In the initial pre-regulation situation the domestic demand and supply curves are given by S_d and D_d respectively while the world supply curve is given by S_w . A market price and quantity of P_1, Q_1 is obtained with domestic production accounting for Q_3Q_1 units. Imposition of a governmental regulation will increase manufacturing costs by P_2P_1 , corresponding to a shift in the supply curve from S_d to S_d' . The world supply curve S_w may shift or remain constant depending on the nature of the regulations and the policies of exporting countries.

In the case of flammability standards, such standards must also be met by foreign manufacturers. Assuming foreign manufacturers face similar cost increases to those met by domestic manufacturers then S_w will shift to S_w' . The new equilibrium price and quantity is P_2, Q_2 . The cost to the consumer is given by the shaded area P_2P_112 which represents the change in consumer surplus due to the price increase (Dardis, 1977).

In the case of worker or environmental regulations there is no change in the world supply curve unless exporting countries adopt similar regulations. This is unlikely since most textile exporting countries are underdeveloped countries with a need for trade and foreign capital which can only be obtained if they maintain their competitive position in the world market. The impact of government regulation (other than flammability standards) is shown in Figure 2.

FIGURE 2

Cost of Government Regulation

The initial equilibrium situation of P_1, Q_1 is identical to that shown in Figure 1. Imposition of a regulation results in a shift of the supply curve from S_d to S_d' while S_w remains unchanged. Two situations are now possible. S_w In the first instance imports expand to meet consumer demand increasing from Q_3Q_1 to Q_5Q_1 while domestic production declines from Q_3Q_1 to Q_5Q_1 . This situation is unlikely, however, since the flow of imports is controlled by trade regulations. In the event that trade regulations are continued, imports are maintained at their former level (Q_3Q_1) while domestic production declines from Q_3Q_1 to Q_5Q_1 . The final equilibrium price and quantity is given by P_2, Q_2 and the cost to the consumer from the price increase is given by the shaded area, P_2P_112 .

A comparison of Figures 1 and 2 indicates some interesting differences in the impact of government regulations on the consumer. While most regulations will entail a cost increase for manufacturers the degree to which the cost increase is passed on to the consumer depends on the particular regulation. In the case of flammability standards both foreign and domestic manufacturers must meet the standard so that the consumer will pay the full cost increase. In some instances the foreign manufacturer may refrain from exporting to the U. S. in view of the availability of other markets and the cost of operating two production lines. In this case the equilibrium price and quantity after the passage of a flammability standard is given by the intersection of the domestic demand and supply curves (S_d' and D_d). Consumer protection, which discourages imports, also ensures producer protection. In contrast to this result, other regulations place the domestic manufacturer at a competitive disadvantage since they cannot be imposed on foreign manufacturers. Unless trade regulations are in effect the domestic industry will suffer disruption. Even with trade regulations the availability of imports means that the full cost increase is unlikely to be passed on to the consumer. Thus the price increase in Figure 2 is less than the cost increase.

Long-Term Cost Consequences to Consumers

Such costs are more difficult to project. Possible long-term cost consequences include the following:

- (a) exit of firms in the domestic textile industry with a consequent reduction in competition,
- (b) change from cotton textile production to man-made textile production due to uncertainty about cot-

- ton dust standards and flammability standards, which would mean a significant reduction in consumer choice, and
- (c) increased energy requirements by the industry to meet government regulations and a reduction in the supply of energy available to consumers.

Conclusion

As mentioned earlier only a selected number of government regulations could be reviewed in this paper. In particular the impact of the Toxic Substances Control Act was not discussed. It is obvious, however, that the textile industry has faced and will continue to face numerous regulations which are promulgated and enforced by many different government agencies. Several conclusions may be drawn from a review of existing regulations:

- (a) Regulations are needed to protect the worker, the environment, and the consumer. Thus in the absence of regulations (or other measures such as taxes) there is no incentive for the individual firm to control dust or noise levels or water pollution since such controls would increase manufacturing costs and place the firm at a competitive disadvantage.
- (b) Prior to the imposition of the regulations the textile products consumer was not paying the true cost of production. The firm's costs reflected the private costs of production but did not include the social costs of worker ill-health or environmental pollution.
- (c) The implementation of regulations means in most instances an increase in manufacturing costs and such costs will eventually be born by the consumer.
- (d) Flammability standards differ from other regulations since the potential beneficiary also incurs the costs. The more specific the regulation, i.e. addressed to certain high risk groups, the greater the correspondence between costs and benefits.
- (e) Much of the current debate concerns the degree of protection which should be required and the necessity for equating costs and benefits from regulations. Thus in the case of water pollution the 1985 goal of zero discharge is increasingly being questioned on the basis of incremental costs and benefits.
- (f) The increase in the number of government regulations affecting the textile industry requires increased coordination on the part of various government agencies if such regulations are to be implemented in the most cost effective manner.

INDUSTRY RESPONSE TO GOVERNMENT REGULATION

David Hillier, American Textile Manufacturers Institute

Abstract

The American textile industry is feeling the deep and serious repercussions of what it calls "The Washington Regulatory Explosion." It is faced with ever-more stringent and expensive environmental and safety and health controls.

In principal, the textile industry does not oppose the goals of these regulations. It, too, promotes a cleaner environment. It works toward a safer and healthier workplace for its employees.

On the other hand, the textile industry believes that it has a responsibility to distinguish between good and bad regulation, both in its own self-interest and the best interests of the nation.

The textile industry believes that every restraint should be most carefully scrutinized and discussed. When the evidence warrants, it opposes bad regulation with all the vigor it commands.

Yet, when a regulation is good, this industry will make every effort to find ways to make it work.

Good afternoon, ladies and gentlemen. My name is David Hillier and I am Assistant General Counsel for Fieldcrest Mills, Incorporated, a diversified manufacturer of textile products, including towels, sheets, blankets, bedspreads, carpets and rugs, with corporate headquarters in Eden, North Carolina.

Fieldcrest is one of many textile firms that is a member of the American Textile Manufacturers Institute. ATMI is the national trade association representing textile companies in 47 of the 50 states. ATMI companies together produce approximately 85 percent of the textile products made in the United States.

It is my pleasure to represent ATMI and the textile industry here today. It is a special honor for me to join the distinguished people on this panel in a discussion of the interdependent interests of consumers, government and industry. My portion of the program focuses on "industry's response to government regulation."

The word "response" reminds me of an exchange between a plumber and one of the federal regulatory agencies in Washington. It seems that the plumber wrote this particular agency saying that he had found hydrochloric acid to be just super for cleaning drains, and, he asked, was it harmless?

The Washington agency replied: "The efficacy of hydrochloric acid is indisputable, but the chlorine residue is incompatible with metallic permanence."

The plumber wrote back saying that he was mighty glad the agency agreed with him. The agency replied: "We cannot assume responsibility for the production of toxic and noxious residues with hydrochloric acid, and suggest that you use an alternate procedure." The plumber was happy to learn that the agency still agreed with him.

Whereupon Washington exploded: "Don't use hydrochloric acid: it eats hell out of the pipes."

I don't know whether this is a true story or not, but it does illustrate a typical response of Washington agencies to problems which exist in our country. The response is illustrative of the way regulatory agencies seem to purposely ignore straightforward and relatively simple answers to complex problems.

The textile industry, as much as any business, has felt the deep and serious repercussions of this regulatory approach. We are faced with ever-more stringent controls on water quality, noise, cotton dust levels, flammability, toxic chemicals and many others.

Many of these controls are, we believe, unnecessary. These controls also present other problems for textiles, and it is my purpose here today to discuss some of these problems with you.

Let me begin by assuring you that the textile industry is not opposed to any and all government regulation per se. This industry's knee does not jerk automatically in violent reaction to all proposed regulation. We believe that "crying wolf" is not an effective way to participate in the political and social process in connection with government regulations.

We do believe, however, that we have a responsibility and an obligation to distinguish between good and bad regulation, both in our own self-interest and the interest of the nation. We also believe we have a duty to make our position known, often done at great expense, when we believe government restraints to be harmful. When a proposed new regulation, however commendable in purpose, would weaken our industry, put thousands out of work, or raise prices beyond people's ability to buy, we believe such a regulation should be most carefully scrutinized and discussed and, if necessary, adamantly opposed with all the vigor we command.

There are several such regulations now facing the textile industry.

The proposed new federal noise standard is an excellent example. The Occupational Safety and Health Administration--OSHA--has proposed a maximum noise level in textile plants of 90 decibels.

It may come as a surprise to some that the textile industry doesn't oppose this goal in principle. We agree that reduced noise levels reaching our workers would provide a more pleasant, safer and healthier working environment.

Where we part company with the regulators is on the means and the cost of achieving this end.

We have taken the position--a very realistic and defensible position--that there is practically no machinery now available which will operate to reduce noise levels in our weaving and spinning rooms to 90 decibels.

We have maintained, and still maintain, that it is presently technologically impossible to attain a 90 decibel standard by means of engineering controls. We have pointed out, even if present equipment were capable of

modification, that the cost would be an estimated \$3 billion. If present textile machinery had to be replaced, rather than modified, the estimated cost in the textile industry for meeting the standard would be \$13 billion.

Even the \$3 billion figure is far in excess of the textile industry's total annual expenditure for new plants and equipment. \$3 billion is also in excess of the industry's total net earnings after taxes. If the government required that this money be spent to convert existing machinery, assuming for the sake of argument this were always possible, hundreds of smaller textile companies would be forced to close. Thousands of people would lose their jobs, and textile growth would come to a standstill.

There is another solution. And it works. We can protect employees now, today, against excessive noise levels. We are already doing it. The method is costly. It involves personnel, time and careful administration. But, it works. It achieves the desired result of reducing textile worker exposure to harmful noise. This solution is a program of personal ear protection combined with a hearing conservation program. This method does not eliminate the noise, but it does prevent the noise from reaching the ears of our people. We are providing personal protective equipment by way of a relatively simple device--ear plugs. More, we are conducting audiometric tests on our employees, continuously measuring their hearing ability.

To us in textiles, this approach seems to be a most reasonable, practical and effective method of meeting the government's objective, pending the day when feasible machinery will be available.

Sometimes I get the feeling that bureaucrats themselves have a hearing deficiency. Our arguments about cost often seem to fall on deaf ears.

Let's take another example. The industry has a problem with cotton dust. It produces a reaction in a few people--by no means all--which causes respiratory difficulties. This condition is called byssinosis. Byssinosis is sometimes called "brown lung" and is unfairly lumped with "black lung," to which coal miners are subject. This is unfair because: there is a correlation between byssinosis and cigarette smoking; because not all cotton textile workers are susceptible to byssinosis; because byssinosis does not progress once a sufferer is removed from the harmful environment; and because the agent in cotton dust which causes byssinosis is not known.

Nevertheless, we want to get rid of byssinosis. So does the government.

OSHA believes the best way to get rid of byssinosis is to reduce the level of respirable cotton dust per cubic meter of air to point-two milligrams. Two-tenths of a milligram of cotton dust would barely fit on the head of a pin. Now imagine this amount of dust dispersed in a whole meter of air--a space larger than a cubic yard.

For the industry to meet the proposed standard of point-two milligrams, the estimated cost is \$2.8 billion--a frightening figure.

The great tragedy of this proposed standard is that it is so unnecessary. We can protect our employees against byssinosis. We are doing it now.

We are measuring the dust level in our plants. We are giving periodic respiratory tests to employees, and we are transferring those few employees who have respiratory problems to areas of our mills where cotton dust is not present. We are providing respirators to some workers. We are installing better filtration equipment.

ATMI has produced a work practices standard which has

been furnished to ATMI member companies, outlining a program of protective measures.

By these means, the industry has proven that textile workers can be effectively and adequately protected from byssinosis.

The textile industry has also taken it upon itself to discover the true prevalence and severity of byssinosis. More than 100,000 tests have been administered to cotton textile workers to determine both their subjective and objective symptoms. The results show that only one percent of textile employees have any such symptoms of the disease. Most of these are simply reactors. . . people who react to cotton dust as some of us react to pollen. Those employees who have any form of disability from byssinosis would be far below that one percent level. Our documented test results--some 2,600 pages--have been submitted to OSHA.

Yet, we still face a multi-billion dollar government imposed dust standard that is unnecessarily stringent.

One more example. The textile industry is required to make children's sleepwear flame resistant. It was the government that ordered the flammability standard, and it was ordered prematurely over the objections of the textile industry. We in textiles repeatedly informed the Congress and the Secretary of Commerce that the necessary technologies and tests for safety and toxicity did not exist. We documented the lack of technologies and cautioned against hasty action without time for thorough toxicity tests. Our pleas again fell on deaf ears.

Just recently, six years after our warnings, the government issued a ban on all children's sleepwear treated with the flame retardant chemical Tris. Tris was the only flame retardant chemical available for polyester at the time the flammability standard was adopted.

Companies in the textile industry did make every test they knew to insure that the flame retardant additives were both effective and safe. And, I repeat, we strongly urged the government to hold off implementing the flammability standard.

Now, because of government action, the industry is faced with an economic loss in the neighborhood of \$200 million. More important, the consumer faces confusion. Mothers are putting their children to bed in their underwear, in hand-me-downs, or in nothing at all.

We in textiles only hope that the consumer knows where the true fault lies and will direct her outrage where it truly belongs.

Each of these regulatory problems I've discussed--and some that I haven't touched upon--have several things in common. First, they are all commendable in their intent. Second, they also involve enormous sums of money, and ignore the damage to this industry of such outlays. Most of them call for technology that doesn't exist.

There is, I think, a third common characteristic of these regulatory problems which has been ignored, overlooked, and misunderstood by both government and most people in our country. That is the ultimate cost to the American consumer.

Suppose, for a moment, that all the proposed regulations affecting textiles were to become law. Imagine, too, that this industry actually spent the billions of dollars required to meet these regulations. Apart from the obvious disaster to the industry itself and its one million employees, what would the impact be on the public?

Obviously, there's no way to precisely measure the probable jump in the price of textiles. No doubt, it would

be astronomical. Just take one example. What happened to the price of children's sleepwear when the flammability rule went into effect? It went up an average of one dollar per garment. Taken by itself, that's not very much. Multiply it by all the children who wear nightwear, and that's still only a drop in the bucket compared to the total cost of this regulation.

Now, try to estimate the ultimate pass-along of the billions of dollars for water preservation, for noise control, for dust reduction, for energy conservation and all the other mandates of government. Who's going to pay?

The obvious answer is the consumer. But is that a correct answer? Suppose all textiles doubled or tripled in price. How many consumers could or would maintain their present buying patterns? How many would have to, or choose to, settle for less, perhaps far less?

No, I don't really expect this to happen, because I believe good, old-fashion common sense will have its say, and we will reach at least some sensible compromise with the government.

This will not happen, however, until the American people become aware of the costs of regulations, and until they recognize the trade-offs involved in cost and a reduced standard of living.

It would be wonderful to have perfectly clear water and pure air. It would be wonderful to have absolutely silent, totally dust-free textile plants which had zero impact on the environment and where no potentially dangerous chemicals were in use, and where everything could be produced without energy. That's idealism at its highest.

But, we must contend with reality. We must participate in the regulatory process without being automatically against all regulation. We must inform the public that compliance with regulations, no matter how beneficial they are, will cost money and the consumer will ultimately pay the tab. Unless we convey this credibly and clearly, the people of this nation will not be in a position to make informed judgements. . .to decide between benefit and cost.

We in the textile industry will continue to cooperate with government in the process of making this nation a better place in which to live and work. We will oppose excessive and unnecessary government regulation. We will point out the effects of bad regulations.

And, when a regulation is good, we will help find ways to make it work.

George B. Sproles, University of Houston
Loren V. Geistfeld, Purdue University

Abstract

This paper presents some major issues and relevant descriptive research findings on consumer satisfaction and dissatisfaction with clothing and textiles. Emphasis is placed on the issues of identifying general levels of consumer satisfaction/dissatisfaction (CS/D), CS/D across specific clothing and textile products, CS/D across general product categories, CS/D with specific product characteristics, identifying the dissatisfied consumer, types of consumer complaints, effects of regulation on CS/D, and consumer satisfaction vs. consumer efficiency. Based on general findings it is estimated that approximately 1 in 5 consumers can indicate dissatisfaction with clothing at any given time, but only a small proportion of those dissatisfied consumers will actually register complaints.

Introduction

A growing amount of recent literature has focused on the problems of defining, conceptualizing and measuring consumer satisfaction/dissatisfaction (CS/D) with products and services. Representative of current approaches to these general issues is a recent collection of papers from a conference conducted by the Marketing Science Institute under sponsorship of the National Science Foundation (Hunt, 1977). The topic has also frequently appeared on programs of the Association for Consumer Research, and was recently the focus of a workshop held at the Indiana University School of Business. These concerted efforts, as well as many individual efforts preceding them, has begun to identify the theoretical, methodological and philosophical issues surrounding investigations of consumer satisfaction and dissatisfaction. The major result is that a relatively well-defined topic area of CS/D is now properly entering the mainstream of contemporary consumer sciences.

This paper will review many of the major issues which can be raised in analyzing CS/D, focusing specifically on the area of CS/D with clothing and textiles. Though many of the general issues regarding CS/D have been identified in recent publications (i.e. Hunt, 1977), it appears that only a limited number of inquiries have focused on the fundamental problems of CS/D within specific product categories such as clothing and textiles.¹ However, it is within such a framework of specific products where the analysis of consumer behavior becomes most meaningful, especially to the pragmatically-focused interests of marketers, public policy makers, consumer affairs professionals and not least of all the ultimate consumer.

There are two specific objectives of this paper. First, we will identify key issue areas related to analyzing CS/D with clothing and textile products. Each identified issue is selected as a key issue because it is a current area of interest among policy makers, business-

men, consumer advocates or researchers. Second, for each issue area we will summarize some recent research and substantive general findings which answer questions raised by the issue. While our emphasis is on clothing and textiles, many of the issues and points discussed are general in nature and can therefore be very relevant to the analysis of consumer satisfaction and dissatisfaction with other categories of consumer products and services.

An Overview of Key Issues

Many issues and sub-issues can be identified. In this paper we will focus on these key areas: 1) What is the magnitude of consumers' general satisfaction and dissatisfaction with the overall product category of clothing and textiles? Sub-issues under this general issue would include CS/D with general prices/price trends, levels of quality, styles/assortments available, types of stores retailing the products, sizes available and so on. Another major sub-issue can focus on identifying the major component parts of the clothing-textile system which are most likely to cause consumer satisfaction or dissatisfaction (i.e. performance of fibers, fabrics, construction, seams, buttons, zippers or other major component parts). 2) To what extent are consumers satisfied with specific products (i.e. jeans, shirts, suits)? Are certain classifications of merchandise more subject to CS/D than others (i.e. categories of men's, women's and children's wear)? 3) How satisfied/dissatisfied are consumers with clothing and textiles as compared to other major product and service categories? Is dissatisfaction relatively more or less serious than in other product categories? 4) What product characteristics of the clothing - textile system in its actual end use are most likely to result in consumer satisfaction or dissatisfaction over the "wear life" of the product? For example, will CS/D result from changes of style-fashionability, economy, ease of care, durability, comfort, dimensional stability or other expectations regarding performance of the product? 5) Who are the dissatisfied consumers? Do they have a unique profile in terms of general orientations toward consuming clothing, lifestyle, and demographic characteristics? 6) What types of clothing and textile complaints are actually registered with retailers and/or manufacturers? How satisfactorily are these handled? What are the principal reasons for those complaints? To what extent does the complaining behavior of consumers represent actual levels of satisfaction/dissatisfaction in the market? 7) How do governmental regulations of clothing and textiles affect CS/D? To what extent is federal regulation more effective than voluntary self-regulation by industry in providing ultimately for consumer satisfaction? 8) Should the clothing and textile market (or any sub-market) be considered to be performing efficiently (or in the consumer's or society's interest) if consumers are satisfied? Is CS/D a legitimate criterion for assessing market performance? Or can a market be performing poorly even when consumers are satisfied? What are the implications for policy makers?

Each of these issues will be briefly discussed in turn. Our treatment of these issues is not meant to be exhaustive, but rather is designed to introduce some major questions and current thought in each area.

¹Several papers in Hunt (1977) focused on housing and foods, and several basic issues relative to those products were conceptualized. See papers by Hempel, Morris, and Handy in that volume.

General Indicators of CS/D

A variety of recent investigations have provided broadly general indications on the magnitude of consumers' satisfaction/dissatisfaction with clothing and textiles. Research conducted by Sproles under sponsorship of the Indiana Cooperative Extension Service has examined a variety of clothing orientations among adult women living in Indiana (Sproles, 1977). The purpose of the investigation was to survey women's interests/priorities in consuming clothing, information seeking behaviors, and purchasing behavior. A number of aspects of this study focused specifically on issues related to CS/D.

The study involved administering a mailed eight page questionnaire to a stratified random sample of 2,000 households in Indiana. The questionnaires were mailed to the adult female head of each household, and two

follow-up mailings including a postcard reminder and a second copy of the questionnaire were used to increase response rates. A total of 989 complete and usable questionnaires was returned. This sample was found to be demographically representative of households in Indiana (and in the U.S. as a whole), with the exception that older and lower income groups were not fully represented. A more complete discussion of the methodology can be found elsewhere (Sproles, 1977).

Our principal interest is with those findings dealing with CS/D. Of the 150 measures included in the survey, approximately 30 dealt either directly or inferentially with general issues of CS/D. Table 1 includes findings for selected Likert-scaled items measuring consumer interests and priorities regarding clothing in general. These items appear to be relevant to satisfaction/dissatisfaction in particular.

TABLE 1

SOME GENERAL INDICATIONS OF CONSUMER SATISFACTION/DISSATISFACTION WITH CLOTHING

INDICATORS	Percent Responding					
	No Response	Strongly Disagree	Disagree	In-Between	Agree	Strongly Agree
Indicators of Satisfaction:						
<u>I usually have one or more outfits of the very latest style.</u>	.2	5.1	19.9	29.4	36.4*	9.0%*
<u>I keep my wardrobe up-to-date with the current fashion.</u>	.6	6.7	19.8	51.0	19.0	2.9%
<u>I am very well informed about current clothing and fashion trends.</u>	0	5.4	17.5	40.8	26.8	9.5%
<u>To me, shopping for clothes is a pleasure.</u>	.1	4.3	15.4	30.4	34.4	15.4%
Indicators of Dissatisfaction:						
<u>Keeping up with changing fashions is too expensive.</u>	.1	2.5	7.7	19.5	37.7	32.5%
<u>I carefully watch how much I spend on clothes.</u>	.7	1.4	3.1	16.1	41.6	37.1%
<u>In general, the quality of clothing in the stores is lower than in the past.</u>	1.0	6.9	15.3	17.8	29.4	29.6%
<u>People are too concerned about their dress.</u>	1.0	6.7	24.7	32.7	23.8	11.2%
<u>Buying clothes out of catalogs without actually seeing them, is too risky.</u>	.4	4.9	14.9	19.6	29.8	30.4%
Indicators of Priorities for CS/D:						
<u>Clothing style is more important than price.</u>	.7	12.1	26.0	30.8	20.8	9.5%
<u>Clothing comfort is more important than style.</u>	.7	.6	3.8	25.6	47.1	22.1%
<u>Clothing quality is more important than price.</u>	.8	1.7	6.8	30.3	42.2	18.2%
<u>Clothing quality is more important than style.</u>	.6	1.9	9.5	38.3	37.6	12.0%

*Read: Of a sample of 989 women in Indiana, 9.0% "strongly agreed" with the statement at the left, 36.4% "agreed" with the statement at the left, etc.

The first three items in Table 1 give an indication of consumer satisfaction with current fashions. These items would appear to imply that perhaps less than 10 percent of consumers would qualify as being highly satisfied with current fashions, though it would also appear that one-third or more of consumers could be considered at least more satisfied than dissatisfied.

The last indicator of satisfaction in Table 1 relates to satisfaction with shopping for clothing. This item indicates that consumers are for the most part pleased with their experiences in shopping for clothes.

The next five items of Table 1 can be classed as indicators of consumer dissatisfaction with clothing and textiles. Collectively these five items imply a substantial degree of general dissatisfaction with clothing in one-third or more of the adult female population. The respondents clearly see changing fashions as expensive, and they view the quality of clothing as lower than in the past. Responses to the item "People are too concerned about their dress" may indicate a dissatisfaction with the social pressures toward conformity in dress. Finally, the last item suggests that many consumers would perceive substantial risks of dissatisfaction with clothing purchased "blind" from catalogs.

The last four items in Table 1 can be termed indicators of priorities for consumer satisfaction/dissatisfaction. Items similar to these can be used to interpret general trends in the determinants of consumer satisfaction. For example, the four items appear to suggest that many consumers would place priority on clothing comfort and "quality" over style and price in judging their satisfaction with clothing and textiles.

Table 2 summarizes problems with clothing reported by consumers participating in the study. The table clearly indicates a great proportion of consumers have experienced dissatisfaction with major physical features or performance characteristics of garments. The most significant area of problems appears to be in construction, with 68 percent of the respondents reporting recent experiences with seams tearing apart. Also notable is the fact that 52 percent reported "lower overall quality" to be a problem with recently purchased clothing.

Table 3 presents consumers' ratings of the importance of selected criteria in influencing their purchases of women's outerwear. The overall findings of this table are that many styling, performance and price features are often or always important to consumers. Only marketing and shopping factors (i.e. brand name, salesperson's advice) and the "most current fashion" were rated important by a small proportion of consumers, and even these factors were clearly important to as much as one-quarter of the subjects. Probably the most important contribution of these findings is to show that most consumers' expectations regarding their clothing and textile purchases are extremely high. They expect their purchases to be almost "perfect" over a wide range of characteristics, and it is not hard to imagine that consumer dissatisfaction could result with frequency under such high expectations.

Several other recent studies provide general indications of CS/D. A recent paper by Plummer (1977) reports findings of a series of studies using items similar or identical to those in Table 1. Different surveys using these items were conducted longitudinally from 1967 to 1975. Table 4 summarizes the percentage of subjects agreeing with each statement for each survey. Each of the three items indicates a clearly declining trend of agreement over the years. Plummer interprets these items to indicate that shopping is becoming more of a "hassle" and that consumers are becoming more casual in their attitudes/approach to dress. He also suggests that measurement of such trends should be a part of a

TABLE 2
PROBLEMS WITH CLOTHING PURCHASED
IN THE PAST YEAR

	PERCENT OF CONSUMERS REPORTING PROBLEM
Poor fit	48%
Fabric wearing out too quickly	40
Colors fade in washing	33
Cleaning instructions not easy to understand	11
Seams tear apart	68
Mistakes in construction	57
Shrinkage when washed	44
Zippers not working	40
Lower overall quality	52

Note: Respondents were allowed to check as many problems as they had experienced.

TABLE 3
IMPORTANCE OF SELECTED CRITERIA IN
CLOTHING PURCHASING DECISIONS:
WOMEN'S OUTERWEAR

CRITERIA FOR CLOTHING PURCHASING DECISIONS	PERCEIVED IMPORTANCE OF SELECTED CRITERIA		
	Seldom or Never Important	Sometimes Important	Often or Always Important
<u>Styling</u>			
Style looks good on my figure	0.5*	2.4*	96.7*
Color of the garment	0.9	10.8	87.9
Pattern or design of the fabric	2.8	11.8	84.7
Conservative styling	8.3	27.4	63.8
The most current fashion	30.7	43.2	25.6
<u>Product Features</u>			
Comfort of the garment	.4	2.0	97.0
Ease of care (washing, cleaning)	1.1	4.4	93.9
Quality of construction	1.5	4.4	93.2

broad framework for analyzing CS/D from a variety of perspectives.

A series of consumer surveys conducted in Syracuse, N.Y., have examined a variety of dimensions of CS/D with both clothing and home furnishings. In the first study involving a sample of 193 returns from a mail survey, Steiniger and Dardis (1971) found most respondents were satisfied with the performance of clothing and textiles. Over 70 percent of subjects were above average in satisfaction, and only 10 percent were below. However, although considerable satisfaction was noted, respondents still reported many problems with durability, appearance, ease of care, and comfort. Sixty-seven percent of the problems with both clothing and home furnishings were associated with durability. These were predominantly in construction of fabric failure (i.e. pilling, seam tears, worn areas), and to a much lesser extent problems with fabric stretching, shrinking, or color change. Finally, a substantial number of consumers mentioned poor performance of "no-iron" clothing and difficulty in cleaning home furnishings.

The second Syracuse study focused on home furnishings made from textiles, and involved a sample of 908 responses to a mailed questionnaire. In this study Nichols and Dardis (1973) found 66 percent of the respondents to be relatively satisfied with their purchases of home furnishings during the past years. However, as in the previous study there were a substantial number of problems reported among dissatisfied consumers who were identified. The majority of those problems (53 percent) involved appearance and ease of care (i.e. soiling, difficulty in cleaning, color changes), while 24 percent were problems of durability. Finally, it is especially notable that some dissatisfaction was expressed for one-fourth of all items purchased.

A follow-up survey was conducted on the 280 dissatisfied consumers in the preceding study. In this follow-up 50 percent of the subjects indicated dissatisfaction with wear and durability, and 44 percent indicated dissatisfaction with appearance and ease of care. This divergence from the earlier findings was explained by the fact that the follow-up focused only on those consumers who reported dissatisfaction, while the previous findings included "satisfied" consumers who still reported "problems". Presumably the problems reported by satisfied consumers were not extremely serious. It would therefore appear that the main concern of the dissatisfied consumer is with durability.

The preceding studies give some broad indications of consumer satisfaction and dissatisfaction with the generic category of clothing and textile products. A number of studies have also focused on analyzing CS/D with specific classifications of merchandise and specific items of clothing. A variety of research approaches ranging from surveys to actual consumer wear tests have been conducted, and the following paragraphs will summarize some approaches and findings of these investigations.

A series of major surveys of consumers' perceptions of "value for the money" received in today's market has been conducted by National Family Opinion, Inc., under sponsorship of The Conference Board (Linden, 1974). The 1974 survey included questions on 45 different products and services, and was administered to a representative sample panel of 10,000 households. Panel members were asked to report if value for the money was "good," "average" or "poor" for the various products and services. Table 5 summarizes findings for clothing and textiles. As Linden (1974) points out, these data show clear dissatisfaction with the value received in clothing and textiles. Of special interest presently is the wide variation in dissatisfaction from one general classification to the next. Men's clothing appears to offer the most satisfaction, but both women's and children's clothing are rated a "poor" value by about half the sample. Regarding home furnishings, satisfaction with carpets is highest for all textile products, but satisfaction with upholstered furniture is comparatively low. Finally, Linden notes a decline in consumer satisfaction with each category as compared to a similar survey conducted a year earlier (Linden, 1974).

Another perspective of CS/D with specific lines of clothing and textiles is offered in research by Hughes (1977). He focused on analyzing consumers' satisfaction with specific purchases reported by a sample of 928 consumers in a large midwestern city. Table 6 summarizes some key findings. In general, about 80 percent of consumers were completely satisfied with their purchases. However, satisfaction clearly varied by lines of merchandise. For example, about 95 percent of the purchasers reported complete satisfaction with men's dress slacks, while only 74 percent were completely satisfied with women's jeans. But perhaps the most significant findings are in the relation between price paid and consumer satisfaction. For 16 of the 22 purchase classes, people who had lower than average satisfaction with their purchases reported a distinctly lower average price paid than those who were completely satisfied.

TABLE 5

CONSUMERS' PERCEPTIONS OF VALUE RECEIVED FOR THE
MONEY IN SELECTED CLOTHING AND TEXTILE PRODUCTS, 1974

CATEGORY	PERCENT RESPONDING		
	Good	Average	Poor
Men's Suits	10.0	61.7	28.3%

Bedspreads	222	78.8	25.07	21.32

Source: Hughes (1977, pp. 314,315,331)

One of the most direct ways of measuring consumer satisfaction with specific products is by conducting actual consumer wear tests. A wear test involves use of a panel of consumers who are given selected brands of a product to actually wear for a period of time, with evaluations of performance made at different stages of the wearings. Such studies are frequently conducted by home economists and industrial producers of products. For example, a study by Stover (1972) focused on consumer satisfaction with durable press shirts, and found that consumers were most satisfied with lighter weight polyester/cotton blends in shirt fabrics. Similarly, a study of consumer acceptance of flame retardant sleepwear, Laughlin and Buddin (1977) found consumers preferred a 65/35 percent blend of cotton/polyester over other tested fabrics.

Such wear test can ultimately have the most "face validity," since consumer satisfaction is actually based on measuring consumers' actual use of the product under controlled experimental conditions. This is one reason why such studies are frequently conducted. However, wear studies have some limitations. In most cases it can be either prohibitively expensive or time-consuming to wear test a complete array of competitive products with a large enough sample of consumers to be statistically representative of the market. Further, a complete wear test may take a long period of time, since the subject must actually wear the garment in his or her "normal" manner. In spite of these obvious limitations, wear tests are thought to be beneficial in forecasting consumer satisfaction, and will continue to be used as a measure of satisfaction.

CS/D Across Product Categories

The next issue which naturally arises focuses on the degree to which consumers are satisfied/dissatisfied with clothing and textiles in comparison to other major categories of consumer products and services. One viewpoint

holds that clothing and textiles is not a principal area of concern in comparison to other areas of consumer problems. For instance, Margolius (1975) has indicated that major problems faced by consumers include higher costs of food, medical care, housing, loans, repairs, and autos, but clothing and textiles are not mentioned. Furthermore, the recent Sentry Insurance study (1977) of consumer issues surveyed numerous consumer concerns and found considerable general concern with prices, qualities, and consumer information, but clothing and textiles was never specifically identified as a problem area. These examples might imply that in the arena of CS/D, there is bigger game than clothing/textile products.

