less explored perspective of regulatory fit (see Zhao and Pechmann 2007 for an exception). Specifically, we test the hypothesis that fit between consumers' chronic and situational regulatory focus enhances their evaluations of and loyalty intentions toward the promoted brand. This proposition builds on past literature which indicates that the experience of regulatory fit enhances the perceived value of an object (Higgins et al. 2003) and attitudes toward a brand (Wan, Hong, and Sternthal 2009).

In particular, we posit that chronically promotion-focused consumers who are exposed to promotion-framed (vs. prevention-framed) consumption messages and experiences will express more favorable attitudes and loyalty intentions toward the focal product. Conversely, chronically prevention-focused consumers are expected to sense regulatory fit, and hence develop more favorable attitudes and intentions, when exposed to prevention-framed (vs. promotion-framed) consumption messages. We believe that chronic regulatory focus prompts individuals to selectively pay attention to messages that help them sustain their orientation. Therefore, messages that fit one's chronic regulatory focus will be perceived as more diagnostic and persuasive, leading to a state of increased satisfaction. This increased satisfaction may be one mechanism underlying the proposed regulatory fit effects.

We tested the present predictions in two studies. Study 1 examined the hypothesized fit effects in the context of a loyalty program. We used a chronic regulatory focus (promotion vs. prevention) x situational regulatory focus (promotion-framing vs. prevention-framing) between-subjects design (N = 103). While chronic regulatory focus was measured as an individual difference factor, situational regulatory focus was induced by framing the description of a loyalty program in terms of presence of positive outcomes (promotion-framing) or absence of negative outcomes (prevention-framing). The dependent variables were preference toward the loyalty program and willingness to join the program. Separate ANOVAs revealed a significant chronic regulatory focus x situational regulatory focus interaction [$F(1,92) = 4.62$, $p<0.03$]; $F(1,92) = 4.64$, $p<0.03$]. As predicted, chronically prevention-focused consumers indicated a higher preference toward and an increased willingness to participate in the loyalty program advertised in prevention (vs. promotion) terms.

The purpose of Study 2 was to extend our earlier findings to a different consumption context, while assessing consumers' loyalty intentions. In this study (N = 247), we induced situational regulatory focus by framing the description of a favorable restaurant dining experience in either promotion or prevention terms. The dependent variables were positive word of mouth and repatronage intentions. Separate ANOVAs confirmed a significant chronic regulatory focus – situational regulatory focus fit effect and provided further support for Study 1 results [$F(1,215) = 5.48$, $p<0.03$; $F(1,215) = 8.00$, $p<0.01$]. Chronically prevention-focused consumers expressed higher levels of positive word of mouth and repatronage intentions toward the restaurant when their consumption experience emphasized attaining prevention (vs. promotion) goals. An additional ANOVA uncovered that the observed fit effects were accompanied by increased levels of satisfaction with the consumption experience [$F(1,215) = 4.23$, $p<0.05$]. Our current efforts are concentrated around studying this potential underlying mechanism in more detail.

Across two experiments, we demonstrated that when consumers detect a fit between their chronic and situational regulatory orientations, they express more favorable attitudes and loyalty intentions toward the advertised product. From a theoretical perspective, the present research offers an additional conceptualization and operationalization of the regulatory fit construct in response to Haws, Dholakia, and Bearden (2010). Consequently, the robustness of the results across two different consumption situations illustrates that the wording of promotional messages constitutes a critical factor for marketers in fostering loyalty among consumers, especially those who are chronically prevention-focused.

When Brand Symbolism Matters: A Social Identity Perspective

Hua Chang, Drexel University, USA
Daniel Korschun, Drexel University, USA

Previous research has examined the effect of brand symbolism on consumers' self concept (Grubb and Grathwohl 1967) and consumer identity (Elliott 1998). However, no research has been done on the role of brand cultural symbolism in the cross-border brand acquisition context. Based on recent studies on brand symbolism (e.g. Escalas and Bettman 2003; White and Dahl 2007) and drawing on social identity theory, we propose that consumers experience a sense of loss when a culturally symbolic brand is acquired by a foreign country, which in turn affects their brand evaluation. Further, consumers' social identity strengthens this relationship.

Brand symbolism refers to the image that a specific brand evokes in the minds of consumers (O'Cass and Frost 2002). Consumers may see a brand as a symbol, with connected meanings which define what consumers value most. Essentially, brand symbolism represents what a brand means to consumers and the emotions or feelings they attach to when purchasing and using it. Consumers may link the symbolic meanings of a brand with their personal identity and social identity, as suggested by social identity theory (Tajfel and Turner 1979). This is

corroborated by the evidence found in previous research that consumers tend to use brand symbolic connections to convey meanings in three different levels: cultural level, shared social group level, and the individual level (Eastman et al. 1999).

Iconic brands are most frequently, if not always, perceived to have rich symbolic images attached to them. According to Holt (2003), iconic brands are successful because "they forged a deep connection with the culture" (p. 43). Iconic brands possess a set of symbolic properties which are unique to American culture and ideology. However, when such an iconic brand is acquired by a foreign country, its unique symbolic connections with American ideology or culture may be replaced by new associations with different culture and ideology. Onkvisit and Shaw (1987) found that consumers tend to evaluate a brand in terms of its symbolic meaning. A recent study also reveals the moderating effect of brand symbolism on consumers' evaluation of in-group and out-group brands (Escalas and Bettman 2005). Since the acquired brand will not possess its original unique symbolic meanings, consumers who were attached to the brand due to its cultural symbolism may suffer a psychological loss and will not perceive the brand as positive as before. Thus we speculate that iconic brand's cultural symbolism will affect how consumers evaluate the brand when the brand is acquired by a foreign country.

One hundred and twenty seven undergraduates were randomly assigned to 2 (priming: identity prime vs. no identity prime) X 2 (brand symbolism: iconic vs. non-iconic) between subjects experimental conditions. Participants were told that they would be completing two separate studies. The social identity priming procedure was adopted from White and Dahl (2007). Participants began to read a short scenario about a foreign company acquiring the focal brands (either iconic or non-iconic). Participants then completed a questionnaire that includes the instruments measuring brand evaluation and purchase intent, sense of loss, and their self-brand connection. Manipulation checks were done to ensure that the focal brands were perceived differently in terms of their cultural symbolic meaning.

ANOVA analysis results indicated that there was significant main effect of brand symbolism on brand evaluation and purchase intent. The interaction effects between brand symbolism and social identity on brand evaluation ($F(1,123) = 5.49$, $p < 0.05$) and purchase intent ($F(1,123) = 8.16$, $p < 0.05$) were significant. A further mediation analysis was also conducted to examine the mediating role of sense of loss in the relationship between brand symbolism and brand evaluation and purchase intent (Baron and Kenny 1986). We assessed whether the β and t values associated with the independent variables were reduced when we controlled for the effects of the mediator. The results showed that controlling the mediator noticeably attenuated the strength of the interaction of brand symbolism and social identity on brand evaluation (from $β$ =.71, t=2.44 to $β$ =.43, t=1.58).

The results in the study supported our prediction that when a culturally symbolic brand was acquired by a foreign country, consumers would experience a sense of loss as their attachment to the brand was replaced by a dissociative group. This relationship is stronger when consumers' social identity is primed. This study contributes to the literature by offering one of the first empirical evidence about the effect of brand cultural symbolism on brand evaluation in a cross-border brand acquisition context. Future research can examine the role of self-brand connection in the relationship between brand symbolism and brand evaluation or the three-way interaction effects between brand symbolism, social identity and self-brand connection. As companies are increasingly using brand acquisition as a strategy to enter a foreign market and create value, they have to understand how consumers view the cross-border mergers and acquisitions and react to brand acquisition.

Influence of Facial Affective Display on Social Judgments

Ze Wang, University of Central Florida, USA
Fan Liu, University of Central Florida, USA

While there is an increasing body of research on the impact of employees' affective displays on consumers' perceptions in dynamic interpersonal interactions (e.g., Lee and Lim 2010; Hennig-Thurau et al. 2006), the role of facial affective displays in static images attracted scattered attention in consumer research. This gap is surprising because the abundance of facial images in promotional materials, advertisements, and billboards suggests that marketers rely heavily on this tactic to elicit intended outcomes. For instance, a dentist may advertise with a positive affective display to highlight his/her friendliness and warmth, whereas a lawyer may use a neutral display to emphasize his/her competence and professionalism. Will a brief exposure to these facial expressions in a single still image be sufficient to form a preliminary impression of the service provider? If so, do neutral and positive affective displays differentially impact two fundamental dimensions of social judgment (i.e., warm and competence)? By addressing these questions, the current research makes an initial attempt to investigate how individuals' facial affectively display embedded in static images impact observers' evaluative judgments.

Drawing on research from social cognition and neuroscience, we posit that even a brief inspection of a facial affective display would be sufficient for observers to extract person knowledge. Face processing is automatic and spontaneous in nature, and inferences can be formed after as little as 40 ms exposure to faces (Todorov, Said, and Verosky in press). Naylor (2007) found that individuals respond to static images of unfamiliar service providers quickly and spontaneously until they form strong and reliable impressions. Interestingly, these judgments at unfamiliarity or zero-acquaintance are consensual and accurate. Adding to this line of research, the current research further examines the consequences of the automatic face processing by focusing on the influence of facial emotional expressions on warmth and competence.

We propose that neutral and positive affective displays differentially influence observers' trait inferences. Competence and warmth are two universal and fundamental dimensions of social cognition. The former refers to agency, dominance, and individualism, whereas the latter contains communality, interdependent, and collectivism (Judd et al. 2005). Research on neutral emotional expression has found evidence that restrained emotion displays reflect mastery of one's life and competence in general (Warner and Shields 2007). For instance, female managers' reacting nonemotionally to a given situation is suggestive of their ability to handle the situation, which is often associated with social power and dominance (Lewis 2000). On the other hand, research on positive affective display suggests that smiling is perceived as an indicator of affiliation or willingness to continue a current social interaction. People who express positive emotions are perceived friendlier and warmer (Barger and Grandey 2006; Hennig-Thurau et al. 2006). Therefore, we argue whereas a neutral facial display engenders perceptions of competence, a positive affective display leads to higher evaluations on warmth.

To test the aforementioned hypothesis, in Study 1, we randomly assigned participants to six conditions with increasing intensity of positive affective displays (neutral, 20 percent smile, 40 percent smile, 60 percent smile, 80 percent smile, and 100 percent smile). These experimental stimuli were facial portraits from MSFDE and NimStim databases. The results of study 1 seemed to suggest that positive affective display enhances judgments of both warmth and competence. The more intense the positive emotional display, the higher ratings on both warmth and competence dimensions. Although unexpected, this result was consistent with the extant research finding in stereotyping literature. When people judge individuals, the warmth and competence perceptions often correlate positively (halo effect), either high in both or low in both (Judd et al. 2005). Another noteworthy finding was the ceiling effect of smiling strength beyond 60 percent smile. The portrait with 60, 80, and 100 percent smiles received similar ratings on both warmth and competence.

Our first objective of Study 2 was to examine whether the facial portrait of a service provider embedded in a print ad can impact customers' judgments of his warmth and competence even before the service is actually rendered. Another objective was to test whether these evaluative judgments can further impact their downstream behavioral outcomes. In the experiment, we included three levels of affective displays (neutral, low-intensity positive affective display/60 percent smiling, and high-intensity positive affective display 100 percent smiling). Participants read a print ad of a real estate agent and subsequently indicate on 7-point scales (not at all/very much) their perceptions of the employee's warmth and competence, attitude toward the service provider, and behavioral intentions. Results of Study 2 were consistent with findings in Study 1. We found that compared to neutral emotional display, positive affective expressions enhanced both warmth and competence perceptions, which further impacted consumers' attitude toward the service provider and their intentions to use the service. Interestingly, as we moved from low-intensity to high-intensity positive affective display, consumers' ratings on service provider's competence decreased. A third study is currently in progress to better elucidate this boomerang effect.

Taken together, our findings suggest that even a brief exposure to facial affective displays embedded in static images can influence observers' social judgments about the displayer's warmth and competence. These impacts may be more complex than previously presumed or common sense predicted.

Buying Violence: Understanding the Appeal of Violence in Popular Media

Laurence Ashworth, Queens University, Canada
Ethan Pancer, Queens University, Canada
Martin Pyle, Queens University, Canada

Violent media is extremely popular. Nearly 70% of prime-time television contains violence (National Television Violence Study, 1998), and approximately 40% of all video games are rated for violent content (Entertainment Software Association, 2009). In 2008, six of the top ten grossing movies featured substantial violence (IMDb, 2010). Although less well documented, violence is a major theme in many popular books and music. In short, violence in media is endemic. Consequently, much of the work on this topic has focused on the effects of exposure. A great deal of research purports to demonstrate a variety of negative effects of exposure to violence, although there are good reasons to question the causal link (Freedman, 2002).

One feature of violent media has remained almost completely unexplored though – the reasons for its appeal. Patterns of spending suggest that consumers enjoy violent media, but research on the topic is scant. What research has manipulated violent content and measured viewer enjoyment has shown either negative or no effects of violence (e.g. Hansen and Hansen, 1990; Sparks, Sherry, and Lubsen, 2005), consistent with Zillmann's (1998) proposition that viewing violence is actually distressing. The purpose of the current work is to examine whether violent content is attractive to consumers and why.

We suggest that violence may be appealing –not due to pleasurable reactions to the depiction of harm by one person on another – but due to the role that violence plays in satisfying other consumer goals – in particular, dominance and justice. Research in evolutionary psychology (Cummins, 1996) and fundamental human motivations (McClelland, 1985) supports the notion that dominance, especially physical dominance, is likely to be intrinsically rewarding. The ability to physically dominate others, in men in particular, is likely to confer reproductive and survival advantages that favor the selection of corresponding physical and psychological characteristics. Although not often referenced in definitions of violent content (e.g. Anderson and Bushman, 2001), domination is often central to violent encounters – the encounter typically concludes with the domination of one party by another. We argue that vicarious reactions to the domination inherent in many violent depictions are one reason for its enjoyment.

Violence can serve other functions too. One notable function, especially in media depictions, is justice. Justice is an important motive in human interactions, the achievement of which should be inherently satisfying. As such, justice may be one of the reasons for the appeal of violence. Violence that allows the satisfaction of justice should be preferred to violence enacted for other reasons. We test both of these ideas, as well as the question of whether consumers approach violence in media across three experiments.

EXPERIMENT 1

Experiment 1 was a 2 (Violence Level: High vs. Low) x 2 (Gender) between-subjects experiment designed to address the question of whether consumers preferentially approach media with violent content. We tested this by creating a synopsis of a wartime movie, loosely based on the film, "Bridge on the River Kwai", and renamed "Complicity" to disguise the origin of the movie. All participants saw the same description, which focused on the plot and meaning of the movie, but included no reference to the violent content. We also included a short review of the movie, which we varied to manipulate perceptions of the extent of violent content. The reviews were identical except for the modification of two sentences to indicate the movie included scenes of realistic violence. The primary dependent variable was the extent to which participants thought they would enjoy the movie (four items, α = .93). An ANOVA revealed a Violence x Gender interaction ($F(1, 91) = 8.92$, $p < .01$) that indicated men thought they would enjoy the movie more when it appeared to be more violent (Ms = 5.66 vs. 4.67), whereas women thought they would enjoy it less (Ms = 3.58 vs. 4.39).

EXPERIMENT 2

Experiment 2 was designed to investigate the role of vicarious reactions to domination in the actual enjoyment of violent depictions. We included three experimental conditions: no violence, violence in which the protagonist dominated, and violence in which the protagonist was dominated. This resulted in a 3 (Violence) x 2 (Gender) between-subjects factorial design. Participants viewed one of three video clips of a recently released video game, "Resident Evil 5". Clips were constructed using footage from teaser-trailers, in-game cut scenes, and actual

gameplay. We created a common two and half minute non-violent segment to which we interspersed one minute of additional footage corresponding to the condition. All clips were designed to be equally exciting and the latter two clips were designed to be equally violent. The final clips used the same 30 second introduction, had a common (arousing) soundtrack, and were three and a half minutes long. The primary dependent variable was attitude towards the videogame (measured by five items, α = .93).

ANOVA revealed a Gender by Violence interaction ($F(2, 154) = 3.36$, $p < .05$). Follow-up analyses within gender revealed that women liked the game less when it contained *any* violence ($M_{\text{No Violence}} = 3.19$ vs. $M_{\text{High Dominance}} = 2.36$ vs. $M_{\text{Low Dominance}} = 2.60$; only the first mean differed from the others), whereas men liked the game less *only* when the protagonist was dominated (Ms = 4.16 vs. 4.34 vs. 3.56; only the latter mean differed from the former). Violent content did appear to lower attitudes, except in men when the violence portrayed high levels of protagonist domination.