It is quite plausible that many areas of consumer problems deserve higher priority than consumer dissatisfaction with clothing and textiles. Nevertheless, there is some evidence that consumer dissatisfaction with clothing and textiles is more substantial than for many other categories of products and services. For instance, in the National Family Opinion study introduced earlier, consumer satisfaction with women's dresses, children's clothing shoes and upholstered furniture was substantially lower than average satisfaction for all items (Linden, 1974). Most items of foods (meats and fresh vegetables), appliances, transportation, life insurance, and TV rated substantially higher than clothing and textiles in general, and only repairs consistently rated lower. Only the categories of men's suits and carpets rated above the average for all items.

A few other studies give some general indications of CS/D across product categories. In one study reported by Plummer (1977), consumers offered judgments on whether or not product quality had improved in the past 20 years. A total of 50 percent of respondents reported clothing as "not as well made." In comparison, products receiving a larger proportion of "not as well made" ratings were houses (77 percent) and autos (70 percent), and those

receiving a lower proportion were household appliances (34 percent), small appliances (31 percent), and TV sets (20 percent). In a 1975 study cited by Plummer (1977, p. 387), clothing was rated as an excellent or good value for the money by 27 percent of consumers. In comparison, lower rated products were gasoline (12 percent), prescription drugs (21 percent), and automobiles (22); higher value for the money ratings went to electrical appliances (37 percent) and fresh foods (39 percent). Data from the Hughes (1977) study also indicate that consumers are generally more satisfied with certain major purchases (i.e. TV, washer, dryer), but for other major purchases the proportion of satisfied purchases generally equals averages for clothing (i.e. furniture, stoves, mattresses, refrigerators, tires, batteries). Finally, in a study by Pfaff (1976), clothing, food and "standard of living" were virtually tied in consumers' ratings of overall satisfaction, but satisfaction with appliances was significantly higher. The conclusion which follows from these studies is that clothing satisfaction among consumers suffers in comparison to a variety of other major purchases, though it is far from being the "worst" area of consumer dissatisfaction.

CS/D With Product Characteristics

Little recent published research has focused on consumer satisfaction as a function of specific product characteristics (attributes) such as styling, durability, ease of care and so on. However, some general principles have become established. Previous investigations by home economists have suggested that for clothing to be satisfactory it must rate high on the product characteristic (s) most important to the consumer, and it also must meet certain "minimum" expectations on other characteristics (Ryan, 1966, pp. 147-152, 178-187). In other words, the consumer must in most cases be relatively satisfied across a number of product characteristics in order to receive overall satisfaction. See Table 3 for current evidence on this point.

Another general principle has been reinforced in a recent exploratory investigation by Swan and Combs (1976). They focused on the contrasting roles of instrumental and expressive product characteristics in influencing CS/D with clothing. Instrumental characteristics were defined as those involving physical performance of the product (i.e. durability, ease of care), while expressive characteristics were related to "psychological" levels of performance (i.e. styling, fashionability). It was found that dissatisfaction with clothing was likely to occur when instrumental characteristics did not meet the consumer's expectations, while satisfaction was most associated with fulfilled expressive expectations. The findings also suggested that the consumer's instrumental requirements must be satisfied before expressive requirements if overall satisfaction is to occur. The major implication of these findings is that:

In judging the performance of a product, the consumer compares a set of performance outcomes to the outcomes that were expected for the item. If the performance of the physical product was below expectations, then the product is likely to be categorized as dissatisfactory. If both instrumental and expressive outcomes were equal to or exceeded expectations, then the consumer will tend to judge the product as satisfactory. (Swan and Combs, 1976, p. 33)

Findings cited earlier in this paper, which showed consumer dissatisfaction to focus mainly on physical performance failures (i.e. failures in construction, durability, ease of care) would seem to lend further support to this proposition.

Identifying the Dissatisfied Consumer

The varied studies we have reviewed indicate a substantial proportion of consumers may be dissatisfied with different aspects of their clothing and textile purchases. Who are these consumers, and what are the characteristics of consumers who are most likely to voice their complaints? There are several studies of consumer dissatisfaction which indicate the dissatisfied consumer has some important characteristics. For example, studies by Liefeld, Edgecombe and White (1975) and Warland, Hermann and Willits (1975) suggest that the consumer who voices dissatisfaction with a purchase is well educated, young, relatively high in income, and above average in social class and group membership. Furthermore, it was found that there are some characteristics of those who experience dissatisfaction but do not voice it. These consumers, according to Warland, Hermann and Willits (1975), are lower income, less well educated individuals who are not involved in consumer and political activities. This finding is supported by Best and Andreassen (1976), who found that households in lower socioeconomic classes tend to perceive fewer problems with their purchases of goods and services and voice their dissatisfaction less frequently than do consumers in higher socioeconomic classes.

However, a number of studies have found that dissatisfied clothing and textile consumers have no distinct demographic or socioeconomic characteristics (Linden, 1974; Nichols and Dardis, 1973; Steiniger and Dardis, 1971). Though some of these findings modestly imply that dissatisfied consumers are in higher income and educational groups, it appears for the most part that dissatisfied clothing consumers are found in all ages and levels of the consumer population.

A preliminary analysis of data from the study of clothing orientations among adult women in Indiana conducted by Sproles (1977) gives more evidence on characteristics of dissatisfied consumers. To conduct the analysis, a general index of consumer dissatisfaction with clothing was formed for each subject by summing four indicators of dissatisfaction presented earlier in Table 1 (the item "I carefully watch how much I spend. . ." was not included in the index). The index was divided into subjects scoring "high" (top one-third of scorers) and those scoring "medium to low" (remainder of subjects). These two groups were cross-tabulated against 27 clothing interests/priorities measures, 24 lifestyle activities, 15 purchasing criteria, consumption indexes for sewing and purchasing, fashion interest, and 11 demographic and socioeconomic measures.

Findings of this preliminary analysis tentatively indicate that the dissatisfied consumer is no different from other consumers in lifestyle activities, demographics and socioeconomic characteristics. There were some tentative indications that the dissatisfied consumer might be concentrated toward younger, middle income groups, but this finding was not significant. It was also found that dissatisfied consumers are no different from other consumers in their level of consumption (purchasing and sewing of clothing). However, it was found that dissatisfied consumers differed significantly from others on a variety of clothing interests and priorities. Specifically, dissatisfied consumers were more likely than others to agree with a variety of statements indicating they are generally price and quality conscious. There were also indications that dissatisfied consumers may be lower in fashion interest than others. Finally, they were significantly more likely than others to rate the specific purchasing criteria of garment cost, choosing garments that wear for a long time, and comfort of the garment as "always important." In short, there appears to be a substantial orientation toward economy-consciousness and quality-consciousness among those consumers who are most likely to report dissatisfaction with clothing.

Types of Consumer Complaints

It is an accepted principle that although many consumers may be dissatisfied with the performance of a product, few will actually submit a formal complaint seeking redress to either the retailer or manufacturer. Nevertheless, those complaints which are actually voiced are frequently thought to be at least modestly representative of the problems consumers actually experience with products and services. Thus actual voiced complaints can be viewed as potential indicators of market performance, areas needing the attention of producers, and problems requiring governmental intervention (regulation) of markets.

It is first useful to summarize some of the major areas in which consumers will voice complaints about products and services. In a broad study of all types of product/service complaints made by consumers, Diamond, Ward and Faber (1976) found that 14 percent encountered a pre-purchase problem, 27 percent experienced a purchase/transaction/delivery problem, 17 percent were unhappy with product performance, 17 percent encountered a guarantee/warranty/contract problem, 26 percent were unhappy with the service/repair rendered and 4 percent encountered a problem with deposits/credit/collections. Of these complaints 34 percent involved specific retail outlets with about 9 percent, each, of these complaints directed towards department stores, clothing stores and discount stores.

In what is perhaps the most comprehensive recent study of consumer dissatisfaction with market performance and subsequent complaining behavior, Best and Andreasen (1976) found that 83.4 percent of the respondents were completely or partially satisfied with their clothing purchases while 13.9 percent experienced some degree of dissatisfaction. When the respondents were asked what types of problems they experienced with clothing purchases, slightly over 6 percent indicated price-related problems while about 28 percent indicated non-price problems (principally problems with product performance). Best and Andreasen note further that across all product and service categories analyzed, 3.1 percent of the perceived problems related to shrinking or fading, 23.2 percent to workmanship, 7.1 percent to fit or size and 6.2 percent to stitching. With respect to clothing, 7.7 percent of all purchases resulted in problems related to poor workmanship, 9.7 percent to price and 30.4 percent to other types of problems. Of those clothing consumers who experienced problems with a purchase, 65.8 percent took no action, 7.0 percent changed shopping patterns, 26.0 percent voiced their problem to the seller and 1.0 percent voiced their problem elsewhere. For those consumers who voiced their dissatisfaction with clothing purchases, 75.3 percent achieved satisfactory redress of their problem while 18.7 percent considered redress received as unsatisfactory. (Best and Andreasen, 1976, pp. 16, 27, 42, 89)

Other investigations have indicated that although consumers may experience dissatisfaction with purchases, only a small proportion will actually register complaints. For example, Steiniger and Dardis (1971) found 56 percent of respondents to a mail survey cited specific performance problems with clothing and linens, but less than one in four of these consumers (23 percent) actually registered complaints. Complaints which were registered centered on problems with durability (73 percent of complaints, on specific problems of construction, stretching/shrinkage, color changes), with appearance and ease of care being the other major problem area (23 percent of complaints). Similarly, of the 34 percent of respondents reporting problems with home furnishings, less than one-fourth (22 percent) registered complaints. For this category complaints also centered on durability (79 percent), with appearance and ease of care being the other major problem area (15 percent).

The more recent study of consumer satisfaction with home furnishings by Nichols and Dardis (1973) further confirms the preceding findings. Just over one-fourth of the dissatisfied consumers registered complaints, with problems relating to durability, appearance and ease of care being predominant. More than half of the complainants were not satisfied with the store's action taken, and most of those who did not complain indicated they felt nothing would be done or it was too much trouble to complain. Finally, they found that the higher the price paid for an unsatisfactory item, the more likely the consumer will register a complaint. This very important finding is consistent with general findings of other researchers (Best and Andreasen, 1976).

Effects of Regulation on CS/D

In the past consumer satisfaction/dissatisfaction with clothing and textiles was probably based primarily on the degree to which products met the consumer's expectations on characteristics including fashionability, quality and economy. However, with the recent growth of market regulation such areas as product safety, product labeling and product warranties have been legitimately installed as criteria for CS/D. However, for these and many other regulatory issues there is currently little empirical evidence indicating the impact of regulations on CS/D with clothing. Nonetheless, we may hypothesize as to how CS/D is influenced.

Perhaps the most controversial issue in regulation involves the safety of clothing products. Recent concerns with fabric flammability and carcinogenic chemical finishes (i.e. the TRIS case) have been dominant in the clothing trades and have received a great deal of publicity. In the past the safety of such items as "platform" shoes and loosely fitted clothing has been questioned both by consumer advocates and medical authorities. At the very least the publicity received by these and other topics has increased consumers' awareness of new clothing problems which involve personal health. This may lead to a variety of results, i.e. fear of the product, fear of specific brands, boycotting of products, and even a general suspicion of clothing products. The ultimate result can be increases in consumer dissatisfaction with the current market.

Product labeling is another current issue among consumer interests. In this area the prospects are that the growing emphasis on informative labeling, both by government and industry, will lead to greater consumer satisfaction. The recent Sentry Insurance study (1977) found that about 18 of every 25 consumers believe there has been an improvement in informative labeling of products. From another perspective, in a survey of consumer attitudes toward nutritional (content) labeling Lenahan et. al. (1972) found that 96.5 percent of the respondents felt nutritional labeling was a good idea, 50.9 percent said they use or would use the labels while 9.2 percent actually used them; however, about 85 percent of the respondents indicated there were positive nonuse benefits, i.e. nutritional labeling would enhance consumer confidence in the food industry, thus increasing satisfaction. Extrapolating these findings to informative labeling for clothing, it is likely consumers would perceive a clothing market with readily accessible informative labeling as presenting a less hostile environment in which to operate regardless of whether or not they actually used the informative labels. Therefore, one could expect informative labeling to reduce the incidence of consumer dissatisfaction, and increase satisfaction.

In the area of informative product labeling, care labeling of clothing and textiles has recently been the central area of concern. Research by Steiniger and Dardis (1971) has indicated informative care labels and tags on clothing can increase consumer satisfaction, probably

because those using the information can minimize damage done to the product in care and cleaning. However, there has recently been extensive discussion as to whether regulations governing permanent care labels attached to clothing and textiles have been a success or failure (Powderly, 1976). Generally the information on care labels has been found to be clear but incomplete, and more detailed instructions have been called for. There has also been a problem with "low labeling," which can mislead a consumer by suggesting one care method when another easier or less costly method might work just as satisfactorily. As a result of these types of problems with care labels, the Federal Trade Commission is currently recommending some major changes in labeling regulations.

Warranties are a third area of general concern, especially since the Magnuson-Moss Warranty Act of 1975 was passed. Only a very few major textile fiber and clothing manufacturers offer what is overtly named a "warranty," but many retailers make it a promoted policy to accept returns of unsatisfactory merchandise. However, there is some question as to whether such warranties can increase satisfaction, and in some cases their effect may be to decrease satisfaction. For instance, the Sentry Insurance study (1977) found over one-half of all consumers surveyed felt warranties were inadequate, nearly fifty percent felt warranties were written mainly for the protection of manufacturers, and more than one-half felt warranties were not understandable. Further, as Gerner and Bryant (1977) have noted, for those manufacturers who have below average warranties, there may be an increase in dissatisfaction. Thus it might seem that if providing consumer satisfaction is a major reason for offering a warranty, some manufacturers or retailers might actually not offer warranties in order to avoid the risks of causing consumer dissatisfaction. It can also be noted that the legal restrictions on warranties, which have been viewed as confusing or complex by many businessmen, might only further encourage that trend. Certainly such results would diminish the force of warranties as an ultimate guarantee of consumer satisfaction.

As indicated earlier, the preceding observations must have the flavor of speculation, for only a limited amount of sophisticated research on the effects of these and other regulatory policies has been done. It should also be pointed out that many actions regarding safety, informative labeling and warranties are voluntarily taken by manufacturers either as a competitive marketing strategy or for other related reasons. Thus more attention to these issues is required, to measure the effectiveness of various voluntary business policies vs. mandatory regulations in providing consumer satisfaction.

Consumer Satisfaction Vs. Consumer Efficiency

The last issue we will briefly introduce regards the extent to which consumer satisfaction implies that a consumer is performing efficiently in choosing products available in the market. As we have noted elsewhere (Sproles, Geistfeld and Badenhop, 1977) the concept of consumer efficiency implies that consumers obtain the maximum possible satisfaction (utility) given available resources. This concept sets a norm against which observed consumption (satisfaction) can be evaluated. Underlying this notion of consumption efficiency is an implicit assumption that consumers operate under full information. Once this is recognized, it becomes apparent that consumer indication of satisfaction with experiences in the marketplace is only a necessary but not a sufficient condition for the existence of consumption efficiency. If perceived satisfaction were based on ignorance, it is possible that upon removal of the ignorance the consumer who once indicated satisfaction may no longer be satisfied. The policy implications of this

are quite clear. If a consumer indicates dissatisfaction consumption efficiency has not been achieved and corrective action may be warranted. If a consumer indicates satisfaction, the extent to which this may or may not indicate consumption efficiency depends upon how stable perceived satisfaction is upon providing additional information. Should perceived satisfaction prove to be unstable, corrective action may also be warranted.

Conclusion

A number of descriptive studies indicate that consumer dissatisfaction with clothing and textiles is widespread, and that this product category may cause greater consumer dissatisfaction than many other major product categories. As a general and perhaps conservative estimate, it would appear that at any given time 1 in 5 consumers (20 percent) is aware of and can report a specific dissatisfaction, usually involving a physical performance characteristic. However, only a small proportion of the dissatisfied consumers, probably less than 1 in 4, may actually register a complaint with the retailer or manufacturer. Thus complaints may not reflect the full magnitude of consumer dissatisfaction, though they may be a proxy measure of the types of problems consumers frequently find dissatisfying.

It would appear that improvement of consumer satisfaction might be made through several strategies. Consumer educational and informative labeling programs could be used to disseminate appropriate information needed by consumers to make satisfactory decisions. In some cases regulation might be warranted to insure all manufacturers and retailers would offer products fulfilling selected critical criteria (i.e. safety, information on product care/use). Finally, programs of voluntary and/or mandatory product standards which are receiving increased discussion in clothing and textile trades (i.e. see ASTM Standardization News, December 1976) may be the long-run solution to problems of product performance and associated dissatisfactions which consumers now report.

There have been a number of exploratory and descriptive research investigations on the issues we have raised. However, more quantitative findings are needed on a number of the issues before well-founded policies can be implemented by either government and business. But researchers should also be warned of the conceptual and methodological difficulties involved in measuring the phenomenon of CS/D (Hunt, 1977).

THE PROCESS OF SETTING STANDARDS AND SOME
CURRENT ISSUES IN STANDARDS

L. J. Sharman
Consumer Product Safety Commission

Abstract

Each year an estimated 21 million Americans are injured in accidents in and around the home. The Consumer Product Safety Commission was formed by Public Law 92-573 with the objective of providing safer consumer products. Using the Flammable Fabrics Act as a basis, textile flammability standards now in effect are outlined and factors relating to their development discussed. Current Commission activities are reviewed.

Each year an estimated 21 million Americans are injured in accidents, including flammability accidents, in and around the home; 100,000 are permanently disabled; and 26,000 are killed. Many of these are product related. The economic and social cost to the Nation has been projected at \$5.5 billion. The urgent need for Federal Regulations to insure safe Consumer products was clearly recognized by Congress when it passed the Consumer Product Safety Act. That act, public law 92-573 was signed into Law by the President, October 1972.

The purposes of the Consumer Product Safety Act stated in the law, are:

- To protect the public against unreasonable risks of injury associated with consumer products;
- To assist consumers to evaluate the comparative safety of consumer products;
- To develop uniform safety standards for consumer products and to minimize conflicting state and local regulations; and
- To promote research and investigation into the causes and prevention of product-related deaths, illnesses and injuries.

To fulfill these purposes, the Consumer Product Safety Act created a new independent federal regulatory agency, the Consumer Product Safety Commission. This Commission headed by five Commissioners came into being in May 1973.

The Consumer Product Safety Act is a new and broader approach to product safety. The act also provided that many consumer product safety regulatory functions originally assigned to other federal agencies were transferred to the Consumer Product Safety Commission. The acts transferred were the Flammable Fabrics Act, the Federal Hazardous Substance Act, the Poison Prevention Packaging Act and the Refrigerator Safety Act.

Using these Acts, the Commission's primary goal is to reduce or eliminate unreasonable risks of injuries associated with consumer products. The Commission was granted broad authority to issue and enforce safety standards for more than 10,000 consumer products. Firearms, Food, Drugs, Cosmetics, Medical Devices, Pesticides, motor vehicles, airplanes and boats are exempted from the Commission's authority under the Consumer Product Safety Act.

When the Commission decides that a safety action is necessary, this action can take a variety of forms from educational programs, or voluntary standards at one end to the setting of mandatory safety standards or banning the product on the other. Imported products are covered by the act. The Commission also has the authority to order public notice, repair, as well as refund and replacement of defective products. The choice of repair, refund, or replacement is left to the manufacturer, distributor or retailer.

Where a mandatory consumer product safety rule is required, it may be a standard covering the performance, composition, contents, design, construction, finish or packaging of a product; the labelling of the product to warn or instruct the consumer as to the products' use; or it may be a rule totally banning the sale of the product. Additionally, rules and regulations may be prescribed for record keeping and other matters related to compliance with a standard or other regulation, and for the general administration of the act.

Of the various acts administered by the Commission, the Consumer Product Safety Act, the Flammable Fabrics Act and the Federal Hazardous Substances Act recognize flammability explicitly as a possible hazard associated with the products covered by the Acts and therefore, as a basis for regulations under the acts. Today, I plan to deal only with the Act which most clearly affects textiles, the Flammable Fabrics Act.

Mandatory Activities on Flammable Fabrics started with the passage by Congress, in 1953, of the Flammable Fabrics Act. The act referenced two voluntary standards, CS 191-53 and CS 192-53 making them mandatory flammability standards. In the case of CS 192-53, only the flammability parts were mandated.

The primary purpose of CS 191-53 was to remove the notorious "torch sweaters" and the highly flammable "Cowboy" play suits from the market. In this regard the standard was successful. As years went by, however, it was clearly evident that this standard was not preventing a significant number of serious flammability accidents. In 1976 the act was amended. The amendments broadened the coverage of the Act to wearing apparel and interior furnishings and gave the Secretary of Commerce the right and responsibility to set new fabric flammability standards where needed. This responsibility was transferred to CPSC by the Consumer Product Safety Act.

Since 1967, five new flammability standards have been promulgated. Two of these cover the flammability of Carpets and Rugs, FF 1-70 (16 CFR 1630) Standard for the Surface Flammability of Carpets and Rugs and FF 2-70 (16 CFR 1631) Standard for the Surface Flammability of small carpets and rugs. Two standards cover Children's Sleepwear, FF 3-71 (16 CFR 1615) Standard for the Flammability of Children's Sleepwear; sizes 0 through 6X and FF 5-74 (16 CFR 1616) Standard for the Flammability of Children's Sleepwear; sizes 7 through 14. The fifth, FF 4-72 (16 CFR 1632) covers the flammability of mattresses.

For all of the above standards the formal development

procedure involved three steps:

(1) Simultaneous publication in the FEDERAL REGISTER of advance notice of finding that a flammability standard may be needed and a notice instituting proceedings for the development of an appropriate flammability standard.

(2) Publication in the FEDERAL REGISTER of the proposed flammability standard for public comment.

(3) Publication in the FEDERAL REGISTER of the adopted flammability standard or notice terminating or suspending the proceeding to establish the standard.

This procedure was simplified by the Commission in 1976 by combining steps (1) and (2) above.

While the formal procedure may involve only 3 or 2 stages, the technical development of a standard involves many stages. Any standard is the result of composite effort by interested and involved people from industry, government and consumer groups. Almost every stage of a standard is a best compromise between the ideal situation and what is most practical and reasonable.

Using the Flammable Fabrics Act as a basis I will attempt to illustrate some of these points.

A standard starts with the determination that some kind of rule or regulation is needed. In the case of flammable fabrics standards these may be based on accident data or laboratory research. The five flammable fabrics standards promulgated to date were based on a combination of injury data and research. Once the potential need for a standard on a product has been determined, then, in-depth accident reports are reviewed to determine the causative factors. In the case of children's sleepwear, for example, the primary ignition source was an open flame while with mattresses the primary ignition source was a cigarette accidentally dropped on the mattress and left to burn. Using the major causative factors a rough test method is set up. Then the detailed work begins of checking possible ramifications and refining the test method.

The problem in the case of carpets and rugs was that of a small ignition source, such as a burning ember from a fireplace, igniting the carpet. This small fire wends its way across the carpet until it encounters other combustible products and ignites the room. For the performance test in the standard, a timed burning tablet is burned on each of eight, oven-dried, horizontal carpet specimens, in a draft protected chamber. A carpet fails the standard if more than one specimen chars 3 inches from its center (specifically to within 1 inch of the edge of an 8 inch hole in the specimen flattening frame).

One of the problems in developing this test method was to find a suitable ignition source which would burn repeatably and reproducibly. An extensive search located a tablet used by doctors in carrying out urine sugar tests. This methenamine tablet burns consistently 110 to 120 seconds. This tablet commonly referred to as the "pill" was incorporated into the test method.

When the carpet and rug work was first undertaken a test method was developed applicable to all types of carpets. A review of accident data and information supplied by the trade indicated that small carpets and rugs, such as bathroom mats, were not as great a hazard as large carpets and rugs. Two standards were, therefore, promulgated. One covers large carpets and rugs (a large carpet or rug is defined as having one dimension greater than 6 feet and a surface area greater than 24 square feet); and the other, small carpets and rugs (a small carpet or rug is defined as having no dimension greater than 6 feet and a surface area not greater than 24 square feet). The test method and acceptance criteria are the

same for both standards. The difference is that small carpets and rugs which fail the standard may be sold provided they are suitably labelled.

The first of the children's sleepwear standards was developed to protect children up to six years of age. Since this is a group of people who, to a large extent, do not have the capability of helping themselves the guiding criterion in developing the standard was - the standard must provide maximum protection for the children involved.

In depth accident reports indicated the primary problem with children's sleepwear to be open flame ignition. A vertical open flame ignition test method was, therefore, selected. In the performance test, oven dried 3.5 X 10 inch specimens are suspended vertically in a holder in a prescribed cabinet and subjected to a small flame for 3 seconds, along the specimens bottom edge. Acceptance criteria are based on char length and residual flame time (burning time of material which falls away from the specimen and continues to burn on the floor of the test cabinet). Tests are required on fabric, seams and trim. The standard includes a sampling plan specifying the required frequency of testing.

During the development of this standard a wide range of factors related to the test method were investigated. One of the most interesting involved the ignition time of the fabric. Prior to the development of the first children's sleepwear standard, most vertical flammability tests involved subjecting the test specimen to a small flame for 12 seconds. During the development of the standard the effect of varying the time the specimen was subjected to the flame was investigated. It was found that with some fabrics the specimen did not ignite with 12 seconds exposure but did ignite with 2 or 3 seconds exposure. Further it was found that a burning specimen could be extinguished by again subjecting the specimen to the igniting flame. There are a number of theories as to why this phenomena occurs. One of the commonly held ones is that of oxygen depletion. Holding the flame under the specimen for a long period of time creates air currents which remove oxygen from the fabric and prevent its ignition or puts the fire out if the specimen is already burning. Based on this work, 3 seconds was selected as the time of flame exposure for the test specimens.

FF 3-71 was the first flammability standard to include sampling plans. Without a sampling plan, a standard does not state how frequently the product must be tested or if a failure occurs what quantity of the product is involved in the failure. Here, as in the test method, a sampling plan is a series of compromises between the ideal and what is practical. One compromise that still bothers some of the purists is that of fabric sample selection. Working with representatives of the textile industry, 5000 linear yards of treated fabric were selected as a fabric production unit for testing purposes. The next question was how to select a representative sample from this unit. The ideal, of course would be to randomly select the test specimens throughout the 5000 yards. This however is not very practical for many reasons. With most textile operations the worst part of the fabric occurs at the beginning or end of the fabric roll. On this basis it was decided that the specimens should be selected from the ends of the 5000 yard production unit.

The second children's sleepwear standard FF 5-74 covers children in the 6 to 12 age range. The test method in this standard is the same as that of FF 3-71. The primary difference is in acceptance criteria. FF 3-71 acceptance criteria involve char length and residual flame time. FF 5-74 involves only char length. Residual flame time was not included in this standard on the basis that the standard covered sleepwear used by older child-

ren who would be capable of helping themselves in the case of a fabric fire.

The last flammable fabrics standard in force today is that for mattresses. Here the primary problem is ignition of the mattress by a lit cigarette accidentally dropped on the mattress. This results in a smoldering fire and the rapid generation of a lethal atmosphere.

In the Standard's performance test, lighted cigarettes are placed on temperature and humidity conditioned mattresses, both on the bare mattress surface and between two layers of sheeting. The cigarettes are placed on smooth surfaces, along the taped edges and in depressions formed by quilting or tufting. A mattress must not ignite from any of 18 cigarettes.

One of the questions raised in developing this test method was what cigarette to use in the test. A wide range of commercial cigarettes was evaluated. For the most part, the burning temperatures of the cigarettes were similar. It was found, however, that unfiltered cigarettes burned much hotter at the butt end than did filter cigarettes. For this reason unfiltered cigarettes were selected for the test method.

Another question area investigated was that of the permanency of any treatment used to make the mattresses resistant to ignition by cigarettes. To check this, the initial test method included a procedure for wetting down the test mattress, drying it and then testing. This procedure was very cumbersome, time consuming and costly. Working with a consultant, who had been employed by industry to develop mattress constructions resistant to cigarette ignition, it was established that there was very little likelihood of a permanency problem. The wetting down requirement was, therefore, dropped from the final test method.

The Commission is also actively working on a number of other areas related to fabric flammability. One of these is the flammability of upholstered furniture. The problem here is similar to that with mattresses - a lit cigarette accidentally dropped on a piece of upholstered furniture, ignition of the furniture item and the relatively rapid generation of a lethal atmosphere. The National Bureau of Standards under contract to the Consumer Product Safety Commission have developed a test method for upholstered furniture. This test is similar to that for mattresses in that it involves determining the resistance of the furniture construction to ignition by cigarettes. The NBS test procedure involves testing of and classifying fabrics for use on upholstered furniture and testing of mock-ups constructed in the same way and of the same materials as would be used in the actual furniture.

The fabric test involves determining the char length of the fabric when exposed to cigarettes over standard substrates. Depending on the results obtained, fabrics are classified as A, B, C or D with A being the most ignition resistant and D the least. None of the fabric classifications represent "failure" under the proposed test method. However, to make upholstered furniture items which will meet the acceptance criteria, fabrics in one classification will in general, have to be used over different upholstery materials and/or methods of construction than will fabrics in other classifications.

To determine the resistance to cigarette ignition of the furniture construction on which the fabric may be used, a mock-up of specific surface locations utilizing the same filling materials and method of construction as would be used for the actual furniture is prepared. Fabrics specified in the test method are used to cover the mock-up. After conditioning, the mock-ups are tested by burning cigarettes in horizontal crevices where seat cushions and vertical panels meet; on seat cushion surface locations including smooth surface, quilt,

tuft, and welt edge; on top surfaces of armrests, on top surfaces of backs and on top surfaces of loose support systems. The number and types of locations to be tested will depend upon the construction and design of the production furniture to be qualified. Three cigarettes are burned at each of the specified locations. If two or more ignitions occur the construction is not acceptable. If one ignition occurs then three additional cigarettes are burned on replicate mock-ups at the ignited location. If none of these results in an ignition, the construction is accepted. This repeat test allows for the detection of fluke ignitions without significantly affecting the safety being provided the consumer. When all mock-up surface locations have been shown to meet the acceptance criteria for a specific fabric class, then furniture may be manufactured using the construction, and any fabric in the specified class or any higher class. This does not apply to class D fabrics where each fabric must be tested with its proposed construction.

In June, the CPSC Commissioners formally considered the upholstered furniture flammability problem. The Commissioners agreed in principal that there is a flammability problem with upholstered furniture and that the Commission's objective should be the production by industry of furniture that would not ignite when a cigarette is allowed to burn on it. Further, they agreed in principal that the NBS test method for cigarette ignition resistance of upholstered furniture was reasonable and repeatable. They expressed concern, however, that the proposed application of the test method (such as frequency of testing) may be too burdensome and restrictive to the industry. CPSC staff were directed to propose alternative test applications for Commission consideration as well as alternative methods of implementing the standard. This work is in progress.

A second area under investigation is that of wearing apparel. Standards have been promulgated for children's sleepwear. Are other standards for specific apparel items needed? CS 191-53 has not prevented many apparel flammability accidents. Is a new general wearing apparel standard needed? Towards this latter end, NBS at the Commission's request has developed a potential test method. This test involves measuring the ignition time and the heat transfer rate of a fabric. Depending on the results obtained, the fabric is classified 1 through 4. The wearing apparel items in which fabric may be used depends on its fabric classification. This test method has become known as the "Mushroom Apparel Flammability Test (MAFT)".

An alternative approach would be to concentrate on only those areas of wearing apparel where injury data indicates the hazard to be high and to develop standards for these. Available data indicate the primary hazard areas to be nightgowns, (those not now covered), Robes and Housecoats (Females only), Pajamas (Male and Female), Dresses, Shirts (Male) and Pants (Male). One potential approach for specified wearing apparel would be a modified form of the children's sleepwear standard FF 5-74. At this time, the Commission has not made a decision on what further action to take. A concept briefing package covering the overall apparel flammability question is being prepared for the Commissioners with a request for guidance to the staff on the approach to be taken.

Lastly, I am sure you are all aware of the tris (2,3 dibromopropyl) phosphate (TBPP) controversy earlier this year. TBPP was used as a flame retardant on a significant portion of the children's sleepwear produced. Industry have requested that the sleepwear standard be amended to permit the use of more untreated fabrics. A discussion paper has been prepared and is now under consideration by the Commissioners covering the aspects of the standard which industry has requested consideration for amendment. These include the need for the residual flame time criteria, the need to test seams and trim, procedure for

conditioning specimens, exclusion of the 0-1 age group, exclusion of tight fitting garments and modification of the sampling plan.

Early in this talk I stated that any standard is the composite effort of all interested and involved people. Through the rest of the talk, I have tried to exemplify these statements. A further exemplification is that such people are on today's session. Rachel Dardis who spoke to you earlier is a member of the National Advisory Committee for the Flammable Fabrics Act. The American Textile Manufacturers Institute along with other textile organizations such as the American Apparel Manufacturers Association and the Man-Made Fiber Producers Association have been a great deal of help in the past and will be in the future. We need such help from all of you.

HUMAN VALUES: A HISTORICAL AND INTERDISCIPLINARY ANALYSIS

C. Joseph Clawson, University of Southern California
Donald E. Vinson, University of Southern California

Abstract

... Values are so inextricably woven into our language, thought and behavior patterns that they have fascinated philosophers for millennia. Yet they have proved so "quick-silvery" and complex that, despite their decisive role in human motivation, we remain desperately ignorant of the laws that govern them. (Toffler, 1969)

One of the most curious anomalies in the field of consumer research has been the lack of attention devoted to human values. This is particularly paradoxical considering that most serious students of human behavior have argued for centuries that values play an important role in personal, social and cultural activity. Where the term "values" has been employed, it has typically been confused with the concept of product attributes by attitude researchers. While a few contemporary studies have emerged suggesting significant correlation between values and consumer behavior (Scott and Lamont, 1972; Vinson and Munson, 1976; Henry, 1976; Vinson, Scott and Lamont, 1977), consumer researchers have, for the most part, adopted a hands-off attitude toward the value construct. In dramatic contrast, marketing practitioners have become very sophisticated in developing advertising and mass communication appeals involving allusions to important human values. In fact, we would argue that marketing appeals have traditionally been highly value oriented. Apparently, marketing practitioners understand what most marketing academics fail to recognize -- human values play an important role in consumer behavior.

What could explain this disparity between what marketers do and what we in academia study? One plausible explanation may be that academics have concentrated their attention and technical skills almost entirely on consumers' more rational beliefs with respect to tangible product attributes and marketing characteristics -- such realities as color, price, taste and availability. A contrasting but much less popularly held view is that practitioners may have forged years ahead of our scientific decision theories. While academic researchers argue about A₁'s and B₁'s and report low R²'s from attitude studies, practitioners are appealing to deep, emotion-laden values and providing powerful stimulation to sales.

In order to emphasize that the analysis of human values is not just another new fad in consumer research, or a minor variation on product attribute studies, we shall present a historical review of the value concept from antiquity to the present day. However, the subject of values has been of intense interest through much of recorded history and has generated a vast literature. Consequently, our discussion must be narrowed by two rules. First, we shall be concerned only with analyzing subjective values that consumers actually hold. These are distinct from objective or true values, as might be determined by scientific facts or religious insights. Second, we shall focus on the values that objects, such as goods and services, have to consumers, but only insofar as market value can be related to specific human values that people themselves hold. This seemingly innocent restriction eliminates almost, but not quite, all of economic theory of consumer demand

for the past two hundred years. What is often called value theory in economics is primarily concerned with market value, not human values.

Historical Perspectives

Initially, most of the thinking on market value and consumer values was contributed by the philosophers and religious leaders of Europe. During the late 1700's, there began to emerge various branches of philosophy which we now call the "social sciences."

Philosophy

Since the days of the ancient Greeks, philosophers have been concerned with values on a rather tangential basis. References to values were unavoidable as Aristotle, Kant, and others discussed aesthetics, or as Plato, Hobbes, and Rousseau deliberated over the problems of government and citizen responsibility. But, as Wekmeister points out (1967), no general theory of values was developed or enunciated by any of these thinkers.

Some ancient insights into the nature and importance of wants, needs, or values as the motivators of consumer demand are worthy of note. Aristotle argued that man obtains greater pleasure from an object when it is his own, for the love of self is a feeling implanted by nature and not given in vain. There is also great pleasure in doing a kindness or service to friends or guests or companions, which is facilitated by possessions (Haney, 1936). Thus pride of possessions and hospitality were identified as what we would now call consumer values.

Buridan (1300-1358) followed Aristotle in stating that the measure of value in goods is to be found in the satisfaction of wants, greater need resulting in higher value. Samuel Pufendorf (1632-1694) asserted that the price or value of any action or thing depends on its fitness to obtain, directly or indirectly, the necessities, conveniences, or pleasures of human life. Nicholas Barbon in 1680 refuted the notion that economic ends are necessarily tangible, or that pleasures and pains have to be physical (*Ibid.*). In parallel thought, Galiani in 1750 stressed the desire for social distinction, in the form of rank, titles, honors, nobility, and authority, which he held to be stronger than the desire for luxuries, which in turn was stronger than the desire of the hungry for food (Georgescu-Roegen, 1968).

Jeremy Bentham (1748-1832), a non-practising lawyer, was a major contributor to the hedonistic and instrumentalistic interpretations of behavior. His Introduction to the Principles of Morals and Legislation (Patterson, 1932) revealed his conviction that cultural values as well as all other instrumental acts are ultimately learned through reinforcement or inhibition, which he called the principle of utility. According to him, utility is that property in any object which produces benefit, advantage, pleasure, good, or happiness, or prevents mischief, pain, evil, or unhappiness to the party making the decision. One of Bentham's less well known works, A Table of the Springs of Action (1815), foreshadowed Kurt Lewin's psychological field theory as well as later compensatory multiattribute models. He

observed that multiple, conflicting motives are often simultaneously at work, with the dominant motive or group of motives determining the final decision (McReynolds, 1969). Bentham's fourteen springs of action foreshadowed by more than a century some of the great value lists to be discussed later. He included taste, sexual appetite, wealth, power, curiosity, amity, reputation, religion, sympathy, antipathy, self-interest, and the pains of labor and physical suffering.

The question of values first began to emerge as a separate and unique issue in Germany during the early 1800's. Indeed, intense scholarly debate as to the source, nature, and even existence of things called values signaled the acknowledgment of axiology (the study of value) as a legitimate and fruitful area of academic inquiry. The basic problem confronting the study of values from a philosophical perspective relates to the axiological question of whether or not values are subjective or objective. Those proposing the "objectivity" of values are in essence suggesting that values are independent of a subject or a valuing consciousness. Conversely, the "subjective" position holds that values owe their existence, their validity, to the subject who does the valuing (Fronzizi, 1963). As a case in point, one could evaluate an individual's appreciation of a beautiful painting as either the recognition of certain values existing and associated with the particular work of art, or as the person's personal preference or liking of the objet d'art which gives it its value.

Meinong was the first subjectivist to address himself to the problem of the nature of values. Something has value, he said, "when it pleases us, and to the extent that it pleases us" (*Ibid.*, p. 34). In a similar vein, Ehrenfels believed, "Things which we desire or covet are valuable, and they are so because we desire and covet them" (*Ibid.*, p. 37). Supporting the subjective position, Bertrand Russell said, "The chief ground for adopting the subjective view of values is the complete impossibility of finding any arguments to prove that this or that has intrinsic value." It is "our desires which confer value" (Russell, 1925).

The objective approach to values was championed by Hartmann and Scheler. These two scholars believed that the study of values represented the investigation of a legitimate scientific field, unlike Russell who held that questions which refer to values were outside the realm of science. Hartmann approached the concept of value in strictly logical terms; to him, the value predicate is a property of concepts rather than objects (Hartmann, 1967). Scheler argued that, if all values were relative to life, as the subjectivists suggest, then life itself could not possibly have any value. Value independence implies their immutability; they are not dependent upon any act, regardless of its nature, be it historical, social, biological or purely individual. It is only knowledge of values which is relative, not values themselves (Fronzizi, p. 82). In addition to values being independent of their corresponding carriers, Scheler held that they exist in a hierarchical order. This order is expressed by "preferring" or "deferring"; we prefer one course of action, one good, one mode of behavior to another as we prefer "a given value to another, regardless of the carrier" (*Ibid.*, p. 84).

Those value philosophers of the objective persuasion acknowledge that valuation is indeed subjective; however, one must distinguish between valuation and value. On this point, Fronzizi states that value is prior to valuation -- if there were no values, what would people evaluate (*Ibid.*, p. 15)? Values then are those things which are evaluated in the valuation process.

Modern social thinkers have generally embraced the objectivist position and regard the emergence of values as a social-cultural process. Nietzsche (1844-1900) inter-

preted the dynamic character of history as the continuous creation and annihilation of values. Men create values which stabilize cultures, albeit temporarily, until these values are subsequently replaced by another set which allow the upsurge of a new human culture (*Ibid.*, p. 33).

Behavioral Sciences

Anthropology. Anthropologists have contributed enormously to the study of human values through their examination of cultural patterns and life styles. Clyde Kluckhohn shifted anthropological thinking away from the view that all cultures are relative. Despite wide differences in customs, there are certain fundamental human values common to all of the diverse cultures of the world (Kluckhohn, 1951). Further, Kluckhohn devoted considerable effort to the classification of values as well as to the distinguishing dimensions of values. Expanding his work, Florence Kluckhohn and Strodtbeck developed a five-part typology of value orientations and employed it to build a theory of cultural variation. They concluded that society requires conformity if man is to be a social animal and that societies create the value system to which men must conform (Kluckhohn and Strodtbeck, 1961).

Another anthropologist interested in values was Dorothy Lee, who studied the Arapesh of New Guinea in their food gathering activities. She discovered that the structuring of their food-getting procedures was appallingly inefficient from the point of view of food production, but it was eminently efficient from the point of view of infusing [values] into their lives (Lee, 1959). As Ayres so appropriately states, ". . . it is perfectly true that every culture includes a considerable admixture of irrationality -- that values exist and are cherished with the highest degree of intensity which owe virtually nothing to science but are virtually pure expressions of community sentiments and attitudes fortified by tribal legends and ceremonials of every kind" (Ayers, 1950).

Sociology. Ferdinand Tonnies regarded values as a critical element in his classic distinction between community and society -- between those systems which emphasized Gemeinschaft (primary, small, traditional, integrated values) and those which stressed Gesellschaft (impersonal, secondary, large, socially differentiated values) (Tonnies, 1957). In a similar vein, Durkheim described his "collective consciousness" as a system of values and beliefs held in common by the members of a society that define what their mutual relations ought to be (Durkheim, 1960). In the case of mechanical solidarity, the group's values are not clearly differentiated from the norms through which they are implemented; in organic solidarity, the norms have independent salience.

The study of values was considered the core of sociological inquiry for Becker (1941). He considered values as indispensable in analyzing judgments of right and wrong, good and bad, superiority and inferiority, usefulness and uselessness, and in determining the means and ends of human action. In agreement, Blau (1964) suggests that a prime determinant of social conduct is the institutionalized system of values in a society. Values define group identity, common standards of morality and achievement and legitimize governing authority. While the sociology literature contains voluminous references to values, some of the more significant contributions involve the following areas of sociological inquiry: measurement and quantitative techniques (Lundberg, 1941); "pattern variable" analysis (Parsons, 1969); deviant behavior (Parsons, 1951); content mobility in education (Turner, 1961); social differentiation (Sorokin, 1947); social exchange (Blau, *op. cit.*); socialization (Brim, 1966); and the theory of values, value system organization and the role of values in social behavior (Rokeach, 1968a, 1968b, 1968-69).

Psychology. Psychologists have generally focused on more narrowly circumscribed constructs such as attitudes, motives, valences, and cathexes. However, in the 1920's, Thomas and Znaniecki recognized the importance of values and defined them as ". . . objective, social elements which impose themselves upon the individual as a given and provoke his reaction" (Thomas and Znaniecki, 1927).

Another early landmark in psychological analysis of values was the publication of the English translation of Spranger's *Types of Men* (Spranger, 1928). Believing that values are reflected in all behavior, Spranger constructed a value system typology which purported to classify men according to six basic personality characteristics. Values could be clustered into systems representing types of men whose personality manifestations tended to be theoretical, economic, aesthetic, social, political, or religious. He did, however, admit that personality did not depend exclusively upon any one of these value orientations in total; he conceded that all six orientations probably exerted influence to varying degrees. Nevertheless, it was his contention that the individual's predominant value orientation structured his personality.

A renowned empirical investigation emerging from the Spranger tradition was undertaken by Allport and Vernon during the early 1930's (Allport and Vernon, 1931). Their study employed an instrument designed to test the relative strength of the values associated with Spranger's six personality types. In replications over a large number of heterogeneous subjects, they reported reliability measures of over .72. Corroborating these findings, Pinter (1933) and Evans (1952) indicate the validity of the "Types of Man" approach to the study of values and support the notion that values are socially learned.

A contemporary of Allport's, also teaching at Harvard in the late 1930's, was Henry A. Murray. As part of a team of clinical investigators, he developed what is one of the most widely used list of needs today (Murray, 1938). The list contains 28 secondary or psychogenic needs and 12 viscerogenic needs. In an easily overlooked passage, Murray clearly pointed out that needs are not identical with values: ". . . From one point of view, the important thing is not whether a subject has a need for Achievement or for Affiliation or for Rejection, but rather what it is he wishes to achieve, affiliate himself with, or reject."

By 1942, Kurt Lewin was conducting research using the equivalent of a simple linear compensatory version of the expectancy-value formula and applied it to a mixture of four product attributes and personal values. These "frames of reference" consisted of expense, health, taste, and status. He asked three questions: (1) What are the values for this group? (2) What is the relative weight of each value? (3) How are specific foods linked with certain values? (Lewin, 1943).

In the mid 1950's Maslow advanced his hierarchical groupings of needs into those that were concerned with safety, security, love, self-esteem, and self-actualization (Maslow, 1954). Morris (Handy, 1970) discussed value theory in considerable detail and developed a list of thirteen "ways to live" which were conceptions of the good life that respondents were asked to rate as to degree of liking. Rosenberg (1956) suggested that values and needs are pervasive in the individual's cognitive structure and attempted to measure the importance of a given value or set of values relative to an attitude object. Thurstone then proposed that values could be measured and, with the aid of the comparative judgment technique, developed a scale of "moral" values (Thurstone, 1954). W. A. Scott described a method for measuring the values and ideologies of a culture (Scott,

1959). Woodruff and Divesta measured the values of college students and showed their relationship to attitudes (Woodruff and Divesta, 1948).

One of the most influential of modern contributors to the psychological theory of personal values is Milton Rokeach. According to Rokeach, adults possess many thousands of attitudes toward specific objects and situations but relatively few terminal and instrumental values -- perhaps only several dozen instrumental values and a few "handfuls" of terminal values (*Ibid.*, 162). This difference in number suggests to him that values and attitudes are connected in a hierarchical system. This cognitively connected, hierarchical structure is arranged along a central-peripheral dimension and in a psychological sense is internally consistent. Any change in one part of the value-attitude system will affect the other parts. However, the most central or salient elements are more resistant to change and, when they do undergo a restructuring, they exert greater influence upon the other components of the system.

The reliability of the Rokeach paradigm has been verified under many replications (Robinson and Shaver, 1971) and Rokeach has found that various combinations of terminal and instrumental values significantly differentiate among people with extremely diverse social and economic status characteristics (Rokeach, 1968-69). Unlike most cognitive approaches to social psychology, his paradigm focuses upon values rather than attitudes. According to Rokeach, values are culturally derived, and define, maintain and regulate the visible social structure; they give it meaning, stability and cohesion. "To say that a person 'has a value' is to say that he has an enduring belief that a specific mode of conduct or end-state of existence is personally and socially preferable to alternative modes of conduct or end-states of existence (Rokeach, 1968, p. 167). Instrumental values relate to modes of conduct and terminal values have to do with preferred end-states of existence. The eighteen terminal and eighteen instrumental values developed by Rokeach had test-retest reliabilities in the .70's after seven weeks (*Ibid.*, p. 167).

Like values, attitudes are also based upon beliefs. But rather than a single belief, they represent the focusing of several beliefs upon an object or situation and predispose the individual to respond in some preferential manner.

For purposes of research in consumer behavior, Rokeach's excellent paradigm contains a few limitations. Three should be noted. One flaw is the use of rank orderings, which, for all its speed and simplicity, is less informative than interval or ratio scaling would be. Equally attractive values are forced into separate rankings. Wide gaps in preference are treated as no different from minuscule gaps.

A second problem is with the instructions, which bias the rankings in favor of deprived values and against satiated values. Saying to a respondent that his task is to arrange the value statements in order of their importance to him, as guiding principles in his life (Rokeach, 1973, p. 358), does not allow him to distinguish between permanent esteem of the value and situational need for the value. For instance, the lowest income respondents rate "a comfortable life" and "clean" relatively high, while wealthy respondents rate them quite low. The low income respondents presumably need, or lack, these conditions, the high income respondents already possess them, but both groups could esteem them equally. Similarly, black Americans need and rate equality very high, while white Americans need it less and rate it as only moderately important (*Ibid.*, p. 393). It is still not known whether there is a real difference between whites and blacks in permanent esteem of equality.

The third drawback is that Rokeach's lists of 18 instrumental values and 18 terminal values appear to omit a substantial number of other values that are held by substantial portions of the populace. They include, for example, Life, Physical Energy, Physical Strength, Physical Attractiveness, Youthfulness, Family, Enjoyment, Power, Leadership, Courage, Individualism, Conformity, Mental Energy, Practicality, and Efficiency. Such values are often appealed to in advertising.

The final psychologist making a distinguished contribution to the theory of human values, applicable to consumer behavior, is McGuire. His most complete analysis is published as a chapter in a book on gratifications obtained through mass communications (McGuire, 1974). His classifications of motives, he believes, "must sensibly be expanded to include lists of instincts, . . . emotions, . . . values, . . . temperaments, . . . and motivation-connoting personality dimensions" (*Ibid.*, p. 170; italics added). The impressive and useful result is a table consisting of 16 classifications of motives.

Value Measurements in Behavioral Sciences. The fertile generation of value-related concepts by anthropologists, sociologists, and psychologists has been paralleled by a stream of value-measurement scales. Twelve scales which may be of use to consumer researchers are reproduced in a single document (Robinson and Shaver, *op. cit.*), with references given after each scale.

Marketing. The first academic contributions to formal marketing thought on consumer values were made by Harvard's Melvin Copeland in 1924. After analyzing the appeals used in 936 advertisements in American magazines published during 1923, he concluded that all the buying motives to which they appealed could be classified on two dimensions. First, when sorted according to the type of decision that was to be made, motives could be sorted into "primary" motives affecting choice of product class, "selective" motives influencing brand choice, and "patronage" motives determining store choice (Copeland, 1924).

The second dimension was considered by Copeland as more basic. He said that motives could also be sorted according to elements entering into the decisions; this resulted in "emotional" motives being distinguished from "rational" motives (*Ibid.*, p. 162).

According to Copeland, the 23 emotional motives had their origin in human instincts and emotions. They represented impulsive or unreasoning promptings to action, and could not be aroused by appeals to reason. Examples from his list are pride of personal appearance, social achievement, expression of artistic taste, romantic instinct, cleanliness, entertainment (*Ibid.*, p. 163-178). These motives closely correspond to the relatively central or global personal values which Rokeach has called instrumental and terminal values. So far as we have been able to ascertain, Copeland was the first marketing scholar to distinguish formally between what we consider as human values, as one category, and what are commonly referred to as product or marketing attributes, as a separate category.

A lengthier classified list of 128 values was developed by Clawson, a student of Allport's (Clawson, 1946, pp. 26-27, 271-274), and was based on content analysis of several hundred best-read advertisements and numerous propaganda materials. Six of the category titles corresponded to Spranger's Types of Men, but two additional categories were included. They consisted of 29 "physical" or biogenic values and seven "general" values.

Clawson also brought to the attention of marketers (1950) several of Lewin's concepts which would be helpful in linking the broad construct of human values with

the more specific marketing construct of buying motives. These concepts included the "achievement level," the "ideal level," and the expectation level, regarded as common to all values.

Even with the tremendous and growing impact of the behavioral sciences upon marketing in recent years, consumer values, as such, have been largely ignored by the discipline. Where they have received attention, they have been employed with almost poetic license and defined with common vernacular. As an example, in 1967, one entire section of the Proceedings of the American Marketing Association was devoted to "Value Systems in a High Level Economy" (Mayer, 1967). However, not one of the papers in this section presented a conceptual or operational definition of values, or related values to marketing theory or practice.

In the area of consumer behavior, values have usually tended to be equated with life style (Bem and Bem, 1973; Ireland and Besner, 1971; Mitchell, 1971), group norms (Kassarjian and Robertson, 1973), or social class differences (Levy, 1973). The life style association appears to be the most popular. In fact, Kelley and Lazer devote one chapter of their book, Managerial Marketing, to "Life Styles and Values" (1973). This title turns out to be somewhat of a misnomer in that little, if any, discussion pertains to values *per se*. Furthermore, nowhere in the chapter are the two constructs conceptually differentiated.

The recent infatuation with attitude models has also led to confusion concerning the role of values in consumer research. Borrowing freely from Rosenberg's value-expectancy conceptualization, marketing scholars have concentrated on the prediction of brand preference using product attributes instead of Rosenberg-type generalized values in their structural equations. Today, many marketing and consumer researchers mistakenly equate "values" with evaluation of product attributes. Although a complete analysis of expectancy-value models is beyond the intended scope of this paper, excellent reviews are available (see Wilkie and Pessemier, 1973; Jacoby, 1976; Hansen, 1977).

There are numerous indications of growing interest in personal values, as distinct from product and marketing attributes, in the marketing literature. One is the "Second Washington Social Indicators Conference to Explore the Response of Business to New Values" (Marketing News, 1973). In addition, there appears to be an emerging body of research devoted to the topic. Scott and Lamont (1972) have presented evidence that global values, product evaluative and descriptive beliefs, and domain-specific values are three separate yet cognitively related variables. Henry (1976) shows significant associations between automobile ownership and personal value-orientations along the Kluckhohn-Strodtbeck lines. Extending Rokeach's paradigm, Vinson, Scott and Lamont (1977) view values as existing at two distinct levels. The first level, referred to as "global" values, contains both instrumental and terminal values. The second level deals with values which refer to desired product attributes and market place transactions and behaviors. Termed "market-specific" or "domain-specific" values, they are cognitively separate but related, and are connected to global values as well as to descriptive and evaluative beliefs.

Vinson and Munson (1976) demonstrate that values could be productively employed as segmentation variables. Vinson, Munson and Nakanishi (1977) demonstrate the validity of the Value Survey for consumer research applications. Munson uses Rokeach's terminal and instrumental values to successfully differentiate consumers of culturally diverse nationalities (1977). And Vinson suggests that differential value orientations represent an important underlying dimension of consumer discontent

(1977).

Howard's new book devotes extensive space to consumer values (1977). He stresses instrumentalism (reflected in his frequent references and examples of lengthy means-end chains), and suggests that terminal values influence a person's choice criteria for a product class, his beliefs about product classes, his attitudes toward product classes, and finally his purchase of a particular product class (*Ibid.*, p. 98). A verbal example suggests that a consumer may perceive a means-end chain as consisting of the following links: meat-protein-energy-work-effectiveness-ambition (*Ibid.*, p. 116). Howard also cites numerous potential applications of consumer values in developing government and marketing policy decisions. However, his own stimulating analysis does not include any rigorous model of the structural elements, causes, or consequences of consumer values.

Conclusion

The study of consumer values shows many signs of becoming a challenging area for research in the years ahead. The most encouraging single indication is that consumer values have already been shown to have significant correlations with consumer behavior and attitudes. Given a solution to some of the present difficulties with the concept, values may prove to be one of the more powerful explanations of, and influences on, consumer behavior. They can perhaps equal or surpass the contributions of other major constructs including attitudes, product attributes, degree of deliberation, product classifications, and life styles. However, the untapped potential of consumer value analysis can be properly harnessed only if certain obstacles and problems can be removed. Our review reveals five major problems:

First of all, the concept of consumer values has not yet been clearly defined. Second, no comprehensive, non-duplicative list of values has been agreed upon by philosophers, behavioral scientists, economists, or marketers. Third, no generally accepted model is as yet available specifying the structural variables of an individual value, its latent or active interactions with other values, or its relations to other predispositions, environment, and behavior. Fourth, no standard method of measuring values has been adopted. Finally, the practical value of values has yet to be demonstrated or rejected conclusively, either in real-life settings or in laboratory settings. Insights into these applications would be needed by policy-makers in such fields as marketing, government, and other areas of planning and leadership.

Need for a Better Definition. Space permits us only to deal with the first and, in our opinion, most pressing of the five problems in value analysis. This is the problem of definition of a value. We may at least define what consumer values are, and what they are not, by indicating the major elements that such a definition should contain. These elements have been distilled from the work of many scholars and has been heavily influenced by our historical review.

(1) A consumer value is a belief. The first element of a proper definition recognizes that a value is a belief held by the consumer. It is not some objective "truth" that might have been tested and accepted by scientists, philosophers, religious leaders, economists, or other observers.

(2) A consumer value is person-centered. The requirement that human values be person-centered immediately reduces the number of eligible values. Person-centered values are those values explicitly connected in the consumer's mind with his own personal well-being or social acceptance, or with the well-being and social acceptance of other persons who are important to him.

This excludes object-centered values, which are those objects, events, activities, or even people in the consumer's environment that have no explicit effect, per se, on him or on significant others. The latter include (a) specific actions or action-sequences that vary from one situation to another, such as searching, buying, storing, processing, using, or repairing; (b) specific products, services, brands, stores, advertisements; (c) a product's or service's physical and marketing attributes; (d) its technical performance characteristics, and (e) its uses. For example, a breakfast drink's calorie content is a nonpersonal attribute. It is an object-value but not, per se, a human value. However, the nutritional effect on people of these calories is a human value, since it is explicitly person-centered. We believe that if we wish to understand the entire range of person-centered values that motivate consumer behavior, we should start, of course, with (1) Rokeach's modes of behavior (instrumental values) and end-states of existence (terminal values), but we would need to add (2) the wide range of biological and social states omitted by Rokeach, such as life, energy, health, sex, physical senses, power, fame, property; (3) relatively complex, long-term, recurrent patterns of personal skills, ideas, objects, and activities, such as good manners, professional competence, a particular religion, a particular political party, patriotism, individualism, physical attractiveness, life style, and personal hobbies, to name a few; and finally (4) specific, short-term personal benefits that are relevant in a wide variety of situations, including time saving, economy, ease, convenience of location, and the like.

The three extra categories we have suggested may of course be intertwined with one another and with the Rokeach-type values. Indeed, they may even be derived from his values. Nevertheless, they have a definite functional autonomy of their own and are often mentioned as goals by consumers and are appealed to by many advertisers, salesmen, political leaders, and other communicators.

(3) A consumer value is perceived as having an underlying positive worth, as an end in itself, for the consumer himself or for significant others, and is organized around a subjective ideal. The subjective worth may be called utility, importance, desirability, liking, approval, loyalty, or other terms that reflect the affective, or evaluative, aspect of every consumer value. The fact that a particular value has subjective worth to a consumer may be revealed in a variety of ways. It is revealed by overt behavior, emotion felt or revealed, and verbal expressions; by vicarious participation in the experiences and emotions of others; and by subconscious or concealed responses. Each value also has a subjectively ideal state, which is preferable to any higher or lower state. For instance, the right amount of generosity is regarded as preferable to the extreme of extravagance as well as to the opposite extreme of miserliness.

(4) A value is perceived as having present or eventual usefulness. Although a value is esteemed in part for its own sake, it is also regarded by the consumer as being an instrument for serving still deeper values. Even the terminal values, says Rokeach, are the conceptual tools and weapons that people use to maintain and enhance their self-esteem (Rokeach, 1973, p. 14), which McDougall called the master sentiment of self-regard (*Ibid.*, p. 14) and Maslow called self-actualization (*Ibid.*, p. 16, Maslow; 1959, p. 123). Even the self-concept would be useful as a criterion for evaluating other values, attitudes, and activities.

(5) A value is enduring. A value is neither completely stable nor completely unstable. If it were the former, it would be impossible for individual and social changes to take place; if the latter, neither personality nor

society would have any continuity (Rokeach, 1973, pp. 5-6). While values remain relatively stable, the needs and behavior derived from them can fluctuate widely. To illustrate, a high subjective worth placed on physical comfort is a relatively enduring value, and is not inconsistent with varying intensity of headaches, nor with purchasing aspirins on some days and not others. Researchers will need to take precautions to measure the relatively permanent, underlying esteem of values, undistorted by transitory needs, surpluses, threats, or inducements.

(6) A consumer value is widely held by many but not all members of a sub-culture, society, nation, or civilization. This element tends to eliminate rare hobbies and personal attachments of isolated individuals from possible classification as consumer values. However, unanimity is not required. An opposite or compromise position on any value may be adopted by a minority within any group being studied, sometimes with, sometimes without the tolerance of the majority. This recognizes the coexistence of rival ideologies, opposing political parties, criminal elements, moral deviates, terrorists, and others with nonconforming life styles within any social grouping. It does not preclude warfare among factions and nations, based partly on differential value systems and partly on differential degrees of deprivation.

(7) A major role of a consumer's value is that of standard or "criterion" he can use in the formulation of attitudes and guidance of behavior. This element is not essential for a "descriptive" definition of values, or what values are. It is of transcendent significance for a functional definition -- what values do. This meaning of value-as-criterion treats values as indirect determinants of all attitudes and actions, whether to adjust to one's physical and social environment, enhance and defend his self-esteem and social conscience, or improve knowledge and growth. It means that attitude objects that perform only limited service as criteria for conflict resolution and decision-making, or that affect only a narrow domain of life situations, would not be defined as values.

(8) A value is derived from, and modified through, personal, social, and cultural learning. Whereas the seventh element emphasized the consequences of a value, the final element underscores the antecedents of a value. It indicates how values originate and change. Being learned early in life, values are historically primitive, probably harder to change than the more specific attitudes and behavior patterns that are derived from them, and are a major source of stability both for the individual and society. However, once they are shifted themselves or severely deprived, they can also be sources of major upheavals. Values thus possess an extremely high degree of centrality in a person's life.

To summarize, any object of interest to a consumer may fall within the definition of a consumer value provided it meets the criteria mentioned above. It can involve any generalized person-centered end-state of existence, mode of behavior, pattern of ideas, grouping of people, biological condition, or direct benefit that is highly esteemed by the consumer himself, or perceived to be esteemed by others who are important to him. It is used by him as a criterion for evaluating a wide variety of other values, objects, activities, and people. It is an enduring type of belief, widely held by the consumer and by many but not all other members of his subculture or society. It is acquired and modified through personal, social, and cultural learning starting early in life, and plays a central role in his decision-making.

VALUES AND CONSUMPTION PATTERNS: A CLOSED LOOP

James M. Carman, University of California, Berkeley

Abstract

The author had proposed a model of life style and consumer behavior that relies strongly on the concept and measurement of values as advanced by Milton Rokeach. Here the work is extended to make it a more comprehensive model of consumer decision making and to make explicit a set of feedback loops to values and life style. The model is explained and some examples of recently emerging life styles are developed.

Introduction

For over a decade, my work in the differentiation of life styles has had a stronger anthropological flavor to it than that of most other researchers in marketing. In the past two years, I have been attracted by the ability of Milton Rokeach, through his work in values, to provide a social psychological basis for my anthropological approach to this topic (Rokeach, 1973). In this paper I will attempt to extend this line of theoretical development by: (1) adding a bit more sociological insights to it and (2) showing how the link from values to subcultures to consumption patterns is actually a loop which feeds back to values, life styles, and subculture.

In this first section, my framework for integrating values, cultures, life styles, and consumption is summarized. In the second section, the model is extended. In the third section, examples of how subcultures emerge and then survive or decline and the importance of the feedback loop in this process will be explained. This section also suggests some public policy implications of this line of research.

My interest in this area stems from my early work in the investigation of social class as a basis for market segmentation. At that time I was critical of the sociological view of social class based largely on status groups or socioeconomic factors such as education. My position was that the groups of interest for the study of consumption patterns were really subcultures. The richness of this area for market segmentation lay in the area of identifying subcultures within the society that tend to be self-perpetuating and are homogeneous with regard to their values, beliefs, motivation, interests, activities, and thereby media exposure behavior. This early literature is summarized in Carman (1965) and Frank, Massy and Wind (1972).

Despite these findings, the social class reviews and research since 1968 largely ignore these conclusions. In some of this work, the construct is not defined; in others it is the idea of status class. It is little wonder that this work under the name of social class has not persisted.

Instead, work along these lines proceeded under such names as "activities, interests, and opinions," "life style," and even "psychographics." This literature has been summarized by Hustad and Pessemier (1974) and Wells (1975). Despite all this flurry of activity, there continues to be nagging questions as to whether there is any theoretical underpinnings to this life style research.

Thus, I was delighted when the work of Rokeach on values seemed to provide a social psychological basis

for this area as I conceptualized it. The framework I developed, shown in Figure 1, is based on a cause and effect relationship between four sets of variables (Carman, 1976/77). Terminal values lead to holding certain instrumental values to be more important than others. These are the causes of interests and assumed roles that, in turn, are the cause of the activities in which one uses time. Each set of variables--terminal values, instrumental values, interests and roles, time use activities--influence consumption behavior both directly and through the other intervening variables. Consumption behavior is defined here to include purchase patterns, search behavior, and media exposure behavior.

More recently, I have added feedback links to indicate that some purchases, search, and media behaviors have an effect that feeds back to alter some values, roles, interests, and activities. It is this area that my thinking of a year ago now appears overly simplistic. The heart of this paper is a strengthening of how the sociological and anthropological inputs to the society also must be at work to determine just which configurations or constellations of values will exist in great enough numbers for a long enough period to be of interest to consumer behaviorists. But first, I believe it would be useful to review just a bit more the problems and experiences to date in measuring values with an emphasis on validity of the Rokeach instrument.

The Measurement of Values

I am struck with the frequency with which we hear and read statements to the effect that little systematic work has been done on the measurement of values. Anthropologists have clearly been interested in linking the study of cultures with the values held by the people of a culture, but anthropologists, working as they do primarily after the fact, are not likely to develop instruments that will satisfy other social scientists. In both sociology and social psychology, values have remained a rather isolated area of study. The reviews of work prior to Rokeach do not build confidence (Dukes, 1955; Robinson and Shaver, 1969). In other fields, the word values is used in unfortunate ways that could be the source of much confusion. In organizational behavior, for example, the word values is used to connote attributes of a job, e.g., interesting, relative wage, advancement opportunity (Pennings, 1970).