EXPERIMENT 3

Experiment 3 was designed to investigate the role of justice in the enjoyment of violence. Participants read a (made-up) passage from a book that described a scene of intense violence enacted by one man on another. Violence was manipulated by providing physical details of the violent acts versus simply naming the acts (e.g. "castration" versus a description of it). We manipulated the justice motive by including a very brief reference that suggested the "victim" was responsible for the death of the enactor's wife, leading to a 2 (Violence) x 2 (Justified) x 2 (Gender) between-subjects design. The primary dependent variable was attitude towards the book (three items, α = .93). An ANOVA revealed a marginally significant three-way interaction ($F(1, 95) = 2.81$, $p < .10$). Follow-up analyses indicated that within men, higher levels of violence led to more positive attitudes only when the violence was justified (Ms = 3.60 vs. 2.52; $F(1, 95) = 3.45$, $p < .07$). Within women, attitudes towards the book were uniformly low, but increased with low levels of justified violence (Ms = 1.50 vs. 2.59; $F(1, 95) = 6.27$, $p < .05$).

Overall, our results suggest that men, but not women, approach violent content in media. The violence itself, however, appears to reduce enjoyment in both men and women unless it satisfies some other motive. Both men and women enjoyed violence that satisfied the justice motive, although they responded to quite different forms of violence. Men enjoyed extreme justified violence; women only enjoyed reduced forms of justified violence. Only men enjoyed vicarious domination, although it was, at least in our experiment, equally offset by negative reactions to the violence itself.

I Love Your Gucci Glasses, You Have Taste vs. I Love Your Joe Glasses, You are Smart
The Role of Self Construal and Brand Status in Compliment Appreciation

Fang Wan, University of Manitoba, Canada
Hesham Fazel, University of Manitoba, Canada
Pingping Qiu, Monash University, Australia

Compliments are conducive to social interactions and communications. Little research has been done to examine the psychological underpinnings of the observed cultural differences in compliment giving and acceptance. Even more scarce attention has been given to extend research on compliments to consumer contexts and study the impact of compliments related to brand usage on consumers' evaluations and preferences of the focal brand. Our work set out to study cultural difference in compliment appreciation (Study 1) and further investigate its implications in brand usage contexts (Study 2 and 3).

CULTURAL DIFFERENCE AND COMPLIMENT APPRECIATION

Self construals are often used as a proxy to uncover cultural differences: how individuals classify or perceive themselves according to the constituted cultural values they follow (Singles & Brown, 2001). In North American culture, there is a reliance on the natural separateness of distinct persons. The normative imperative of this culture is to become independent from others and to determine and convey one's unique attributes (Markus & Kitayama, 1991, see also Triandis, 1995). However, Asians cultures have interdependent self-concepts that emphasize the connectedness between themselves and others (Morris & Peng, 1994; Hong et al., 2000). North Americans, who typically have independent self-construals, are likely to view social compliments as a matter of personal choice, indicative of compliment givers' genuine liking of self,

therefore, are more likely to appreciate social compliments. Individuals with interdependent self construals view compliment givers as more likely to have ulterior motives (Park, 1998).

Therefore we propose that individuals with independent self construals are more likely to appreciate social compliments than those with interdependent self construals. We further propose that the difference in independent and interdependent individuals' reaction toward social compliments are due to perceived sincerity of the compliment givers. As a result, perceived sincerity of social compliments mediates the relationship between self construals and compliment appreciation. We test these propositions in study 1. We predict that brand status moderates the relationship of self construal and compliment appreciation. Interdependent individuals will feel less appreciative than self interdependent individuals when receiving a compliment about their low brand status (Study 2). We further propose that interdependent individuals may perceive the compliment on brand usage when brand status is low to be less sincere, which mediate the relationship of the interaction of brand status and self construal and compliment appreciation (study 3).

Study1.

Study 1 examined the impact of self construal on social compliment appreciation and the mediating role of perceived sincerity of the compliment giver. 175 undergraduate students in a major Canadian university participated in the study for course credit. They were asked to read a general compliment scenario. Then they filled out a survey measuring their appreciation of the compliment with 2 items (appreciation & grateful $\alpha = .73$), perceived sincerity of the compliment giver with single item and their cultural orientations with 24 items Self-construal scale (Singelis, 1994), self-independent 12 items ($\alpha = .76$) and self-interdependent 12 items ($\alpha = .79$).

Since our goal was to test the differences between independent and interdependent self-construal individuals; we focused on participants who score higher than the average score on either independents or interdependent and a relatively low score on the other. Accordingly, we eliminated participants who score higher (lower) than the average score on both independents and interdependent scale. This procedure enabled us to use data from 79 participants, 41 independent, 38 interdependent.

ANOVA tests on dependent variables confirmed our expectation that high independent individuals were more likely than interdependent individuals to felt more appreciated when receiving a compliment ($F = 2.915$, $p = .09$), and perceived the sincerity of the compliment giver to be higher ($F = 8.292$, $p < .05$) (Table 1a). Simple mediation analyses revealed that perceived sincerity mediated the relationship between self-construal and appreciation of social compliments (Table 1b).

Table 1a. Study 1 ANOVA Results

	Self- Construal		F value	p value
	Independent	Interdependent		
Appreciation	6.065	5.68	2.915	.09 *
Perceived sincerity	5.826	5.062	8.292	.013**

- *** <.09 Marginally Sig.**
- ****< .05**

Table 1b. Study 1 Simple Mediation Analyses

MD	Path	Step	b	SE	t	p
Perceived sincerity	1	c	.378	.221	1.707	.096
	2	a	.764	.294	2.594	.013
	3	b	.316	.106	2.980	.005
	4	c'	.161	.226	.714	.480
Soble Test:			Z	Sig (p-2tailed)		
			1.9588	**0.050**		

Study 2.

We intended to examine the moderator effect of brand high status on feeling of appreciation when receiving social compliment. In study 2 we run 2 (self construal: independent vs. interdependent) x 2 (brand status: high vs. low) experimental design. 80 university students participated in exchange for partial course credits. They were asked to read a scenario where a compliment was made about Gucci (Joe) sunglasses. The dependent variables and self construal scales were identical as in Study 1. For manipulation check, ANOVA tests on brand status variables were significant. Compared to Joe brand, Gucci is perceived to be more prestigious ($F = 23.123$, $p = .000$) and to have higher status ($F = 34.351$, $p = .000$) (Table 2a). ANOVA tests on dependent variables (appreciation) showed significant interaction effect of brand status and self construal, suggesting that independent self construal (vs. self interdependent construal) are more appreciative to compliment when they receive it on low brand status and less appreciative when they receive it on high brand status (Table 2b).

Table 2a. Study 2 Manipulation Check

	Brand status		F value	p value
	Low (Joe)	High (Gucci)		
Brand perceived to be prestigious	3.258	5.031	23.123	.000***
Brand perceived to have high status	2.849	5.250	34.351	.000***

- **<.05
- ***<.001

Table 2b. Study 2 (Self-Construal * Brand Status)

Dependent variable	Brand Status* Self-Construal		F value	F value	p value
Appreciative	High	Independent	4.36	3. 107	.09*
		Interdependent	5.43		
	Low	Independent	5.9	3.50	.07*
		Interdependent	5.00		

- **<.05
- ***<.001

Study 3.

We intended to examine the effect of self construal and brand status interaction on compliment appreciation and also test the mediation role of perceived sincerity. 64 undergraduate students in a major Canadian university participated in the study. We used the binary regression tool to categorize the indicators of self construal and brand status. The following is a description of the binary variables:

ANOVA test resulted in a significant interaction of brand status and self construal as in Study 2, suggesting that independent individuals are more appreciative of brand compliment than interdependent when focal brand has low status (M =5.92 vs. M =5.00). Also, our findings indicate that perceived sincerity partially mediate the relationship of self construal and brand status interaction on compliment appreciation (Table 3).

Table 3. Study 3 ANOVA Results
Mean effect

DV: Appreciation	F value	p value
Self-Construal	.037	.848
Brand Status	2.057	.158
Self-Construal * Brand Status	6.516	.014**

Simple Mediation

DV: Appreciation	F value	p value
Self-Construal	.804	.374
Brand Status	.831	.366
Self-Construal * Brand Status	5.890	.019**
Perceived sincerity	11.549	.001***

- **<.05
- ***<.001

DISCUSSION

Our next step is to replicate our research with participants from different cultures. In addition, we plan to employ interpersonal en-counters to add external validity to our scenario studies. Further, we will explore self construal effects on brand related variables (e.g. brand attachment, loyalty and discover if appreciation compliment effects brand relationship.

Unveiling the Underlying Mechanism for the Matching Effect between Construal Levels and Message Frames: How and Why Do Matches between Gain versus Loss Frames and Construal Levels Enhance Persuasion?

Yun Lee, University of Iowa, USA
Jing (Alice) Wang, University of Iowa, USA
Catherine A. Cole, University of Iowa, USA

This research investigates *how* and *why* different construal levels and different appeal frames jointly influence persuasion. We contend that individuals using high-level consturals preferentially pay attention to appeals framed by gains, whereas those using low-level construals selectively focus on appeals framed by losses, and thus this matching should impact persuasion. This perspective has yet to be investigated directly. Its consequences as well as the specific mechanism underlying these consequences are still to be unveiled. Thus, the current research addresses this gap. In what follows, we briefly review relevant literatures. We then report three sets of experiments and conclude with a brief discussion of contributions of this research.

Construal Level, Message Frames, and Functional Matching Mechanisms

Construal level theory (CLT) posits that when people use different levels of construal, they selectively include and exclude relevant or irrelevant features of an attitude object (Fujita et al. 2006a). Specifically, high-level construals preferentially capture abstract and global features of an attitude object, but low-level consturals, preferentially capture its concrete and local features.(Liberman and Trope 1998).

A closer look at the message framing literature offers some insight into how message frames are linked with different levels of construal. For example, research on message frames has demonstrated that loss frames are more persuasive when individuals process them locally (Förster and Higgins 2005), more in-depth (Block and Keller 1995; Shiv et al. 1997) and in details (Maheswaran and Meyers-Levy 1990), whereas gain frames are more persuasive when people process them globally (Förster and Higgins 2005) in less details (Maheswaran and Meyers-Levy 1990; Shiv et al. 1997).

Given these findings suggesting that gain- versus loss frames are related with the features of high- versus low-level construals, I argue that individuals using high-level construals are more likely to attend to gain-framed appeals, whereas those using low-level construals are

more likely to focus on loss-framed appeals, and it influences persuasion. I refer to these predictions as the enhanced attention mechanism of the matching effect and test it across five experiments.

Experiment 1

Experiment 1 tests the hypothesis that matching high-level construals with gain frames and low-level construals with loss frames will encourage participants to pay more attention to the appeals they evaluate, and thus influence persuasion.

METHOD

I randomly assigned participants to one of the four conditions in a 2(frames: gain vs. loss) × 2 (construal level: high vs. low) between-subjects design. Participants read information about heart disease and appeals advocating a diagnostic blood test. I manipulated construal level by making the appeals either why-laden (e.g., *why* people need to take a diagnostic blood test) or how-laden (e.g., *How* to take a diagnostic blood test). I manipulated message frames by framing the appeals in terms of either gains or losses (e.g., If you (don't) take a diagnostic blood test, you can find (fail to find) out your current cholesterol level). I then asked participants to indicate their intentions to take the blood test (1 = not at all likely ~ 7 = very likely). They also indicated the extent to which they paid attention to the appeals (1=not at all ~7=very much).

RESULTS

Behavioral intentions

A 2 (framing) × 2 (construal level) ANOVA on behavioral intentions yielded a significant interaction effect ($F(1, 109) = 8.37$, $p < .01$). When the appeals were why-laden (high level), presenting these appeals in a gain frame was more persuasive than in a loss frame ($Mgain = 5.30$, $Mloss = 4$; $F(1, 53) = 4.17$, $p < .0565$), whereas when the message was how-laden (low levels), presenting these appeals in a loss frame was more persuasive than in a gain frame ($Mgain = 4.44$, $Mloss = 5.36$; ; $F(1, 56) = 4.34$, $p < .05$).

The mediating role of attention

Conducting a series of regression analyses (Baron and Kenny 1986) confirmed that the matching effect on behavioral intentions was mediated by attention.

The findings from experiment 1 show that attention mediates the matching effect. Experiment 2 adds processing fluency into the picture.

Experiment 2

Two objectives guide the design of experiment 2: 1) to examine the relationship between processing fluency and attention, and 2) to increase the robustness of the found effects.

METHOD

Participants were randomly assigned to one of the conditions of a 2(frames: gain vs. loss) × 2 (construal level: high vs. low) between-subjects design. For the construal level manipulation, participants were asked to write about *why* they need to improve and maintain health (high level) vs. *how* they can improve and maintain health (low level) (Freitas et al. 2004). Then they were presented with an advertisement of a fictitious printer whose ad appeals were gain vs. loss framed (e.g., Don't miss out on (Get) printing-pro for great looking documents and web-page printing!) and asked to evaluate it. They were also asked to indicate the degree to which they paid attention to the ad information and answer processing fluency items (1=hard to process, hard to understand, hard to comprehend ~7=easy to process, easy to understand, easy to comprehend).

RESULTS

Attitudes

A 2 (framing) × 2 (construal level) ANOVA on brand attitudes yielded a significant interaction effect ($F(1, 108) = 13.08$, $p < .001$). When participants viewed the gain-framed message under high-level construals ($Mgain = 5.11$, $Mloss = 4.10$; $F(1, 55) = 9.74$, $p < .005$) and when they viewed the loss-framed message under low-level construals ($Mgain = 4.16$, $Mloss = 5.07$ $F(1, 53) = 4.65$, $p < .05$), their brand attitudes were more favorable than any other conditons.

The relationship between processing fluency and attention

Conducting a series of regression analyses demonstrated that matches enhance attention, which in turn increases processing fluency and favorable brand attitudes.

The results from experiment 2 indicate that attention mediates the matching effect on processing fluency and on brand attitudes. Experiment 3 tests whether attention given to matching information is reflected in greater sensitivity to its argument strength (Fujita et al. 2008; Petty and Wegener 1998).

Experiment 3

The objectives of experiment 3 are: 1) to examine whether consumers under matching conditions devote greater attention to message processing and thus are more sensitive to argument strength than consumers in non-matching conditions, and 2) to increase generalizability and robustness of the found effects.

METHOD

Participants were randomly assigned to one of the conditions of a 2(frames: gain vs. loss) × 2 (construal level: high vs. low) × 2 (argument strength: strong vs. weak) between-subjects design. Participants were presented with the information about a wildlife conservation fundraising campaign. Construal level was manipulated as dedicated to protecting a specific North Atlantic Right whale, named Simmon (low level), or North Atlantic Right whales in general (high level). Argument strength was manipulated by presenting arguments that strongly or weakly endorsed the fund-raiser (e.g., 100% (50%) of your financial donation goes toward helping Simoon (North Atlantic Right whales)!). Message frames were manipulated within the stimuli (e.g., Get (Don't lose) a chance to help and save Simoon (North Atlantic Right whales)!). Then participants were asked to indicate how likely they are willing to donate (1=not at all likely ~ 7=very likely). They were also asked to answer processing fluency and attention items.

RESULTS

Willingness to donate

To test the main hypotheses, I recoded the data to reflect matches (a gain frame and high level, a loss frame and low level) and mismatches (a gain frame and low level, a loss frame and high level) between argument strength. The data were then analyzed with a 2 (match: match vs. mismatch) × 2 (argument strength: strong vs. weak) between-subjects ANOVA on willingness to donate. It yielded significant argument strength and match main effects. These main effects were qualified by a two-way interaction effect ($F(1, 141) = 13.02$, $p < .001$). As predicted, matches supported by weak arguments resulted in less willingness to donate than matches supported by strong arguments ($M_{match,strong} = 4.79$, $M_{match, weak} = 3.46$; $F(1, 72) = 14.64$, $p < .001$).

The relationship between processing fluency and attention

Running a series of regression analyses indicated that matches enhance perceived attention, and thus increases processing fluency and willingness to donate.

DISCUSSION

By demonstrating the enhanced attention mechanism underlying the matching effects between construal levels and gain versus loss frames, the current research contributes to the literatures on functional matching, message framing and construal level. This research also has managerial implications for marketing managers in that it suggests a strategic way to use message frames and construal level to enhance persuasive effectiveness.