However, it appears to me that much of this confusion and criticism can not be applied to Rokeach. Robinson and Shaver state that their review of the literature shows that all values fall into five broad categories: (1) means vs. ends, (2) good vs. evil, (3) aesthetics, (4) intellectual, and (5) economic. Rokeach includes all of these categories in his instrument. Similarly, the Bales and Couch Value Profile (1969) that received some validity from the work of Withey (1965) includes dimensions that also are tapped by Rokeach. At these meetings last year, Vinson, Munson, and Nakanishi (1976) reported on a study that confirms the Rokeach instrument as tapping values that can differentiate among consumer groups. Also in marketing, Scott and Lamont (1973) have found the Rokeach framework useful.

Finally, later in this paper we will refer to a theory of Etzioni (1972) suggesting that when groups of

persons find their values not in harmony with the balance of their culture, they are likely to respond with changes of instrumental values, interests, activities, consumption, and media habits that follow patterns of: (1) hedonism, (2) substitution of symbols for things as relevant objects of value, (3) empathy and community with those of similar value incoherence, and (4) collective activist behavior. While Etzioni did not do it, his theory is completely testable with the Rokeach instrument. Thus, it is not true that the Rokeach Value Survey is just another attempt to measure values that is on thin ice. It has had an incredible amount of testing in a wide variety of applications. One may want to modify the scales in particular applications, but we believe we can convince you that Rokeach provides a framework and a measure of values that are applicable in anthropology, sociology, psychology, and consumer research.

Extension of the Model

I said earlier that the addition of simple feedback loops to Figure 1 oversimplifies the link between values, life styles, and consumption. Certainly models of consumer segmentation like that of Wilkie and Cohen (1977) that link demographic variables, socioeconomic variables, and personality variables as causes of media exposure, life style, and AIO are oversimplified to the point that I believe they are not useful for theory development. To demonstrate this point, we will enrich our model by the inclusion of more sociological concepts.

First, it will be useful to be more specific about the definition of life style. The term is not used in Figure 1. Nor, for that matter, is "subculture." A subculture is a collective which shares values. It has considerable consensus with respect to values, meanings, and the role of social institutions. It is enduring and self-perpetuating. It may exist across a range of socioeconomic classes, but it is a self-conscious collective. Its members consciously identify with it. Southern white Anglo-Saxon Protestants are an example of a subculture.

Although the term is poorly defined in the contemporary literature, life style is probably best thought of in terms of activities, interests, and opinions that become reflected in terms of media and consumption patterns (Zablocki and Kanter, 1976, 270-71). Figure 1 suggests that these patterns come from shared values. In marketing, we are interested in identifying segments of people who share life styles. By this definition, a subculture consciously shares a small number of distinct life styles.

The difference between a subculture and a life style is its enduring capabilities. A life style segment does not necessarily build up an institutional structure for endurance and perpetuation. It is identified by AIO and consumption behavior. Marketers are interested in identifying life style segments and constellations of values held by these segments. They and all social scientists are interested in tracing the dynamic development of a life style to see if it shows signs of developing into a new subculture. The transition of a life style will give clues as to how it might evolve and whether or not it will develop into a new subculture.

An example would be the "whole earth" movement--the return of young, healthy adults to a rural society that places an emphasis on living harmoniously with nature and on self-sufficiency. This is a life style and it is a viable market segment for many sellers. If you doubt this, I suggest you count the percentage of

advertising in the magazine, Whole Earth News. Will it endure? On the one hand, it appears to resist institutionalization. It is almost a life style of the hermit. On the other hand, there are signs of institutional development.

The point of this digression into life styles and subcultures is to point out that we must be careful we understand where values fit into a broader social structure if we are to find values useful in consumer research. Note that it is only a first step to show that there is a correlation between holding certain values and particular consumption patterns. Such a correlation may say something about the validity of the Rokeach Value Survey, but it does not take us very far toward a theory that relates values to consumption patterns. We need to do more work in three other areas to make headway in theory development. First, we need to build and test a theory that is richer in its specification of the linkage between values, other socioeconomic and demographic variables, cultural variables, life styles, and consumption. Second, we need to do more to identify general life style segments. Third, we need to have better explanations of the evolution of these life style segments. Figure 2 offers a small contribution toward these ends.

Figure 2 is an expansion of Figure 1, but it also contains some changes. These will be described first. The concept of life style now appears explicitly and is defined as roles, interests, time use activities, consumption, shopping, and media patterns. The life style construct is then treated as a single construct. Values continue to be principal inputs to life style. Three new factors have been added on the left side of the figure: subcultures, social institutions, and exogenous forces.

Subculture is shown as it was defined above, i.e., an enduring collective identified by its life styles and by a coherent value system perpetuated through an institutional framework. The Southern WASP is an example of a persistent subculture that has a unique constellation of values including conservatism, tradition loving, family loyalty, and religion (Reed, 1972). Reed hypothesizes that the institutions and individual values required to sustain this value constellation continue because southerners see themselves as a suppressed minority who need to maintain defense mechanisms against continued external pressures. Suppression as a factor encouraging endurance is not represented in Figure 2.

In contrast, social institutions appear to be of sufficient importance in the formation and perpetuation of value constellations that this factor has been added to the diagram. The representation is designed to show the importance of institutions as necessary reinforcers of specific values or constellations of values. Institutions form around or accept a particular value structure. They help the subculture they serve to maintain a consensus of coherent values. They act as orderly change agents to adjust value constellations through time. It should be emphasized that these institutions function well in accomplishing slow, orderly change. They are not change agents and respond badly to sudden changes thrust upon them. Established churches are the prime example of such institutions.

In order to simplify the feedback links in the diagram, the feedback to values is shown only to terminal values. Likewise, the feedback loop from consumption and media patterns is shown only to instrumental values. One should not reject the hypothesis that both feedbacks go to both kinds of values. Similarly, the feedbacks from purchases to values and life styles are not explicitly hypothesized.

FIGURE 1
THE ORIGINAL MODEL

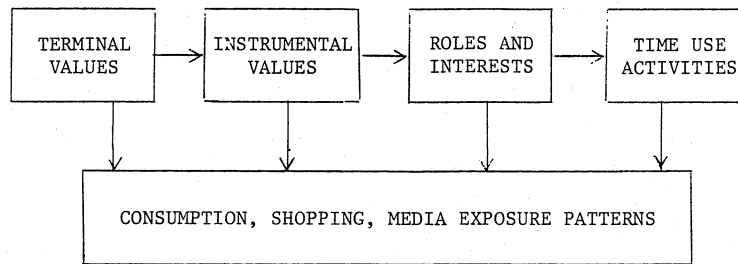

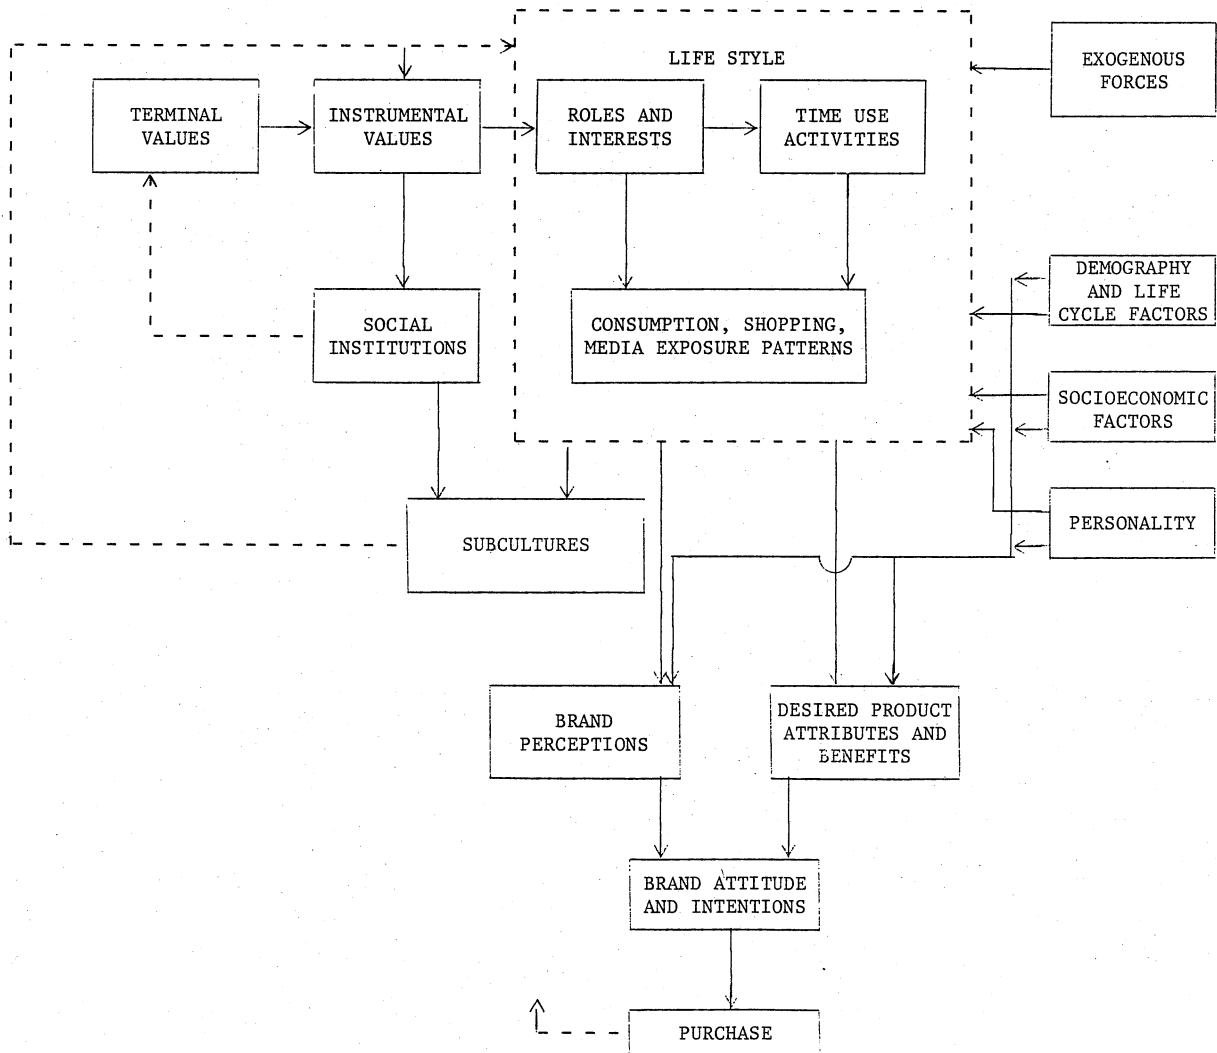

FIGURE 2
AN EXPANDED MODEL OF VALUES, LIFE STYLES, AND CONSUMPTION

The exogenous forces box has been added to indicate that often life styles can emerge from factors outside personal factors such as values, personality, life cycle, and socioeconomic factors. It is in this area that the anthropologist and sociologist have the most to contribute to the processes under study. Many anthropologists believe that new life styles proliferate during periods of societal breakdown (Kroeber, 1957). Thus, some hypothesize that the war in Southeast Asia in the 1960s was a major contributor to the emergence of unusual life styles.

Other exogenous factors that might be influencing life style development today are evident but not as often discussed. Increases in real income and the substitution of capital for labor is an interesting current example. A reasonable hypothesis for the emergence of a number of life styles that are more self-oriented and leisure oriented is that increased real income and leisure time have permitted life styles that previously were not possible (Gartner and Riessman, 1974; Nicosia, 1974). If this were true, then one would expect to observe an increase in work-oriented values and life styles during recession and an increase in play-oriented life styles during prosperity. While not formally tested to my knowledge, this is a plausible testable hypothesis useful to consumer research and greatly aided by the measurement of values.

For example, consider social programs designed to urge people to conserve energy and, in the West, water. Is there value congruence between the program and existing or emerging values and life styles? In California it appears that water conservation is more successful than gasoline conservation. People with different value constellations may have different responses to conservation efforts between the two commodities. Were this to be true, then the appeals used to achieve conservation should be different and should be based on an analysis of differences in values.

Returning to the description of Figure 2, look next at the three factors on the right below "exogenous factors." These three, demographic factors, socioeconomic factors, and personality, are the conventional determinants of purchase behavior one finds in the literature. They are added here for two reasons. First, for comprehensiveness. For a complete understanding of the influence of values and life style on consumption, it is necessary to integrate these concepts into a comprehensive model. Second, it is important to see that it is suggested that these three conventional determinants influence consumer behavior in two ways. One is the conventional direct links to brand perceptions and to desired benefits and attributes. I call this conventional for it appears this way in the popular comprehensive models.

The second way is through life style. Some life styles we observe are highly dependent on life cycle. For example, there are life styles that attract only the young and others that appeal to only the retired. There are other life styles that are dominated by economic considerations. For example, there is increasing concern in this country for the "underclass," that tenacious subculture on long-term welfare who seem to be drifting farther and farther from the mainstream of American life. Finally, there is a long tradition in sociology of research in occupational impact on life style (Kanter, 1976b).

This double effect of the conventional determinants of consumer behavior--directly and through life style--is not original with this model. It has been suggested by others. Plummer (1977), for example, has suggested a similar idea based on a theory of George Kelly (1955) that people make decisions using two construct systems:

"superordinate constructs" are those stable constructs that flow from life style and subculture and "subordinate constructs" that are short-term, problem-solving constructs.

Before closing this description of Figure 2, it may be useful to make one comment about the lower boxes on brand perceptions, brand attributes, attitudes, intentions, and purchase. It was not our desire here to be innovative or controversial. It did, however, seem desirable to tie our value and life style discussion into conventional models of individual choice decisions.

Closing the Loop

In this last section, the model will be exercised a bit by application of Etzioni's (1972) four life style responses to value incongruence. Earlier in this paper these responses were introduced in terms of values. The four responses are renamed using Rokeach terms rather than Etzioni terms. They are an increase in the importance of the values: (1) hedonism--a pleasurable, enjoyable life, happiness and contentment; (2) etherealization--inner harmony, a world of beauty, culture and art; (3) community--true friendship, equality among men; (4) activism--a lasting contribution, social consciousness. (Some of these terms are those of Zablocki and Kanter, 1976.) In each case, it is possible to trace a change in value constellation to a new life style to a consumption pattern and potentially a feedback to new values. In addition, each raises some interesting public policy questions that would yield to research on particular areas of values and life styles. This exercise may provide the reader with a bit more understanding of how the model operates and some of the research topics that flow from the model.

Hedonism

Etzioni (1972, 8) states that hedonism develops when the normative values of a society lose meaning and disintegrate without being replaced by new norms. What life styles and consumption patterns are associated with an increase in popularity of this value constellation? Sexual freedom as an ideological position, the drug culture, self-fulfillment, encounter groups, EST, human potential movements, and a personal shrink are all consumption efforts aimed at replacing societal norms with an assurance of being right with one's self. A better understanding of these trends in life styles could lead to a better understanding of rational public policy toward community mental health and drug abuse programs.

Etherealization

Etherealization is the substitution of symbols for things as objects of value. This shift follows disenchantment with the value of capital accumulation and with an unwillingness or inability to work hard enough to acquire "things." Symbols are relatively costless and in infinite supply. The practice has often been observed among the very poor, for example, in Latin America. The life style and consumption patterns that emerge from this new value constellation are an increase in the popularity of fundamentalist religions, mystical Eastern religions, religions based on poverty, natural foods, ecology and natural beauty. Note that the increase in aesthetic values has led to considerable pressures on government for greater support of open spaces, endangered animals, arts, and continuing education. Understanding the nature of these changes in values should lead to a more rational method for prioritizing government programs in these areas. Note that these new religions appeal to the former constellation (via the inner harmony route) and to the next

constellation (via the monastic route).

Community

People may seek to replace old value norms with new ones by clustering with other persons perceived to share similar value constellations. These might be existing communities, i.e., one might return to a known institution or community when the outside world looks frightening or one might seek to find a new utopian community. This decade has provided us with many examples of both kinds, but certainly closed communal enclaves with some ethnic and religious homogeneity have experienced periods of popularity at many times in the history of the western world. Clearly, communal living results in drastic life style change. Community need not always take the form of a commune or be in a rural setting. Gangs of youths in low-income inner-city areas also fall into this category. They too are not unique to the sixties and seventies, and also result from value incongruence. Note that forming physical community is a technique for institutionalization that could lead to a subculture with a normative set of values and an institutional structure for reinforcing these values. A better understanding of urban community life styles could lead to an improved public policy toward a whole host of poverty problems including frustration, personal bankruptcies, crime, and the disenfranchised consumer.

Activism

When the formation of a physical community is not possible, one alternative is a community organized for political activism. Thus, again, these four responses are not mutually exclusive. Many communities are politically active and many activists work through communities. A political or social movement is not a life style, "but because a social movement involves an ideology that orients its followers toward a coherent set of values, the context of the social movement generally provides an opportunity for a life-style to develop around it" (Zablocki and Kanter, 1976, 292). Again, the movement might become institutionalized to the point that it is value reinforcing.

THE EUROPEANIZING OF AMERICA:
A STUDY IN CHANGING VALUES

Donald L. Kanter, University of Southern California

Abstract

The theses is that technological, environmental, governmental and economic changes in America have produced changes in terminal and instrumental consumer values. Metaphorically speaking, these changes appear to approximate the European mode in terms of their social-psychological implications. These specific value changes are identified along with some of their marketing and advertising consequences.

Introduction

With American products, fast food franchises, and United States multinational corporations girdling the globe, one has customarily thought in terms of the Americanizing of Europe, not the opposite. Changes, however, in the external conditions in America seem to have occurred producing changes in terminal and instrumental consumer values and attitudes (Rokeach, 1973; Rokeach, 1960).

Interestingly enough, this rapid shift in socio-psychological outlook seems to more or less approximate a European mode in terms of behavior as well as weltanschauung. It should not be startling to say these changes have vast implications for consumer marketing strategy (Katona, 1971).

There will be fewer retreats for Americans to former days of conspicuous consumption. External conditions--technological, psychological, environmental and governmental--are the constraints.

For instance, government has become an anonymous, regulatory force in American life with all the depersonalization this implies. As the bureaucratic structure, described by Max Weber and Prof. Merton, has mushroomed, Americans have come to question the immediacy and responsiveness of the Democratic process. Recent candidates of both major political parties have campaigned on this point.

Moreover, Americans no longer perceive that they control the world, so to speak. European countries lost their colonies long ago and felt the destruction of two world wars. It is only recently, however, that Americans have felt diminished power over world affairs, with all of the concomitant threats to security and potency this implies. Terrorism, along with diminished control, has also become part of the collective unconscious, adding to feelings of general slippage and unrest.

To add to this decline of perceived omnipotence is the realization and acceptance of finite and limited resources. It is, for example, a significant development that American oil companies have undertaken massive advertising campaigns urging consumers to conserve their product, petroleum, not to consume it.

Under these changing conditions, marketing premises posited over the last twenty years of the "Marketing Revolution" are virtually invalid. Those assumptions of unlimited affluence, boundless food, fuel, and productivity; and--most importantly--a vision of the American consumer as voracious, eager, hungry, and greedy, no longer seem accurate (Webster, 1974).

The future has arrived bringing changed aspirations and new social and sexual roles. Americans will make new attempts to cope with increasing depersonalization and anonymity brought about by over-population and bureaucracy as well as inflation and psychological diminution. People are seeking different means of achieving equilibrium in a continuously clamorous world, bringing about different ways of consuming and evaluating goods and services.

It is in these differences--the response to a changing total environment--that the Europeanizing of America may be seen. Clearly, the analogy is imperfect; but it may be descriptive of a new values constellation. As conditions of scarcity, bureaucracy and inflation--recurring European experiences--occur in this country, the modes of adjustment appear to become closer in substance and style.

The Changes

First there is the American loss of innocence. Something very simple is meant by this loss of innocence which goes beyond Mark Twain, Edith Wharton or Henry James. Americans never before had military and diplomatic defeats approaching the magnitude of Viet Nam. They had not recently come close to a Watergate or an international oil cartel, or known crime and violence to such an unprecedented and televised extent.

What is the significance, however, of loss of innocence to the Europeanized American? It means, among other things, that what is vulnerable and uncertain about life has been brought home to most Americans. Certain mainstream cultural assumptions lost validity in the late 60's and the life of everyday quiet desperation is not so easily tolerated among many people. People feel they cannot manipulate their destinies as much, formerly an article of faith. This contributes to feelings of anomie. Psychologists might say that the locus of control has shifted from the self to external forces (Thornbill, 1975).

America's adult generation was raised to believe that one can be virtually anything he wants to be, including President of the United States. But Americans are moving towards a more fatalistic attitude, resembling that found in Europe ("que sera, sera"). There is a lowered expectation about the ability to manipulate one's environment. In addition, the parameters have been narrowed in regard to the invincibility of self-help. Boundless optimism in achieving traditional American goals seems inappropriate.

A related aspect of Europeanizing is the enormous growth in skepticism and cynicism. People question other people's motives more than before. The concept of the blunt, open-faced American, a gulleless, Candidate-like character, is not a valued aspiration. In the current environment this does not help survival.

What does this increased cynicism mean? For one thing, authority figures are suspect. A study conducted at the University of Southern California to examine reactions to public service advertisements about illegal drugs is illustrative (Kanter, 1974).

Star athletes (ostensibly reference group symbols) in

effect said: "I can't do my thing if I'm high on drugs." These ads elicited disbelief in 88% of the grade school children tested. When questioned further, the students felt one can't play that kind of game without being high and that the revered athletes were lying.

The current American approach to skepticism and cynicism may be characterized in part as trading off. This approach recognizes that things are rarely absolute, ("What do I have to give for what I get?") People appear to have arrived at a certain shrewdness in their dealings with this realistic and cynical approach to life. "Street smarts" have become operative in our society. In a phrase, this is the ability to "aim off"--to take one's time. Don't quite reveal oneself; maintain a facade; feign ignorance. This is the time-honored peasant's protection.

Another basic characteristic of Europeanizing is the changing time-frame of Americans. No longer is immediate response a virtue. From the customary American spontaneity and rapid closure, people tend to feel that it is notoriously unsafe to enter into a situation, to make decisions without waiting for events to clarify. This is an old English technique of negotiation identified by Charles Dickens in Bleak House in the 1860's, when he spoke of "fogging the issue." In other words, conditions change, hence wait, it may even go away--if not, continue to obscure the point and postpone a decision.

But a most crucial element of this phenomenon is that people want time--almost more than things. The marketing implications of this are enormous. Time will be a reward assuming many forms--longer holidays and shorter workweeks; temporal instead of financial bonuses.

The Europeanizing of Americans is also expressed in new levels of aspiration. Not everyone wants to grow up to be President or leader. Many would prefer simply to "play the game," collect time and have fun, being cooler and less hassled. Increasingly, aspirations are not so much power oriented as time oriented: Narcissism or self-absorption is the new patriotism, up to a point. This is absolutely crucial to the leisure, automotive, cosmetic, and a multitude of other businesses.

The trade-offs between risk taking and security are also changing. As corporations--including multinationals--grow, loyalty does not tend to keep pace, it is actually quite limited. People prefer to keep their options open. By "hanging loose," to use the argot, one doesn't have to commit all that much of oneself. One may try something, stay detached, then move--a shrewd "street-smart's" way of operating. Literally, take the money and run.

Also, there is a growing appreciation of natural simplicity and a European-type sensuality. Americans have come to realize the existence of basic body truths; that biological man is a very natural entity, smells and sights included.

In terms of sex, for instance, more people wallow less in guilt than in pleasure, no matter how transient or shallow. But discretion, rather than confrontation (I've sinned) is the style of coping with an extracurricular relationship because people accept that simple bodily functions are natural, not perverse.

Along with these simplicities come things like walking out, European promenading. Even in those American cities where inhabitants fear there's no place to walk safely after dark, the urge is transformed as it were into getting away; the Friday afternoon get-away is becoming a mass ritual. People are more pastoral rather than less. Camping is enjoying phenomenal growth in

popularity. Clothing for the rugged outdoor life--blue jeans, hiking boots, work shirts--is high fashion.

The natural and simplistic trends have led, among other things, to a reevaluation of the foods one eats. The empty calories of junk foods are now part of the mental geography of most people, not only mothers. "Health" foods, as they were called, are now everyday fare.

Notions of quality and obsolescence have also undergone changes re-emerging in highly European form. More and more, Americans purchase goods for reasons of durability and repairability not just for the sake of change, even if they pay more initially. Automobiles are expected to last longer; refrigerators are expected to last longer. Things are nurtured not discarded.

This emerging mentality is an expansion of the idea that less is more. Things and their accumulation bring far fewer rewards than do accumulation of time, leisure, and freedom in being one's self.

Related to simplicity and the downplay of accumulation is a new esteem for physical fitness. Exhilaration for a bike ride or a ski slope are just as important as shopping (with all its psychic transactional satisfactions) for the odd piece of furniture. This means, among other things, new channels for dollars and opportunities to express individuality in even eccentric kinds of ways.

Europeans have lived with scarcity, limited resources and minimal locus-of-control feelings and have developed other means for asserting their dignity and individuality. This is the situation Americans are not dealing with. As Americans come to face limits on their positions, possessions and power, their quest for viable modes to assert themselves becomes crucial. This phenomenon of self-assertion under new environmental conditions can impact the advertising and marketing processes. This question will not be examined using Advertising as an example.

Advertising Strategy and the New Values

How may these insights about the emerging state of the consumer mind be used to further communications between manufacturer and consumer? The position this paper takes is that understanding the values orientation of the consumer should help to develop more sympathetic and instrumental approaches to communication from manufacturers which are perceived as such by consumers (Delano, 1975).

The opportunity lies in the recognition that people are actively searching for an identity in an increasingly depersonalized world. In this process, they're trying to discover not only themselves, but also these goods and services which might give them a certain individuality and uniqueness. It is as if the Americans are using goods and services to reach a sharper level of separation from their homogenized peers. In a comparatively materialistic society, the substitution of "things" for spirituality is probably a natural if not altogether salutary outgrowth of on-going values trends.

Helping consumers to discover elements of a brand's uniqueness (to them) is really a major function of advertising and communications. Advertising drops cues, hints and generally leads the consumer to rethink his relationship to brands that he may have taken for granted.

By rethinking his relationship he is, in effect, projecting an element of discovery of "me-ness" upon a brand product or service. In many cases, it is not enough (or too much) to tell people directly what brand benefits are: It probably is a more reinforcing learning process for the consumer to discover for himself

that there is a fit between a brand and himself. Discovery for oneself becomes critical when the perception of authority figures is unfavorable as it is in the present values configuration.

In other words, to communicate effectively within the context of current values the consumer must intrude himself, aided and guided by advertising cues and suggestions. This Discovery Process is one way out of anonymity and depersonalization into identity partly through goods and services. And therein lies its enormous attraction to the consumers of the 1980's who do value uniqueness even though they are pessimistic about achieving it.

Rightly or wrongly, then, consumption is one of the last remaining avenues of self-expression in most Western cultures. To quote Lester A. Delano, President of Campbell-Ewald International:

"Viewed this way, it seems evident that advertising's role is to tap the consumer's Discovery Process by continually surfacing new cues to help the consumer in his on-going search and to get him constantly to rethink his relationship to the brand instead of taking it for granted. There is ample evidence--ignored by many advertisers--that repeating the same cue (advertising) over and over is wasteful in the extreme."

"We need many inputs, many cues . . . but of the kind that helps people to discover things. The kind that gets them to project themselves into the message. To involve themselves in our selling argument, so to speak, we must personalize the message so that the consumer can respond personally and we must be unafraid to be slightly fuzzy, unclear, funny, incongruous or ambiguous . . . just as people are. In this way we can draw the consumer in, let him make his own closure."

The use of The Discovery Process techniques, e.g. ambiguity, novelty, incongruity, etc., has attraction for the consumers because it is a way through an increasingly computerized, depersonalized existence. The very process of searching for these goods and services while distinguishing one from the others is rewarding per se. The excessive preoccupation with self has gone so far as to be labeled by New York Magazine when they call it the "Me Decade." It is as if people are urgently trying to hivel themselves off from mediocrity, ordinariness and conformity.

Consumer Research and The Discovery Process

If one postulates that the thrust of marketing advertising productivity is to trigger The Discovery Process, then it is possible to measure advertising to see if in fact it does get people to rethink, reopen, or underscore their relationship toward the brand. In other words, it is possible to see if an advertisement--in pretesting conditions--does make for links to the self or the shock of recognition (Kanter, 1970).

It is possible to set up codes to classify response to advertising pretests which do in fact measure whether The Discovery Process has been activated. These codes, in rough terms, relate to at least the following:

- a brand's character in terms of expanding the consumer's fantasy
- personal problem solving
- projecting and elaborating the advertisement
- uncovering unsuspected relationships to the brand

- the rehearsal for purchase
- the embracing of symbology
- and the general process of dialogue with the advertisement.

The point is that each of the above responses may be measured and evaluated in the pretesting situation. This fact allows the manufacturer to be able to predict what will be sensible, appealing, and meaningful to his customers before spending a great deal of money on an actual campaign.

Conclusion

It has been the contention of this paper that significant changes in values are taking place in the United States which more often than not approximate the European model. Some of these tendencies have been described and some of their implications drawn. Moreover, the use of the techniques of The Discovery Process have been discussed as a way through general consumer depersonalization.

Finally, the measurement implications have been mentioned and the opportunity for pretesting developed.

It is indeed the aware and sensitive marketing person who understands his audience well enough to stay in appropriate touch with it. As values change in society so must the marketing approach.

CONSUMERS' REACTIONS TO SEX IN TV COMMERCIALS

Deborah K. Johnson, Needham, Harper & Steers
 Kay Satow, Needham, Harper & Steers

Abstract

This paper explores viewers reactions to sexual material in TV commercials. Findings from a large scale quantitative survey and a small scale qualitative study are reported and implications for advertisers are discussed.

Sex in Commercials

Last year's concern about sex and violence on television has switched to this year's concern about sex on TV. Newspapers and magazines are filled with articles about the new sexual permissiveness. But are consumers aware of this trend? Are they bothered by sex on the airwaves? And closer to our hearts, as an advertising agency, do they feel there is too much sex in commercials?

To answer these questions and more we fielded two studies: a quantitative lifestyle study and a qualitative follow-up to determine consumers reactions. Before presenting our results, we invite the reader to test his sexual I.Q. with the following test.

Sex Test

Please indicate whether you think each of the following statements is true or false. DO NOT copy from your neighbors.

- T F 1. Most people feel there is too little sex on commercials.
- T F 2. Older men are less concerned with sex on TV than younger men; thus the phrase "dirty old man."
- T F 3. Women who are concerned about sex on TV point to soap operas as prime offenders.
- T F 4. Unlike the discriminating younger women, older women hate all sexy commercials.
- T F 5. Many people don't find sexual innuendo offensive. They don't even know what it is.
- T F 6. Women expect sex in men's ads. After all men are beasts.

Do People Feel That TV Commercials Place Too Much Emphasis on Sex?

While published studies (e.g. TV Guide 1975) indicate that the majority of viewers object to the amount of sex on TV, we were not certain whether these objections extended to commercials as well as programs. For all we knew they may have felt there wasn't enough sex on commercials. To answer this question we turned to data from the Needham, Harper & Steers 1977 Life Style Study.

Every year NH&S mails a large scale consumer survey to 2000 married men and 2000 married women from the Market Facts' mail panel. Our response rate is high, averaging around 85% for women and 75% for men and the obtained sample matches the U.S. married population on age, edu-

cation, income and area of residence. The Life Style Study includes over 850 questions covering a wide range of activities, interests, opinions, product usage and media habits. Luckily for us one of the questions directly concerned attitudes toward sex on commercials. Respondents were asked to indicate on a 6-point scale the extent to which they agreed/disagreed with the statement, "TV commercials place too much emphasis on sex."

The responses to this question, shown in Table 1 clearly illustrate that the majority of our respondents agreed that TV commercials place too much emphasis on sex, and also that women tend to feel more strongly about this than men (79% of the women and 68% of the men showed at least moderate agreement with the statement).

TABLE 1
 "TV commercials place too Much Emphasis on Sex"

We discovered also that Age and Education are related to the degree of concern expressed over sex in commercials. As shown in Tables 2 and 3 strong agreement with the statement that "TV commercials place too much emphasis on sex" increases with age and decreases with education for both men and women.

TABLE 2
 % of Each Age Group That Definitely Agree That "TV Commercials Place too Much Emphasis on Sex"

TABLE 3

% of Each Education Group that Definitely Agree That "TV Commercials Place too Much Emphasis on Sex"

So far our findings made a good deal of sense and had presented us with no great surprises.

What TV Shows do People Who Are Bothered by Sex Watch?

The NH&S Life Style Study also asks about TV program viewership. We expected to find that TV preferences would reflect concern over the amount of sexual material on TV. For example, we expected concerned women to watch family shows, certain situation comedies and other wholesome TV fare. Table 4 presents some of the favorite TV programs of these women. Some of these shows made perfect sense to us. The Waltons, Walt Disney, Little House on the Prairie are all about as wholesome as you can get. Mary Tyler Moore and Rhoda are basically nice girls and Archie Bunker would be just as upset about sex in commercials as respondents are. BUT there at the far right hand portion of the Table is a show that doesn't seem to belong, that makes no sense at all, that boggles the mind.

TABLE 4

Viewing Habits of Women Who Agree That "TV Commercials Place too Much Emphasis on Sex"

Over 40% of these women watch Soap Operas. Yet soap operas are filled with sexual material - bedhopping, infidelity, promiscuity, etc., etc. The attitude that there was too much sex on TV seemed totally incompatible with the behavior of watching soaps. It was at this point that we realized that we really had no idea as to what exactly people meant when they said that TV commercials have too much sex.

So we decided to stop looking at numbers and to start talking to some real live consumers. Six focus groups were conducted in September, 1977: three with blue-collar homemakers; three with white-collar homemakers. Women were also segregated by age: two groups were conducted with younger women, 18-25; two groups of middle-aged women, 30-40; and two groups with women 55+ years of age or older. All were married homemakers. Because our goal was to determine precisely what people were objecting to in terms of sex on TV, respondents were all prerecruited to agree with the statement, "TV commercials place too much emphasis on sex".

We began the groups by asking what TV programs they liked to watch. And sure enough, just as in the quantitative study, Family and soap operas were right up there with more wholesome TV shows. Why the anomaly?

Respondents were quick to point out there was no anomaly in their minds. They don't object to all sex on TV. They object to the wrong kinds of sex on TV. They like soap operas; they loathe Soap. Why the distinction?

They say sex is OK under certain conditions. It's all right when sex is implicit, not explicit. They rarely show anything in soap operas; you're saved the potential embarrassment by a quick cut-away. Sex is also all right when handled in a moral context. In soap operas, the heroes and villains are broadly drawn and easily recognizable. The sinners are eventually punished; the good guys are rewarded. They also say sex is always all right when you're prepared for it. And you're rarely more prepared than when watching a soap. Soap operas and Family also have the virtue of being shown at suitable hours, either the kids are away at school during the day, or safely tucked in bed at night.

Soap, on the other hand, is seen as being just the opposite. It doesn't show sex in a moral context; sex is treated lightly and deviant sexual behavior is condoned. Because it's immoral sex, respondents are far more likely to feel that any sexual nuance or innuendo is by default explicit.

How About Sex in Commercials

After exploring our respondents' attitudes toward sex on television we turned to the topic of commercials. We asked the women to give us examples of commercials that had "too much sex". The following commercials were mentioned most frequently: Noxema Shave Cream, Bic Lighter, Bic Razor, Ultra Bright, Muriel Cigars, Pearl Drops Underalls, Aviance, Shower Massage, Chicago Health Club, Tickle. Also mentioned frequently were a variety of commercials for "intimate" feminine products. After a general discussion about sex in commercials we showed the women four of these commercials (Bic Razor, Underalls, Muriel Cigars, Aviance Perfume) and explored their reactions in some detail.

By the end of our groups we felt we had a pretty good idea of what these women find offensive in commercials and why.

Sexual Innuendo

The Bic Razor commercial is a prime example of sexual innuendo. Here is a brief synopsis: It is a young man's wedding day. His sly uncle tells him to use Bic and get stroked in the morning (get it?) At the wedding his bride to be announces that he got stroked that very morning and now will get stroked every morning. The groom looks embarrassed, as well he might.

The young women in our groups characterized sexual innuendo as crude locker room humor. They found such suggestive insinuations embarrassing when others were present and offensive at all times. Any why shouldn't they feel this way - wouldn't everyone?

Well, not quite everyone. The older women saw nothing offensive in the Bic commercial and thought, in fact, it was kind of cute. When the moderator pointed out that the young women had found it offensive, the Edith Bunker syndrome took over. Older women would pause, look puzzled, frown their brows, and then say, "Ohhhhh... they couldn't mean..." Older women concluded only people with dirty minds would think that; younger women all had dirty minds. The only point about Bic that everyone agreed on was, "Well, at least it will go over the kids heads. They're not going to ask me about it".

Intimate Products and The Body

Consider this advertising for Underalls: Two girls are walking down the street away from the camera. The camera zooms in on their -uh- rear ends. One girl looks terrific. The other has panty lines and looks just awful. The girl with the problem tells us that underalls "make you look like I wish I looked."

In discussing what they hate in commercials women repeatedly mentioned that really intimate products should not be advertised on TV at all, and while panty hose may be considered less intimate than Kotex, it still constitutes an intimate product. In addition, women had already told us that certain parts of the body are inherently offensive and surely rear ends would fall into that category. We were therefore fully expecting our respondents to render scathing judgement upon this ad as it combined two inherently offensive elements - intimate products and bodily parts.

But in fact they liked it and didn't find it offensive at all. Sure the commercial focused on rear ends, but that was part of the product's reason for being. Panty lines are part of life; Underalls one way to get around them. As long as focusing on rear ends focuses the viewers attention on the product's primary benefit, it's not offensive.

The supposition that a focus on the product's primary benefit rather than on sex is important in mitigating offensiveness is supported by womens' reactions to another version of the Underalls ad. This particular ad ends with the line "Underalls makes me look like I'm not wearing nothing," and women hate it.

In addition to being grammatically incorrect, looking like one is not wearing nothing is not viewed as a primary benefit of buying Underalls. Women don't want to look like they are not wearing nothing and don't like people who do.

Male Fantasy Ads

What is a male fantasy ad? Well, let us give you an example. The ad for Muriel cigars is a male fantasy ad and goes something like this: A man sits working in his office alone at night and pulls out a cigar. A

super-sexy woman appears from nowhere and lights his cigar. She sings that he should let Muriel turn him on while she slithers around the office and ends up sitting on his lap.

You can always spot a male fantasy ad by the presence of two key elements: (1) foxy ladies, and (2) scenarios written by sexist piggy writers. The young women in our groups found this ad the most offensive of all the ads we showed them. Not only do they object to ads that place women in demeaning roles (lighting cigars, being at a man's beck and call) -- as any liberated woman would -- but in addition to that they find male fantasy ads personally threatening. Sexy women in ads make them wonder, "Is that how my husband wishes I looked?" This particular ad made them wonder, "Is that what my husband does at the office late?" Male fantasy ads contain unusually attractive women in unrealistic situations. It is this very lack of realism that young women find threatening and offensive.

But older women liked this commercial. Why? In part their consciousness hasn't been raised; it doesn't dawn on them that they should be offended. And even if the thought had crossed their minds they say, "Listen, honey. At my age anything that will get him excited just ain't half bad." In fact, one 64 year old grandmotherly type named Dorothy could hardly wait to get home and slink around her cigar-smoking husband singing, "Let Dorothy turn you on, that is my desire..." Moreover, they assert sex is always OK for traditional men's products. After all, they're advertising to men, not to them.

Female Fantasy Ads

If the Muriel ad is an example of a male fantasy ad then the Aviance ad is an example of a female fantasy ad: A beautiful young wife and mother is in the kitchen decked out in apron, rubber gloves - the whole housewife bit. Suddenly she begins a striptease while a female voice sings that she has had a full day of motherhood but is going to have an Aviance night. Scene shifts and she's in a bathtub full of Aviance bubble bath. Scene shifts and she's spraying Aviance perfume down her half opened blouse. Scene shifts to her fantastically handsome husband arriving at the door with flowers.

As it turns out young blue collar women hate female fantasy ads almost as much as they hate male fantasy ads. While they report that the bath scene and striptease are mildly offensive the main reason they hate this ad is because it portrays an unrealistic unattainable situation. They would all like to be in that situation but their lives just aren't like that. Their husbands don't come to the door with flowers like that and probably don't look like that either. Nor can they so conveniently get rid of their kids at night. They are unable to empathize with such female fantasy ads; instead they find them threatening and therefore offensive.

This time it was white collar young women who disagreed. The Aviance commercial was one of their favorites. They empathize with the commercial, and know just what it feels like to be in her situation. Maybe their husbands don't look quite like that, but they'd like them to. And they say it's good to show their children that "mothers and fathers love each other." The two older segments were split: some liked it, some couldn't relate, and some were just plain neutral.

Immoral Behavior

There is one thing that women of all ages agree on. Immorality offends them. The ads for both Bic Razors and Muriel Cigars violated our respondents' moral standards, which can be briefly summarized as follows: Physical

intimacy should only occur between consenting married adults (and even then only off-camera). In the Bic commercial he got "stroked" and they weren't even married yet. The Muriel ad was even worse - they weren't even engaged. At least the Aviance ad was about married people (and all of our groups made reference to this fact.)

Sexy Programs VS. Sexy Commercials

We think we've learned several things about commercials from this study. All offensive commercials are not created equal: they're not equally offensive, they're not offensive for the same reason, and they're not even offensive to the same people. But one still unanswered question occurred to us. Which is more offensive: sexy programs, or sexy commercials?

Even though some TV commercials are considered pretty offensive it made sense to us that TV programs would be considered even worse. For one thing TV programs last longer than commercials. If a commercial contains offensive material it will be over in a minute or less, but offensive programs go on and on and on. And besides sexual material is far more explicit on programs. And finally - how would any commercial possibly be as offensive as Soap which church groups have called: "leering sensationalism under the guise of comedy."

So we thought. Actually these groups were more offended by commercials. For one thing, there's no time for elaborate plot development -- in fact for almost any plot development in a 30 or 60-second commercial. Any sex used comes through that much clearer. And as a corollary they say you don't know sex is coming in a TV commercial. In TV programs, they build (and sometimes build and build) to sexual scenes; in commercials, wham bam, and it's over. Finally, they say sexy television commercials are harder to avoid. You know not to watch certain programs because you find them offensive. But commercials hit you out of the blue. By the time you get up to turn the channel, the offensive commercial is over.

Discussion

What do we think all this means? We think it means several things. First, sex is acceptable for certain products, products with no other reason for being than to increase allurements: cosmetics, perfume, and aftershave all fall in this category. Sex is also okay for advertising traditional masculine products, at least for non-liberated women: sex and beer, cars, liquor, and cigars mesh beautifully.

In addition, sex is permissible in female fantasies for young white collar women and male fantasies for older women. Sex is also all right when used in morally acceptable, eg. married, situations. And finally sex can be used when it's closely tied to the product's primary benefit.

We also learned that, for women at least, a commercial's offensiveness depends in part on the viewing situation -- on whether the viewer is alone or with others. Commercials are more offensive when others are present. Children giggle and ask difficult questions, husbands giggle and make offensive comments, and the presence of guests such as "my uncle, the priest" causes embarrassment. In the case of TV commercials, sex is more fun alone.

Finally, consumers, or at least these six groups, believe that television is an intrusive medium. Yes, you invite television into your home, but no, you don't want it to embarrass you. And even more than embarrass

you don't want it to foster immorality or to change existing sexual mores. Women aren't worried about changing their own mores. They're worried about people with impressionable minds, most specifically, their young children and all "those weirdos out there" who can be confused quite easily, and taught values the respondents don't believe in. As far as these women were concerned, TV not only mirrors social norms, it can change them. And that's potentially dangerous.

SEX ON TELEVISION, MORE OR LESS

William S. Rubens, National Broadcasting Company

Abstract

Are sex and violence substitutes for each other? There is no precedent or reason to think that they are. Yet they are frequently linked. While they are both emotional issues, they are distinct issues. The concern with television violence is derived from the possibility that it increases crime and delinquency. There is consensus in society that any such effects are undesirable. In contrast, there is no such societal agreement about the effects of television sex. Commercial television is the most conservative of the mass media when it comes to sex. There is no "real sex" on TV, only in-endo.

Some of the problems involved in discussing sex are well illustrated by a recent story in the New York Times. College biology students were asked to invite their parents to a seminar on pornography. After several pornographic films had been shown, one of the mothers volunteered that she had seen a porno flick before when her husband had brought one home. Shocked, her daughter the student blurted out "Mother!" Suddenly realizing what she had done, the daughter lamely explained to the class, "Well, after all, they are my parents."

When Dr. Wells asked me if I would be willing to serve on this panel about sex and TV, he also asked if I would address the question a lot of people have been asking lately: will sex fill the void created by the reduction of television violence?

As a researcher it was natural for me to think about the implications of the question before addressing myself to the answer.

This question is like the old saw, "Have you stopped beating your wife?" It seems to imply that sex and violence are functional equivalents in programming -- each one can simply replace the other. This assumption has little basis in fact. Also, the question as posed confuses two issues which must be kept separate: sex and violence. Just for the record, I want to state at the outset that I am opposed to the latter and in favor of the former. Finally, the question does not define what is meant by "sex" on television.

In my opinion, there is no sex on television. However, I've heard from people who watch the same programs I do who think they're saturated with sex.

I will cover some of these issues, try to answer the question that was intended, and discuss some research concerns I have with respect to sex on television -- and conclude with a discussion of network policy.

Sex And Violence: Functional Equivalents?

First, what about the assumption that sex and violence are substitutes for each other? There is no precedent suggesting that they are. If we look at theatrical movies, we can infer that sex and violence have escalated at the same time. Many movies show explicit sex and explicit violence as well. However this has not been the typical pattern in television. On TV, most of the action-adventure programs have little to do with sex and much of the so-called sex on TV occurs in comedies.

Furthermore, protests over television sex started some time ago when complaints about violence were also increasing. In other words, if those complaints reflect an increase in sex on TV, this increase took place before the reduction of action-adventure shows this season. Finally, the programming this season does not support the argument that sex takes over where violence leaves off. Action-adventure shows were replaced with all kinds of programs: new nonviolent dramas like "Man from Atlantis" and "Lou Grant," variety shows like "Redd Foxx," and all kinds of comedies -- including "Soap." Neither the new programs nor the networks' policies in replacing violent programs show any uniform pattern.

I think that all these developments show that there is no reason to think of sex and violence as functional equivalents. The content of television programs and the directions programming is taking are determined through complex processes which affect sex and violence independently.

Sex And Violence On TV: Two Different Issues

Sex and violence on television are emotional issues. Rational debate about them has been further impeded by the catch phrase "sex and violence" which lumps the issues together as if they were more or less the same. Indeed, the phrase is sometimes run together as though the two were one word: "sexanviolence." But for the broadcaster they are very distinct issues.

The concern with television violence is derived from the possibility that it increases crime and delinquency. The networks have reduced the amount of violence in their programming even though it has not been established that TV has actually affected crime or delinquency.

NBC maintains a panel of distinguished social scientists to advise Standards and Programming on potential harmful effects. Also, the networks' Broadcast Standards departments systematically supervise programming and attempt to eliminate portrayals of potentially harmful actions.

There is consensus in the society that any such effects are undesirable; no rational person would argue that there is merit in teaching or causing someone else to inflict harm on others and to act violently. As a result, broadcasters have the responsibility to act in a way which minimizes the chances of any such harmful effects.

In contrast, there is no such agreement about sex on television. Some people feel that sex is a legitimate topic for television to handle. Others feel that showing or discussing anything sexual on TV is in bad taste -- or "filthy." But the opinions of both groups are based on moral value judgments. And as far as perceived consequences are concerned, people generally agree that violence is anti-social and has harmful consequences, but there is no such consensus about sex.

In addition, there is no evidence that TV viewing affects sexual behavior and attitudes. There is little research on this issue, but NBC has collected some relevant data. As you may know, we are in the process of reporting on a 3-year longitudinal study on the effect of TV exposure on the behavior of children and teenagers.

The teenage portion included some questions on the boys' sexual behavior and attitudes. Therefore, we were able to analyze whether teenage boys who watched a lot of TV programs with sexual overtones of any kind were more likely to "neck," "go all the way," or have more liberal attitudes about such matters than boys who watched very little of these kinds of programs. We found that television viewing had no measurable effect on such behavior or attitudes. Even if we had found an effect there would be people who would argue for the philosophy, "make love, not war."

Since there is no moral consensus and since there is no scientific evidence of harmful effects, it is the responsibility of the broadcaster to analyze carefully what the controversy is all about. We can begin by asking what is this "sex on TV" that many people seem to get upset about?

What Is TV Sex Really Like?

Earlier this year, Eli Rubinstein and other researchers at the State University of New York at Stony Brook published the findings of the first content analysis addressing the issue of sex on television. After analyzing 61 prime time programs the authors reached this conclusion (I quote):

"The major finding was that physical intimacy appeared most often in less sensuous forms than one would expect from the public criticism of the portrayal of sexuality on current television programming."

If "sex on TV" means "showing people having sex," the finding was clear: there isn't any sex on TV. TV shows couples kissing and embracing, sex is discussed in a restrained manner, and there is innuendo -- but never actual sex.

These findings appeared to be surprising to the Stony Brook researchers; they aren't to me. There is little doubt that commercial television is the most conservative of the mass media when it comes to sex. Every variation of sexual activity has been shown in recent theatrical movies and has been described in recent books, and not far behind are Playboy, Penthouse, and Hustler, which rank among the nation's best-selling magazines.

If there is no "real sex" on TV, it is important to clarify what critics of TV "sex" are complaining about. One reason Rubinstein and his co-researchers expected real, sensuous sex on TV is that, as they point out, polls indicate that a clear majority of the American people think there is too much sex on TV and that many find "scenes of sex" more objectionable than violence on television. But the poll questions were as vague as the "Is sex going to replace violence" question: they do not clarify what people regard as "television sex," what they do and do not object to.

Opinions About Sex On TV

Critics of sex on television tend to assume that it is a firmly established fact that most Americans are critical of television sex. I deny that facts about attitudes concerning sex on TV have been established and I deny that the available data suggest that most Americans are critical of TV sex.

Among the few sources of information on this subject are a TV Guide poll, the mail we get, and public statements by organizations.

First, in April 1976 a TV Guide poll found that 58% of the respondents answered "yes" to the following: "In your opinion, is there too much emphasis on sex on TV?" Most researchers would agree that this is a classic example of the biased question. It uses emotional, value-laden words, its terms are vague and undefined, and it presents the respondent not with both sides of the issue, but with only one choice, tempting him into yea-saying. So the question is predestined to elicit a biased response and, in our judgment, is not an accurate gauge of public opinion on the issue.

However, even an accurately worded question would probably not be a good measure of opinions on this issue. There is hardly any subject more difficult to investigate than sexual behavior and attitudes, and it is unlikely that any one question can produce valid results.

This problem illustrates a favorite maxim of mine: Just because you ask a question and get an answer does not mean you have obtained information.

I can ask a question about virtually any topic. But it does not follow that the answers I get reflect genuine opinions on the issues I am trying to ask about. Surveys about sex attitudes probably fit this description better than almost any other topic.

The people who will not cooperate in a survey have different attitudes from those who will. This was a problem with the Kinsey report and has been a problem with all sex studies since, up to and including the Hite Report.

Consider, for example, Redbook Magazine's recent study on male sexuality, entitled "What Sex Means To The Man You Love." They printed the questionnaire in their magazine and asked their readers to hand the questionnaire to "the man you love" to fill out and send in. Mind you, the woman is not to peek at his answers.

Now let's look at some of the questions:

"How do you think your degree of sexual satisfaction compares with other men's? In the past few months who has been your main sexual partner? With how many other women have you had sexual relationships since your present relationship began? And finally: Please describe in some detail the most enjoyable sexual experience you've had."

Apart from the issue of self-selection, to believe that all 116 such questions get answered without underclaiming or overclaiming, strains my credulity. I guess this is what the statistician means by a "minimum likelihood" event.

However even when carefully done, the subject of sex presents special problems. For instance a study reported in Psychology Today found that a sample of college students -- usually considered a very liberated group -- experienced a surprising degree of blockage and embarrassment when questioned about the sexual activity of their own parents. As with the shocked girl in the New York Times story, the thought that their very own parents are still having sex seems to overwhelm some members of this presumably laid-back generation.

So as a researcher I have to remain highly skeptical over the ability of research to overcome the problems of response and non-response biases and extract the full truth on this emotional and guilt-laden subject of sex.

Viewer mail and public statements by organizations do not help much in an assessment of public opinion either. Organizations, whether small or large, are not representative of the public and neither is viewer mail. During the whole of last year, NBC received only 3,300 complaints about sex or morality on TV, less than 2% of the total letters received. Many of these letters are not about sex per se but are about sex in combination with sacrilege or with ridicule of prominent figures. This number also includes 900 letters from organized write-in campaigns.

It is interesting to learn what kinds of things these critics object to. There are very rare instances in which many letters and public complaints express dissatisfaction with a specific program or program segment. An example of this is criticism of a scene in an NBC movie, "Born Innocent," and the current furor over ABC's "Soap." In fact, numerous groups and individuals around the country were taking positions criticizing "Soap" even before it went on the air.

Most of the complaints, apart from these few specifics, are about everything on TV that could be construed as being related to sex: pretty girls in bikinis, jokes and innuendos in comedies and on talk shows, as well as dramatic treatment of topics such as rape. All these things are seen as "filth" and "permissiveness" on TV, which is perceived as endangering the "moral fiber" of this country.

But there are other voices. Some months ago I attended a seminar conducted by the Institute on Human Behavior dealing with sexuality and television. Basically it was the purpose of those running the conference to exhort the producers and networks' Program and Standards people to take a more forceful and perhaps more enlightened position in dealing with sexuality. The Institute urged more realistic portrayals of themes such as homosexuality, sex and the aged, and sex education for children.

It quickly became clear that the Hollywood creative community would be willing to incorporate these topics thematically into their programs. It became equally clear that this was not the problem. The resistance to frank portrayal of sexuality in TV rests with concerns of church groups, of affiliates, and of advertisers about offending American sensibilities and tastes, albeit minority tastes.

Thus the situation clearly reflects the lack of consensus about sexual issues in this society. The debate about sex on TV mirrors the society's own debates about the changing moral standards concerning sex. TV finds itself in the crossfire between opposing viewpoints.

TV Networks And Sex On TV

As sexual behavior and values have changed, television has changed. But it has not changed faster than society. TV is not and does not want to be a trendsetter of the sexual revolution. In fact, it lags behind the prevailing attitudes. And there is no reason to assume that the networks will alter that basic policy in the future. The reason is that this country's system of broadcasting has a built-in set of checks and balances which prevents programming from over-stepping the boundaries of what most people consider good taste. Programming decisions result from a complex interplay of many forces, which does not favor the emergence of radical trends.

Let's take a closer look at this interplay. The participants are the three networks with their program

departments, broadcast standards departments, and, of course, their managements. Then there are the producers, affiliates, and advertisers -- and last, but certainly not least, there is the viewing public.

The "viewing public" itself, as we have seen, is by no means of one mind on the issue of sex on TV. Attitudes toward sex, as exemplified in a Gallup question on "whether standards regarding the sale of sexually explicit material should be stricter than they are now" vary by age ... by sex... by education ... and by region of the country. For example, Gallup found 53% in the South favoring stricter standards, versus only 36% in the West. TV Guide's loaded question applying specifically to television, showed similar differences.

Reflecting these differences within the viewing public in the entire array of network affiliates -- themselves a vital element in the system of checks and balances governing television content. These affiliated stations are charged by the Communications Act with license responsibility for what they air. They represent a broad spectrum of political ideology, regional variation in taste and viewpoint, reflecting their close contact with their respective communities. As a general tendency, in the matters we're discussing here, we find there is commonly more concern about violence in the North-east, and more concern about sex in the South.

A second factor in the interplay of checks and balances is the force of competition among the three networks -- a factor which favors innovation. Today, one network appears to be giving viewers more cheesecake and making greater use of sexual overtones. Within the networks, we have program departments and broadcast standards departments with conflicting views over how innovative television should be. The people in these departments have different values and therefore often come up with different answers. The same is true of the network managements and producers.

A case in point is the different opinions about "Soap" mentioned earlier; it is a very complex question whether another network would have carried "Soap" or not.

From the first proposal of a program concept until the final edit of an episode, all these people -- writers, producers, directors, network management, programmers, and editors -- exert an influence. As a result, "Soap" done by another network -- and a whole different set of people -- would not have looked exactly the same.

But network managements not only take into account the views of their own executives and suppliers, they are also very sensitive to public reaction, including that of the critics and pressure groups. Similarly the advertisers, too, listen to the public, the critics and the pressure groups. In general, advertisers exert a conservative influence on the network management, since they do not want to see their product advertised in a program which might possibly annoy many viewers. Clearly, compromise is necessary to effectively balance the variety of views.

No wonder, then, that television has been slow to change with the times. The creative forces which press for innovation are nearly always restrained by conservative forces. Let me give an example: a few years ago, ABC was offered an innovative program. The network did not want to risk anything at that point so the program was offered to CBS and they scheduled it. "All In The Family" became a hit -- and also became the precursor of a host of programs with social messages, with the result that today we hardly think of "All In The Family" as the innovative program it was.

Other examples which justify network decisions to put innovative programs on the air despite opposition from some viewer groups include NBC's development of "Laugh-In," which was put on the air with the full fore-knowledge that some viewers might be concerned. There were indeed some protests, but the majority of the viewers welcomed the innovation, and incidentally "Laugh-In" became a hit. NBC's "Saturday Night Live" went through a similar process.

And we should not forget daytime serials. Our research indicates that most women viewers appreciate the treatment of all kinds of adult themes in daytime programming which they would not like to see during prime time, because in the afternoon they can relate to what they see on the screen in relative privacy.

Future Trends

It seems clear that in the current situation where there is no consensus about sexual attitudes and behavior, it is not possible for TV programmers to please everybody. The best policy under such circumstances is to try to steer a middle course. The networks have been doing just that, and they will not depart from that policy. However, TV will not go back to the standards of the 50's. It is the responsibility of broadcasters not to allow a minority of conservative critics to act as censors for the majority of viewers.

Indeed this is my main concern, the implied censorship issue raised by the ability of small pressure groups to influence what is seen by the American public. Even without direct formal censorship by the government, the pressure of these interest-groups can exert a chilling effect which in a subtler and more insidious manner produces the same consequences as formal, explicit censorship.

On the other hand, we have a responsibility to resist those who want television to become a leader in the sexual revolution. We have to continue being responsive to the majority of our viewers. If we don't, we invite government censorship. Especially in an emotional issue like this, the threat of government intervention is very real.

It is for all these reasons -- because of our responsibility to the viewer, the affiliate, the advertiser, because of our sensitivity to the minorities who criticize our programming, and because of our determination to avoid censorship -- that network television will change with the times, but on matters of sex will still remain the most conservative of media.

MEN AND WOMEN ON THE TUBE:
SEX AND SEX-STEREOTYPES ON TELEVISION

Susan Hesselbart, Florida State University

Abstract

Televised sexuality is examined in the context of gender stereotypes for three recent programs. Sex on television is usually implicit and--more important--unpleasant for television characters. Since the sexes are portrayed in stereotyped roles, even when the intention is "role-reversal", and often exploit each other, it is not surprising that televised sex is not much fun.

"Journalism is a lot more than blood and sex." Doris Day to Clark Gable in "Teacher's Pet". The outcry of concern over violence and sex on television today seems hardly to have progressed from "Teacher's Pet" nearly 20 years ago. However, this paper does not deal with the number of televised sexual episodes on television nor their explicitness. In fact, it is fair to say that there is very little explicit sex currently on television (e.g., Franzblau, *et al.*, 1977). Even on the program "Soap", roundly criticized for sexual explicitness before its premiere, there is little explicit sex--despite continual chatter from "Soap" characters on the topic. At this point, televised sexuality eerily resembles early 1960's movies and more explicit programs than "Soap" have already appeared on public television (e.g., "Poldark" during early 1977) with almost no averse publicity.

Rather, this paper concerns whether and how the "new adult" programs of the late 1970's portray sexuality as part of a gender stereotyped and segregated world. Obviously, sex is one of the most intimate relationships that can occur between women and men. However, sex on television can appear in different guises, from an affair deeply intertwined into the rest of the characters' lives to a "TV dinner quickie". Thus, the perspective here resembles content analyses of gender stereotypes in children's books (e.g., Weitzman, *et al.*, 1972), pornography (e.g., Smith, 1976), or everyday interaction (e.g., Henley, 1977). I am especially interested in how three programs during 1977 depart from or reinforce traditional gender patterns: the short-lived Norman Lear comedy, "All That Glitters"; ABC's "Soap"; and CBS' "We've Got Each Other."

These three programs were selected for several reasons. First, all are aimed at adults. The syndicated "All That Glitters" was usually shown in the late evenings, "Soap" carries messages about "parental discretion", while the themes of "We've Got Each Other" are aimed more at adults than children. Second, these programs were billed as a departure from traditional treatments of sex roles and/or sexuality. "Soap" has been designated the first prime time series to feature sexuality. "All That Glitters" was extensively advertised as a "sex-role reversal" comedy. "We've Got Each Other" has also been described as a role-reversal comedy (although less extreme than "All That Glitters"). Third, each series has featured some sexuality, from the explicit dialogue in "Soap", the constant sexual conquests in "All That Glitters" to the wedded couple on "We've Got Each Other". Thus in many ways, these programs have been viewed as harbingers of the future of sex and sex-roles on television.

Using these examples, this paper focuses on three main areas. First, the characters and settings will be described with reference to sex roles on television. The

second area concerns interpersonal relations between women and men. Finally, sex and gender are examined in reference to sex stereotypes in television characters and their interaction.

Gender Roles On Television

Certainly, the United States is a gender segregated society in many ways. Ample research documents polarized stereotypes of the sexes in all segments of the population, sex-typed labor markets, and segregated leisure activities (see Hesselbart, forth-coming, for a review). Nevertheless, television exaggerates this segregation--even when its intent is to do the reverse.

Several studies have addressed gender roles in the mass media. Unlike most American women in the late 1970's, few female television characters are employed, although, oddly enough, employed television women work at jobs largely occupied by men in "real life." On commercials, women are the voice--but not the voice--that sells products. Women are relatively likely to be victims, but not perpetrators of violent crime. And, women on television are younger and more physically attractive than their male counterparts (see, e.g., Isber and Cantor, 1975; Gerbner, *et al.*, 1977).

What happens when commercial television tries to be innovative in gender roles? As we shall see below, the "new" programs are still imprisoned by stereotypes.

"All That Glitters" explicitly stressed sex-role reversal. In this series, women were employed and men stayed at home. Within the work world, women were professionals and managers; employed men were secretarial and service staff. Men viewed for female attention, for marriage and for security, while the "masculinized" women ignored their families and thought only of business and sexual conquest. After only a few months, this series folded. According to some television critics, the viewing public was not ready for a role-reversal comedy.

However, "All That Glitters" only changed the surface of gender-stereotyping. Stereotypically, husbands or boyfriends were usually older than their wives or girlfriends. Women executives acted short-tempered and bitchy. Women mused in bars for long scenes about the characteristics and relationships of their boyfriends--again more in line with feminine than masculine stereotypes. And, as discussed below, the more subtle aspects of interpersonal dominance between the sexes remained unchanged.

"We've Got Each Other" is a "softer" version of role-reversal. Judy Hibbard is an office manager for a temperamental photographer. Her husband, Stewart, is a "Househusband" who cooks and cleans while Judy goes out to work. However, Stewart is employed (writing mail-order catalogues), and, moreover "takes Judy out to eat". Meanwhile, Judy is the emotional one, losing her temper easily and concerned about her attractiveness to men (Stewart, meanwhile, feels he is already attractive to women).

"Soap" makes no pretense at role-reversal, but, if anything, emerges as more insulting to both sexes than most of prime time television. First, nearly every

character is incompetent.¹ Seemingly wealthy Chester Tate is poor at business and stoops to shady practices. His wife is easily deceived about Chester's affairs, her daughter's affairs, and her son's pornography collection. Women are generally stereotyped as peabrains, manipulators, or nymphomaniacs (one exception is Mary Campbell). The men are reduced to throwing food (which the women clean up). Homosexuals are stereotyped as trans-sexuals desiring sex-change operations and Mary's son is a drag queen who looks better than his mother in dressess.

My point is not that television should have programs on role-reversal or sexuality. Rather, it is that these "departures" from traditionalism are trapped by stereotypic writing and directing. For example, men on "All That Glitters" usually portrayed the most negative female stereotypes--frumpy housewives, dilettantes, sexual manipulators. Female characters did not portray any more flattering portraits of men--Don Juans, unconcerned fathers, or heartless businessmen. Reverse such stereotypes back to their traditional gender and the characters on "Soap" emerge. Even on "We've Got Each Other," more gentle in tone, Judy is a totally incompetent cook who burns toast and opens bacon with her teeth (a common stereotype of men at home) and Stewart's work is not to be taken seriously.

Television does not yet seem capable of portraying an "androgynous" world (e.g., see Bem, 1975) in which characters combine both desirable male and female traits. Versions of "role-reversal" which tacitly accept traditional gender stereotypes appear to be television's answer to greater sex-role egalitarianism. We shall see below that dominance patterns between the sexes are also traditional, again, even when "role-reversal" is the program topic.

Dominance And Gender On Television

In American society, the sexes are not only considered to be very different from each other, but men are usually expected to dominate women. Domination can be explicit, as in the male commercial characters who tell women how to do the wash or when women are employees but rarely the boss. However, more subtle dominance relations are also expressed in mixed-sex interaction.

Researchers such as Henley (1977) focus on nonverbal gestures that convey dominance. For example, status superiors (employers, parents) touch status inferiors (employees, children) far more frequently than the reverse. Setting conversational topics or interrupting others also signifies status. Superiors are more likely to "first-name" inferiors than the other way around.

Dominance patterns on programs such as "All That Glitters" provide further insight on why "role-reversal" television never quite seems realistic. While who earns the money or who keeps house may be gender-interchanged, more subtle patterns of sex-status continue. The result is jarring to those who consciously or nonconsciously are aware of dominance between men and women.

Take, for example, "All That Glitters." Continually, male secretaries casually touched their female bosses, while women touched men only in love, sex, or familial situations. Men interrupted women or introduced new conversational topics. While women sometimes lost interest, they tolerated these intrusions of personal space in a way that seldom occurs in traditional gender interaction (e.g., see West, 1977).

In "We've Got Each Other," it is Stewart who criticizes Judy's appearance or who persuades Judy to return to the job she quit. As in "The Mary Tyler Moore Show," Judy's boss calls her by her first name, although he is

"Mr. Jerome." However, it is interesting to note that Judy is slightly taller than her husband--a nonverbal detail that lends greater credence to this program's claims of "role-reversal."