Disabilities and the Internet;
Understanding Consumers with Visual Impairments

William Jones, Wayne State University, USA
Terry Childers, Iowa State University, USA
Fred Morgan, Wayne State University, USA

Heralded as a great equalizer, the Internet once promised to eliminate disabling spaces by creating a barrier-free virtual "commons" where consumers of all types could interact in the marketplace. However, studies suggest that persons with disabilities are less likely to own computers, to have Internet access, and to make online purchases than persons without disabilities (Kaye, 2000a, 2000b). Moreover, online use is not automatically assured even if computers and the Internet are available. Both industry and academic web studies have shown that a substantial number of web sites are not useable by persons with disabilities since their content is not transmitted accurately, clearly, or completely (e.g., Schaefer, 2003). In fact, numerous prominent retailers have been challenged in court for web accessibility violations (Kretchmer and Carveth, 2003). These lawsuits are saddening given web-based technology's potential to achieve a sense of normalcy and facilitate shopping independence for consumers with disabilities.

Because of numerous, but addressable limitations, a sizeable market of consumers is likely to have experienced difficulties shopping online. Statistically, persons with disabilities represent 20 percent of the United States' population, collectively larger than the size of major ethnic groups (National Organization on Disability, 2005). Surprisingly, some firms argue that the market is not large enough to warrant special accommodations online (Heim, 2000). In fact, estimates of the disposable income of persons with disabilities vary from more than $176 billion (Johnson, 2000) to approximately 1 trillion (Milliman, 2002). Despite such significant potential, this substantial market has largely been overlooked both online and offline (Baker, Stephens, and Hill, 2002). To increase the welfare of all consumers, research is needed to understand the needs, behaviors, and perceptions of individuals possessing different forms of sensory, motor, and cognitive impairments. Our research was designed to provide insights on how these individuals feel toward online shopping. We first conduct a study that examines the utility and usability of online web sites across individuals possessing a broad range of disabilities. A second study examines whether online shopping can empower consumers with visual and hearing impairments to better achieve their retail shopping goals.

STUDY 1

To investigate whether online shopping experiences of consumers with disabilities differed from that of consumers without disabilities, we conducted a multi-group structural equations analysis of the Childers et al. (2001) adaption of the technology acceptance model (TAM) to groups of participants with or without disabilities. Participants were 383 participants without disabilities and 75 participants with disabilities that responded as Internet shoppers in an annual e-commerce telephone survey.

After establishing adequate reliability as well as convergent and discriminant validity of the model, we estimated the model via maximum likelihood estimation. Tests of measurement equality indicated that the measurement portion of the model was comparable across the two groups. Model fit indices meet moderate to excellent norms (Byrne 1998).

Overall, we found strong support for ease of use and usefulness as antecedents of attitudes toward online shopping irrespective of disability. Attitudes are also predictive of purchase behavior, the first study to our knowledge that has moved beyond behavioral intention to predict actual online purchase behavior. Comparing the relative effects of usefulness, we find consistent with our predictions that it is equally predictive of attitudes for consumers with and without disabilities. However, inconsistent with our predictions was that ease of use was not attenuated by mobility status. The many obstacles confronting individuals with impairments when shopping online led us to predict a weaker relationship between attitudes and ease of use among the disabled. One possibility may be that not all disabilities may face the same obstacles to online purchasing.

STUDY 2

In Study 2, we re-assess the model used in Study 1 by making model comparisons between groups of consumers with visual impairments, with hearing impairments, and without disabilities. Kaufman-Scarborough and Childers (2009) have shown previously that empowerment may be related to perceived usefulness and ease of use in online shopping environments. We therefore extend the original model by incorporating a measure psychological empowerment (Zimmerman, Israel, Schulz, and Checkoway 1992) as an antecedent of consumers' perceived usefulness and ease of use decision variables.

Overall, we find strong support for the role of empowerment in better understanding the use of online shopping by individuals with visual impairments. These results are consistent with the underlying theme of empowerment, which seemed to motivate many of the legal challenges (Study 2). Feelings of empowerment provide insight as to the importance of this personal characteristic of the disabled that leads them to possess stronger perceptions of the utility of meeting their shopping needs by engaging in online purchasing. We also find that ease of using the Internet for online shopping is related to empowerment for both groups of disabled consumers as well. However, we do not find that disability status is differentially related to ease of use as we had predicted. Different from the overall disability results of Study 1, attitudes were a stronger predictor of purchases in the non-impaired sample relative to the visually and hearing impaired with the latter two not significantly different. The direction of our empowerment findings was consistent with the premise that for those visually impaired, empowerment did not predict ease of use as strongly as found in a comparison disability group with a hearing impairment as well as for individuals without impairments.

Unfair or Unfavorable? Social Comparisons, Attributions of Responsibility and the Spontaneous Activation of (Un)Fairness Concerns

Laurence Ashworth, Queens University, Canada
Lindsay McShane, Queens University, Canada
Svetlana Davis, Queens University, Canada

Fairness judgments are an important determinant of satisfaction and other behaviors directed towards the firm (e.g. Gregoire and Fisher, 2008). Fairness and unfairness judgments are also assumed to arise across a wide variety of different circumstances, including, for example, as a consequence of firms' service failures (e.g. rude or slow service; Tax, Brown and Chandrashekaran 1998). We question whether fairness is psychologically meaningful in these situations or if it simply reflects general dissatisfaction with the circumstances.

We argue that if explicitly asked, consumers can always form fairness judgments by assessing whether they are deserving of a given outcome or treatment. Generally speaking, they are likely to see themselves as deserving of favorable outcomes/treatments and undeserving of unfavorable ones. Thus, when consumers are asked to rate service failures, when they are unfavorable, they are likely to report them as unfair. We argue, however, that service failures do not necessarily naturally elicit fairness concerns. For instance, imagine a situation where you go to a restaurant and your server is rude. If you were explicitly asked about fairness, the extant literature suggests that you would likely indicate that the situation was relatively unfair in that you do not believe that you deserved to be treated in that way (Smith, Bolton and Wagner 1999; Tax, Brown and Chandrashekaran 1998). However, without being asked about fairness, how likely are consumers to frame the situation in terms of fairness? It seems unlikely. Taking steps to address this apparent conflict, the current research investigates a) when consumers are more or less likely to spontaneously frame a situation in terms of unfairness and b) how these spontaneous fairness judgments relate to solicited fairness judgments.

We argue that fairness violations are more likely to be spontaneously activated when deservingness concerns are salient. Deservingness assessments have been shown to be important in shaping fairness judgments (Feather 1999). Many theories of distributive justice suggest that fairness occurs when people receive in proportion to what they deserve (Adams 1965; Feather 1999). Unfairness results when that person's deservingness is violated. Although typically discussed in terms of distributive injustice, deservingness seems important in assessing service failures. We argue that being explicitly asked about fairness demands that the consumer consider whether they deserve the service failure. The result is that consumers are likely to deem service failures as unfair irrespective of whether they actually framed the situation in terms of fairness. In contrast, we argue that the spontaneous activation of fairness concerns requires that some aspect of the situation makes deservingness salient. Of interest then is what makes deservingness salient?

We predict, initially, that social comparisons make deservingness salient, thus making consumers more likely to spontaneously consider the fairness of their outcome. The logic here is that, when some other consumer receives more favorable treatment (e.g., a better price or quicker service), deservingness is activated by the presence of a clear standard for what they should have received (i.e., the same as the other consumer). We suggest that the relative concreteness of this standard increases the likelihood that the consumer will expressly consider whether they received what they deserved. We test these ideas in Study 1.

STUDY 1

In Study 1 we manipulated the presence or absence of a service failure (by varying the speed of service at a restaurant), as well as the presence or absence of social comparison information, leading to a 2 (Social Comparison Information: Yes, No) x 2 (Service Speed: Normal, Slow) between-subjects experiment. Before responding to any measures, we asked participants to list all relevant thoughts, which we coded for fairness concerns. Participants were also directly asked whether they naturally thought about fairness when reading the scenario. Finally, we asked participants to rate the extent to which the situation was unfair using standard measures.

An ANOVA showed that, when explicitly asked about fairness, participants' fairness judgments reflected both service failure and social comparison information. Specifically, social comparisons and service failures independently exacerbated perceived unfairness (Ms=3.76 vs. 5.59 and Ms=3.98 vs. 5.37, Fs(1,153)= 77.66 and 45.05, ps <.001). However, the thought listings indicated that participants were likely to spontaneously think about unfairness *only* when social comparison information was present ($\chi^2(1)=13.30 p <.001$). While the presence or absence of service failure had no effect ($\chi^2(1)=2.17 p > .1$). Measures of whether fairness was a spontaneous reaction to the scenario supported these results. Consumers reported being more likely to think about unfairness when social comparison information was provided (Ms=5.12 vs. 4.04, F (1,153)=23.0, p <.001). There was no significant difference across presence or absence of service failure ($F < 1$).

This study identifies a situation where reported fairness measures diverge from when consumers are likely to naturally think about unfairness. Specifically, consumers deemed service failures unfair when explicitly asked but did not naturally frame these situations in terms of fairness unless social comparison information was present. There are, however, situations where we would expect alignment between reported fairness and spontaneous thoughts. Specifically, when upward social comparison information is available, we expect elements of the exchange that exacerbate perceived unfairness to make consumers both more likely to spontaneously think about unfairness and to report the situation as more unfair when asked. We argue that attributions of seller responsibility for the service failure is one such element. We predict that the more consumers hold the seller responsible for the service failure, the more likely they are to naturally frame the situation as unfair and, when asked, to report the situation as more unfair. We explore these ideas in Study 2.

STUDY 2

In Study 2 we manipulated whether the seller was responsible for the service failure Information about another consumers' superior outcome (faster service) was always present. We measured fairness in same ways as in Study 1. An ANOVA indicated that, when explicitly asked about fairness, participants reported that they perceived the situation as more unfair when they attributed responsibility to the seller (Ms=3.44 vs. 4.64, F(1,54)= 7.64 p <.01). As expected, our analysis of the thought listings revealed that participants were also more likely to naturally think about unfairness in this situation ($\chi^2(1)=5.35 p <.05$). Finally, when directly asked, participants reported being more likely to frame this situation in terms of fairness (Ms=3.60 vs. 4.55, F (1,53)=5.05 and p <.05).

DISCUSSION

This research takes initial steps to identify certain conditions under which consumers are likely to naturally think about fairness violations (e.g., presence of social comparison information) and how these relate to reported fairness perceptions. This research suggests that while fair can be applied to a wide range of situations, doing so may entail thinking about the situation differently than how consumers naturally do. Finally, although previous research suggests that service failures such as inattentive service are by definition unfair, our research shows that, depending on the situation, consumers may not consider fairness a relevant construct.

The Dissociative Nature of Product Enthusiasts

Jeffrey Lee, Harvard Business School, USA

Decades of consumer research have led to the conclusion that fans are an integral part of a product's success. Fans can make up a substantial proportion of a product customer base, and serve as a reliable source of revenue in both good times and bad. Acknowledging the importance of strong consumer supporters, a significant body of literature in branding research has focused on brand loyalty and how to increase it (Jacoby and Chestnut, 1978; Dick and Basu, 1994). Aside from providing a steady stream of consumers, efforts to promote consumer loyalists can also lead to the development of "brand ambassadors" and increased positive word-of-mouth (Godes, 2004) for the given product or brand (Godes, 2004). Furthermore, the development of brand communities (Muniz and O'Guinn, 2001) can result in a network of supporters who reinforce each others' positive opinions of the brand, which can further strengthen brand loyalty among these consumers.

Given that extant literature on the many positive effects of consumer loyalists, it seems that marketing practitioners should always generate as much enthusiasm for their products and brands as possible. Yet some recent research suggests that fans of a product can ironically have a negative impact on other consumers in terms of their likelihood of purchase (Naylor et al., 2011). Specifically, this research suggests

that when non-fans are perceived to be dissimilar, consumers are less likely to purchase items from a brand relative to when fans are similar, heterogeneous or ambiguous. In a similar vein, my project also explores how fans can affect non-fans. I focus on heterogeneity among fans, in terms of their interest level towards a given product. As opposed to a "fan" of a product, I define consumers as "product enthusiasts" when they exhibit a relatively high level of interest in a product.

Intuitively, one might expect the high-levels of interest from product enthusiasts to positively influence other consumers' adoption of a product. Yet if the enthusiasm of product enthusiasts is perceived to be extreme, it is possible that their highly-positive opinions could be discounted, or even worse, result in reactance such that the product's diffusion is negatively impacted. Some behavioral decision research suggests that the extreme opinions of others are merely ignored in final decision-making (Harries et al., 2004). However, because products can be signals of identity tied to associative and dissociative groups (Dahl and White, 2007), strong opinions by product enthusiasts can result in dissociative inferences about the fans of the product. In this case, these extremely positive opinions would not be ignored; rather, product enthusiasts could ironically cause reactance against the product from non-fans.

I conducted four studies to test the effects of product enthusiasts on other consumers' purchase considerations. In Study 1, I recruited 90 subjects to complete a survey on a hypothetical new cell-phone. I provided subjects with a distribution of the interest levels of ten of their friends and acquaintances towards this new cell-phone. In one of the three conditions, subjects were told that all ten network ties were "slightly interested" in the cell-phone, whereas in the other two conditions, subjects were told that one of the ties was either "moderately interested" (the fan condition) or "extremely interested" (the product-enthusiast condition). Participant ratings of their own interest in the new cell-phone varied marginally across conditions, $F(2, 86) = 2.810$, $p < .066$. However, subsequent planned comparisons indicated that participants' interest-level ratings in the product-enthusiast condition ($M = 2.00$, $SD = 0.617$) were significantly lower than the other two conditions, $t(86) = 2.356$, p < 0.021.

Study 2 extends the results of Study 1 by providing subjects with real-world information about a television show. In one condition, subjects are merely provided with a description of the show (control condition), whereas in the second condition, subjects are presented with information about product enthusiasts of the show. Subjects were significantly less likely to watch the television show ($t(45) = 3.448$, p < 0.00), the pilot episode, ($t(45) = 3.220$, p < 0.00), and the first season ($t(45) = 3.156$, p < 0.00) in the product-enthusiast condition relative to the control condition.

Study 3 replicates Study 2, except that subjects are provided with information about a hypothetical television show, and a comparison is made between fans and product enthusiasts to test for potential mediators of the latter group's negative influence. Subjects were significantly less likely to become eventual fans of the television show ($t(84) = 2.782$, p < 0.007) in the product enthusiast condition relative to the fan condition. A mediation analysis indicated that the negative impact of the product-enthusiast is mediated by the dissociative nature of the product enthusiast (Sobel z = -2.5117, p < .012). This supports the account that product-enthusiasts are dissociative, and that their positive opinions of the product are not merely ignored, but factored *negatively* into other consumers' judgments of the focal product.

In Study 4, I tested the possibility that the dissociative perception of product-enthusiasts is moderated by the life-cycle of the producing brand. Specifically, brands that are more established may be more successful in accommodating product-enthusiasts, because they provide legitimacy for the product in ways that new brands cannot. Study 4 replicates the design of Study 2 in new water bottles, and varies whether the brand is positioned under an established brand or not. A 2 (control versus product-enthusiast) X 2 (established versus un-established brand) between-subjects ANOVA revealed that product-enthusiasts lowered subjects' likelihood of purchasing the water bottle in the un-established brand condition, but not the established brand condition. The predicted interaction between product enthusiasm and established branding was marginally significant, $F(1, 114) = 3.244$, p < 0.07.

Collectively, these findings suggest that product-enthusiasts can negatively impact a product's adoption (Studies 1 and 2), that this effect is explained by the dissociative element of these enthusiasts (Study 3). Furthermore, this effect is most pronounced when the producing brand is less established (Study 4). This implication of these results is that practitioners need to be careful in managing product enthusiasts to maintain their ability to attract potential new consumers.

Physical States Effects on Judgment

Consumers are often affected by a variety of physical states (Mobini et al. 1997, Loewenstein 1996). Being hungry or tired may affect the way consumers judge and choose among products (Read and Leuuwen 1998). The way a product would be experienced varies according to consumers' physical states. For instance, if you're hungry, food may appear tastier. In other words, the experience of consuming a product is imagined as it would be given the consumer's current state (Gilbert et al. 2002).

These judgmental biases are typically regarded as being errors. However, they may in fact be adaptive by helping immediate action calibration. By considering how current physical states would affect consumption experiences, consumers can make choices that are appropriate to their current state. It is when stretching current experiences inappropriately to future states, and planning in a way that neglects temporal differences between the current time and the future time, that consumers may commit errors, and potentially make suboptimal choices (Gilbert et al. 2000, 2002).

Functional Judgment: Needing More Means Seeing Less

The reasons and mechanisms leading consumers to make biased judgments and choices of products when in particular physical states are not fully understood at this time. One potential hypothesis concerns the functional view of perception and judgment, whereby judgments are not meant to be objective, but rather to direct people towards action. Objects are not seen as they are, but in terms of the actions they afford and the goals and functions they might fulfill (Gibson 1979).

One domain in which the functional view has become increasingly accepted in the past two decades concerns pleasure and pain. Pleasure and pain are assumed to be targeted towards guiding people's actions (e.g., Carver 2001, Morris 1999). Pain alerts the person that something is wrong, and motivates avoidance or actions meant to eliminate the source of pain, whereas pleasure signifies beneficial stimuli, and is supposed to motivate approach behavior.

Pleasure and pain are at root subjective experiences. However, functional experiences may generalize to supposedly objective domains, potentially biasing judgment of such dimensions as product size or the energy provided by food. If you are tired, inclines may seem steeper and distances longer (Proffitt 2006). Similarly, other dimensions of the environment or particular stimuli in it may be distorted to reflect the manner in which they would be experienced by the consumer in their current state.

In the case of hunger, the energy food provides may be judged not objectively but rather in terms of the person's subjective energy needs. Hungry people require more energy, such that in relative terms any particular food provides less energy. Note that such a prediction would not be derived without the functional view of the biasing effects of physical state on perception and judgment. This may be reflected in consumers' evaluations of the energy provided by foods, and potentially alter consumer choices accordingly (e.g., eat more, buy more food). The studies shown here are meant to provide an initial demonstration of such biasing effects of hunger on energy estimation.

Study 1: If you haven't had breakfast, it's all diet food

Methods. Participants in this study (N=70) were students who reported normally having breakfast and lunch. They were instructed to fast for 18 hours. For analyses, we split participants to two groups according to compliance – whether or not they skipped breakfast.

Each participant rated seven different food items (which served as repeated measures). Participants rated how caloric they thought items were on a 9-point scale (from not at all caloric to very caloric).

Results. Participants who skipped breakfast (47.15) evaluated foods as more caloric (lsmean=5.66) than did participants who had eaten breakfast (lsmeans=6.01), $F(1,64)=3.89$, $p=.05$. The result supports the notion that hungry people evaluate food as being less caloric.

Study 2: Being hungry means never having to say it's fattening

The next study aimed to replicate the first study's results using a different dependent measure and measured hunger. Obtaining an effect of hunger on calorie estimation would be a stronger demonstration of the effect given the noisiness of calorie estimates. Further, hunger measures are in a way cleaner measures of people's needs or motivations than not eating, since people may be differentially hungry following a period of "fasting".

Methods. Participants in this study (N=52) were asked to estimate the number of calories in eight grocery food items. Hunger levels were measured on a 9-point scale (from not at all hungry to very hungry). Participants were split to a low and high hunger group via median split.

Results. High-hunger participants evaluated food items as containing, on average, fewer calories (596.54) than did low-hunger participants (988.62): $F(1, 50)=4.21$, $p<.05$.

GENERAL DISCUSSION

The current studies demonstrated that calorie estimates are systematically altered by people's hunger state. This prediction derived from a functional view of judgment, which maintains that people see products subjectively, in terms of the manner in which they serve current needs.

Notably, the findings contrast what would be predicted from views of motivated reasoning, according to which people see what they want to see (e.g, Balcetis and Dunning 2006). In a classic though much-disputed study in social psychology, for example, poorer kids saw coins as being larger (Bruner and Goodman 1947).

In our current view, though, people see what they *need* to see, that is, how objects supply their current needs, in subjective terms. Needing more means an object is *less*, not more, in subjective terms. Indeed, initial findings from research-in-progress by the authors shows that enhanced needs make needed objects appear *smaller*, not bigger.

Further studies will attempt to explain the mechanism behind such incorporation of subjective experiences into the manner in which participants see products. Specifically, the studies would test the role of simulations of upcoming experiences as the means by which a person's subjective experience of a product given current physical state is incorporated in judgment (Tal and Wansink 2011).

Single-Brand Experience vs. Multiple-Brand Experience:
Another perspective on consumer preference formation

Mitchell Hamilton, Syracuse University, USA
Omar Woodham, North Carolina State A&T, USA

For decades, the consumer preference formation process has fascinated marketing researchers. Though versatile in nature, consumer preference literature typically encompasses the following buyer learning constructs: prior knowledge and order-of-entry (Robinson & Fornell 1985; Carpenter & Nakamoto 1989; Kardes & Kalyanaram 1992; Kerin et al. 1992). While the marketing and psychology fields have merged together to offer a wealth of knowledge dedicated to the consumer preference formation process (Carpenter & Nakamoto 1989; Arnould 1989; Mantel & Kardes 1999), a majority of these studies assume that a consumer forms her/his preferences in the following sequence: (1st) Prior to experiencing a product, a consumer's preferences are weakly formed due to the lack of product category knowledge and the ambiguity of the ideal attribute combination; (2nd) the consumer's initial experience with the new product category typically involves the pioneering brand; and (3rd) after the initial product trial, the consumer experiences some of the competing brands while constantly updating her/his preferences.

Absent from the consumer preference formation literature is the consideration of a consumer that has only experienced a single brand, even though other competing brands exist. Occasionally, consumption habits are passed down through familial generations, whether intentionally or unintentionally. For example, a young college student that is away from home may be undeterred from her/his rigid routine of using Tide when doing laundry because "that's the brand my mother always used". Also, consider a consumer that is completely satisfied after her/his initial product trial experience and has always been a firm believer in the "if it's not broke, then don't fix it" school of thought. These types of consumers may not feel the urge to try any of the competing brands (Fournier 1998).

Would these "single-brand" consumers affect the dynamics of the traditional consumer preference formation model offered by Carpenter & Nakamoto (1989)? After all, the Merriam-Webster dictionary does define preference as, "the act, fact, or principle of giving advantages to some over others." A single-brand consumer lacks the trial experience with regards to the competing brands; therefore, a single-brand consumer could not possibly develop preferences that are as strong as or stronger than a consumer with "multiple-brand" experiences. Or could they? The current paper addresses these questions and also offers an alternative perspective on the notion of first-mover's advantage. This perspective emphasizes the combined importance of a consumer's first encounter with a particular product category and the brand encountered during this initial experience (which may or may not involve the first-mover brand). The current authors refer to this as "experienced-first advantage".

THE STUDY

The purpose of this study is to distinguish the impact of single-brand user experience on the preference formation process, from the impact of multiple-brand user experience. The authors seek to answer the following question: Who develops stronger brand preferences, consumers that have only used a single brand within a product category or consumers that have used multiple brands?

Methodology

Brand user experience is operationalized into one single-brand group (experienced-first customers) and two multiple-brand groups (win-back customers; variety-seeking customers). Subjects are naturally selected based upon the following criteria:

- Experienced-First Customer

    o   Has at least five years of product usage experience within the product category

    o   Has not used more than one brand within the product category

    o   Currently considers himself/herself to be brand loyal

- Win-Back Customer

    o   Has at least five years of product usage experience within the product category

    o   Has used more than one brand within the product category

    o   Currently considers himself/herself to be brand loyal

- Variety-Seeking Customer

    o   Has at least five years of product usage experience within the product category

o   Has used more than one brand within the product category

        o   Does not currently consider himself/herself to be brand loyal

The data is collected using an online survey. For each of the groups, brand preference strength is measured using two types of conjoint analyses, choice-based (a decompositional, top-down approach) and self-explicated (a compositional, bottom-up approach). Each groups' level of brand preference strength is indicated by the intra-correlation and intra-variance between the two conjoint analyses. Brand preference strength will have a positive relationship with the correlation and a negative relationship with the variance.

Findings

The preliminary results suggest that experienced-first and variety-seeking customers both form preferences that are stronger than the preferences formed by win-back customers. Furthermore, the brand preference strength of experienced-first and variety-seeking customers appear to be equally strong.

The authors posit that: (1) win-back customers are not fully satisfied with their current brand but have decided to settle upon the best option; and (2) experienced-first and variety-seeking customers are both sufficiently satisfied with their brand selections. However, further data is needed to support these claims.

Until Death Do Us Part: Consumer Response to Brand Elimination

Kendra Hart, Ivey Business School, University of Western Ontario, Canada

Intuition tells us that there must be some degree of disappointment for consumers when their favourite brands are gone. Researchers have demonstrated consumer relationships with brands (Fournier 1998), consumer attachment to brands (Park, Macinnis, and Priester 2006), and self-brand connections (Escalas and Bettman 2003, 2005). Clearly, brands play an important part in consumers' lives.

Although anecdotal reports of consumer response to high profile brand discontinuation exist in the popular media, there is a paucity of scholarly research in this area. There is little empirical evidence of the dimensions and breadth of consumer felt response to a brand's elimination from the marketplace. Ignorance of consumer response leads to an underdeveloped sense of the consumer mindset when looking to fill the brand void with a competitive offering. It also demonstrates a weaker understanding of the dimensions of consumer-brand relationships. This study seeks to begin to drill down on the dimensions of consumer emotional response in an effort to envisage potential consumer behavioural response.

Understanding the various dimensions, strength and causes of emotions in a consumption context can help marketers to better understand and predict resulting consumer behaviour (Watson and Spence 2007). Appraisal theories have outlined how emotions stem from cognitive appraisals individuals make about situations or events relevant to their well-being (Bagozzi, Gopinath, and Nyer 1999). Arguably, the loss of a favoured brand can be seen as affecting well-being for those who have strong ties to the brand.

METHOD

This exploratory study was conducted via an online survey with 125 respondents. Participants were asked to think about a favourite brand that they like to buy, followed by instructions to write about their history with the brand and what it means to them. Subsequently, they read a fictitious newspaper article that mentioned that the brand was going to be pulled from the marketplace shortly. Participants were then asked to write about their thoughts and feelings about this news, as well as a few open-ended questions about their relationship with the brand.

FINDINGS

Analyzing participant response to open-ended questions, informants demonstrated a wide variety of emotional response. Expectedly, a large number of consumers expressed a degree of resignation and sad acceptance. Although many respondents expressed their sorrow at losing a favored brand, and their concern about finding an adequate replacement, many displayed a sense of fatalism about the event. This response is not unexpected, given the inconvenience, but not impossibility, of replacing a dead brand.

However, a deeper analysis of the comments led to an emergent pattern of consumer response that showed three interesting dominant themes. These three themes are interralted, and consistent with important dimensions of relationships previously unexamined in the consumer-brand relationship domain.

Theme #1: Risk and Regret

"I would be really bummed because I took a risk on this brand and then I got bit in the rear because it flopped and I actually enjoyed using it"

Relationships with any partner involve a degree of vulnerability. Consumers not only run the risk of relationship dissatisfaction, but also the risk of rejection and relationship discontinuance. Analysis of consumer responses revealed themes of risk awareness and relationship regret that is consistent with research in the interpersonal domain (Bartholomew 1990).

Theme #2: Abandonment and Betrayal

"Betrayed. After all these years of devotion, they had to get rid of something that I had known and trusted and enjoyed for many years"

Trust in a relationship partner's commitment to the relationship is another element of relationship vulnerability. Research on interpersonal rejection has highlighted the impact of perceptions of abandonment and betrayal across several interpersonal domains (Shackelford and Buss 1996).

"I think they just give up and abandon their own brand"

It is interesting to note that the themes of abandonment and betrayal did not end with the consumer. Rather, respondents expressed concerns over the firm's duty to the brand itself, as well as to the customer.

Theme #3: Embarrassment and Shame

"I would be embarrassed that the thing I used for years isn't there anymore"

One last theme regards the role of shame after the end of a relationship. As in interpersonal relationships, the unwanted end of a relationship can often lead to feelings of embarrassment for the partner that is left behind, and impact the individual's willingness to pursue a new relationship (Claesson and Sohlberg 2002).

DISCUSSION

This study is a first attempt to dimensionalize and delineate consumer response to brand elimination. The results of initial data collection show that consumers have deeper reactions than mere annoyance or displeasure. Themes of relationship risk and betrayal have implications not only for firms looking to reduce their brand offerings, but for competitors seeking to build new relationships with consumers who have lost a brand. Additional, more extensive data is currently being collected in an attempt to further this research to address not only the question of consumer response but also the following: How do consumers continue on in the face of this loss and negotiate replacing the brand with a competitor? Do different types of loss lead to differences in subsequent consumer search? How do consumers continue on with other brand offered by the firm in the face of a singular elimination? This knowledge would have value for surviving brands that want to capture these consumers, as well as brand competitors.

Rooting Value: Identity Negotiations From Juxtaposing Past and Present

Leah Carter Schneider, York University, Canada
Julia Creet, York University, Canada

The postmodern landscape hinders the formation of deep, long-lasting, and personally significant connections with others and to create a cohesive sense of self (Firat and Venkatesh, 1995; Cova 1997). Consumer research has shown that consumers utilize marketplace products, resources, discourses, and sites to form identities and to create communities and neotribes with one another both in the real world and virtual world (e.g., Thompson and Hirschman 1995; Solomon 1983; Muñiz and O'Guinn 2001; Cova 1997; Cova and Cova 2002; Kozinets 1997). Participating in marketplace communities allows individuals to express one's identity, or to adopt new identities based on desire for acceptance from the focal social group (Schouten and McAlexander 1995). Products and services that facilitate connecting individuals together, such as Facebook, are also increasingly valued in the marketplace for their linking capabilities (Cova 1997). Relationships and identity work therefore seem to be interwoven in the modern market arena, and facilitated by the adoption and use of specific market products. However, consumers may also use marketplace offerings to form alternative relationships with others beyond traditional social interactions that create opportunities for more intense identity work.

The mobility of individuals to move from place to place, as well as the myriad of identity positions offered through the marketplace, most likely contribute to some consumers experiencing continued and heightened senses of dislocation, disconnection, and identity confusion (e.g., Peñaloza 1994; Askegaard, Arnould, and Kjeldgaard 2005; Ustuner and Holt 2007). In this paper, we present and explore the rooting value, or the identity value of marketplace activities that ground a person's sense of self as individuals confront their identities. Specifically, we focus on the genealogical market, a site in which consumers learn about and form relationships with their ancestors as they build their family trees. We propose that consumer identity work is not only influenced by personal actions, choices, or preferences, but also by the process of encountering and negotiating personally relevant information and relationships discovered through market activities.

Drawing on consumer identity and consumer sociality (e.g., tribes, communities, and family) research, we aim to explore consumer identity questions that arise when consumers work to learn about their ancestors. We address questions of the motivations for individuals to undertake genealogical work, and the identity value and challenges to an individual's self-concept that genealogical findings create. In order to address the research questions, we utilize data from: (1) in-depth interviews with individual and professional genealogists, (2) netnographic data of online forums of genealogical enthusiasts and amateurs, and (3) active participant notes, as the secondary author engaged in her own genealogical quest. Using an iterative data analysis process between the two authors, common themes were generated and compared in order to identify the identity work that emerged as consumers search for their ancestors.

Preliminary findings from the data suggest that the genealogical market represents a site of intense, personal identity negotiations. Individual consumers experienced a spectrum of motivations that lead them to conduct their own genealogical work, including coping with separation and loss, such as moving away from "home" or the death of a loved one, and a desire to understand family quirks, traits, and qualities that are passed through generations. However, we found that a significant motivation for undertaking genealogical work aligned with questions about one's identity and roots. By building their family history tree, informants cultivated feelings of connection to and belonging with others whose lives directly led to and influenced their traits, quirks, physical location, and values. Stories, such as great-great grandfather's who crossed the plains in dire conditions, greatly enhanced the connection with and identity value of ancestors to the present day descendant. The sense of belonging that genealogical work generated provided informants with a redefined concept of who they are, as they then incorporated the histories, stories, and characteristics of their forefathers into their own identities. Informants' self-concepts were therefore not restricted to their own life choices, consumption decisions, occupations, and so on; rather, their self-identity was deconstructed and reorganized according to their family history.