Again, the argument is not that television should have more series on "role-reversal" (or even androgyny). However, the experiments tried to date are internally contradictory. If women are the status superiors ("All That Glitters", "We've Got Each Other"), they should be portrayed that way, both in demographics and in interpersonal interaction. Otherwise, the audience is at least subliminally aware that the characters and roles do not "fit."

Despite attempted innovation, television has fared poorly in its attempts to deal with traditional sex-roles. Stereotyped characters and dominance patterns continue. It should come as not surprise that such trends also occur when television deals with sexuality. Since sexuality is one arena where cross-sex interaction is nearly a cultural mandate, these stereotypes become important in the rather melancholy portrayal of sex on television.

Sex And Sex Roles On Television

An important issue in television violence concerns what viewers learn from filmed hostility. For example, increased television viewing correlates with a "jungle world" perspective in which others are untrustworthy (e.g., Gerbner and Gross, 1974; Gerbner, et al., 1977). The debate on television aggression and subsequent viewer aggression is too long and well known to reproduce here. Give such attention to televised violence, it seems reasonable to wonder what lessons viewers receive about sexuality.

First, viewers certainly do not receive a sex manual. As mentioned earlier, televised sex is far more implicit than explicit. The programs discussed here are not exceptions. At most, characters embrace or are shown adjacent in bed. While "Soap" characters discuss sex, they do so in vague terms (e.g., "that glowing feeling" or "his you-know"). "Soap" hardly constitutes an action comedy. Sex is generally unpleasant on these "new adult" comedies. Even while "Soap's" Jessica glows from her affair with a tennis instructor (who is also her daughter's lover), she is filled with guilt. Her attempts to confess to her husband fail, since he is engrossed with simultaneously juggling several affairs and is being blackmailed by his secretary (and ex-lover). Jessica's sister Mary must cope with an impotent husband who blames her for the impotency. The sexual encounters on "All That Glitters" were similarly joyless. Male "sex objects" worried about their attractiveness, propriety, or "keeping score", while the female "aggressors" faced either one night stands or troublesome lovers. Sex is far from fun on television comedies.

Third, sex on these programs is usually a tool. Sex is used for blackmail; material gain, manipulation, or to reassure the participant about his/her physical attractiveness. Thus, sex is done to (or from) but rarely with others. Given such motives, it is no wonder that no one looks very happy.

On Television comedies, sex also seems to provide one of the few opportunities for cross-sex interaction. In "All That Glitters", (besides affairs) cross-sex interaction was restricted to employer-employee relations or arguments between spouses. "Soap" is much the same. Outside of sex, blackmail, or spats, the sexes do not work, chat or play together. "We've Got Each Other" provides a partial contrast: Judy and Stewart are friends: they are able to convivially discuss everyday

affairs as well as lounge in bed in identical pajamas.

To summarize then, televised sex is usually implicit and apparently not much fun for the participants. It is hard to see how the situation could be otherwise when sex is a manipulative strategy (often used by women or "role-reversed" men to gain power) and the sexes have little common ground (which would appear inevitable given the stereotyped characters). These are lessons to viewers that many of us deplore. But, certainly, televised sex appears to be far from the hedonistic orgies envisioned by some television critics and pressure groups.

Conclusions

"All That Glitters," "Soap," and "We've Got Each Other" were selected for discussion in this paper because each, in its own way, has been conceived as an innovation in television programming vis a vis sexuality and gender roles. Despite attempts at innovations, however, these programs are old wine in new bottles: traditional sex stereotypes and patterns of gender domination continue. The sex-typed inelasticity of the characters and their relations spill over into televised portrayal of sexuality. In a world in which women (or role-reversed men) must worry about security and lack efficacy, using sex for manipulation seems logical. When women and men are portrayed as so different as to make friendship unlikely, joyous sexuality is also unlikely.

What can we expect in the future of television? Out in the "real world," the labor force participation of women and men is converging, people are divorcing more, and marrying and reproducing less. In its fashion, television is attempting to reflect such changes.

Whether or not "role-reversal" comedy or more explicit sexuality become television staples depend on how well these concepts "sell." "All That Glitters" had a short season and "We've Got Each Other" is doing very poorly in weekly ratings. In this paper, I have suggested that unattractive characters may be as important in the low success of these programs as the "role reversal" concept. In addition, the inconsistencies between concept and execution in these two programs renders the characters and situations unbelievable. "Soap", on the other hand, is currently a success, although a recent article stated that an attempt will be made to render the characters more three-dimensional.

It is a shame that television has done so comparatively little with the concepts of sexuality and sex roles. Both are certainly important issues and could be well-treated in humor. How a couple treats sexuality in the context of a caring relationship, or how to raise a family in a time of changes are two examples of topics that television comedy could address. But, with notable exceptions, prime time broadcasters have expended little imagination to explore such issues. In the future, I hope that they will try.

ENERGY CONSERVATION AND TRAVEL BEHAVIOR

Jeffrey S. Milstein, Ph.D.
Department of Energy
Washington, D.C. 20461

Abstract

Americans use one quarter of all energy consumed in the United States in automobile passenger travel. This paper describes the ways Americans could reduce this energy consumption, and, using empirical data, describes the extent to which these energy-conserving behaviors are or are not being practiced.¹

The Energy Problem

Today, with only 5 percent of the world's population, Americans are consuming 30 percent of the world's petroleum production.² This consumption of oil comes at an increasingly high cost, for this Nation must import an increasingly larger share of its oil. Imports for the first half of this year amount to 47 percent of total consumption, compared to 39 percent for the first half of 1976. The cost of this imported oil is growing at a staggering rate: this year alone U.S. citizens will pay foreign oil producers \$45 billion for the oil we are importing! This is up from \$37 billion in 1976, \$27 billion in 1975, \$8 billion in 1973, and only \$4 billion in 1971. Moreover, 41 percent of these imports come from countries that have shut off the flow of oil to us in the past, and could again.³ The potentially enormous negative consequences for our economy if oil is again shut off, as well as the consequences for our national security and independence of our foreign policies, are urgent national and international reasons for the citizens of our Nation to consume less energy.

Travel by Car: A Great User of Energy

What has this to do with travel behavior? Passenger travel is an enormous user of our energy, particularly of petroleum. Sixteen percent of all our energy is used directly in passenger travel. Nine-tenths of all passenger travel is in automobiles. Travel by car uses 57 percent of all energy used in transportation in the United States. (Air passenger travel is a distant second, using 6 percent of U.S. transportation energy.)

About 2 out of every 5 BTU's of energy used in automobile passenger travel is used indirectly. Thus, to the 14 percent of all our energy directly consumed by automobiles as gasoline and oil, one must add such energy use for automobile travel as manufacture of motor vehicles, parts, tires, and repairs (about 4 percent more of our total energy use); highway construction (about 2 percent); and petroleum refining and distribution losses (about 5 percent). Thus, directly and indirectly, automobile passenger travel uses one-fourth of all our Nation's energy and

an even greater percentage of our oil--about 30 percent.⁴ American cars are now using about 1 out of every 10 barrels of oil produced in the world! As a major consumer of energy then, automobile travel by Americans is a major focus for energy conservation measures.

The Department of Energy and its predecessor organizations have recommended for almost 4 years various ways that private citizens and consumers can reduce their energy use. In the area of transportation behavior, I will go through those major recommendations and then describe (using empirical data) the extent to which the American public is or is not practicing these ways to conserve energy.

Buying Efficient Cars

The first travel-related behavior that saves energy is for people to buy efficient cars that suit their needs. In 1977, the average miles per gallon of new cars sold, including imports, was 18.6 miles per gallon. That was up from 17.6 in 1976, 15.6 in 1975, and 13.9 in 1974.⁵ Thus, from 1974 to 1977, there has been a 34 percent increase in new car fuel efficiency. This has come about as car manufacturers have been required by law to increase the average efficiency of new cars.

Related to the operating fuel efficiency of new cars is their size. Smaller cars also use less indirect energy, such as that necessary to produce additional amounts of steel for larger cars. The market shares for different sizes of cars, including imports, in 1977 and 1976 are as follows:⁶

	1977	1976
Subcompacts	25%	23%
Compacts	22%	25%
Intermediates	28%	28%
Full-size	24%	23%
Vans	1%	1%

Note that part of the increase in subcompact sales from 1976 to 1977 includes an increase in foreign car sales from 14 percent of the total market in 1976 to 19 percent in 1977. Nine out of ten foreign cars are subcompact

⁴"National Transportation: Trends and Choices," U.S. Department of Transportation, January, 1977, p. 33.

⁵Data are from the Motor Vehicle Manufacturer's Association.

⁶These data are from January 1 to August 20, for the respective years. The data comes from Wards Communications, Inc.

¹The findings and interpretations in this paper should not be interpreted as necessarily representing the official policies, either expressed or implied, of the Department of Energy or of the U.S. Government.

²Federal Energy News, FEA, Aug. 29, 1977.

³Federal Energy News, FEA, Aug. 29, 1977.

in size. Thus, part of the gain in the new car fleet's fuel efficiency is due to the increased sales of foreign cars. While importing cars hurts our balance of payments, it does not also make the United States strategically vulnerable as does the importing of oil.

Ridesharing

Ridesharing, especially to and from work, but also including shopping with a neighbor, is one of the best ways that American consumers could cut down on their vehicle miles traveled and therefore save energy. A three-person carpool uses just one-third of the energy that the three people driving alone would use. About one-third of all private automobile mileage is for commuters to and from work. If the average occupancy (currently 1.3 people per commuter car) were increased by just one person, not only would each commuter reduce his cost, energy use, and driving stress, but the Nation would save more than 700,000 barrels of gasoline per day.⁷ This is approximately one barrel out of every ten for gasoline that Americans use. If just one gallon of gasoline were saved each week for each automobile in the country, we would save about 5.2 billion gallons of gasoline in a year or about 7 percent of all the demand created by all of our passenger cars.

The empirical data shows that half of all trips have only one occupant per car. Of trips to and from work, approximately three out of four were in one-occupant cars.⁸ A 1973-74 national survey of work trips shows that approximately one out of four persons is going to and from work in a vehicle with two or more people.^{9, 10}

Though these data come from studies by the Department of Transportation in 1972 and 1973, more recent FEA surveys I have directed show that carpooling has not significantly increased since the oil embargo of 1973-74.

Carpooling varies tremendously around the country: as many as half the people in Washington, D.C., and in Minneapolis-St. Paul carpool to work. Moreover, where special carpool facilities exist, such as the Shirley Highway bus and carpool express lanes into Washington, D.C., from Northern Virginia, we find as many as three out of five people in these corridors taking cars are in carpools. But on a national basis, the great energy savings potential of carpooling and vanpooling is far from being realized.

Public Transit

Public transit uses just one-sixth to one-third the energy per passenger mile that single occupancy cars do.¹¹ How-

⁹"Nationwide Personal Transportation Study: Home to Work Trips and Travel," Report No. 8, August 1973, DOT/Federal Highway Administration.

¹⁰Note that the distribution of vehicles is somewhat different from the distribution of persons because of multiple occupancy in carpools.

¹¹"Buses Hailed, Rail Transit Scored in Energy-Use Study by Congress," New York Times, Sept. 23, 1977, p. 18.

ever, various studies show that only 6 to 8 percent of the public takes public transportation to and from work.¹²

In the FEA surveys that I have directed, an analysis of why people do or do not use public transit for going to and from work shows that 17 percent of the total public say that mass transit does not run at the right times, 11 percent say it does not go where they need to go, 9 percent say it does not run often enough, 8 percent say it takes longer, 5 percent say that they do not because public transit encounters delays and holdups, 4 percent cite overcrowding on public transit, and 1 percent cite dirty vehicles as the drawback from their point of view.¹³

In a multivariate analysis of the FEA survey data, we found that half of the users of public transit encountered heavy traffic and jammed highways on the way to and from work, whereas only 27 percent of the drivers of their own car did so, and 38 percent of carpoolers did so. We infer from this that traffic jams or heavy traffic are important inducements for people to take public transit. An analysis of the 30 percent of our total population who have a choice between taking cars or public transit to and from work (i.e. have public transit available to them) shows that the factors people seem to consider in taking public transit are: the distance and duration of travel, the convenience and timing of the schedules, the proximity of the transit line to where they work and live, the cost of the travel, and whether or not they encounter heavy traffic or traffic jams on the way to and from work.¹⁴

Analysis of the FEA survey data also show that a large fraction of the people who take public transit are also people who would carpool and vice versa. These people are different in their attitudes and behavior from people who drive alone to and from work. An important implication from this finding is that promoting public transit ridership might be at the expense of some carpooling, and the promotion of carpooling might be at some expense to public transit ridership. Again, the enormous potential for energy savings in public transit riding is not being realized.

Walking

Five percent of the public walks to and from work. The percentage who use this energy saving mode of transportation appears small, but is nearly as large as the percentage who take public transportation to and from work.¹⁵

Vacation Travel

In a recent survey, it was found that six out of ten households in the United States took one or more vacation

¹²"Nationwide Personal Transportation Study: Home to Work Trips and Travel," Report No. 8, August 1973, U.S. DOT/Federal Highway Administration; also, FEA survey by Opinion Research Corporation, 1975, Vols. 11 & 12.

¹⁴"General Public Behavior and Attitudes," Highlight Report Vol. XII, FEA, July, 1975.

¹⁵"Consumer Attitudes, Knowledge and Behavior Regarding Energy Conservation," FEA, December, 1976.

trips in 1976, and half of all households took a vacation trip by car. The average number of trips taken by vacationing households was more than two trips per year. Half of the households who take vacation trips take two or more vacation trips per year. On vacation trips, the average travel party consists of three people (typically a family). The average mileage driven per year is about 3,500 for all household vacations. (This is about a quarter of all miles driven per year.) The median income of families taking automobile vacation trips in 1976 is about a quarter higher than the median income for all families in the United States (i.e., \$17,640 versus \$14,000 per year).¹⁶

Vacation travel took a temporary dip during the Spring of 1974 during the oil embargo, and during the 1975 recession. Vacation travel increased, however, in 1976 and again in 1977. Thus, energy-conserving travel behavior such as vacationing near home, staying in one place instead of traveling around, and taking a train or bus instead of the family car, have not been significantly practiced since the oil embargo and subsequent recession. Americans continue to use a large amount of energy on their vacation travel--an integral part of the lifestyles of a majority of Americans.

Driving Slower: The 55 Mile Per Hour Speed Limit

Most automobiles get about 20 percent more miles per gallon on the highway at 55 miles per hour than they do at 70 miles per hour. Fatal automobile accidents are also less likely at the slower speeds. Thus there are both energy and safety reasons to drive slower on the highway.

In 1973, the mean speed on the highways which had free flow conditions (i.e., the 45 percent of American roads which have only the 55 mile per hour speed limit as a control) was 60 miles per hour with a standard deviation of 10. In 1974, the mean speed dropped to 55 miles per hour with a standard deviation of 6.17

In 1977, the majority of States have average speeds between 55 and 60 miles per hour. This shift in the mean speed that occurred between 1973 and 1974 (when the 55 mile per hour speed limit became law in every State) has continued since 1974. The proportionate gasoline savings have also continued as a result of people driving at this more efficient speed on the open highway.¹⁸

Other Efficient Driving Behaviors

There are other driving techniques that a careful driver can use to get 20 percent more miles per gallon than the average driver and 50 percent more than a wasteful one. These techniques include accelerating smoothly and moderately, driving at a steady pace, avoiding stop and go traffic, minimizing braking, not letting the motor idle for more than a minute, not overfilling the gasoline tank,

¹⁶"The 1977 Automobile Travel Intention Survey" December 2, 1976, unpublished paper by James J. Gibson, 3M National Advertising Company.

¹⁸U.S. DOT/Federal Highway Administration, Highway Statistics Division, "Quarterly Speed Summary," June 1977.

planning trips carefully, having the car tuned (3-9 percent savings), keeping the engine air filter clean, checking tire pressure regularly (2 percent savings per pound of underinflation), using radial tires (3-10 percent savings) and removing unnecessary weight from the car.¹⁹

Reliable and valid data on these kinds of behavior on the part of drivers is not readily available. But it is a part of travel behavior where energy savings can add up to significant amounts.

The Bottom Line: Gasoline Consumption

Distilling all automobile travel behavior down to the bottom line of gasoline consumption, we find that motor gasoline demand for January through August of 1977 averaged 7.1 million barrels per day, or 81 percent of our imports. That is nearly 300 million gallons of gasoline per day. While that averages only 2 2/3's gallons per automobile per day (or an average of about 40 miles driven per day), it is an amount that is 2.1 percent higher than the average for 1976.

Since 1972, gasoline consumption has been increasing at an average annual rate of 2.6 percent per year. However, new car registrations have been increasing an average of 3.3 percent per year from 1972 to 1976,²¹ which is slightly faster than gasoline consumption. Thus, even though in the aggregate, Americans are using more gasoline in cars, on a per capita basis, there has been a slight amount of energy conservation in gasoline used by the American people. (One explanation for this is that in the growing number of two-car families, the second car is not driven as much on long family vacation trips.)

Conclusion

In summary, Americans appear to be making some progress in conserving energy in such areas as buying more efficient cars and driving slower on the highways, but little or no progress in such other important areas as carpooling, using public transit, and reducing vacation travel. The challenge that lies before us still is to reduce by significant, rather than trivial amounts, the fuel consumption of Americans as they travel. We must use all of the means possible to save energy. We cannot forget or ignore the enormous international and domestic economic and political stakes that are present in this challenge.

CONSUMER ORIENTED TRANSPORTATION PLANNING:
AN INTEGRATED METHODOLOGY FOR MODELING
CONSUMER PERCEPTIONS, PREFERENCE AND BEHAVIOR

Alice M. Tybout, Northwestern University
John R. Hauser, Northwestern University
Frank S. Koppelman, Northwestern University

Abstract

This paper presents research examining a model of consumer transportation behavior which integrates system characteristics, perceptions, preference, choice and situational constraints. The research findings are used to develop and evaluate strategies designed to increase consumer acceptance of public transportation.

Introduction

Public officials and private citizens alike acknowledge the need for local public transportation. Public transportation is viewed as necessary both to provide mobility to individuals who do not have any private means of transportation and to offer an alternative to private transportation for all individuals. In addition, public transportation is perceived to be desirable because it offers advantages over private transportation in terms of energy efficiency, environmental pollution, and congestion.

However, several observations indicate that individual and community needs are often not well met by existing public transportation systems. Most local transportation services require substantial operating and capital subsidies, while at the same time, have considerable excess capacity, particularly during off-peak hours. Furthermore, the low utilization of public transportation and the attendant prevalence of private auto trips has resulted in traffic congestion, parking problems, and environmental pollution in many communities, and has contributed to national gasoline shortages.

If strategies are to be developed to gain consumer acceptance of public transportation, a clearer understanding of consumer transportation behavior is required. Specifically, research must be undertaken to:

- (1) identify and measure consumer perceptions of transportation alternatives and examine how such perceptions are developed. (i.e. their relationship to actual system characteristics),
- (2) determine the relationship between consumers' perceptions and their mode preference and choice,
- (3) provide a strong test of the relationships established in (1) and (2). This can be done by developing and implementing strategies based on the knowledge accumulated in (1), (2), predicting the impact of these strategies on perceptions, preference and choice and then evaluating their actual impact on these factors.

In this paper the preliminary results of research undertaken to address the above issues is reported. First the relevant literature is reviewed. Then, the research method and results are summarized. Finally, the practical and theoretical findings are discussed and plans for future research are outlined.

The Literature

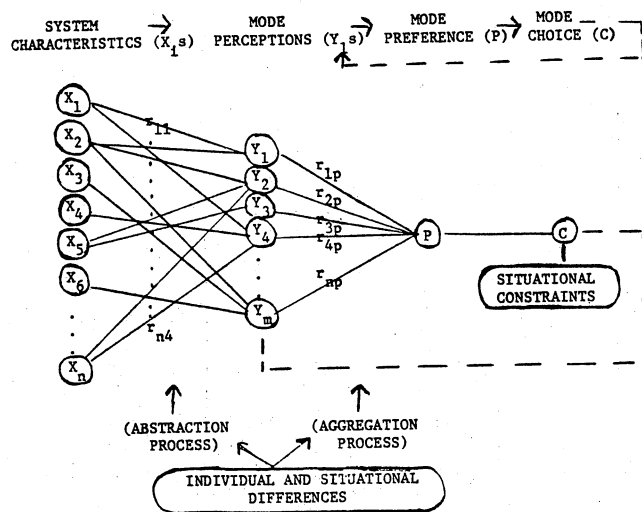

Efforts to understand consumer transportation behavior began in the late 1950's with aggregate studies correlating system characteristics (e.g. travel time, frequency, cost etc.) and community characteristics (e.g. income, education, density etc.) with demand for transportation alternatives (Martin, Memmett, and Bone, 1961; McLynn and Woronha, 1969; Quandt and Banmol, 1966, SARC 1963). Although these models performed well in special circumstances, they did not adequately represent consumer behavior and they gave little guidance for the development of strategies to directly influence such behavior. As a result, disaggregate demand models were developed in the early 1970's to examine the relationships between these variables and mode choice on the level of the individual consumer (Ben-Akvia, 1973; Charles River Associates, 1972; Koppelman, 1975; McFadden, 1970). These disaggregate models, which are still widely used today, lead to a clearer specification of the relationship between system characteristics, consumer demographics and mode choice than did aggregate models. However, like the aggregate models, they concentrate on system and community characteristics. Thus, they fail to provide an understanding of consumers' transportation decision making processes and are not sensitive to the wide set of strategies that can be developed to influence consumer behavior without expensive changes in system characteristics. Additional research is required to gain a better understanding of the consumer and make available the full range of strategic opportunities to community transportation planners and managers.

The critical factor present in consumers' decision making but absent in traditional demand models is consumers' perceptions, which mediate the relationship between system characteristics and mode choice. In recent years several transportation researchers have acknowledged the importance of perceptual variables (e.g. convenience, comfort) and have focused on quantifying these variables so that they can be included, along with system characteristics such as time and cost, in disaggregate mode choice models (Nicolaidis, 1975; Spear, 1976). While this effort to quantify perceptions is important it is not sufficient. An adequate understanding of the relationship between perceptions, system characteristics, preference and choice is also needed.

One way of viewing the interrelationship between system characteristics, perceptions, preference and choice is given by the model of consumer transportation decision making in Figure 1. This model, which is an extension of Brunswick's lens model (see Brunswick, 1952, Hammond, 1966), is similar to models which have been used to describe consumer response to new products/services (Green and Wind, 1975; Hauser and Urban, 1977; Pessemer, 1977). In the model, the system characteristics (x_i 's) serve as cues used by the consumer in forming his perceptions (i.e. evaluation of convenience, safety, comfort, liking etc.) of the various modes. Each system characteristic is an imperfect indicator of any particular perception and the degree of the association between

these factors is represented by the r_{ij} s. Thus, travel time may serve as a partial indicator of convenience for a particular mode. Furthermore, a system characteristic such as travel time may influence several different perceptions in different ways (i.e. travel time may be negatively correlated with convenience but positively correlated with safety). This process of using system characteristics as cues in forming perceptions is called abstraction. Once perceptions are formed they are aggregated to determine choice. A degree of association between the perceptions and preference is represented by the r_{ip} s. Preference, tempered by situational constraints such as mode availability, in turn, directs choice. Finally, choice and experience may feed back modifying mode perceptions. All situational and individual differences not represented in this basic model influence decision making by influencing the manner in which the individual forms perceptions or aggregates perceptions to direct choice.

FIGURE 1
A MODEL OF CONSUMER TRANSPORTATION BEHAVIOR

There are several practical implications of this model. First, if the model accurately represents consumers' transportation decision making, then researchers should concentrate their efforts on understanding the abstraction and aggregation processes (i.e. are linear or non-linear models used etc.) and should not confound these two processes by using both system characteristics and perceptions in one model predicting preference or choice since these variables are likely to be highly correlated. Nor should they develop mode choice models from system characteristics directly. Second, because the model represents the stages in the consumer decision making process it can help the planner or manager diagnose problems in the transportation system. Problems may either be the result of actual system performance, consumer misperceptions of that performance or the importance consumers place on various perceptions. Finally, the model provides an understanding of transportation consumers which can serve as the basis for developing a broad range of strategies to influence consumer mode choice decisions. Using this model strategies which focus on directly altering consumer perceptions or choice may be considered in addition to traditional service modification strategies. For these reasons the model in Figure 1 was used as a basis for the study reported here.

The major objective of our research is to examine the relationships between consumers' mode perceptions, preference, and choice (i.e. the aggregation process) as a basis for developing strategies to modify consumers'

choice. We also examine the adequacy of the model in ordering the relationships between system characteristics, perceptions, preference and choice. However, we do not address the abstraction process in this paper since insufficient data was collected to fully investigate it.

The Study

Context

The research was conducted in the city of Evanston, Illinois, in cooperation with the City Manager's Office. Evanston is a northern suburb of Chicago, with a population of approximately 80,000. The Evanston public transit system includes: a rapid transit system which serves Evanston and connects with the Chicago rapid transit system, access to the Chicago Northwestern Railroad which runs directly from the northern suburbs to downtown Chicago, and a local bus service.

The transit problems of the City of Evanston are typical of many suburban cities. Poor public transit service (i.e. variability in lead time and run time, lack of coordination between modes, and a system not tailored to the needs of the community) combined with relatively high auto ownership has resulted in significant excess capacity on the public transit system, especially during off-peak hours. As a result of low ridership and high fixed operating costs, an annual subsidy of \$300,000 is required to maintain the transit system. Therefore the City of Evanston provides a good context for research designed to understand consumers' travel behavior and evaluate strategies for increasing public transportation ridership.

Method

Our approach to gaining an understanding of consumer travel behavior entailed developing an instrument for collecting individual data on the variables in the model in Figure 1 and then using this data to test the relationships between these variables and to generate and evaluate strategies designed to alter consumers' behavior. In this section the development of the research instrument and the data collection process are described.

The primary research instrument used was a set of mail questionnaires. Questionnaires were selected for the data collection because they provided the most efficient means of collecting quantitative data on the major variables in the model for a large cross section of the population.¹ The questionnaires were administered by mail because this method allowed us to reach a broader cross section of the population than alternative methods (i.e. telephone or personal interview) and it allowed consumers to respond to the questionnaires, which were quite lengthy, at their leisure.

The development of the questionnaires was a complex, lengthy process. First, input was obtained from three major sources; a usage audit, focus group interviews

¹However, the use of a questionnaire, especially a mail questionnaire made it impossible to assess actual system characteristics for the respondents at the same point in time as other variables were measured. Instead only perceptions of system characteristics were obtained. A separate study was conducted to explore the relationship between actual and perceived system performance. This study found no significant differences between actual and perceived measures of these factors. Therefore, it appears that these measures can be used interchangeably in this context.

and a review of the literature. The usage audit served to identify the most frequently used modes of transportation for various trip purposes within the community. These frequently used modes were then included in the questionnaires for consumer evaluation (space and time constraints prohibited requesting individuals to evaluate all modes). The focus group interviews and the literature review served to : 1) generate a list of transportation service attributes important to consumers to be used in evaluating modes in the final questionnaire and 2) provide "semantics" so that the questionnaire could be phrased in the language of the consumer. Since these inputs indicated that there were differences in the transportation alternatives available and the relevance of various transportation attributes for different types of trips, three different versions of the questionnaire were developed for each of three major types of trips: trips to work or school, non-work trips to the CBD, and non-work trips to areas in the city other than the CBD.

On the basis of the focus groups and literature review, scales measuring attributes of transportation services important to consumers were developed and evaluated. This entailed generating an exhaustive list of attributes and then reducing this list to a manageable set of critical attributes (21-25 scales per mode) on the basis of the results of two pretests in which individuals in the community used the attributes to evaluate several modes and also indicated their mode preference and choice. (For more details on the scale development process see Hauser, Tybout, and Koppelman, 1977).

Once the scales were developed, the remaining sections of the questionnaires were drafted and a pretest of the entire questionnaire was conducted. Results of this pretest were used to uncover and correct any problems or omissions in the questionnaire. In addition, the completed pretest questionnaires were used in a pre-analysis. This process entailed performing a full-scale statistical analysis on these responses to ensure that the questionnaire provided all the data necessary for the analysis planned on the final questionnaire. A few missing items were discovered and subsequently added, but the most important result of preanalysis was the recognition that mode-specific attributes, popular in the transportation literature, are not compatible with perceptual models unless certain key steps are taken. These steps require that either there be parallel generic attributes for all modes or if attribute has no parallel for a mode (i.e. walk access for the walk mode) or there be a clear extreme direction for that mode (i.e. walk access is zero). Based on the pretest and pre-analysis the final questionnaires were developed, printed and mailed to a random sample of the target population (1900 work/school trip, 1900 nonwork trip to the CBD and 950 nonwork trip to non-CBD destinations questionnaires were sent.) A follow up post-card was sent to every respondent seven days after the questionnaire mailing, urging them to return the questionnaire.

A summary of the sections of the questionnaire used in the analysis reported here is given below.

- (1) system characteristics. Respondents gave estimates of: travel time, broken down by access, wait, and on-vehicle time; bus frequency during rush and non-rush hours; the distance to the nearest bus stop; and bus seat availability. They also provided data which was used to compute auto availability (i.e. they reported the number of drivers and autos in their household).
- (2) perceptions. Respondents evaluated each of the three frequently used modes (car, bus, and walk) by responding to 21-25 statements about mode attributes on a 5 point, strongly agree to strongly disagree Likert scale. Respondents also expressed their feelings about each mode in terms of their affect, personal

normative beliefs, social normative beliefs and level of commitment by responding to 6-9 statements regarding these factors on a 5 point Likert scale from strongly agree to strongly disagree.²

- (3) preference. Respondents rank ordered the three modes - bus, auto and walk - in terms of their preference.
- (4) choice. Respondents indicated the mode which they had used for their most recent nonwork trip to the CBD and also estimated the frequency with which they had used each of the available modes for similar trips in the past two months.
- (5) consumer and situational differences. Participants responded to a battery of demographic questions (i.e. age, income, education etc.) and also described characteristics of their most recent trip to downtown Evanston (i.e. purpose, time of day etc.).

Results³

Respondents. Forty-one percent (782 out of 1900) of the individuals who received the nonwork trip to downtown Evanston returned it. Five hundred of these responses were selected for analysis on the basis of completeness of response to the attribute ratings and preference rankings questions. Comparison of the demographic characteristics of this sample with 1970 census data indicated that it was reasonably representative of the Evanston population, although some distinctions did exist (see Koppelman, Hauser and Tybout, 1977, for details on data screening and sample representativeness).

Description of System Characteristics. Although consumers' perceptions of a variety of system characteristics (i.e. travel time, frequency, bus seat availability, bus accessibility and auto availability) were measured, some of these variables require special coding before they can be used in the analysis. Therefore, only travel time and car availability are discussed here.

Walk travel time for trips to downtown Evanston was perceived to range between 1-5 minutes and 86-90 minutes, while vehicular travel time for similar trips ranged from 1-5 minutes to 26-30 minutes for car and 1-5 minutes to 56-60 minutes for bus. Car availability ranged between 0.0 auto/driver to 3.0 autos/driver, however 97% had one or less autos/driver.

Description of Perceptions of Mode Attributes. The questionnaire measured consumers' perceptions of three modes - bus, walk, and car passenger or driver - on 25 attributes. Respondents' evaluations of the modes on these attributes are summarized in Table 1.

²Historically, transportation researchers have only focused on one psychological dimension, beliefs about attributes of the object (e.g. perception of mode convenience, comfort etc.). Many other psychological variables have been demonstrated to influence behavior, including affect (an individual's liking-disliking of an object, see Ostrom, 1969), personal normative beliefs (an individual's perception of what he ought to do, see Schwartz and Tessler, 1972), social normative beliefs (an individual's perception of what others want him to do, see Fishbein, 1972), and level of commitment, (how easily is the individual's intended behavior influenced by unanticipated events, see Wicker, 1971). These perceptions have been included in our questionnaire so that their contribution to the explanation of transportation behavior can be examined.

³Analysis of this data set is still in process, therefore these results are preliminary.

*THE RATINGS WHICH APPEAR IN THIS TABLE WERE STANDARDIZED BY INDIVIDUALS ACROSS STIMULI AND SCALES TO REMOVE ANY TENDENCY OF AN INDIVIDUAL TO USE ONLY PART OF THE RANGE IN THE SCALE. IN ADDITION, ALL NEGATIVELY WORDED SCALES WERE MATHEMATICALLY RESERVED SO THAT HIGHER NUMERICAL VALUES IMPLY BETTER RATINGS.

An examination of the ratings in Table 2 indicates that, in general, car is perceived favorably and outscores bus and walk. However, on cost ("inexpensive") and driver stress attributes ("fear of injury", "annoyed by others") car fares less well. In contrast, bus is relatively poorly perceived. It receives high ratings only on cost and stress related attributes and is viewed negatively in terms of service attributes. Walk is rated highly in terms of attributes measuring cost, service availability and environment, but is also seen as time consuming and requiring considerable effort to use.

Factor analysis was used to reduce these 25 transportation service attributes to a smaller set of underlying dimensions. This was done for two reasons: 1) consumers do not actually process information about each of the 25 attributes when making an evaluation or choice regarding transportation alternatives (see Bruner, Goodnow and Austin, 1959). Instead they reduce the information to a smaller more manageable set of factors that capture the essence of the larger set. Thus, a simpler perceptual structure more closely approximates consumers' utilization of perceptual information in decision making. 2) This simpler structure helps managers and analysts better understand consumer processes so that they can formulate strategies to affect the most crucial components of consumer response. And, 3) factor analysis enables the analyst to make dimensions orthogonal, thus reducing multicollinearity and leading to stable coefficients when the dimensions are used in preference and choice models.