Although the identity work that occurred at the nexus of integrating one's life to one's ancestors generally led to positive outcomes for individuals and satisfied their desire for connection with their ancestors, some consumers experienced discord and tension as a result of their genealogical findings. By perceiving family history as the roots through which personal identity is grounded, information discovered that contradicted current understanding of one's identity led to crises of identity. New information brought to light through genealogy regarding family ethnicity, living relations previously unknown to them due to infidelities, secrets, and so on, provided a catalyst for confronting one's sense of self. Having to "come to terms with" such information led to identity work that involved the rejection of family history information as a way to maintain and protect the identity or a significant redefining of self. Others engaged in critical evaluation of the self, as they renegotiated their personal identities in connection to the new information.

Thus, the rooting value of connecting past with present in the genealogical market is generated as individuals learn of, analyze, and either accept/reject family history findings. By engaging in genealogical work, consumers are able to use the past in order to root themselves in the present, either by linking themselves to their family history or by disengaging with the family history and reinforcing their personal identity as it stood prior to genealogical work. The marketplace, by engaging and enticing consumers to "find themselves" through family history, acts as an arena for centering and rooting identity to anchor points either in the past or present as consumers integrate, restructure, or attempt to maintain their personal sense of self.

A Poison by Any Other Name: Aversion to Functional Food Chemicals

Aner Tal, Cornell University, USA
Brian Wansink, Cornell University, USA

In recent years a growing number of consumers has drifted away from additive-laden food and towards organic foods (Greene and Dimitri 2003). In the process, some consumers have developed an aversion to "artificial" foods (Rozin 2005). The passion for organic, additive-free foods, is a complex and understudied phenomena. One factor potentially driving the movement towards organic food is a growing belief that additives are unhealthy. This may indeed be true for some additives, but untrue for others. Consumers, however, may overgeneralize and suppose that all additives are "bad for you".

In judging a food to be less appealing due to additives contained, consumers may rely on cues leading to intuitive judgment rather than on detailed information processing, in accordance with an overall tendency for heuristic processing in the marketplace (Olshavsky and Granobis 1979, Hoyer 1984). Particular cues may associationally trigger aversive reactions to products that are perceived to be harmful due to additives contained.

One cue that may be dominant in leading consumers to perceive a product as harmful is the presence of an ingredient that sounds "chemical". Consumers may know that some chemicals are harmful, and generalize that "all chemicals are bad", similar to other learned associations such as "healthy=not tasty" (Ragunathan et al. 2006). Thus, the mere presence of a chemical-sounding ingredient may suffice to trigger reduced evaluation of a product.

Chemical-sounding names may harm product evaluation not just on relevant dimensions (e.g., health). Rather, their effects may generalize to other product dimensions. For instance, consumers may anticipate worse taste for products that contain "suspicious" additives. This may emanate from contagion from one product dimension to another, or from a generalized negative halo that imbues "chemicalized" products. Such effects might operate in similar manner to how consumers reduce evaluations of products that are touched by disgusting elements (Morales and Fitzsimons 2007).

Study 1: Chemical vs. descriptive name reduces taste evaluation

The first study aimed to test whether consumers would predict lower tastiness for snacks that were reported to have "sodium benzoate" (a food preservative) rather than "food preservative".

Method. Participants (*N*=52) were shown a picture of a cookie and told that the cookie contained either "food preservative" or "sodium benzoate". They were then asked to rate how tasty they think they cookie is on a taste of 1 (=not at all) to 9 (=very much).

Results. Participants rated the cookie as less tasty (*M*=5.3) when reading it contained "sodium benzoate" than they did when reading it contained "food preservative" (*M*=7), *p*=.001. This despite the relatively innocuous name of the preservative (reminiscent of salt, or, sound-wise, soda).

Study 2: Knowledge of chemical function doesn't undo chemical halo

The second study wanted to examine whether learning of a chemical's function would undo the negative effects of knowing a product contained it. The study also aimed to increase the generality of the previous study's findings by adding a control condition where participants were told the cookies contained "milk chocolate" rather than "food preservative". In addition, the study contained a different preservative name: "potassium sorbate". This would allow testing whether there was something special that made "sodium benzoate" abnormally lower ratings. Finally, the study contained one additional condition (for a total of 4 conditions) where the words "food preservative" were written in parentheses by the chemical additive name. This was meant to examine whether knowing the chemicals' function would undo their detrimental effects on product evaluation.

Results. There was a significant effect of condition on rated tastiness: $F(5, 100)=3.86$, $p=.003$. Ratings were lower for the chemical-name conditions (*M*=5.89) than for the non-preservative condition (*M*=7) and the food preservative condition (*M*=6.94). Note that having a food preservative *did not lower evaluations*, only having a chemical-sounding additive reduced evaluations. Further, evaluations were reduced by the chemical presence even when participants knew the function of the additives (*M*=5.56), $p>.5$.

Proposed Study: Confirmatory Processing

A followup study will aim to show that containing chemical ingredients harms not only judgment, but actual product experience and choice. Through confirmatory, top-down processing, consumers may come to experience a product as less tasty, congruent with their "chemical-induced" expectations (Ha and Hoch 1989, Shiv et al. 2005).

Further studies may demonstrate the dependence of the aversive reaction to chemical-sounding additives on heuristic processing, showing increased adverse effects of chemical sounding names under cognitive load.

In addition, studies will aim to get a better hold of the mechanisms driving the phenomena. Study 2 ruled argues against harmful effects of chemical names on product evaluations being due to unfamiliarity (not knowing what the ingredient is). Additional studies will explore whether the effects of chemical-names on evaluations are due to negative associations that are activated by chemical names.

Mishap or Justification? Whether Segregating Losses Is Bad or Good Depends on Responsibility for the Outcome

Dilney Goncalves, IE Business School, Spain

Gains and losses can often be presented in a piecemeal format or integrated. For example, the cost of repairing a car can be broken down in each individual part and labor. Gain and loss integration versus segregation has been extensively studied under the framework of Mental Accounting theory. Mental Accounting predicts that people are happier when their gains are segregated and their losses are integrated (Thaler, 1985). Whereas the basic assumption has been well documented, especially in the gains domain, less is known about how people process integrated versus segregated outcomes, especially losses.

If negative events can be painful, they can also help people minimize the pain of a loss if they provide reasons that help justify the loss. In this research we examine a loss rationalization hypothesis whereby segregating losses yields more positive evaluations if it helps rationalize the loss but yields more negative evaluations otherwise. When people feel responsible for a loss, they may automatically and unconsciously engage in rationalization processes that make the hedonic impact of the event less severe (Gilbert et al. 1998). If people are accountable for a loss they are motivated to rationalize the loss. When losses are segregated, each component of the overall loss could potentially be a justification. Thus, a segregated loss would present more opportunities for justification than an integrated one where each individual component is a (potential) reason to justify the loss. We predict that the effect of reasons on the evaluation of losses is moderated by the motivation one has to justify the loss such that (1) for people who feel responsible for the loss, reasons help justify the loss, making it less painful and (2) for people who do not feel responsible for the loss, reasons for the loss are evaluated as mishaps, making the loss more painful.

The first study tested whether segregating the cause for a loss has an impact independent of segregating the monetary value. This study used a 2 (monetary outcome: integrated vs. segregated) X 2 (cause vs. cause) between-subjects design. Participants were recruited online and were randomly assigned to one of the four experimental conditions. They read a scenario describing a situation where they had to pay for an unexpected expense (car taxes in the first replicate and house repair in the second). In the integrated monetary frame, participants saw only the total amount (e.g., $450). In the segregated monetary frame, they saw a list of items followed by the total ($260, $90, $80, $20). Participants in the cause condition were told that they had to pay for "registration and inspection fees" and "state and CO_2 taxes." Participants in the integrated, no-cause condition were not told anything about the source of the taxes. Those in the segregated, no-cause condition were shown a list of non-descriptive items (i.e., A, B, C, D). After imagining that they were in the situation described, participants stated how unhappy they would feel with the expense on a 7-point scale anchored in "not at all unhappy" and "extremely unhappy." Planned contrasts showed that participants in the integrated, no-cause condition felt significantly less unhappy (M=4.42) than participants in the other three conditions (M=5.03; p<0.05). Furthermore, evaluations in the integrated, reasons condition (M=5.03) and the two segregated conditions ($M_{reasons}$=4.96; $M_{no-reasons}$=5.10) did not differ. This pattern replicates previous research and – in addition – shows that segregating causes has a similar effect to segregating the monetary value of the outcome.

The second study, tests the moderating role of responsibility. This study has a 2 (responsible vs. non-responsible) X 3 (completely-integrated vs. monetary-integrated vs. completely-segregated) between-subjects design. Participants in the responsible condition were told that they knowingly parked the car in a no-parking zone. Those in the non-responsible condition were told that they did so unknowingly. Participants were told that their car got towed. Those in the completely-integrated condition were told that they had to "pay $200 to re-

cover your car." Those in the monetary-integrated condition also read "(for parking ticket and towing service)." Finally, participants in the completely-segregated condition saw "parking ticket: $80; towing service: $120." The dependent variable is unhappiness with the expense (as in study 1). A significant responsibility by reasons interaction ($F_{2,110}$=3.53; p<0.05) supports our prediction: whereas for non-responsible participants, reasons represented unfortunate events and increased unhappiness ($M_{completely-integrated}$=6.14; $M_{monetary-integrated}$=6.45; $M_{completely-segregated}$=6.69) whereas for responsible participants, reasons helped them rationalize and decreased unhappiness ($M_{completely-integrated}$=6.19; $M_{monetary-integrated}$ =5.58; $M_{completely-segregated}$=5.37).

A third vignette study provides preliminary evidence that if individual components cannot be used to justify the loss, segregating a loss does not make it less painful even if people are motivated to rationalize it. These two experiments suggest that reasons play an important role in how people evaluate negative outcomes. The negative impact of losses can be minimized by using appropriate description: losses should be segregated when individual components help (and there is motivation to) justify a bad decision and integrated otherwise.

Losing Sight of the Struggle:
Consumer Activism in the Age of New Media and Hypervisuality

Amanda Earley, York University, Canada

Anti-Consumerist Activism on the Web

Since the beginnings of the Internet, activists have argued that it would be the first form of mass media that would belong to the people, and would consequently have liberatory potential. It has been used for organizing, coordinating events, political education, and grassroots reportage. The study of cyberactivism is an ideal complement to ongoing discussions of consumer resistance (Kozinets and Handelman, 2004; Kozinets, 2002) and liberatory conceptions of consumer behavior (Murray and Ozanne, 1991), and brings much-needed work on new media and the politics of consumer culture into the field of consumer behavior.

There have been numerous scholarly attempts to document cyberactivist practices, including Martha McCaughey and Michael D. Ayers' edited collection which chronicles the use of cyberactivist tactics by groups ranging from first-world "hacktivists" to the Zapatistas (2003). Most of the authors in the collection take on a celebratory tone, practically declaring a new age for political organizing and democracy.

These academic activists are not in bad company, as seen in coverage of the recent Twitter revolutions in Moldova, Iran, and Egypt. Within the media studies camp, Henry Jenkins is perhaps the best known proponent of the democratizing potential of the Internet. Jenkins' analysis centers on the enormous potential in the Internet, for the political process as well as for market activity (2006). He and his colleagues have argued that the internet enables a new participatory culture defined by low barriers to entry, collaboration, social connection, and a sense that the activity is valuable (2006). Here, consumers become producers or at least "prosumers," creating content and shaping market offerings by collaborating with companies.

New Media is not, however, free from detractors, academic and otherwise. Even in the case of the Tehran "Twitter Revolution," journalists passions quickly cooled as many started to question the relationship between the Internet and politics (Moaveni, 2010; Morozov, 2009). The majority of technology scholars tend to be critical, rather than celebratory. Michael Margolis and David Resnick contested the position that the Internet will bring about a long-awaited perfect democractic society, arguing that "...ordinary politics and commercial activity have invaded and captured cyberspace. Virtual reality has grown to resemble the real world," (2000, p. 2).

Legal studies scholar Cass Sunstein took this argument one step further by explicating how, in the age of the internet, democracies are moving farther from the ideal of deliberation and closer to a direct democracy based on immediate desires. This is fueled by processes of specialization and filtering that allow individuals to radically filter what they see, hear, and consider (2000, 2007). Sunstein contends that the new political ideal is that of the consumer democracy, where free choice of goods and free movement of capital is paramount to other social goals. This ideal has infected the web, as commerce dominates in the form of shopping, advertising, and consumers' discussions of products.

Examining Consumer Cyberactivism: The Case of the Toronto G20

The substantive example of the Toronto G20 was used to examine the above debates in a real-world context. Two types of media production were examined: traditional, mainstream media representations of the events, and activist-produced media productions. The coverage was both in print and digital formats. For the digital material posted by activists, attention was paid to the communities and connections underlying the posts. That said, the project is not a full netnography, as the researcher was an observer rather than a participant observer (Kozinets, 2009).

The media representations frequently juxtaposed texts and photographs, so both discursive and visual methods were employed. That said, the vast majority of the media space was in the form of photographs, so primacy is given to the visual in the analysis. Often, the text was as small as a caption or a Facebook comment, and thus served as an aid to the visual analysis moreso than an independent cultural text.

All media were subjected to open and axial coding, as explicated by Strauss and Corbin (1998). Emmison and Smith's *Researching the Visual* (2000) and Sturken and Cartwright's *Practices of Looking* (2001) provided guidance for reading and coding the content of visual images. 87 images were analyzed for the journalistic side, and 3,450 were read for the activists. Narratives of anti-consumerism activist media production and mainstream media production emerged from this analysis.

For the journalists, two main themes emerged. The first, *practiced neutrality*, is defined by presenting a large range of actors (activists, police officers, vandals) without judgment or a political analysis. The second theme is the *creation of iconic content*. The mainstream media were responsible for taking the photographs that were the most widely circulated. Two photographs and video footage of a police car on fire quickly became the dominant representations of the protest, and were circulated widely.

Two powerful narratives emerged from the activists' photographs. The first, *journalism by other means*, refers to grassroots journalist work performed by activists. Here, activists attempt to document the events in much the same way as journalists, but with supposed improved to authenticity, politicization, and choice of events. The second narrative is that of *strategic political communications*, intended to sell audiences on a particular story. In this way, activists created "marketing content" for the movement. Such claims should be read critically in light of the media studies literature, especially Sunstein's (2000, 2007) work on channels on the Internet. Sunstein argues that such self-produced strategic communications rarely reach beyond a narrow audience that already agrees with a cause, and that the acceptance of marginal and alternative channels may further disrepute the cause.

The presentation will feature further categories of activist media production, including *anarcho-porn*, images that valorize property destruction and other anarchist protest tactics; *protest tourism*, images that replicate the tropes of tourist photography, communicating little more than "we were here;" and *documenting documentation*, wherein protestors took photographs of journalists, police, and other protestors documenting the events. This latter category is of particular interest, especially when read in the contexts of activists' distrust of mainstream media, which is argued to serve corporate interests.

Ideal Affect as a Basis of Judgment in Experiential and Material Purchases

Yoon Ji Shim, Seoul National University, South Korea
Incheol Choi, Seoul National University, South Korea

Previous literatures in consumer research suggest that affect plays a crucial role in consumer decision making (Bagozzi, Gopinath, & Nyer, 1999; Cohen & Areni, 1991). Despite the emphasized role of affect in consumer behavior, most of the studies have mainly focused on how consumers' *actual affect* influences on their choices (MacInnis, Patrick, & Park, 2006); moreover, it has also not been investigated in which purchasing types consumers would make decisions primarily based on affective factors. In the present research, we investigated the role of *anticipated affect* as a basis of judgment in two different purchasing types: experiential and material purchases. The anticipated affect in the context of consumption would strongly be related to *ideal affect*, the affective states that people would like to feel (Tsai, Knutson, & Fung, 2006), in that most people might mainly anticipate positive feelings from their purchasing decisions or choices (Mellers & Mcgraw, 2001). According to Tsai (2007), ideal affect consists of two-level of arousal positive affect states: high-arousal positive affect (HAP) states such as excitement, enthusiasm, and elation and low-arousal positive affect (LAP) states such as calmness, peacefulness, and serenity, and individual differences in ideal affect may account for diverse behavioral consequences especially in mood-producing behavior.

In the present research, we hypothesized that people are likely to make different choices depending on their ideal affect that they would like to experience from purchasing behavior. More importantly, we predicted that ideal affect may play a more central role in experiential purchases where the object of which is associated with having a life experience than in material purchases where the object is possession itself (Van Boven & Gilovich, 2003) because affective experiences consumers pursue from purchasing choices would be more closely related to experiential purchases than to material purchases (Kwortnik & Ross, 2007). In order to examine these hypotheses, we conducted two main experiments.

In Study 1, we examined whether people make choices which correspond to their ideal affect more in experiential purchases than in material purchases when asked to make purchase decisions for self. We posited that people would have different ideal affect depending on

their age and gender and would make purchasing choices based on their own ideal affect. In Study 2, we investigated the role of affect in purchasing situations where giving gifts for other people or recommending others to purchase products or services. We predicted that people would make decisions based on ideal affect for others whom one is intending to give a gift or suggest buying (hereafter referred to as "ideal affect for targets") rather than their own ideal affect when they make choices for other people. More importantly, we also examined whether people lay greater emphasis on affective factors when they engage in experiential purchases for others than in material purchases.

Experimental methods and procedures were exactly the same between in Study 1 and in Study 2. There were two parts of the main experiment in the present research. In the first part, participants' ideal affect scores (ideal affect scores for targets for Study 2) were measured. In the second part, after few weeks later, participants were asked to complete the option choice task. This task depicted purchasing situations where people consume various experiential and material products. We chose a total of 20 categories to which people can easily access in our daily life: 11 categories for experiential purchases such as vacation places, movies, and hobbies and 9 categories for material purchases such as shoes, alarm clocks, and USB flash drives. For each of 20 item categories, we selected two stimuli as a pair; one is for HAP option and the other is for LAP option. Participants were asked to choose only one of two options in each pair for themselves in Study 1 and for others in Study 2. By calculating the number of HAP options chosen by participants in each domain, we could examine whether people make choices based on their ideal affect in Study 1 and ideal affect for targets in Study 2.

The results of Study 1 demonstrated that people have different ideal affect depending on their ages and make purchasing choices based on their ideal affect in experiential purchases but not in material purchases when they make decisions for themselves. Consequently, the effect of participants' age on purchase decisions was partially mediated by ideal affect for self only in the experiential purchases but not in material purchases. On the other hand, the results of Study 2 confirmed that people have different ideal affect for targets depending on targets' age and gender, and more importantly, ideal affect for targets did predict choices not only in experiential purchases but also material purchases. Consequently, ideal affect for targets partially mediated the relationship between targets' age and choices in both of experiential and material purchases.

In conclusion, the overall results of the present research provide confirming evidence that people are likely to employ ideal affect as a basis of judgment and make decisions relied on it especially when they engaging in experiential consumptions regardless whether the target of purchases is self or others.

Furthermore, the interesting reversal regarding material purchases observed in Study 1 and 2 indicate that people are likely to use different strategies to make decisions for themselves and for other people especially in material purchases. Since the present research do not draw an absolute conclusion regarding why people show such self-other difference in material purchases, future studies need to be done to probe the underlying mechanism of this self-other difference. Lastly, the findings of the present research have valuable implications for the market place. For example, it will be of benefit for marketers who promote experiential goods such as tour packages and tickets for performance to understand ideal affect of their target consumers whom they intend to sell their products and to make promotions by emphasizing the affective states which will be elicited from consumer decisions. Moreover, this finding would be extended to gift-giving situations.

The Meaning of Border and Its Effects on Cross-Border Consumption

Emre Ulusoy, University of Texas - Pan American, USA

Even though the U.S.-Mexico border represents one of the most voluminous consumer and product traffic in the world and thus comprises a prominent context for researching cross-border mobility and consumption, that border has not attracted deserved attention among academics. Further, much of the existing research on cross-border mobility and consumption takes a modernist view and focuses on economic and rational aspects of border crossing. Few studies take alternative views (e.g., postmodernist) to examine how the profound and in-depth meanings of border affect cross-border experiences, (im)mobility and consumption. Therefore, this study examines the perceived meanings of the U.S.-Mexico border and the interplay of these meanings with consumer cross-border experiences, (im)mobility and consumption.

The term border has different meanings in different contexts, and these meanings change through time and space. In its broad sense, border is a separation of two entities from each other resulting in division, differentiation and dissimilarity. In addition to its conventional meaning, U.S-Mexico border has symbolic, socially constructed (Wonders 2006) and hyperreal meanings (Duarte-Herrera 2001). The mean-

ings of border also vary in the process of globalization by the applications of debordering and rebordering processes (Stetter 2008) and by the engendered fragmentation of globalization (Fırat 1997).

I draw on the data collected through 37 interviews with consumers who cross the U.S.-Mexico border, some frequently and some infrequently, to understand perceived meanings of that border in the local community. Several intriguing themes emerged from the analysis. Generally speaking, consumers (re)interpret borders differently, and given their familiarity with the fluid and polysemous meanings of that border, their narratives contain paradoxical articulations of the meanings of border.

The first theme taps the paradoxical feelings of security and ambivalence. Seeking order, comfort, security, and pleasant consumption experiences, many people believe that these ideals are intimately linked to the U.S.-Mexico border. Border is thus a vital component of their everyday lives. These people also report of structural influences that the border imposes upon them, leading to discomfort, feelings of self-doubt, and stress when they get closer to the border.

The second theme is resistance against the materialization of the symbolic. Those who see the border as a means of order, security and comfort condemn the wall that the Bush administration intended to build between the U.S. and Mexico. These consumers consider the border to be crucial for maintaining order and security in the region, but allude to the proposed wall as a means of discrimination. They feel that the wall will render the symbolically 'fair' order to a visibly 'discriminatory' mechanism. Although they feel that no wall can stop them from crossing over, they fear that it will make the border more palpable and definite to local people's detriment.

The third paradoxical theme introduces the border as a symbolic obstacle and consumption as reward. Local people encounter numerous difficulties while crossing the border. They wait in lengthy lines everyday, sometimes under excruciating conditions. But once they are done crossing the border, they often indulge themselves in consumption experiences available on "the other" side. Therefore, the border is a symbolic obstacle in the way of alluring consumption time, and the act of crossing it generates a mysterious and thrilling experience. It is apparent from the narratives that such sensational swings would not be possible or the same if the border was to be removed.

The fourth theme is "border as fragmentation." Fırat (1995) argues that "fragmentation of the metanarrative allows the liberation and acceptance of indifferences, as well as putting an end to the dominance of any one regime of truth." Consistent with this argument, interviewees view (a) border as a force that symbolically maintains and intensifies these differences, and (b) globalization as a force engendering fragmentation and availing desired experiences of whatever, whenever. Postconsumers are contemporary people who produce their selves and create their images within and through meaningful experiences they seek in life primarily through consumptions (Fırat 1997). Border-crossers are prime examples of postconsumers. More specifically, Mexicans who cross the border, do so in part due to their liking for the 'American Dream' and American lifestyles. Symbolically, the border represents such ideal images.

The fifth theme is "border as a privilege." Mexicans perceive border as a privilege since, for many, being able to cross the border and experience "the other" side (the U.S.) is a privilege. Crossing over to the U.S. makes Mexicans feel special, different, or even part of a superior social class in their native communities.

The last theme is "social construction of border reality and hyperreality." Many Mexicans believe and articulate that U.S. is 'better' than Mexico in almost every aspect even when they do not see any difference between the two countries in terms of the quality and variety of products and services. Advertising and media play eminent roles in the construction of border hyperreality.

It's Smiling at Me: Satisfying Social Needs Through Consumer Products

James A. Mourey, University of Michigan, USA
Jenny G. Olson, University of Michigan, USA
Carolyn Yoon, University of Michigan, USA

Beginning with imaginary friends and teddy bears in childhood, human beings demonstrate a fundamental need for belonging that continues across the lifespan (Baumeister & Leary, 1995; Maslow, 1943). Although social needs are often fulfilled through contact with other people, it seems plausible that consumer products could fulfill similar needs. For example, consumers might purchase goods and services hoping to attain love, affection, and emotional pleasure. Rather than calling a friend when feeling lonely, a person may choose to indulge in comfort food or shop online. Seeking social need fulfillment through products may, paradoxically, serve as a detriment to interpersonal relationship development and maintenance. The objective of the current research is to explore how the consumption of products, in general, can come at the cost of social relationships when products satisfy the needs customarily fulfilled by other people.

Just how far people supplement human interactions with product interactions is a matter warranting careful study. Research suggests the possibility of consumers developing relationships with nonsocial objects that mirror interpersonal relationships (Aggarwal, 2004). Fournier (1998) identified brands as viable relationship partners where one party in the exchange is a person who receives significant social benefits.

Further evidence indicates that individuals readily perceive objects as gendered (Guthrie, 2007), brands as having personality (Aaker, 1997), and brand-related characters as human (Rook & Levy, 1999). Social exclusion may play a role in these findings, however, such that those who are craving human contact may more readily "see" people in their products. Research by Epley, Waytz, Akalis, and Cacioppo (2008) shows that people who feel more chronically disconnected from others and lonely anthropomorphize more than those who feel more connected. Indeed, individuals who are well integrated in their social networks are less likely to seek additional bonds relative to their more deprived counterparts (Baumeister & Leary, 1995).

In the present research, we examine in two studies the link between social exclusion and consumer products. We propose that when a social need exists, products may satisfy it in a way similar to people, which reduces the likelihood of seeking interpersonal fulfillment. Baumeister and Leary (1995) propose, but never empirically test, that social relationships "…should substitute for each other, to some extent, as would be indicated by effective replacement of lost relationship partners and by a capacity for social relatedness in one sphere to overcome potential ill effects of social deprivation in another sphere." We seek to demonstrate that consumers who perceive a void in affiliative bonds may be able to derive similar social benefits by forming relationships with and consuming products.

Study 1 utilized a 3(social inclusion/social exclusion/control) × 2(anthropomorphized/non-anthropomorphized product) between-subjects design. Undergraduates were randomly assigned to one of three essay conditions: social inclusion ("write about a time you felt very included by other people"), social exclusion ("a time you felt very excluded by other people), or a nonsocial negative control ("a time you did worse than expected on an academic assignment"). Participants were then presented information about iRobot's Roomba. This product was deemed appropriate because previous research indicates owners readily personalize the robot, which creates emotional engagement (Sung, Grinter, & Christensen, 2009). Participants were shown either an anthropomorphized (i.e., rotated 180 degrees from its original orientation so that it appears to be smiling) or nonanthropomorphized (i.e., rotated 90 degrees so it appears on its side) version. Aggarwal and McGill (2007) utilized a similar manipulation where they exposed participants to a picture of the front of a car that had been modified by a computer graphics professional. Specifically, the grille was positioned to be either pointing up in a smile or down in a frown. A series of rating scales followed Roomba presentation to assess product perceptions.

Results revealed a significant interaction between the two independent variables for purchase likelihood, after controlling for Roomba ownership. Means suggest that the anthropomorphized version was generally preferred among both socially included and excluded individuals, but not for those in the control condition. More importantly, socially excluded participants expressed a greater likelihood of buying the anthropomorphized Roomba over its nonanthropomorphized counterpart. A second key variable was willingness to pay for a Roomba, controlling for current ownership. Results yielded a marginally significant interaction between the two independent variables. Assessing the means revealed a similar pattern to purchase likelihood such that the socially included and excluded groups were willing to spend more money on an anthropomorphized Roomba than the control group. Conversely, the control and included groups were willing to spend noticeably more on the nonanthropomorphized Roomba compared to the socially excluded group. Taken as a whole, the socially excluded individuals are willing to pay a premium to obtain a humanlike product over its nonhuman counterpart.

Study 2 replicated Study 1 with a more heterogeneous sample and focused on social behaviors rather than product perceptions. A similar design was used: 1) individuals wrote about a time they felt either socially included or excluded (no control group), 2) viewed either an anthropomorphized or nonanthropomorphized Roomba, and 3) responded to a series of items including whether they wanted to wait alone or with others for subsequent tasks. Results yielded a significant interaction between the two independent variables in desire for social contact. Means indicate that those made to feel excluded were more likely to prefer waiting alone when presented with an anthropomorphized version of the Roomba compared to those also made to feel excluded who were presented with a nonanthropomorphized version. Presumably, the excluded individuals were able to "fill the void" when presented a humanlike product.

In sum, we find initial evidence for the idea that people's perceptions of their social inclusion and exclusion 1) influence the kinds of products they might buy, and 2) those products influence their social behaviors. Additional studies are already underway to replicate these effects with other products and to elucidate the mechanisms driving these effects. We hope future results will further support our central argument: If social needs can be satisfied through products, consumers may not seek fulfillment through other people and, therefore, increase their risk of negatively impacting real social relationships, perpetuating a cycle of consumption at the expense of social interaction.

"Customer prioritization: profit enhancing or threat inducing?"

Svetlana Davis, Queens University, Canada
Peter Dacin, Queens University, Canada

Customer prioritization is a widely used strategy in which a company separates customers into groupings based on an estimated life-time worth (Zeithaml, Rust, and Lemon, 2001) and gains efficiency by concentrating on serving the most profitable (high priority) customers while spending less energy and resources on low priority customers. In this research, we suggest that along with these positive outcomes, customer prioritization strategies can also lead to negative consequences. Particularly, we suggest that different offerings that are tailored to different customer groups could potentially threaten the strong self-brand connection among strongly attached customers. We further predict that as a mechanism to restore this self-brand connection, some customers with strong brand attachment will feel entitled to receive better treatment from the firm. Given that increased customer's entitlement could be costly for the companies (Butori, 2010), it is important to investigate the potential downside of customer prioritization strategies.

Customers strongly attached to brands often protect the strong connection and feeling of "oneness" that they have with the brand. However, the different treatment that occurs under a customer prioritization strategy could imply a threat to this connection. Specifically examining customers with strong brand attachment, a mismatch between their perception of the brand proximity to their self (or extended self) and the company's implied brand proximity (that is defined by high/low priority customer groupings and their corresponding treatments under customer prioritization) will be likely.

So how do customers with strong attachment protect brand proximity when the company imposes distance between the customer and the brand through prioritization strategies? We suggest that such customers will attempt to restore proximity with the brand by increasing expectations to receive better treatment from the company (which we label "entitlement"). This increase in expectations to receive better treatment will then minimize the distance between the self and the brand and allow for restoration of the brand-self proximity. That is, to maintain proximity with the brand, customers who are strongly attached to the brand will increase their feelings of entitlement to better treatment, especially when comparing the treatment they receive to corresponding treatment of customers in other priority groups (i.e. they assess the perceived treatment gap). This comparison results in increased feelings of entitlement for better treatment (due to a desire to maintain proximity with the brand).

METHOD:

The goal of this study is to show how a customer prioritization strategy in combination with strong brand attachment could result in increased feelings of threat to self brand connection, leading to feelings of increased entitlement. To achieve this goal, this study employed 2 x 2 between subject design with 2 levels of measured brand attachment (strong/weak), 2 levels of randomly assigned priority groups (high/low priority) in the context of a treatment gap (credible) assessment. This study measured entitlement as a dependent variable, while controlling for a more stable entitlement conceptualized as a personality trait.

RESULTS:

Consistent with our predictions, an ANOVA test indicated that brand attachment predicted an increase in threat to self-brand connection ($F(1) = 7.24$, $p < .05$). Furthermore, following Baron and Kenny (1986), we tested for mediation. The result showed that threat to the self brand connection fully mediated the relationship between brand attachment and entitlement, confirming that customers with strong brand attachment experience increased threat to self-brand connection compared to those that have low brand attachment (Ms=3.55 vs. 3.11, Fs(1,264)= 4.837 and , ps <.05) and this increases their entitlement (Ms=4.20 vs. 3.80, Fs(1,264)= 6.712 and , ps <.05).

DISCUSSION AND CONTRIBUTIONS:

This research shows that while the use of customer prioritization strategies promise the company higher efficiency and effectiveness (Zeithaml et al., 2001), it could also backfire in increased costs for handling customers' complaints due to an increased sense of entitlement.

Further, the literature on entitlement (e.g. Butori, 2010) has mostly been concerned with the conceptualization of entitlement as a stable personality trait. My research shows that this entitlement can also be conceptualized as situation-specific. This conceptualization holds all main distinctions of the construct itself. In particular, the entitlement is a belief that one should receive desirable treatment with little consideration of actual deservingness. Further, this entitlement can occur from the desire of customers with strong brand attachment to maintain proximity with the brand when such proximity maintenance is threatened (e.g. under conditions of a customer prioritization strategies).

While the literature on brand attachment (e.g. Park, Macinnis, Eisingerich and Iacobucci, forthcoming) suggests that strong brand attachments can offer advantages to firms (such as loyalty, brand display, readiness to pay a price premium and other benefits), this research introduces a note of caution on strong brand attachments, as it shows that such customers can also develop an increased sense of situation-specific entitlement and as a result demand special treatment which could be costly for the firm. This suggests that strong consumer-brand attachments can become a potential liability associated with customer prioritization strategies.