Factor analysis of the attribute ratings was undertaken for two through six dimensions using common factor analysis with iterations and varimax rotation. The solutions for the various dimensions were compared on the basis of interpretability, explanatory power and accuracy in predicting preference. On the basis of this analysis the three dimension solution was chosen as the best one.

The factor loadings for the three dimension solution appear in Table 2 and mode perceptions on these dimensions are graphed in Figure 2. The three factors - which have been labeled general service and safety, convenience and accessibility and psychological comfort - account for 45% of the variance in the original attribute ratings. This is consistent with previous studies of this nature (see

Hauser and Urban, 1977). As Figure 2 demonstrates, car is perceived most favorably on the general service dimension but is viewed less favorably than alternative modes on the convenience/accessibility and psychological comfort dimensions. Bus is viewed poorly on the general service and convenience/accessibility dimension, but receives the most favorable evaluation on the psychological comfort (i.e. freedom from hassles) dimension. Finally, walk scores extremely poorly on the general service dimension, well on the convenience/accessibility dimension, and moderately well on the psychological comfort dimension.

FACTOR 1 - GENERAL SERVICE AND SAFETY
FACTOR 2 - CONVENIENCE AND ACCESSIBILITY
FACTOR 3 - PSYCHOLOGICAL COMFORT

FIGURE 2
MODE PERCEPTIONS IN THREE FACTOR SPACE

Description of Feelings About Modes (Perceptions of Factors other than Mode Attributes). In an effort to determine whether psychological or perceptual factors other than evaluations of mode attributes influence transportation preference and choice, a variety of non-attribute perceptions of the three modes were measured (i.e. affect, personal normative beliefs, social normative beliefs, extraneous events). These measures were then factor analyzed to develop an aggregate measure of feelings toward each mode.⁴ The factor loadings for the

⁴This approach was taken because each of the original variables was measured by only a few questions per mode and therefore these measures were likely to be unstable if used separately. However, when the variables are combined for each mode they provide a fairly reliable index of a more general feeling toward the mode.

three resulting factors - a car feelings factor, bus feelings factor and walk feelings factor - are presented in Table 3. These factors account for 39% of the variance in the original set of questions.

Preference and Choice. First preference was clearly dominated by car (71% stated this as their first preference), while bus did well in terms of second preference (58% stated bus was their second preference). Consistent with the preference ratings, 66% stated that they had chosen car for their most recent trip. Furthermore, cross-tabulation of first preference and choice data indicated that the vast majority of respondents (76%) chose their most preferred mode. However, it is interesting to note that a significant number of individuals (24%) did not choose their most preferred mode, perhaps due to situational constraints such as availability. This highlights the importance of consumers' second preferences and suggests an area of opportunity for public transportation.

Relationship Between Model Variables. Our model of consumer travel behavior states that the impact of system characteristics on preference and choice is mediated by consumer perceptions. Therefore, system characteristics should be more highly correlated with perceptions of mode attributes than with preference. Examination of Table 4 indicates that this is the case for the travel time variables. Walk travel time is most highly correlated with perceptions of general service ($r = -.63$) while vehicular travel time is most highly correlated with perceptions of convenience/accessibility ($r = -.41$). However, auto availability (APD) is highly correlated with not only perceptions of general service, but also preference and choice. This is probably partially attributable to the fact that none of the attribute scales directly measured mode availability. However, auto availability may also have a high correlation with choice because it operates as a situational constraint rather than a system characteristic. If this is the case auto availability is probably best used as a segmentation variable rather than as an independent variable in mod-

els predicting perception, preference or choice.

*NONSIGNIFICANT AT .05 LEVEL

The perceptual variables (cognitive dimensions and feelings) are viewed as the determinants of preference. Therefore, these variables should be relatively independent and highly correlated with preference. In general these conditions are met. The intercorrelations between these variables are low and they are all significantly related to preference.

Finally, preference and situational constraints are viewed as the determinants of choice. Thus, choice should be highly correlated with these variables. Consistent with this expectation, Table 4 indicates that choice is most highly correlated with preference ($r = .66$) and next most highly correlated with a situational constraint - auto availability ($r = .54$). Therefore, we conclude that examination of the correlation matrix provides support for our model of consumer transportation behavior. Next, we will examine the aggregation process posited by this model in more detail.

The Aggregation Process - Preference Models. Preference models based on consumer perceptions were developed. First preference logit was used to statistically estimate the importance weights for the variables in the models. These models, which are presented in Table 5, are summarized below.

In Model 1 the three cognitive dimensions (factor scores) are used to predict preference. The importance weights for these dimensions in this model follow the same pattern as their identification in factor space. General service is the most important variable. Convenience and accessibility is next most important. And, psychological comfort is least important.

In Model 2, the factor scores for respondents' feelings about each mode are added to Model 2. The addition of these variables improves the prediction and explanation of preference by a small but statistically significant amounts ($p < .01$). This finding supports our belief

that perceptual variables other than evaluations of mode attributes influence preference and suggests that efforts to alter preference should consider these variables.

PERCENT PREDICTED INFORMATION	78.1% 53.3%	80.8% 56%

*WEIGHTS IN BRACKETS ARE STANDARDIZED IMPORTANCE WEIGHTS FOR THE COGNITIVE DIMENSIONS ALONE IN THIS MODE.

In general, the models presented in Table 5 do a good job of predicting first preference. The percent of first preferences correctly predicted by these models are all significantly higher than the percent which would be correctly predicted using a market share model (54.7%) or an equally likely model (33.3%). The information measure reported gives the percent of uncertainty (entropy) explained. This measure is an information theoretic interpretation (Hauser, 1977) of a pseudo R² measure (McFadden, 1970). Similar models were developed to predict rank preference using a rank logit model and the rank ordering of variables and interpretation were the same.

Choice Models. Since situational variables as well as preference affect choice a related set of models were developed to predict choice. These models, which were based on the multinomial revealed preference logit formulation (McFadden, 1970) are summarized in Table 6.

Model 1 in Table 6 uses only factor scores for the three cognitive dimensions to predict mode choice. In this model the importance weights for the dimensions were determined in the choice model. This procedure for determining the importance weights was compared to the alternative procedure of using importance weights established in the first preference Model 1. The two models yielded highly similar results. The only difference was the lowered importance of psychological comfort in the choice model. (Future papers will explore this issue further). Since most interpretations were similar for the two procedures and prediction was improved significantly (.05 level) when the importance weights were determined in the choice model, this procedure was used in the models reported here.

In Model 2 the factor scores for feelings about the three modes are added to Model 1. The addition of these three factors improves the prediction and explanation of choice behavior by a small but significant (.01 level) amount.

*ALL VARIABLES EXCEPT THOSE STARRED ARE SIGNIFICANT AT THE .05 LEVEL

In summary, the choice models in Table 6 generally do an excellent job of predicting mode choice for respondents most recent trip to downtown Evanston. All predictions are substantially better than market share or equally likely models would allow. Models predicting respondents' reported frequency of choice over the last two months were also developed. In general these models were similar to those shown in Table 6.

Segmentation Using Consumer and Situational Characteristics. As depicted in the model (Figure 1), consumer and situational characteristics may influence mode preference and choice by influencing the aggregation process or by influencing choice directly. When these factors have a substantial impact on this process, a clearer understanding of consumer transportation behavior may be obtained by segmenting on these variables and developing separate choice and preference models for each segment.

Two approaches to segmentation may be employed. One approach entails identifying segments in the population on the basis of differences in the descriptive characteristics of individuals (i.e. demographics) or situations (i.e. trip characteristics). An alternative approach involves identifying segments that are behaviorally homogenous and distinct (i.e. segments that respond to transportation alternatives similarly and differently than other segments). In an effort to increase our understanding of consumer transportation behavior we employed both of these approaches to segmentation. First, we examined the impact of segmenting on each of four individual and situational descriptive characteristics - age, education, knowledge of the bus system and auto availability - on the prediction and explanation of mode choice.⁵ A Chi square test was used to assess the significance of each basis of segmentation. Only two of the four bases, age and auto availability, were significant. Choice models developed for the subgroups of these significant bases of segmentation are reported in Table 7.

The choice models for the auto availability subgroups indicate that those with low auto availability place less

⁵ Since preference and choice models were highly similar only choice models were examined in the segmentation analysis. Tests of other descriptive bases of segmentation will be conducted in the future.

emphasis on the general services offered by alternative modes and are influenced more by feelings about bus and walk than those with high auto availability. Similarly, the choice models for the age subgroups indicate that individuals under thirty are primarily influenced by the general service and the convenience/accessibility of modes and their negative feelings about car. In contrast the mode choice among middle-aged individuals appears to be primarily determined by general service. The elderly, although significantly influenced by mode attributes (i.e. general service and convenience/accessibility), are most heavily influenced by their feelings about the bus in making mode choice decisions.

An attempt was also made to segment on the basis of individuals' response to transportation alternatives. To identify individuals with similar behavioral responses, a cluster analysis was performed on the factor scores for feelings toward the modes. Using this procedure four segments were identified. These segments represented different reactions to the available modes; one was open-minded (i.e. positive about all modes), one was anti-walk (i.e. negative about walk, neutral about other modes), one was anti-car (i.e. negative about car, positive about other modes), and one was anti-bus (i.e. negative about bus, positive about other modes). Furthermore these segments represented different types of people (e.g. anti-car tended to be male university students with relatively low income etc.). However, this basis for segmentation was not significant in terms of improving the prediction and explanation of mode choice, therefore the models for these subgroups are not reported here.

In summary, the segmentation analysis demonstrates that a significantly better explanation of consumer travel behavior may be obtained by breaking the population down into distinct subgroups. This increased understanding can be helpful in guiding strategy development.

Discussion and Plans for Future Research

In general, the research results support our model of consumer transportation behavior. However, a more stringent test of the model requires the manipulation of model variables and observation of their effects. This test is necessary not only from a theoretical perspective (i.e. to test the causality of hypothesized relationships between variables), but also from a practical perspective. The model is only of value to transportation managers and planners if it can help them generate and select effective strategies for influencing consumer mode choice. Therefore, in this section, the research results will be used to generate strategies for altering consumers' mode choice and future research to evaluate these strategies will be outlined.

In accord with our model, five basic types of strategies for influencing mode choice may be generated. These strategies, each focusing on a different model variable, are summarized below.

- (1) Modification of System Characteristics. Strategies designed to modify system characteristics (i.e. product strategies) are appropriate when the system does not meet consumers' needs on some dimension and this dimension is significantly related to perceptions which influence preference and choice. System strategies may range from reducing bus fares or increasing bus frequency to introducing a new paratransit mode.
- (2) Modification of Consumer Perceptions. Strategies designed to modify consumer perceptions directly (i.e. not by modifying system characteristics) are appropriate when consumers are either uninformed or misinformed about the system. Here the task is to provide consumers with accurate information. In addition, modification of consumer perceptions may also be ap-

propriate when consumers have accurate information about the system but interpret that information negatively (e.g. they know that the bus runs every half hour and interpret that as poor service). When this occurs persuasion may be employed in an effort to alter the individuals' interpretation of the information.

- (3) Modification of Consumer Preference. Strategies designed to modify consumer preference may be employed when consumers' perceptions are accurate but low importance is placed on perceptions of public transportation which are positive and high importance is placed on those which are negative. In this situation the task is one of changing the importance weights so that dimensions on which public transportation performs well receive greater emphasis. Persuasive appeals may be used to do this.
- (4) Modification of Situational Constraints. Strategies designed to modify situational constraints are appropriate when these factors have a significant impact on mode choice (i.e. auto availability, parking availability etc. may influence mode choice). This approach entails manipulation of situational factors so that incentives or disincentives for particular mode choices result (e.g. restricting parking in downtown areas may discourage car trips). These strategies tend to be perceived as more coercive than other types of strategies and they are often difficult to implement since legislation and regulation changes may be required. Thus, constraint modification strategies are typically only used when other strategies have failed.
- (5) Modification of Behavior. Strategies designed to modify individuals' choice behavior directly are appropriate when consumers are reluctant to try a particular service but there is reason to believe that if they tried it they would like it. Promotional strategies such as free rides, discount coupons etc. may be used to encourage trial.

Now, let us use the research findings to determine what strategies are likely to increase public transit ridership in the Evanston community. First, we will examine strategies for the entire community. Then, we will discuss strategies tailored to the behavior of subgroups in the community.

The research results indicate that perceptions of general service provided by alternative modes are the most important determinant of preference and choice for the community as a whole. Thus, one strategy for increasing public transportation ridership is to improve the perceptions of the general service public transportation provides. To do this we must first examine the specific attributes which make up the general service dimension (Table 2). Attributes loading heavily on the general service factor are "on time" "correct temperature" "errands take little time", "little effort involved", "get to destination quickly", "no problems in bad weather", "easy to carry packages", "safe at night", "easy to travel with small children", and "not tiring". Of these attributes bus scores very poorly on the six that are underlined. Next, we must attempt to determine whether the low evaluation of bus on these dimensions is the result of poor system performance or a misperception of system performance by consumers.

Evidence from a separate study in which system performance was monitored indicates that, in general, the system runs on schedule (see Bernstein, Knall and Lindauer, 1977). Therefore it appears that the low "on time" rating for bus is not the result of poor system performance but rather it stems from consumers' misperceptions or lack of information regarding the system. This in-

terpretation is also supported by the finding that consumers generally could not correctly answer questions regarding the bus schedule. As a result, one strategy for improving bus general service would be to inform consumers about the good "on time" performance of the bus and educate them about the bus schedule.

In contrast, evidence from the same study of system performance suggests that consumers accurately perceive the bus travel time from their homes to downtown Evanston. Thus, the negative evaluation of bus on quickness related attributes is not due to a misperception but instead is the result of a negative interpretation of an accurate perception. Two alternative strategies for improving the "quickness" evaluation of bus and thereby improving the general service rating are appropriate: (1) modify the service (e.g., implement express buses) and (2) use persuasive communications to convince consumers that they should reinterpret the actual quickness more favorably.

Similarly, examination of the bus system performance indicates that consumers' negative perceptions of the ease of carrying packages and traveling with children on the bus are probably well founded. Perceptions of ease of carrying packages could be made more positive by altering the service to include special package racks, etc. Strategies which would increase the ease of traveling with children on the bus are not readily apparent.

Finally, consumers' poor rating of bus safety at night has some basis in reality (i.e. rapes and muggings have occurred in the past), however consumers may be overreacting to one or two isolated incidents that have been highly publicized. A two-pronged approach to improving evaluations to bus safety may be appropriate: (1) change bus system to improve safety (e.g. add guards, improve lighting etc.) and (2) inform public that actual crime rate is quite low.

The above strategies for increasing public transit ridership are all based on improving consumers' evaluation of bus on the general service dimension. An alternative approach would be to use persuasive communications to increase the relative importance of the psychological comfort dimension where bus already outperforms car and walk. This might entail stressing the importance of getting to one's destination without being hassled (e.g. Greyhound's "leave the driving to us"). Or, emphasis could be placed on improving consumers' feelings about the bus and the importance of these feelings. The bus feeling factor is a function of liking for the bus, believing one ought to ride the bus, and believing significant others (e.g. family, friends) would approve of one riding the bus. Thus, strategies might focus on making the bus ride more pleasant (e.g. attractive colors, music, etc.), emphasizing one's obligation to ride the bus to conserve energy, reduce environmental pollution and please one's friends, family, coworkers, etc. Finally, once changes in the bus system have been made and it appears that the service is one that meets the needs of the consumer, strategies to alter behavior (i.e. encourage trial), such as coupons, free rides, etc. may be appropriate to help alter consumer perceptions.

The same procedure used to develop strategies for the community as a whole can be used to develop strategies for subgroups in the population. Table 7 indicates that individuals who have low auto availability place less emphasis on general service, where bus performs poorly, and more emphasis on feelings about the bus than those with high auto availability. This suggests that situational constraints which reduce auto availability will have a positive impact on bus ridership. In addition, the data provide guidelines for the development

of specific strategies to reach each of these segments (i.e. focus on general service strategies for those with high auto availability and use strategies designed to improve bus feelings and general service strategies for those with low auto availability).

The choice models for the age segments also suggest using different strategies to increase public transportation ridership within age group. Members of the youth segment are strongly influenced by their feelings about the car, which tend to be negative. Thus, strategies to increase public transit ridership among the young could make their negative feelings about car salient and present bus as a more attractive alternative. The middle-aged segment is heavily influenced by perceptions of general service, therefore the strategies for improving general service discussed earlier are appropriate for increasing public transit ridership among this group. In contrast, the elderly's mode choice is largely influenced by their feelings about the bus, thus strategies for enhancing bus feelings discussed earlier are particularly appropriate for this segment. Furthermore general service and convenience/accessibility are of equal importance for the elderly and young, therefore strategies effecting either of these dimensions are likely to have a similar impact.

We have illustrated how the model can be used to generate strategies for influencing mode choice. The next step in our research program will be an evaluation of these strategies. This evaluation will entail comparing the estimated costs of implementing each strategy (i.e. materials/equipment personnel time etc.) with its estimated benefits (i.e. predicted impact on ridership, subsidies, etc.). (An on-line computer package is currently being developed for this purpose). In addition, strategies will be evaluated in terms of their feasibility (i.e. whether there are any legal constraints which would affect their implementation such as labor union regulations). On the basis of this evaluation a set of strategies will be implemented and their effects will be monitored to test the accuracy of our model of consumer behavior. For example, the model predicts that changes in general service will have the greatest impact on middle aged individuals and will have less impact on the young and the elderly. Furthermore, the model predicts that strategies to reduce travel time will have a greater impact on perceptions of general service than ones which increase availability (i.e. extend hours of operation). Implementation of two strategies, one which reduces travel time and one which extends the hours of service and monitoring the impact of these strategies through direct measurement of demand (i.e. ridership counts, fare box revenues etc.), and responses to consumer surveys (i.e. surveys measuring consumers' awareness, perceptions, preference and choice in response to these changes) would allow testing these model based predictions.

FUNCTIONAL MEASUREMENT ANALYSIS OF SPATIAL AND TRAVEL BEHAVIOR

Jordan J. Louviere, University of Wyoming
 Irwin P. Levin, University of Iowa

Abstract

This paper overviews theory and methodology derived from Information Integration Theory or Functional Measurement and illustrates its application to several problems in modeling spatial choice and travel behavior. The applications involve both laboratory and field studies of human judgment: Consumer self-estimates of patronage on alternative public bus systems; consumer estimates of the attractiveness of alternative supermarkets; and consumer estimates of the attractiveness of alternative towns as places to live. All studies demonstrate highly significant monotonic relationships between modeled evaluations and corresponding real-world choice behavior.

Introduction

The purpose of this paper is to briefly overview the theory and methodology of Functional Measurement and illustrate its application through a brief discussion of several studies of spatial choice and travel behavior. Functional Measurement refers to a three-pronged approach to understanding and modeling human judgment and decision-making. The approach was developed by Norman Anderson and his associates (Anderson, 1970, 1976a, b, 1977; Shanteau and Troutman, 1975; Levin and Gray, 1976; Louviere, 1978; Louviere and Norman, 1977; Norman and Louviere, 1974; Norman, 1977). These three prongs are:

1. The establishment of interval scale measures for stimuli and response;
2. The establishment of the functional rule relating stimuli to response;
3. The establishment of the psychophysical rule relating physical and subjective measures of stimuli.

Functional Measurement Theory

Thus, the goal of the Functional Measurement approach is to develop mathematical expressions which describe the processes by which individuals and groups thereof process stimulus information in order to make judgments, decisions, choices, etc. The theory is concerned with multiple causation in that it postulates that individuals evaluate or make decisions about multi-attribute alternatives by means of simple algebraic "mental rules." In the present context, we would say that consumers of transportation products evaluate these products by means of simple algebraic combinations of attributes which the alternatives possess. As an example, we might postulate that consumers choose among or allocate their choices among alternative transportation modes for their trips to work by evaluating salient attributes of each mode, combining these separate evaluations into an overall mode evaluation in a manner which can be described algebraically, and selecting the mode with the highest evaluation most often. We might suppose, for example, that an individual weights each attribute separately and sums all the weighted attribute evaluations to assign an overall evaluation. This would lead to the following linear model(s):

$$E_i = \sum_j w_{ij} e_{ij} \quad (1)$$

$$E_i = \frac{\sum_j w_{ij} e_{ij}}{\sum_j w_{ij}} \quad (2)$$

depending upon whether the process is additive or averaging. E_i is the overall evaluation assigned to alternative i , w_{ij} is the weight assigned to each of the separate evaluations (e_{ij}) of the j attributes.

This has been a common assumption in much empirical work in marketing, geography, psychology and transportation (see Slovic and Lichtenstein, 1971; Slovic, Fischhoff, and Lichtenstein, 1977; and Wilkie and Pessemier, 1973 for a review). Unfortunately, when this assumption is put to the adequate test demanded for these models, as in the empirical work to be reported below, it has often been rejected. Rather, support has generally been given for one or the other of two alternative models:

$$E_i = \frac{\sum_{ij} w_{ij} e_{ij}}{\sum_{ij} w_{ij}} + k'' \quad (3)$$

$$E_i = \pi \prod_j w_{ij} e_{ij} + k' = k \pi e_{ij} + k' \quad (4)$$

Equation 3 is the expression for a differentially weighted averaging model in which the weight parameters (w_{ij}) are different for each different level (i) of each different attribute. Thus, there would be $i \times j$ weight values. The model is nonlinear because the denominator is different (non-constant) for each ij combination. Equation 4 is the multiplicative rule for the evaluations. Even though the attributes may have different weights, the weights are not mathematically distinguishable. Both equations 3 and 4 have intercept terms (k' , k'') to permit the existence of an arbitrary zero in the response scale (E_i), the requirement for an interval measure of evaluation.

There is an important conceptual difference between the models expressed in equations 3 and 4 and those expressed in equations 1 and 2. The linear models (equations 1 and 2) imply that the various attributes have independent effects on the overall evaluation of a multi-attribute system. By contrast, the nonlinear models (equations 3 and 4) imply that one or more attributes can modify the effect of others. Such modifying effects can be an important component of consumer decision processes. In an example to be described in more detail later, the effect of the sex of a potential carpool rider on the desirability of carpooling depended on whether or not the rider was a prior acquaintance of the respondent. Statistically, this difference corresponds to lack of interaction effects for the linear models and the discovery of systematic interaction effects for the nonlinear models.

Thus, the theory and methodology of functional measurement is concerned with the diagnosis and testing of these and other algebraic rules. In spirit, therefore, it is similar to conjoint measurement (Krantz and Tversky, 1971) or multi-attribute utility theory (Keeney and Raiffa, 1976) but is superior on methodological grounds in that:

1. It possesses a validity test by which an hypothesized model may be rejected, if false. That is, it has an error theory.

2. It can handle continuous, interval-level numerical values as well as ordinal data.
3. It provides an efficient way of diagnosing and testing both marginal and joint relationships without resort to scaling things one-at-a-time.
4. The statistical methodology is well-understood, easily applied and robust. It is the same methodology for testing significance and estimating parameters for general linear statistical models.

Functional Measurement Methodology

We will illustrate the manner in which the methodology is applied with reference to adding and multiplying models (1 and 4). Suppose we hypothesize that consumer trips by bus are conditional upon fare (F), frequency of service (S) and distance to closest stop (D). We can then write:

$$E_{ij} = k + w_1 F_i + w_2 S_i + w_3 D_i + E_{ij}, \text{ or} \quad (5)$$

$$E_{ij} = k' + k'' \pi F_i S_i D_i + E_{ij} \quad (6)$$

where E_{ij} is the overall evaluation given by consumer i to alternative j , the k 's are scaling constants, w 's are weight parameters and E_{ij} is an error term assumed to be normally distributed with zero mean and unit variance.

Equation 5 is testable by having each consumer (i) make a numerical evaluation of each alternative (j). How this is done will be ignored because extended treatments are available elsewhere (Anderson, 1974, 1976; Louviere, 1978). We assume that E_i is some response or judgment (decision, degree of preference, etc.) observed on an interval scale. The only restriction, which may be considerably relaxed, is that the j alternatives be chosen such that they constitute the cells of a factorial or fractional factorial combination of the experimental variables. Again, standard treatments of experimental design are available and will not be elaborated here (see, e.g., Winer, 1962; Snedecor and Cochran, 1968). We will agree to term a complete design with all possible combinations of experimental factors a full factorial (FF); while designs that are fractionated and have some effects aliased or confounded with other effects we will term fractional factorial designs (FFD).

If the j alternatives are selected by means of an FF or FFD plan, then equations 5 and 6 may be tested. Either analysis of variance or multiple linear regression may be used to test these equations. These equations predict that certain effects (parameters) will be significant or nonsignificant. In particular, equation 5 predicts that only the main effects will be significant, while equation 6 predicts that both main and interaction effects will be significant. The pattern of these effects is critical because alternative algebraic formulations imply alternative patterns (see Anderson, 1974, 1976). Detailed treatments of the testing and/or diagnosis of these models are available elsewhere (see Anderson, 1974, 1976 for example) and will not be pursued here.

All of these tests are complemented by graphical plots of the data: Briefly, equation 5 predicts that all main effects plots (graphing the marginal means against their experimental values) will be linear and that all interaction plots will consist of a series of parallel straight lines, with slopes equal to the corresponding w 's (see Anderson, 1974, 1976 for detailed discussion). Similarly, equation 6 predicts that the main effects plots will be the same as equation 5, but the interaction plots will not: they will consist of a series of diverging straight lines (see Anderson, 1974, 1976 for a detailed treatment). Both the statistical and the graphical evidence must agree. Ordinarily both are

employed in diagnosis and testing. We will now illustrate the application of the approach in a series of brief empirical examples. These examples include: 1) consumer evaluations of alternative bus systems to satisfy general transportation needs; 2) consumer evaluations of alternative carpooling scenarios; 3) consumer evaluation of alternative grocery shopping destinations; and 4) consumer evaluation of alternative towns as places to live.

Empirical Applications

Bus System Evaluations. Beginning in 1972, a series of studies was undertaken by Louviere, Norman, Levin and their associates to examine the process by which consumers trade-off attributes of public bus systems. The results are summarized elsewhere (Norman and Louviere, 1974; Louviere and Norman, 1977; Norman, 1977, Levin and Gray, 1977; and Levin, 1978) and will be briefly restated here.

In an initial study of consumer trade-offs, using students as subjects at the University of Iowa, it was found that the students both individually, and as a group, acted "as if" they employed a multiplicative process in evaluating "how frequently" they might use 27 alternative bus systems that differed in fare, headways and walking distance to closest stop. It was also demonstrated that the marginal relationships between these factors and the subjective response was nonlinear, describable by power functions of the form $y = a + bx^c$.

This study was followed by a second in which trip purpose, fare, walking distance, hours of operation and number of stops between origin and destination were covaried in a series of sub-factorial designs according to the method of differential information developed by Norman (1976). For each trip purpose, subjects evaluated four three-factor subdesigns. This permits uniquely separable estimates of the weight parameters in the context of a geometric averaging model, which is a multiplicative model. Results supported the model and revealed that the weights on each factor differed by trip purpose: Fare had a higher weight for shopping than work trips; walking distance had a higher weight for work trips than shopping trips; the number of intervening stops had a greater effect than hours of operation for work trips, but the reverse was true for shopping trips. Additional studies (e.g., Wilf, 1974 and Louviere, Meyer, Stetzer and Beavers, 1974) have also supported multiplicative evaluation processes. Unfortunately, all of these preliminary studies were conducted with college students.

Two recent studies of nonstudent employees at the University of Iowa, however, have yielded somewhat different results (Meyer, Levin and Louviere, 1978). These studies manipulated time difference of bus over car, cost difference of car over bus and number of other passengers. Thus, subjects were given situations to evaluate described by different excess travel time by bus, higher costs by car, and number of other individuals present (to simulate drive alone, car pool, or transit).

A cluster analysis was used to define homogeneous groups of subjects according to the pattern of their responses to the alternative situations. The clusters grouped respondents who favored the car, were neutral and who favored the bus (The response scale used was a 150 millimeter line, marked off by "certain to take car" or "certain to take bus" at either end. Clusters included subjects who responded toward the car end, the bus end, or in the middle, on the average). Graphs of the data from each group revealed that only car biased subjects exhibited multiplicative evaluation processes. Both other groups exhibited processes best described by the

differentially weighted averaging model of equation 3. However, more research is required to extend the generality of these findings past the experiment, its context and this group of subjects.

In another phase of these Iowa studies, the authors fit a modified regression equation to actual bus patronage behavior of the employees. Respondents were asked to estimate the number of bus trips made to work in the previous month, the distance from their residence to work, whether bus or car was more expensive for the trip and whether they felt that the bus was really available to them to make the trip (yes/no). From the experimental data, a measure of bias toward one or the other mode can be derived: it is each respondent's grand mean response over all evaluations. It was hypothesized that this measure captures a wide array of attitudinal effects and that it would have a significant effect on actual (reported) patronage. The following model was tested:

$$\begin{aligned} \text{Proportion of trips by bus} = & (b_1 \text{ Grand Mean} + b_2 \text{ Home--} \\ & \text{Work Distance} + b_3 \text{ Is Car} \\ & \text{Cheaper (1 = Yes)}) \times \\ & \text{Whether Bus Available} \\ & (\text{No} = 0) + E \end{aligned} \quad (7)$$

This equation accounts for almost 80% of the variation in the data from 97 respondents, with the grand mean factor (bias) alone accounting for almost 70%. A second analysis in which respondents were classed by usual mode and employing equation 7 in a binary discriminant analysis permitted 94% correct classification, a figure that compares well with more traditional disaggregate models such as the multinomial logit (Domencich and McFadden, 1975). A missing element in these studies has been an analysis of the extent to which group membership can be predicted by sociodemographic and environmental measures for each individual. The results strongly suggest that if individual grand mean responses are predictable from forecastable socioenvironmental and demographic variables, mode choice can be readily forecast. Work is proceeding to test these notions on several projects, but is not available at this writing.

Consumer Carpooling Decisions. Traditional analyses of factors in carpooling have avoided nonquantitative factors such as interpersonal variables because of difficulties in their measurement. However, recent studies by Levin, Mosell, Lamka, Savage, and Gray (1977) and Mosell, Lamka, and Levin (1977) have included factors such as the sex of potential carpool riders and whether or not the respondent had a prior acquaintance with other potential riders. The functional measurement approach allows an analysis of how each factor combines with each other factor to determine the potential desirability of a carpool.

Results indicate that interpersonal factors have an effect on judged carpool desirability comparable to the effects of more traditional time and cost factors. In particular, the desirability of an alternative carpool description can be described as an average of the desirability of the individual potential riders, and the desirability of an individual potential rider can be described as a multiplicative function of sex and acquaintanceship. Thus, if the potential rider is an acquaintance, the sex of the rider is of little or no consequence. If the rider is not an acquaintance, sex is important, and both male and female respondents prefer a female rider. Acquaintanceship by itself appears to have a dramatic effect on carpool desirability: Extremely low ratings are given to carpools with no acquaintances, but if even one potential rider is identified as an acquaintance, the desirability of carpooling increases dramatically. This finding is currently

being pursued as a means for incorporating interpersonal factors in carpool promotional programs with the aid of funding from the Urban Mass Transit Administration.

Consumer Evaluation of Alternative Grocery Shopping Destinations. Studies of samples of the general population of Tallahassee, Florida and Laramie, Wyoming have applied the Functional Measurement approach to the identification of consumer evaluation functions and the use of these functions to predict actual store patronage. On the basis of preliminary survey work in both cities, it was found that consumers apparently traded-off perceived prices, selections, and convenience in choosing real supermarkets. A Functional Measurement experiment which varied levels of these three factors in a 3³ FF plan was evaluated by random samples of citizens in the two cities drawn from telephone directories.

Data analysis confirmed the a priori hypothesis that consumers would act "as if" they employed a multiplicative evaluation process in judging stores described by combinations of the three factors. Respondents were asked to supply a numerical evaluation of "how good" each of a list of real supermarkets with which they felt familiar was on each experimental factor (prices, selection, convenience). The judgment scale was the same as that employed in the experiment--a 20 category rating scale. The average category value assigned to each real supermarket on each factor is its expected scale value on that factor if the experimental results are approximately true. Then these values may be combined according to the following rule:

$$E_i = p_i \cdot s_i \cdot c_i \quad (8)$$

where E_i is the expected overall evaluation or "utility" associated with each of the i ($= 13$ in Tallahassee; $= 6$ in Laramie) real supermarkets and p_i , s_i and c_i are, respectively, the average value of price, selection and convenience ratings. Then, by measuring either patronage (Tallahassee) or gross yearly sales (Laramie) we hypothesize:

$$B_i = f(E_i) \quad (9)$$

where B_i is the measure of patronage or sales and E_i is defined in 8. In both cities B_i was linearly related to E_i : The correlation was .93 in Tallahassee and .96 in Laramie. Again, more research is needed to extend the generality of these findings.

Consumer Evaluation of Alternative Towns as Places to Live. Resource exploitation is proceeding rapidly in the Rocky Mountain West and a major concern is understanding and predicting which towns nonlocal employees will choose for their residences when they are brought in to western industrial sites. One simple hypothesis is that they will trade-off the amenities offered by the town with commuting distance to work. It is now well-known that the number of various types of goods and services offered in central places is linearly related to the population base of those places (see, e.g., Berry, 1967). Hence, a range of 10 services were predicted from population sizes of 250, 500, 1000, 1500, 2000 and 2500 and were arranged in a series of 36 different paragraph descriptions which listed the population, the number of each type of good and service available and one of six (15, 30, 45, 60, 75, 90 miles) different commuting distances. This is a 6 x 6 FF plan because amenities are perfectly linearly related to population and cannot be statistically separated.