Finally, companies that employ prioritization strategies need to account for additional costs that could occur due to customers' increased sense of entitlement. For example, such additional costs could occur when customers complain or demand a better treatment from the company etc. Thus, while a customer prioritization strategy separates customers into different priority groupings based on the amount of worth that each customer represents for the company, my research suggests that such a separation would also benefit from consideration of brand attachment.

The Interactive Effects of Self-Connection and Self-Esteem in the Affect Transfer Process of Consumer Brand Extension Evaluations

Zhuohao Chen, Warwick Business School, University of Warwick, UK

Qing Wang, Warwick Business School, University of Warwick, UK

Brand extension research has been increasingly critical as the expansion of consumers' psychological cognitive and affective boundary endows brands with more and more opportunities to enter new and distant categories. Although pioneer research asserts similarity between the parent brand and brand extension category as a key determinant of consumer brand extension evaluations (e.g. (Aaker and Keller 1990), (Park et al. 1991)), more and more brand extensions challenge this rule, e.g. Pepsi music, Virgin Cola, National Geographic garments, etc. Although such aggressive brand extensions are beyond consumers' imagination, consumers are not reluctant to accept them. On the other hand, however, Coke music, Vodafone Cola and Wall Street Journal garments would be more difficult to be accepted. A possible explanation is that the trait of excitement generates an affect transfer mechanism in which brand personality induces high-esteem consumers to be so risk-seeking in brand extension evaluation that they transfer their self-connection directly to the new product regardless of the extension distance.

Two mechanisms can be identified to understand the influence of brand personality on consumer brand extension attitude. On one hand, prior research follows a cognitive stream, arguing that a process of fit is a key mechanism of brand extension evaluation, in which perceived fit consists of three dimensions. First, category-based fit assumes that feature similarity is the basis of categorization (Tversky 1977) therefore similar category or feature (e.g., white appliance) leads to a favorable brand extension (Boush and Loken 1991). Next, further research finds consumers evaluate fit with a specific benefit or goal (Broniarczyk and Alba 1994; Martin and Stewart 2001). Specifically, similar context of usage aiming at a benefit (e.g. tooth brush and toothpaste for the benefit of dental health) increases perceived fit (Joiner 2006; Ratneshwar and Shocker 1991). Third, brand-based fit theory underlies the fit of brand image or brand concept (Park et al. 1991), which is accessible when consumers evaluate symbolic brand extensions. Here, brand-based fit is a relatively broad concept (Czellar 2003) so that brand personality fit can be viewed as a critical facet of it. In terms of this steam, consumers experience a fitting process in which the fit between brand extension category and original brand personality is evaluated. If this fit is higher, the brand extension attitude is more positive. In addition, self-connection facilitates consumer's understanding of brand personality fit in that brand affect generates relational holistic and schematic thinking (Ahluwalia 2008; Monga and John 2007) thereby fit being more easily perceived for distant extensions. If a consumer is emotionally attached to a brand, he is more likely to find such fit. In this mechanism, therefore, brand personality fit plays a mediation role between self-connection and brand extension attitude.

On the other hand, recent research in brand extension has put more attention to the affective process (e.g. (Barone and Miniard 2002; Barone et al. 2000; Yeung and Wyer Jr. 2005). Compared with cognitive evaluation, affect transfer is an abstract, schematic, symbolic and self-expressive process. Evidences show that parent brand affect can be directly transferred to brand extension attitude without mediation of perceived fit if a consumer has a high brand-elicited affect or loves the brand (Yeung and Wyer Jr. 2005). Such brand affect is usually generated by brand relationship including self-brand connection (Fournier 1998). The theoretical assumption of self-brand connection mechanism underlies that consumers are involved in a subconscious matching process when a brand personality is congruent with their self-images. The more self-brand congruity there is, the more this consumer favors the brand (Sirgy 1982), as a symbolic brand with distinct personality helps the consumer express himself and reduce the inconsistency between actual and desired self (Belk 1988). However, it is suggested that different dimensions of brand personality have asymmetric effects when a brand transgression occurs. For example, consumers tolerate a service failure of an exciting brand more than that of a sincere brand (Aaker et al. 2004). Individual attachment styles play a moderating role in self-connection as well (Swaminathan et al. 2009). Further, not all consumers follow this affect transfer process. Individual difference, particularly in personality traits such as self-esteem and self-construal, triggers the brand extension attitude formation approach (Ahluwalia 2008). We suggests that self-esteem is a moderator of the relationship between self-connection and brand extension attitude, i.e. affect transfer process. Higher self-esteem makes consumers more enthusiastic, optimistic and risk-seeking (Schaninger 1976) about aggressive brand extensions.

In summary, current research explicates the influence of brand personality and self-esteem on brand extension evaluation in three mechanisms. First, perceived fit is a mediator between self-connection and brand extension attitude. Second, self-connection influences brand extension attitude directly in the affect transfer process. Third, self-esteem moderates the affect transfer mechanism.

A pilot study was conducted in China to verify the conceptual model. Two real mobile telecommunication brands under China Mobile were used as parents brands (M-zone as exciting brand and G-tone as competent brand). Two pretests verified brand personality representations and the distance of fictitious brand extensions. In the main study, 232 students of a Chinese university were recruited to evaluate two

brand extensions from eight fictitious extensions varying from low (e.g. wristwatches) to medium category fit (e.g. MP3 player and PDA) and low (PDA for M-zone and MP3 for G-tone) to high brand personality fit (e.g. MP3 for M-zone and PDA for G-tone) before they were required to report perceived fit, self-brand connection and self-esteem. Finally 461 evaluations were collected. Preliminary analysis results indicate good supports for the hypotheses. First, results of structural equation modelling confirm the baseline model, in which brand extension attitude is influenced by both brand personality fit and self-connection. Second, grouped structural models show a complete mediating model (self-connection→ perceived fit→brand extension attitude) in low self-esteem group, where the influence of self-connection on brand extension attitude was non-significant (b= .13, t=1.86, p>.05), while a partial mediating model (both self-connection→ perceived fit→ brand extension attitude and self-connection →brand extension attitude) in high self-esteem group, where self-connection has significant influence on brand extension attitude (b= .24, t=3.34, p< .001).

The results support the moderating effect of self-esteem on the affect transfer mechanism, i.e. high self-esteem triggers affect transfer in consumer brand extension evaluations. This indicates that high self-esteem may be a good predictor of affect transfer as high self-esteem consumers are more likely to judge a brand extension in terms of existing brand affect. Further research will adopt lab experiments to investigate every single mechanism, where self-esteem and self-connection will be manipulated respectively.

A Two-Stage Cognition Model of Online Shopping

Wei Chen, University of Connecticut, USA
Shuai Yang, University of Connecticut, USA
Sixing Chen, University of Connecticut, USA

With the development of internet marketing, more and more information with various sources and formats become available online. As a consequence, online shoppers are often faced information overload, which leads to choice deferrals (Dhar 1997; Iyengar and Lepper 2000). A recent study finds that engaging in unconscious information processing could help consumers to reduce their information overload and increase their product evaluations (Messner and Wanke 2011). Although unconscious cognition is useful in such an information rich environment, conscious processing performs better in low information context (Messner and Wanke 2011). To date the studies have mainly

focused on a relatively stable information environment, i.e., the information amount is constant. By contrast, our study provides a dynamic framework of information load. Specifically, we propose a two-stage cognition model. At stage one, consumers facing lots of information will unconsciously process information, and at stage two, when information load is reduced, conscious processing will dominate. Such a two-stage method could utilize the advantages of both unconscious and conscious cognitions.

Raghubir and Krishna (1996) have proposed a two-stage approach of distance judgment, through which people develop an initial judgment unconsciously and make a conscious reevaluation later. Online shoppers could apply a similar manner that they engage in thin-slice judgments of products when they first see information, such as pictures, and then update their judgment by reviewing further information, such as textural descriptions (Peracchio and Luna 2006).

Individuals have limited capabilities to process information (Miller 1956) and a likely outcome could be the unconscious processing (Dijksterhuis 2004; Dijksterhuis and Nordgren 2006). How does unconscious processing occur in an online context? The products listed online often contain information such as pictures and some textual descriptions. Compared to textual descriptions, pictures are more salient and require less effort to process and people prefer to use such an effort-saving heuristic even if it might lead to a biased estimation (Raghubir and Krishna 1996). Consumers could associate pictures with products characteristics (Mitchell and Olson 1981). Given the fact that consumers often spend very limited time on each website (Wolfinbarger and Gilly 2001), such association is likely unconscious and consumers could use it to reduce the information load, creating a short list of product alternatives and evaluating them consciously later.

We speculate that mental contamination, i.e., unwanted thoughts generated by unconscious processing (Wilson and Brekke 1994), might result from the interaction between unconscious and conscious cognitions from two stages. To avoid or correct such mental contamination, people need to be aware of it and have motivation to correct it (Wilson and Brekke 1994). When information in the second stage of the process is consistent with that in the first stage, i.e., the product information consumers obtain from the picture is congruent with that acquired from textural description, individuals will fail to correct mental contamination due to lack of awareness. Even if the two cognitions are inconsistent, people are more likely to believe that the new propositions are false in their realm of beliefs and it is difficult to reject false propositions when their cognitive capacity is taxed (Gilbert 1991, 1993). If people who are lowly involved with the product, they are not motivated enough to correct source confusion, thus, they cannot move beyond their first judgment (Wilson and Brekke 1994). Only when consumers are highly involved with the product, they have strong motivations to conceal the truth about products, through a closer look at other information (Weisbuch and Ambady 2010). High involvement can focus their cognitive effort to comprehend product information (Celsi and Olson 1988).

Study 1 examines the relationship between information load and consumers' information processing method. Subjects are asked to choose a *soft* tissue from an assortment of tissue products that contain both pictorial and textural information. We adopt the design from Mitchell and Olson (1981) that some pictures convey the information of *softness* while others do not. Moreover, some textural descriptions explicitly state the word *soft* while others do not. The combinations of pictures and texts are randomized. For low (vs. high) information load condition, subjects are asked to choose from 5 (vs. 20) tissue products. Manipulation check indicates that subjects feel much low (vs. high) information load when choosing from 5 (vs. 20) products. Preliminary results show that when information load is low (vs. high), subjects are more likely to choose the product with *soft* explicitly stated in textural description (vs. product with a picture that conveys the idea of *softness*).

Study 2 investigates whether consumers will reduce the information load using unconscious processing and consciously process the remaining information. Subjects are asked to choose a *soft* tissue from 20 tissue products that contain both pictorial and textural information. Subjects are instructed that they can put some of the products into the *shopping cart* and make the decision later. The product information is manipulated the same as that in study 1, and we record the time subjects spend on filling the *shopping cart* and on final decision. Preliminary study suggests that at stage 1, subjects rely more on the picture to reduce the information load while at stage 2, subjects depend more on the textural description to make the choice. Also, the time subjects spend on each tissue product at stage 1 is less than that at stage 2.

Study 3 focuses on the effect of information consistency between unconscious and conscious cognitions on product choice, as well as the moderating role of involvement. The study is a 2 (information consistency: yes vs. no) by 2 (involvement: low vs. high) design. The dependent measure is subjects' purchase likelihood (7-point scale: very unlikely to very likely). The picture contains a kitten which is believed to indicate *softness* (Mitchell and Olson 1981), and in consistent (vs. inconsistent) situation, the textural descriptions explicitly state the word soft (vs. non-soft). Subjects in low (vs. high) involvement condition are told that the tissue will not (vs. will) be available in near future (Petty, Cacioppo, and Schumann 1983). The data collection is on progress and results will be reported later.

Trust in Financial Investments: Who or What Really Counts

Christopher Ruppel, Johannes Gutenberg-University Mainz, Germany
Sabine Einwiller, Johannes Gutenberg-University Mainz, Germany

The latest upheavals in the financial markets revitalized the debate on the role of customer trust in banks and in the financial system in general and stimulated discussions as well as actions concerning stricter rules and regulations in this sector. Several studies in marketing have shown that trust in a firm or its representatives can positively impact on customers' behavior, also in the financial sector. Only few studies, however, have taken the institutional environment in which the action takes place into account. One exception is the study conducted by Grayson, Johnson and Chen (2008) who distinguish between 'narrow scope trust' referring to trust in individual firms and their representatives and 'broad scope trust' referring to system trust and generalized trust. The authors highlight the role of trust in the broader context as an antecedent and narrow scope trust as a mediator for customer satisfaction. The specific role of the consumer's trust in the banker, i.e. the person advising the financial investment decision, was however not clarified. We argue that differentiating between the bank as an organization and the advisor as a person is significant, because the personal relationship between customer and financial advisor can play a crucial role in financial decision making (e.g. Howcroft, Hewer, and Durkin 2003). To gain an extensive view on the mechanisms of trust in financial decision making, we therefore propose to differentiate between the following three objects of trust: the financial system, the bank and the financial advisor.

In developing a model of trust in financial investments we drew on attitude theories (Ajzen 1991; Fazio 1990) and former definitions of trust (Lewis and Weigert 1985; McKnight, Cummings, and Chervany 1998) according to which trust shall be conceptualized as a multidimensional construct, comprising a cognitive evaluation of the trust objects, a positive expectation as well as a behavioral intention to invest and thereby accept vulnerability (Rousseau et al. 1998). Thus, the final model comprised the three objects of trust (trust in the system, the bank and the financial advisor) and as mediating variable the customer's trusting expectation that the investment decision was good, worthwhile and low-risk (trusting expectation). The target variable was the customer's trusting behavioral intention to make an investment at the respective bank (trusting intention). As potential influencing variables on trust in the bank we tested the reputation of the bank and the familiarity and satisfaction with the bank, and as potential antecedents of trust in the advisor familiarity and satisfaction.

To test the model, an online survey was conducted among private investors between January and March 2010. Participants were recruited by tapping personal networks and applying a pyramid scheme. Participants were asked to answer the questions with respect to their latest investment. The analysis builds on 145 cases. Data were analyzed using structural equation modeling with Partial Least Squares (PLS) on account of two crucial advantages: it allows representing both formative and reflective latent constructs (Jarvis et al. 2003) and even with small sample sizes it generates robust results (Chin and Newsted 1999). Evaluation of the measurement model produced satisfying results: For reflective constructs (a) indicator reliability, (b) construct reliability (c) convergent validity and (d) discriminant validity were assessed. In the final model (a) factor loadings exceeded a minimal acceptable value of 0.7 and were significant at $p < 0.05$, (b) composite reliability was greater than 0.7, (c) the average variance extracted exceeded the threshold of 0.6 for each construct, and (d) the Fornell-Larcker-Criterion (1981) was met for each latent variable. Concerning formative constructs (here: familiarity) *multicollinearity* was investigated by the variance inflation factor, which in every case fell below the recommended threshold of 5 (Diamantopoulos et. al. 2008). Evaluation of the structural model was also supporting our model: All except two of the path coefficients were significant at $p < 0.05$. Path coefficients show that trust in the system only exerts a moderate influence on the trusting expectation ($b = 0.145$) and the trusting intention ($b = 0.103$). Strong effects, however, originate from trust in the bank and trust in the advisor. While trust in the bank exerts its influence on the trusting intention mainly through the person's trusting expectation ($b = 0.343$), trust in the advisor has the strongest direct effect on the trusting intention ($b = 0.324$). Calculating total effects reveals that trust in the advisor is the main driver of a trusting intention ($b_{tot} = 0.399$ vs. $b_{tot} = 2.88$ for trust in the bank respectively $b_{tot} = 0.148$ for trust in the system). The variable exerting the strongest influence on trust in the bank is its reputation ($b = 0.470$); familiarity was the variable most relevant for trust in the advisor ($b = 0.532$). The high predictive power of the model is indicated by R^2 values exceeding a value of 0.36 for all endogenous constructs. The corresponding Stone-Geisser test criterion Q^2 exceeding the threshold of 0 for dependent variables suggests likewise a strong predictive relevance (Chin 1998).

Our study shows that the complex phenomenon of trust demands a similarly comprehensive conceptualization. For the specific context of this research, the model reveals that although the institutional environment in which the decision takes place is relevant, however, that investing is a very personal business: While system trust only marginally influences private investors' decision making, our research suggests

that trusting the person who advises the investor in his or her decision making is most important. It is important to note that the research was conducted during turbulent times, namely within the context of a dramatic financial crisis. Perceived uncertainty which was most likely enhanced by the situation might have amplified the role of trust in the advisor. Further research shall clarify the influence of situation specific uncertainty for the role of the different objects of trust in engendering a trusting expectation and intention.

Price on the Top of the Price: Effect of Sales Tax and Product Price on Consumers' Estimates of the Total Purchase Price

Igor Makienko, Universty of Nevada, Reno, USA

If consumers are well aware of sale taxes but do not see them on price tags does this mean that they are not influenced by this universal surcharge when they estimate the total purchase price? In our research we explore the impact of sale taxes on consumers' estimations of the total purchase price in traditional retail settings and suggest that price level will moderate the impact of sale taxes on consumers' estimations of the total purchase price.

Too tired to care: the selfish impulse and the will to be fair

Sachin Banker, MIT, USA

The studies presented here aim to address the apparent conflict that exists in proposed accounts of the nature of fairness versus self-interest motives. While some neuroscientific evidence has provided support for the view that the concern for fairness relies on an emotional impulse that must be controlled in order to act in rational self-interest, other evidence has supported an opposing view that the concern for fairness is instead realized through the control of selfish impulses. The two psychological theories generated from this neural evidence were tested using ego-depletion methods and provide support for the latter view that people are in fact driven by selfish impulses that must be resisted in order to enact fair outcomes. Moreover, it is also found that more general implementation of altruistic, reciprocal, as well as efficiency norms requires the control of self-interested impulses. This evidence offers important implications regarding consumer behavior that differ dramatically from those generated by the conflicting account.

THEORETICAL BACKGROUND

In a seminal study, Sanfey et.al. (2003) had subjects play an ultimatum game while placed in an fMRI. Faced with a choice to accept or reject a proposed split of an endowment, subjects had to weigh their desire for a fair outcome against a desire for money. It was found that rejections of especially low, unfair offers was associated with activation in the anterior insula, a region of the brain thought to be involved in the representation of feelings of pain and disgust, and this finding is taken to be indicative of the fact that motives for fairness are subserved by emotional impulses that must be regulated to act in an economically normative manner.

However, in a study that had subjects play an ultimatum game while temporarily disrupting activity in the right DLPFC, an area of the brain implicated in the cognitive control of impulse, subjects actually accepted unfair offers more often (Knoch et.al. 2006). This finding runs

counter to the prediction of the previous story, since if control is required to regulate the impulse to reject unfair offers, disruption should decrease rather than increase acceptances. Instead, this evidence is taken to be indicative of the fact that people are driven by selfish impulses that must be controlled to act according to social and cultural fairness norms.

Together, these neural data are suggestive of two competing psychological accounts. In particular, each view proposes a relationship between an impulse and a controlled motive. In one view, there exists an emotional impulse for fairness that must be controlled to act in rational self-interest. In the opposing view, there exists a selfish impulse that must be controlled to act in line with fairness norms. Since the relationship between neural activity and the corresponding psychological constructs remains somewhat tenuous, existing data are not conclusive about either view. Fortunately though, there are established behavioral methods of manipulating these constructs.

Theories of self-regulation provide behavioral predictions regarding the way in which controlled motives versus impulsive motives may present. In specific, the strength model of self-control posits that there exists a common and depletable self-regulatory resource that is required to overcome impulses and that can be drained in the short run through any self-regulatory act (Baumeister, Vohs, Tice 2007). For example, simply controlling one's emotions during a dramatic video can reduce scores on the seemingly unrelated task of gripping a handgrip as long as possible (Muraven, Tice, Baumeister 1998). Thus, after ego-depletion we should expect to see increases in rejections of unfair offers in an ultimatum game if the fair-impulse view is accurate and decreases in rejections if the selfish-impulse view is accurate.

EXPERIMENTAL DESIGN

A series of 4 studies were conducted, each involving an ego-depletion manipulation and incentive compatible play in well-explored economic games. Studies 1a-c observe altruistic and reciprocal behavior in the dictator game and ultimatum game, and Study 2 observes behavior in taxation games that allow a number of particular fairness concerns, including efficiency, to be distinguished.

Study 1: Depletion three-ways

In Study 1a, subjects were depleted with a forced choice task that required some subjects to choose carrots rather than cookies. If in the undepleted condition, subjects were instead forced to choose cookies over carrots. Subjects then participated in a dictator game and responded to offers in an ultimatum game. Study 1b appropriates the vicarious depletion findings from Ackerman et al (2009) and Study 1c applies a typing task manipulation previously used in Muraven et al (2006). The results of these manipulations are similar to those reported below.

The findings indicate that depleted individuals exhibit a diminished concern for altruism than their undepleted counterparts, giving on average $2.56 vs. $3.72 (t(50)=2.08, p=0.0428) in the dictator game. Selfish offers of $0 increased dramatically under depletion, from 7% to 43% (t(50)=3.38, p<0.01). In addition, it is also found that depleted individuals exhibit a diminished concern for reciprocal fairness relative to their undepleted counterparts, only rejecting unfair $1 offers 42% of the time compared to the more normal value of 68% exhibited by undepleted subjects (for $1 offers t(50)=1.87, p=0.06; for $2 offers 33% vs. 58%, t(50)=1.72, p=0.09; similar logit results).

Study 2: Taxation games

In Study 2, subjects were depleted with a typing task manipulation similar to that used in Study 1c and subsequently played the 4 taxation games in Engelmann and Strobel (2004). Findings indicate that preference for efficient allocations decreases under depletion, choosing the efficient option 18.9% of the time under depletion versus 40.7% (t(89)=-2.23, p=0.028).

IMPLICATIONS

Concern for fairness constitutes an important driver of consumer behavior. However, the current findings suggest that the tendency to rely on fairness motives depends crucially on the extent to which the consumer is able to overcome impulses in the particular situation. If for example a person were overloaded with stimuli or decisions, we would expect them to be less willing to donate to charitable causes but more willing to pay unfair prices for goods. The findings also suggest that resisting a steak for a salad would have an effect of reducing tips for the waiter or waitress.

How Does Skinny Sell?
Body Size and Pricing Effects on Advertising Effectiveness and Body Esteem

Maxim Polonsky, University of Connecticut, USA
Ioannis Kareklas, Washington State University, USA

Marketers claim that skinny models sell products well (Gillian, 2000). Research findings on exposure to thin models and advertising effectiveness are mixed. Women generally feel thin fashion models are more elegant and interesting (Martin et al., 2007), and tend to associate thin with happiness, desirability, and status (Tiggermann, 2003). On the other hand, Dittmar and Howard (2004) have shown that the exposure to thin ideals in ads may harm an individual's body esteem, and there is no difference between thin and average-size models in terms of advertising effectiveness (i.e. product and ad evaluation, and purchase intention).

When asked about most important aspects in women's life, approximately fifty percent of American females indicate their shape and weight (The Downing Street Group, LLC, 2007). For young women especially, pressures to be thin contributes to lower self-esteem, body image disturbances, and eating disorders, with as many as fifty percent of undergraduate females expressing body dissatisfaction (Bearman et al., 2006).

Research shows that between 1970–1990, the emphasis on fitness increased, and the body shape of models tended to become thinner (Guillen and Barr, 1994). The content analysis of popular fashion magazines from 1959 to 1999 found a significant decrease in models' body sizes during the 80s and 90s (Sypeck et al., 2004). Botta (1999), for example, found that exposure to thin body sizes had an influence on young female's endorsement of the ideal thin body and the likelihood to use media models to define what their own bodies should look like. The relationship between exposure to thin-ideal and body image disturbances was also demonstrated in experimental research (Bessenoff, 2006; Dittmar & Howard, 2004) and supported by two meta-analytic reviews (Grabe et al., 2008; Groesz et al., 2002).

Important moderators of the relationship between exposure to thin ideals in the media and body-related disturbances are social comparison tendency and thin-ideal internalization. Internalization of thin-ideal has been viewed as an important risk factor that contributes to developing of eating disorders. Thin-ideal internalization refers to the extent to which an individual accepts the thin-ideal standard of beauty and attractiveness as her own and engages in behaviors that supposedly help to approximate these standards (Thompson et al., 1999).

As a theory, social comparison posits that individuals compare themselves to others to determine their own relative levels of abilities (Festinger, 1954). There are two directions for social comparison: an upward comparison that is made when comparison others are perceived to be more fortunate; and a downward comparison that refers to less fortunate comparison others. Research suggests that when discrepancies between the self and the comparison standard arise, people are motivated to change the self to be more like the comparison standard. Upward comparisons in particular lead to negative moods and lower self-esteem (Gibbons & Gerard, 1989). Social comparison processes may be unintentional, environmentally imposed, and even unwanted (Lyubomirsky & Ross, 1997). Richins (1991) pointed out that that social comparison with media models has unfavorable consequences for female body esteem, since the media body ideal is unattainable. That is why women who are more likely to compare their body to media models have higher levels of body dissatisfaction and lower levels of self-esteem (Stormer & Thompson, 1996).

From the review above, the marketing dilemma is evident: images that are effective in selling products may also harm consumers. We conducted two experiments in order to investigate the dilemma closely. In the first online experiment, 145 female participants were randomly assigned into one of the three print ad body size conditions: thin, average, and plus-size. Specifically, we investigated the effects of the model body size on advertising effectiveness (attitude toward the ad, attitude toward the model, and purchase intention), as well as on body-esteem and weight lose intention. Upon login onto the website, participants were randomized into one of the three conditions and told that that they are participating in a marketing research study that explores different communication and appeal strategies (print vs. video, reading detailed information versus watching a short ad, sex appeal vs. humor, etc.) for two product categories – computers and women shoes. After completing pre-test, participants in each condition were referred to CNET.com page "Best 5 desktops" (http://reviews.cnet.com/best-desktops/?tag=leftColumnArea1.0) or similar updated page, and asked to read short one-paragraph review for each of the five computers. Next, participants were asked to answer filler questions about their liking, preference, and purchase intention for any of the reviewed computers. Upon the completion, study participants saw the experimental ad and filled a post-test questionnaire that consisted of a) questions about advertising effectiveness (e.g. ad evaluation, purchase intention, willingness to pay), and b) body-esteem scale and questions about dieting and weight loss. Participants were deceived that the later part of the post-test was an unrelated small scale survey study that will be used to design health interventions.

Our results indicate that participants in the thin condition estimated price to be higher relative to the participants in the plus-size and average conditions (F = 3.587, p < .05, means = $60, $65, and $85 for plus-size, average, and thin conditions respectively). We find a similar pattern for other advertising effectiveness variables, with the thin condition having a positive effect on willingness to pay (F = 3.317, p < .05; means = $30, $32, $38 for plus-size, average, and thin conditions respectively), attitude toward the model (F = 5.812, p < .05; means = 3.1, 3.6, 4.1) and attitude toward the ad (F = 3.17, p < .05; means = 3.2, 3.6, 4). It is important to note that the participants' purchase intention was identical in the average and thin conditions (F=3.12, p < .05; means = 2.5, 3.1, 3.1 for plus-size, average, and thin conditions).

In regards to body-related outcomes, we find that in the thin condition participants reported lower levels of body-esteem (F=3.02, p = .05) and higher desire to lose weight (F = 5.174, p < .05; means in pounds = 9, 9, 14). To summarize, in the thin model body size condition, participants viewed the ad and the model more positively, estimated the price to be higher, and were more likely to indicate their willingness to pay higher price and their purchase intention. On the other hand, this same condition made female participants feel bad about their bodies, and affected their desire to lose weight.

Our second experiment employed a between-subject 3 x 2 factorial design, investigating the effect of exposure condition (ads featuring thin models, plus-size models, and average models) and price (low and high) on the following outcomes: 1) advertising effectiveness (attitude toward the ad, purchase intention), and 2) body esteem and weight loss intention. The main difference from our Experiment 1 is the

introduction of price as an independent variable. We introduce price variable because, as mentioned above, thin is associated with status. We manipulate price and attempt to investigate whether price interacts with model body size to create the perception of quality and to elicit generally more favorable attitudes toward advertisements. At the same time, we investigate how body X price interaction affects consumers' body-esteem and weight loss intentions. Our preliminary results suggest that thin body size condition loses its advertising effectiveness when paired with low price. Generally the main effect for model body size disappears virtually in every variable of interest.

Brand Suicide? Memory and Liking of Negative Brand Names

Duncan Guest, Lugano University, Switzerland
Zachary Estes, University of Warwick, UK
Michael Gibbert, Lugano Universty, Switzerland
David Mazursky, Hebrew University, Israel

Brand names can convey important attributes of a product, and can more generally impact the brand image itself. For instance, brand names such as *Dove* and *Apple* implicitly convey positivity. However, some products are marketed with distinctly negative brand names, such as *Burn* energy drink, *Fat Bastard* chardonnay, and *Poison* perfume. What are the consequences of such negative brand names for consumer behavior? Might they bestow certain benefits that outweigh their negative connotations? We report two experiments that investigate this question. Specifically, a wealth of psychological research indicates that negative words are more memorable than neutral words, and some preliminary evidence suggests that negative stimuli become less negative with repeated exposures. We therefore predicted that, relative to neutral brand names, negative brand names would be better remembered (H1) and would become less negative with repeated presentations (H2).

Experiment 1 investigated whether negative brand names are better remembered than neutral brand names (H1). Eighty-four undergraduates viewed a series of slides containing one negative brand name (e.g., *Poison*) and one neutral name (e.g., *Obsession*), with a different novel logo presented above each brand name. Half the brand names were presented in blue font and half in red. The negative and neutral names differed in valence but were matched for word length and frequency. We then tested participants' recognition memory of (1) the brand names, (2) their color, and (3) their associated logos. Based on cognitive research, we hypothesized that negative brand names would not only be more memorable than neutral names, but also that they would evoke better memory for contextual details such as font color and logo. Results supported these predictions. Relative to neutral names, negative brand names elicited significantly better recognition ($p < .05$) of the

brand (71% vs. 65%), its color (55% vs. 49%), and its associated logo (58% vs. 54%). Evidently, negative branding evokes better memory for the brand name and its contextual details (e.g., color, logo).

Experiment 2 investigated attitudes toward negative brand names. Our primary interest was whether attitudes to negative brand names would improve across exposures (H2), as some prior research suggests that emotional stimuli become less extreme with repeated exposures. Secondarily, we also varied two dimensions of negative stimuli, namely, their extremity and their arousal. Negative words can be more or less extreme, and they can be high or low in arousal. Thus, 48 undergraduates evaluated the same brand-product pairs at three different times. Hypothetical brand names varied in extremity and arousal, producing a 2 (extremity: extreme, moderate) X 2 (arousal: high, low) within-participants design, with five brand-product pairs in each condition. All brand names were paired randomly with a neutral object, such as *Hatred* chair (extreme, high), *Grief* stove (extreme, low), *Trouble* clock (moderate, high), and *Neglect* cabinet (moderate, low). At time 1 (t1), each brand-product pair appeared for 13 seconds, and respondents evaluated how much they liked it (1 = "not at all"…7 = "very much"). Participants evaluated their liking of each brand-product pair again six hours later (t2) and two weeks later (t3). At t3 participants first were given a complete list of brand and product names, and they were asked to match the brands with the products that they had seen previously.

A 2 (extreme, moderate) X 2 (high, low arousal) x 3 (t1, t2, t3) repeated measures ANOVA on liking ratings indicated that all three main effects were significant ($p < .05$). Specifically, (1) moderately negative brands were liked more than extremely negative brands, (2) highly arousing brands were liked more than less arousing brands, and (3) brands were generally liked more across times. However, these effects were qualified by two interactions. First, valence and arousal interacted, with a larger effect of arousal among moderate brands than among extreme brands. Second, arousal and time interacted, with a significant effect of time only among moderately arousing brands. Extremity and arousal both affected memory identification scores at t3 as well, with better memory for extreme brands than for moderate brands, and for highly arousing brands than for less arousing brands. Interestingly, liking and memory were not directly related: Moderate brands were liked more, but extreme brands were better remembered. Thus, as predicted, negative brands tended to become less negative across exposures. Moreover, extremity and arousal both affected liking and memory of brands and products.

In sum, negative brand names are more memorable than neutral names, and repeated exposures increase liking of negative names. This exposure effect on liking was observed among low-arousal names such as *Gloom* but not among high-arousal names such as *Torture*. Those high-arousal brand names, however, were more memorable than the low-arousal names. Thus, negative brand names may be particularly memorable, but repeated advertising may be necessary to overcome consumers' initial dislike of them. Managers therefore need to think carefully about whether the benefits gleaned from making the brand stand out at the point of sale and in memory outweigh the negative perceptions created when using a negative brand name. Furthermore, because negative brand names are evaluated worst at initial exposure, a marketing strategy should consider advertising the brand for some time prior to product release to enable consumers to overcome initial negative perceptions.