Seventy-five staff, faculty and student volunteers at the University of Wyoming judged "how desirable" each town alternative would be to them as a place to live if they had a job at an industrial site x miles away in Western Wyoming. Analytical results confirmed the

a priori hypothesis that subjects would act "as if" they processed the information in a multiplicative manner, similar to a gravity model. The following equation was found to describe the data well:

$$E_i = ae^{-b\text{Distance}_i} (c + d\text{Population}_i^p) \quad (10)$$

where a, b, c, d and p are empirical parameters and E_i is the observed average evaluation given to the i towns ($i = 36$).

A set of real choice proportions for seven different industrial sites in three states was available to test the model (Old West Commission, 1975). Let p_i be the observed proportion of nonlocal employees from a particular plant that chose town i as a residence. Because the commuting distances and populations of the i towns can be approximated, they may be substituted in equation 11 to yield \hat{E}_i --the expected evaluation or utility which the experimental subjects would have assigned the i towns had those distance and population combinations been used in the experiment. We then hypothesized that $p_i = f(E_i)$.

The graph of p_i vs. E_i is highly monotonic and can be approximated by a function of the form, $p_i = a'e^{b'E_i}$. The correlation between the two sets of observations is .92 ($i = 56$). It is clear (at least in this study) that a simple transformation exists to map responses or utilities into expected choice proportions. A model may then be re-estimated on expected choice proportions and used to forecast the number (or proportion) of employees at plant i that will choose town j as a residence.

Summary

This paper has reviewed and briefly described and discussed theory and methodology from the Functional Measurement approach to modeling consumer information processing in judgment. It was demonstrated that consumer trade-off functions can be readily derived for a wide class of applied problems and that these functions are related to actual consumer behavior and can be used to forecast same. A considerable amount of research remains, however, to develop an understanding of the generality of the models across samples, places and individual consumer groups. Moreover, little is known about the effects, if any, of social, demographic and environmental factors on the individual decision function. Such knowledge is necessary to implement the models for practical forecasting problems.

Perhaps the most important conclusion is that individual decision processes can be diagnosed and modeled using simple experimental designs and statistical tools. Models are derived empirically and many applications have shown the typical a priori assumption of linear forms to be inadequate to describe real-world behavior. This extends work that began in the laboratory in 1962 to real field problems and demonstrates that the approach can be most useful in understanding consumer travel decision processes.

EXTENDED CONJOINT ANALYSIS WITH INTENSITY MEASURES
AND COMPUTER ASSISTED INTERVIEWS:
APPLICATIONS TO TELECOMMUNICATION AND TRAVEL

John R. Hauser, Northwestern University
Steven M. Shugan, University of Rochester

Abstract

This paper reports two advances in the measurement of consumer preferences. First, a general theory extends conjoint measurement from ordinal measures (rank order only) to more effective and efficient intensity measures (interval, ratio, or hybrid). Tests are given to identify the appropriate theory to describe consumer response and procedures are given to estimate the preference functions. Second, a marketing information system (P.A.R.I.S.) is described which can automatically encode any questionnaire on an interactive computer system for computer assisted interviewing. P.A.R.I.S. has special commands for the preference measurement questions; it automatically stores all data in special files for easy access and has a subroutine for the improved conjoint analysis. The general theory as implemented through P.A.R.I.S. is illustrated with a case application to the analysis of consumer preference for new telecommunications technology. Comparisons are made to standard conjoint analysis and to preference regression.

Introduction

To design new transportation or communication services, managers and analysts must understand how consumers will react to such services and must be able to predict the subsequent usage of those services. An important component in this analysis is the measurement of consumer preferences, i.e., the measurement of how consumers value the various attributes of transportation or communications service and how they aggregate these valuations to form an overall evaluation of each alternative.

A number of techniques have been used in both marketing and in transportation to measure or estimate consumer preferences. The first set of techniques, which we will call "group-level" techniques, are used extensively in transportation demand analysis and include the "dis-aggregate behavioral demand models." These techniques normally represent the preference value p_{ij} , that individual i places on alternative j as a weighted sum of i 's perception of j with respect to a set of attributes. If w_k is the "group" weight for attribute k , and x_{ijk} is i 's perception of j with respect to k , then the model is represented by $p_{ij} = \sum_k w_k x_{ijk}$. Among the techniques used are logit analysis (McFadden, 1970), preference regression (Urban, 1975), and maximum score. The advantage of these models is that they are relatively easy to estimate because they are based on statistical analysis of consumers' preference or choice among existing services. Their disadvantages are that they merge individual difference and estimate group weights (w_k) rather than individual weights (w_{ik}) and that the simple linear form may not accurately represent consumer behavior (Farquhar, 1977; Hauser and Urban, 1977b, Keeney and Raiffa, 1976). Their primary use is as a preliminary screening process to identify important attributes and provide "first order" predictions.

As the design of the product or service is refined, analysts need stronger measures and an ability to better understand the mapping of perceptions into preference. Furthermore, for various segmentation strategies it is important to identify individual differ-

ences by measuring preference functions for each individual consumer. These "individual-level" techniques normally represent preference, p_{ij} , as a sum or product of non-linear functions of the attributes, i.e., $p_{ij} = \sum_k u_{ijk}(x_{ijk})$. Among these techniques are conjoint analysis (Tversky, 1967; Green and Wind, 1973), trade-off analysis (Johnson, 1974), direct utility assessment (Hauser and Urban, 1977b). The advantages of these models are that they provide more detailed identification of individual differences and that their non-linear forms are more sensitive to decreasing returns and risk aversion effects (Raiffa, 1970). Their disadvantages are that they are more expensive because they normally require a personal interview, that they must often expand the stimuli set to pseudo-products (products represented by their attribute levels) to get sufficient degrees of freedom for estimation, and that the consumer task is often tedious. When compared to group-level techniques the "individual-level" techniques are more accurate but more expensive. Because of their advantages, these techniques have definite use in the design of transportation services if used judiciously (Green and Wind, 1975; Market Facts, 1976), but there is a definite need for improvement to make them more efficient and cost effective.

This paper covers two parallel improvements in the measurement of individual-level preference functions. The first, evaluation theory, generalizes conjoint analysis to stronger, more efficient measures of preference. These intensity measures are shown in an empirical example to improve prediction relative to both conjoint analysis and a representative "group-level" technique--preference regression. The second improvement, interactive interviewing, provides for more cost-effective measurement and faster, less expensive analysis. The general theory and the interactive interviewing system are covered in detail in two separate papers available upon request from the authors (Hauser and Shugan, 1977; Shugan and Hauser, 1977).

Theory Based on Intensity Measures

Standard conjoint analysis is an effective technique to measure consumer preference, but the consumer task is quite tedious requiring the consumer to rank order 20-40 "products" (actual or pseudo-products) in terms of preference. As a result, many researchers have modified conjoint analysis to reduce the consumer task. For example, Green and Wind (1975) use a fractional factorial design to reduce the number of stimuli. Johnson (1974) uses tradeoff matrices that require consumers to rank order "products" where only two attributes vary at a time. Hauser and Urban (1977b) use von Neumann-Morgenstern theory to formulate indifference questions¹ that require consumers to set an attribute level of one product such that it is equal in preference to another fully-specified product. All three procedures simplify the consumer task, but applications still require 20-40 minute interviews.

¹Indifference questions are a limiting case of rank order questions.

Furthermore, each theory measures ordinal preference, i.e., a ranking over "products,"² rather than intensity of preference. Although a set of conjoint models over a consumer population estimates how many people choose each product, conjoint analysis does not estimate ratio, interval or probabilistic preferences. Such intensity measures are potentially better indicators of the consumer evaluation process and more accurate predictors of behavior.

If conjoint analysis could be extended to intensity measures such as dollar metric (Pessemier, 1977) or constant sum paired comparisons (Torgenson, 1958), it is reasonable to posit that more information could be gathered per question and as a result, fewer questions need be asked. (See figure 1 for an example of a constant sum paired comparison [CSPC] question.) Furthermore, if the consumer gives consistent answers, it may be possible to measure preference functions that incorporate intensity of preference. Support for this con-

jecture comes from recent simulation and empirical results (Green, 1976; Carmone, Green and Jain, 1976; Cattin and Wittink, 1976; Hauser and Urban, 1977a) which show that conjoint analysis is robust with respect to the metric/non-metric assumption. In fact, there are definite indications that the metric models which treat ordinal data as interval data can outperform their non-metric counterparts. Further support comes from Silk and Urban (1976) who report tremendous success with CSPC for actual products chosen in simulated purchase environment (over 80% of the uncertainty in behavior explained). The natural extension would then be to use intensity measures directly rather than arbitrarily forming interval data from ordinal data.

But conjoint theory (Tversky, 1967) as well as utility theory (von Neumann-Morgenstern, 1947) is based on ordinal preference. Before intensity measures can be used, assumptions and properties of the measures and preference functions must be identified. Tests must be developed to determine whether the consumer reacts consistently to the task and to determine what theory best explains his or her answers. This will determine whether the preference function should exhibit ordinal, interval, ratio, probabilistic, or hybrid properties.

Hauser and Shugan (1977) show that consumer reaction to intensity measures can be represented by a general equation based on property operators and measurement relations. They show that two axioms--property asymmetry and property transitivity--are necessary for consistency of the representations and a general independence property--evaluative independence--provides simple decompositions for ease of estimation. Rather than cover

²Von Neumann-Morgenstern preference functions can handle lotteries, i.e., products with uncertain or risky attributes.

the detailed derivations in this paper, we will simply state the results for four special cases: ordinal, interval, ratio, and hybrid.

Conjoint Analysis (Ordinal Theory)

Ordinal theory is based on the standard assumption that the intensity measures give only rank order information. I.e., consider the CSPC question in figure 1. Let x_k be the value of the k^{th} attribute, e.g., scent $(k=2)^j$, for the j^{th} product, e.g., product A ($j=1$). Let $x_j = (x_{j1}, x_{j2}, \dots, x_{jk})$. Let a_{ij} be the number of chips allocated to product i when comparing i and j , and let $a_{ji} = 100 - a_{ij}$. Let $u(x_j)$ be the preference function that a_{ji} maps the attributes x_j into a measure of preference, i.e., $p_j = u(x_j)$ where p_j is a scalar measure of "goodness" for product j . In this notation ordinal theory is simply stated:

$$a_{ij} \geq a_{ji} \text{ implies } u(x_i) \geq u(x_j) \quad (1)$$

Property transitivity is ordinary transitivity. I.e., if δ_{ij} is defined such that $\delta_{ij} = 1$ if $a_{ij} > a_{ji}$, $\delta_{ij} = 0$ if $a_{ij} = a_{ji}$, and $\delta_{ij} = -1$ if $a_{ij} < a_{ji}$ then property transitivity among three products-- i , j and k --is given by:

$$\delta_{ij} + \delta_{jk} - \delta_{ik} = \delta_{ij} \delta_{jk} \delta_{ik} \quad (2)$$

Under evaluative independence (which is known in ordinal theory as pairwise preferential independence [Ting, 1971; Farquhar, 1977; Keeney and Raiffa, 1976]) it can be shown that the appropriate decomposition is:

$$u(x_j) = u_1(x_{j1}) + u_2(x_{j2}) + \dots + u_k(x_{jk}) \quad (3)$$

Equations 1, 2 and 3 can also be extended to handle risky alternatives, i.e., products with uncertain attribute levels by the use of von Neumann-Morgenstern theory. Equations 1 and 2 are extended to lotteries (Keeney and Raiffa, 1976; Hauser and Urban, 1977a; Hauser, 1976) and equation 3 becomes Keeney's quasi-additive form (Keeney, 1972).

Estimation is by standard conjoint estimation (Green and Wind, 1975; Johnson, 1974; Srinivasan and Shocker, 1973) or, for risky alternatives, with direct utility assessment (Hauser and Urban, 1977b).

Intensity Measures (Interval Theory)

Conjoint analysis has proven successful in the past but ordinal theory uses only part of the information in CSPC or equivalent measures. An alternative theory, based on fundamental axioms by Shapley (1975) is interval theory. This is given simply by:

$$u(x_i) - u(x_j) = a_{ij} - a_{ji} \quad (4)$$

The test of consistency is additive transitivity.

$$(a_{ij} - a_{ji}) + (a_{jk} - a_{kj}) = (a_{ik} - a_{ki}) \quad (5)$$

Under evaluative independence, the decomposition is again additive:

$$u(x_j) = u_1(x_{j1}) + u_2(x_{j2}) + \dots + u_k(x_{jk}) \quad (6)$$

If we discretize each $u_k(x_{jk})$, i.e., define $u_k(x_{jk}) = \sum_{\ell} \lambda_{\ell k} \delta_{\ell k j}$ where $\delta_{\ell k j} = 1$ if product j has attribute k at level ℓ and $\delta_{\ell k j} = 0$ otherwise, then the estimation equation is:

$$a_{ij} - a_{ji} = \sum_k \sum_{\ell} \lambda_{\ell k} (\delta_{\ell k i} - \delta_{\ell k j}) + \text{error} \quad (7)$$

The part-worths, λ_{jk} , are estimated with ordinary least squares regress (OLS) or linear programming (Srinivasan and Shocker, 1973).

Intensity Measures (Ratio Theory)

Originally CSPC is based on a ratio assumption (Torgenson, 1958). Hauser and Shugan (1977) show that the ratio assumption can be extended from comparisons over physical products to comparisons over attribute bundles. This theory is given by:

$$u(x_i)/u(x_j) = a_{ij}/a_{ji} \quad (8)$$

The test of consistency is multiplicative transitivity:

$$(a_{ij}/a_{ji}) \cdot (a_{jk}/a_{kj}) = (a_{ik}/a_{ki}) \quad (9)$$

It can be shown that the appropriate decomposition is multiplicative:

$$u(x_j) = u_1(x_{j1}) \cdot u_2(x_{j2}) \cdot u_3(x_{j3}) \cdot \dots \cdot u_K(x_{jK}) \quad (10)$$

If we discretize $u_k(x_{jk})$ as an interval theory, then under the logarithmic transformation the estimation equation becomes:³

$$\log(a_{ij}/a_{ji}) = \sum_k \sum_l (\delta_{lki} - \delta_{lkj}) \log \lambda_{lk} + \text{error} \quad (11)$$

The part worths, λ_{lk} , are obtained from estimates of $\log \lambda_{lk}$ based on OLS or linear programming.

Hybrid Theories

Given the general form it is possible to extend the above theories. One that we have found most useful is a hybrid theory to investigate non-linearities at the extreme end of the scales. The form is a combination of the ratio and interval theories:

$$u(x_i) - (a_{ij}/a_{ji})^\gamma u(x_j) = \beta(a_{ij} - a_{ji}) \quad (12)$$

Note that if $\gamma \rightarrow 0$, $\beta \rightarrow 1$ the interval theory applies, if $\gamma \rightarrow 1$, $\beta \rightarrow 0$ the ratio theory applies. In between estimation is based on non-linear estimation routines (Abelman, 1976; Cohen, 1975). Note also that if $\gamma = 0$ or $\beta = 0$, linear techniques apply.

Tests to Identify Appropriate Theory

The above four theories are representative of the possible theories that can result from the general form.⁴ They illustrate the breadth of possible procedures to estimate preference functions based on CSPC questions. To proceed further we must devise a test to empirically distinguish how each consumer reacts to the CSPC questions. With this test we can first observe how the consumer responds to a given battery of questions and then based on his or her responses branch to the appropriate theory and estimation. To perform this test, consider all product triplets and define a_{ik}^I as the closest integer such that the interval test, equation 5, holds. Define a_{ik}^R as the closest integer such that the ratio test, equation 9, holds. These differences minimize the scale differences inherent when comparing "errors" in equations 7 and 11. Suppose that a_{ik} is the

³ The appropriate functional representation is multiplicative in the λ_{lk} terms raised to the δ_{lkj} power.

⁴ Hauser and Shugan (1977) cover other theories such as stochastic preference which includes an individual level logit model.

respondent's actual answer, then define the following absolute error tests:

$$T_I = (1/n) \sum_t | a_{ik}^I - a_{ik} | \quad (13)$$

$$T_R = (1/n) \sum_t | a_{ik}^R - a_{ik} | \quad (14)$$

where the summation is over all possible tests, t , within a design and n is the number of such tests. If $T_I \leq T_R$, then the consumer is more likely responding via the interval theory. If $T_I < T_I$, then it is more likely the ratio theory applies. If both T_I and T_R are above some cutoff, T_c , reject both theories. (In practice we have found $T_c = 20$ is a good cutoff. Furthermore, we have found that the root mean square error modification of equations 13 and 14 give similar results.)

Summary

This section has reviewed the results of a theory based on intensity of preference. In particular it has stated the appropriate functional forms and has given equations to estimate preference functions via each theory. Finally, it has given a test to distinguish from a set of data, which theory best describes how consumers are reacting to the CSPC scales.

As stated earlier, these theories have great potential for accuracy because they utilize more information in consumer judgments than do the existing methods of conjoint analysis and preference regression. This remains to be shown. Following a discussion of computer assisted measurement, the section on application will give empirical evidence to support this conjecture, but first we will digress to illustrate how one can practically measure such functions.

Computer Assisted Consumer Measurement and Data Analysis

The general intensity theory makes possible the estimation of preference functions based on CSPC data. Because we expect that more information is contained in this data, we expect that the general theory will lead to improved accuracy or conversely, the same accuracy but with fewer questions. But this theory depends on our ability to quickly and efficiently ask CSPC questions. To do this we developed a marketing information system, P.A.R.I.S., which can implement a general questionnaire but which has special capabilities built in to implement CSPC questions. Furthermore, P.A.R.I.S. automatically encodes the data and sets up computer files for easy access and analysis. Special subroutines access the stored CSPC data and estimate the preference functions. The details of the P.A.R.I.S. system are contained in Shugan and Hauser (1977). We will describe here some of the features as they relate to preference measurement.

Development of an Interactive Program

The P.A.R.I.S. system allows the researcher to develop an interactive questionnaire as easily as a written question might be developed. The researcher would accomplish this development in three steps.

First, the researcher constructs a questionnaire using the P.A.R.I.S. language. This language consists of simple commands to print questions, record answers, check ranges, branch based on consumer response, etc. The language, which consists of over thirty commands, is sufficiently general to implement most market research questionnaires.

⁵ Preference Assessment and Retrieval Information System

Second, the written questionnaire is either punched on ordinary data cards or written on-line to computer storage (tape or disc). A single command activates the P.A.R.I.S. Q-compiler which converts the human-oriented language into an alpha-numeric, machine-oriented language and sets up the appropriate files to record and decode answers and sets up a system to time and record how long it took each consumer to answer each question. The Q-compiler also checks the questionnaire for coding errors and provides a summary of each question's status, thus alerting the researcher of possible errors in questionnaire design.

Finally, the compiled version of the questionnaire is automatically input to a "mass storage" program. This program stores the questions in a format allowing efficient computer access to any question in any order. The questionnaire is now ready for implementation.

Development of a Dynamic Market Research Data Base

The actual administration of the questionnaire is accomplished either by seating a respondent at a portable terminal (e.g., Cathode-Ray tube CRT) or by allowing an interviewer to interactively record answers while obtaining them in person by telephone. In either case, P.A.R.I.S. adds the response to the data base together with the time and date when entered. The computer then provides instantaneous range-checking to insure each response is in the legitimate range allowed for that response. Illegal responses (e.g., "yes" when his/her age is asked) may be followed by a gentle computer response informing the respondent or interviewer of an error and providing a clarifying instruction. Once a legitimate response is obtained, the range of that response can determine the next question. For example, if the respondent can only evaluate three brands of deodorants, perception questions about non-relevant brands can be avoided. This branching permits very efficient questioning, minimizing the actual number of questions asked to the most relevant questions for the consumer.

When the interview is completed, summary statistics are automatically provided. Management can access all interviews to date or some selected portion of them. Statistical analysis can be performed periodically and selectively. A master file allows a researcher to determine at a glance the current sample size, progress for the entire study, and how long each questionnaire administration took. More detailed information, e.g., how long a partial question's administration took and the answer given, can be obtained from the main database record. A special comment file records qualitative responses for easy access and analysis. We have found record and comment information, together with the feature that all answers are recorded regardless of whether a question is reasked because of an improper response, is very valuable for the development of test questionnaires. All answers, including mistakes, can be accessed to fully pretest a questionnaire.

Special Constant Sum Paired Comparison Commands

P.A.R.I.S. is designed with special commands for preference analysis by conjoint or evaluation theory. For example, a single command "READ n CHIPS" sets up a constant sum paired comparison question with automatic range checks and tests to ensure that the consumers' responses sum to n. If the responses do not sum to n, or if negative or non-numeric answers are given, the system diagnoses the problem and informs the respondent of his or her mistake. The form for quick answers or a longer form with more explanation. See figure 1 for an example of the short form. Furthermore, the system automatically sets up a computer routine to encode the constant sum response and place it in the record file

for easy access. This encoded data is input to a related subroutine which uses linear programming to estimate the preference functions. This subroutine is a modification for constant sum data of ideas expressed by Srinivasan and Shocker (1973) in LINMAP. Experience to date has shown that the constant sum paired comparison task for preference measurement is readily accepted by consumers.

Typical Questionnaire

The next section reports an empirical application of a typical questionnaire and gives an example (figure 2) of what the consumer sees. We will put off this discussion until that section.

Empirical Example: Telecommunications Innovations⁶

Previous sections presented the results of a general theory for intensity of preference and described a marketing information system to implement that theory. We present here an empirical example of the use of P.A.R.I.S. to estimate intensity of preference functions. The remainder of this section is taken from section 3 of Hauser and Shugan (1977). The entire paper is available from the authors.

The empirical problem is to design a mix of telecommunications technology for use in a small research community. Scientific research requires effective communication among scientists, but in many government laboratories cooperating scientists and managers find themselves in buildings 2-3 miles apart. Furthermore, laboratories, such as Los Alamos Scientific Laboratory (LASL) in New Mexico, do much of their work for federal agencies and there is a strong need for effective communication with managers and policy makers in Washington, D.C. Currently, the most common means of communication are telephone (39% in LASL) and personal visit (58% in LASL), with only a small percentage (3% in LASL) of the interactions using other means. The National Science Foundation would like to enhance communication among the scientists, managers, and policy makers with an improved system that is more effective than telephone for technical communication, yet more efficient than personal visit in terms of cost, time, and energy. Among the options being considered are closed circuit television, telecopiers (facsimile transfer devices or teletypewriters), and narrow-band televideo systems (an attachment to the telephone which transmits still pictures over voice-grade telephone lines). But since the laboratories have limited budgets, each laboratory would like to implement the communications system that would be most cost-effective. To do this the laboratories need to know how scientists and managers would react to the various systems.

Study Design. To address this problem we used the normative methodology described in Hauser and Urban (1977a) to identify the relevant dimensions that describe communications options and to identify the relative importances of these dimensions. These dimensions form the basis for the CSPC questions used in the estimation of preference functions.

First, consumer focus groups were run and analyzed to produce an indication of the choice process, consumer semantics, and a set of 25 attribute scales to character-

⁶ The majority of this section is taken from John R. Hauser and Steven M. Shugan, "Efficient Measurement of Consumer Preference Functions: A General Theory for Intensity of Preference," Working paper, Department of Marketing, Northwestern University, Evanston, Illinois, July, 1977.

ize consumer reactions to communication technology. Based on the focus groups and on previous research in the area of communications, a mail-back questionnaire was designed and implemented in which consumers rated telephone, personal visit, and the three new communications options (1-page concept statements) on the 25 attribute scales. Factor analysis of the response revealed two perceptual dimensions labeled "ease of use" and "effectiveness." Ease of use correlates with the ability to find the right person, save time, eliminate paperwork, and get a quick response as well as saving hassle, planning, time and cost; effectiveness correlates with the ability to exchange scientific and technical information, persuade people, convey all forms of information, control the impression you want to make, monitor people, operations, and equipment, yield a high level of human interaction, solve problems, express feelings, and enhance idea development.

Scientific and managerial communication is complex and it is probable that the communications needs would vary by individual depending upon his or her requirements. Thus, to accurately analyze preferences for communications options, we need to stratify by use scenario (purpose, distance between communicators, relation of communicators, etc.) and estimate preference functions within each category. Evaluation theory is used to measure these preference functions.

Consumer Measurement. Based on the results of the mail questionnaire, a preference assessment questionnaire was designed to measure the CSPC data needed for the preference functions. This questionnaire was then implemented via P.A.R.I.S. to scientists and managers at IASL and practicing managers enrolled in Northwestern University's Managers Program (evening work toward a master's in management). The questionnaire contained six sections: (1) warmup questions, (2) questions to establish a scenario for usage, (3) consumer rating of effectiveness and ease of use for the existing options and concept statements, (4) the CSPC questions, (5) preference ranking and usage intent for the existing products and the concepts, and (6) various personal and demographic questions and comments.

Example questions of section 2 are shown in figure 2. Review figure 1 for an example of a CSPC question. Note that the "questionnaire" handles out of range responses by gently informing the respondent of his mistake and asking for a new response.

Section 3 of the questionnaire was included to acquaint consumers with the measurement scales for effectiveness and ease of use and to provide us with their perceptions of each product or concept. Section 5 provided preference measures for the actual products and concepts. These measures were used to validate predictions made by each theory based on CSPC questions.

The complete questionnaire contained 96 questions including 16 CSPC questions and took about 15-30 minutes to complete. The administration cost including on-line hookup was about \$1 per respondent on a CDC-6400 (\$510 per cpu hour). The comparative results reported below are based on the sample of 41 practicing managers.

Results. Figure 3 gives the perceptual maps positioning of the five stimuli based on factor scores (mail survey) and the direct measures (preference survey). The close agreement of the relative stimuli position in the two maps supports the direct measures of effectiveness and ease of use as sufficient for the preference analysis. (Note that teletype terminals, used in the mail questionnaire, was revised to facsimile transfer devices in the preference questionnaire.)

The heuristic T-test with a cutoff of $T = 20$ indicated that 51.2% of the consumers were ratio, 31.2% interval, and 17.1% at most ordinal. The median minimum T_r , T_R was 13.1 with an interquartile range of 10.6-17.9. Based on the T-test we would expect that models based on one of the intensity of preference models would outperform standard ordinal estimation (conjoint analysis).

Table 1 compares first preference predictions based on linear programming estimates for the ratio, interval, and ordinal theories. For completeness, these predictions were compared to preference regression (Urban, 1975) which is an aggregate technique that assumes the same preference function for all consumers. Preference regression is widely used in the marketing literature and is representative of aggregate models such as aggregate monotonic regression (Hauser and Urban, 1977b) and logit analysis (McFadden, 1970). Recent studies have shown that predictions based on these three models are similar.

Inspection of table 1 shows that the intensity of preference theories do improve predictions over the existing models--preference regression and conjoint analysis. Furthermore, these predictions are quite good--72% of those products or concepts predicted first were indeed preferred. Detailed analysis of individual predictions reveals that the improved prediction comes primarily because the intensity of preference theories can discriminate between products that the ordinal (conjoint) theory predicted as being equal in preference. (E.g., the ratio theory might predict telephone as first preference while conjoint analysis would predict that

Preference Regression	65.2	18.5	7.1	4.6	4.5

Most Preferred Product was Predicted (%)

telephone was tied with NBVT for first preference.) Thus conjoint analysis is a "correct" representation of consumer preference, but the intensity of preference theories produce preference functions that can better discriminate among products.

The comparison of preference regression and conjoint analysis is mixed. Preference regression is better at recovering first preference, but, as with any aggregate technique, it makes large errors on some individuals. Thus, table 2 compares the techniques on their ability to correctly predict market preference shares. Again the intensity of preference models provide improved predictions relative to both existing techniques. Note

(Actual) (36.6) (46.3) (9.8) (4.9) (2.4)

Predicted Market Share (%)

that conjoint does better than preference regression--probably because the effect of ties is less pronounced on market shares. All models do well compared to the 17.2% error that results from random prediction.

The over prediction of preference for the concepts results from the effect that consumers tend to choose an existing alternative when it is tied with a concept in predicted preference. Future research will expand evaluation theory to include this "preference inertia" effect (Neslin, 1976). Empirically when the models are applied to existing alternatives only, the mean absolute error is reduced to 1.4% for ratio. Furthermore, all relative comparisons remain the same.

Predictive accuracy is important for the evaluation of alternative products, but to improve the design of new products managers need diagnostic information to help them understand consumer preferences and thus design improved products. Although preference functions are estimated at the individual level, it is useful to present summary statistics (mean, variance, median, interquartile range) to represent the population. Figure 4 is a graph of the average preference functions. (The "utility" of effectiveness is scaled 0 to 1 for consistent comparison.) Note that the average individual functions (ratio, interval, ordinal) are quite close, although relative to the others the ordinal theory overestimates the importance of ease of use. The interpretations are quite intuitive with decreasing returns on effectiveness and a slight threshold on ease of use. These results are consistent with the above conclusion that conjoint analysis provides "correct" representations of consumer preference and that the improvements achieved by intensity of preference theories result from improved discrimination among individual preference functions.

On the other hand, preference regression gives counter-intuitive increasing returns functions, although its estimate of relative importance (ratio of maximum utilities) is consistent with the individual level preference theories. This result coupled with the predictive results suggests that the individual level measurement can better explain the details of consumer preference and identify individual differences, but preference regression, which could be done without the second survey, is adequate for a first pass at analyzing the data.

FIGURE 4
Comparisons of Preference Functions

Δ-----Δ Interval
 □-----□ Ratio
 o.....o Ordinal (Conjoint Analysis)
 x-----x Preference Regression

The final question is whether $T_o = 20$ is a good cutoff for the heuristic error measure. If the CSPC responses from consumers with $T_o > 20$ and $T_R > 20$ are indistinguishable from ordinal preference then any theory--ratio, interval or ordinal--should give similar predictions or at best only as good as ordinal based predictions. Furthermore, we would expect the predictive capability to be similar to that for ordinal applied to the general population. Empirically for the 17% of the consumers with $T_o, T_R > 20$, we found that the predictions of each theory were almost identical giving an overall preference recovery of 57.1%, 28.6%, 14.3%, 0%, and 0%. This recovery agrees well with the ordinal theory (row 1 of table 3).

Thus the empirical evidence supports the conjecture that the intensity of preference theories can provide improved predictions and useful diagnostic information relative to existing theories such as conjoint analysis and preference regression. Existing techniques do well, as evidenced by tables 1 and 2, but the more general theory can make more efficient and effective use of consumer preference judgments. Clearly, this empirical example is a first application and test of the general theory but it does indicate that consumers can provide consistent CSPC judgments for products specified by attribute levels and that the majority of consumers give CSPC judgments that contain more extractable information than judgments based on the ordinal task used in conjoint analysis. Even for the 17% who gave at most ordinal results, the intensity measures did as well as the ordinal based conjoint analysis.

Summary

Consumer preference measurement is important for the design of new transportation and communications services. This paper has summarized the results of two improvements in the measurement of consumer preferences: (1) a general theory for intensity of preference which extends ordinal conjoint analysis to more efficient CSPC measures and (2) an interactive computer interviewing system and marketing research information system that makes this form of preference measurement more feasible.

The empirical results are promising. Direct comparisons show that the intensity theory as implemented through P.A.R.I.S. can improve existing techniques. Clearly, this is one test in a particular application, but it does raise important issues and is encouraging for further development of both the intensity measures and the interactive system.

Acknowledgment

The empirical study in section 4 was funded by a grant from the National Science Foundation, DS176-09479, Stuart Meyer principal investigator. We wish also to thank R. J. Taschek and T. Norris at Los Alamos Scientific Laboratory for their valuable assistance in the study.

Abstract

Random coefficient models, in general, and the Hedonic Demand Model (HDM) in particular, are reviewed to show their basic properties and relevance to consumer research. Links to the three traditional tools of multiattribute models, individual differences scaling, and market segmentation are established. An empirical application of the HDM to auto demand is described. The conclusion integrates the review of the HDM and random coefficient models, generally, with consumer research objectives and requirements.

Introduction

Recent econometric modeling developments using random coefficients for probability choice behavior can be linked to prior consumer research on multiattribute models, individual differences scaling, and market segmentation. An experimental econometric technique estimates a hedonic demand model which incorporates selected elements from each of the other three standard analytical procedures from market research. Therefore, the new econometric modeling developments can be readily inserted into the array of consumer research analysis tools by reviewing the standard methodological procedures to show their relationship to the hedonic demand model.

Consumer research procedures, such as multiattribute models, are often connected with psychological assumptions of one kind or another. For example, Fishbein (1967) speculated that attitudes toward an object are a function of beliefs about the attributes of that object and the value of those attributes to a consumer. Several variations of his basic assumption have been proposed by Lehmann (1971), Hansen (1969) and others, and empirical research evaluates the nature of the relationships between attitudes toward an object, beliefs about the attributes of a product, and the importance or value of those attributes to consumers (Sheth and Tuncalp, 1975; Sheth, 1973). Individual differences scaling is another consumer research tool which relies heavily on psychological principles. In this case, the early work on nonmetric multidimensional scaling (Shepard, 1962a, 1962b; Kruskal, 1964a, 1964b) was followed into its extension so that each individual could be represented with a separate multidimensional space (Carroll, 1972; Carroll and Chang, 1970; Cliff, 1968; Tucker and Messick, 1963). Applications of individual differences scaling within consumer research are multitudinous (e.g., Green and Rao, 1972; Dobson and Nicolaidis, 1976; Benjamin, 1977).

Market segmentation builds on sociological concepts which respect the importance of groups of consumers relative to individual consumers. A fundamental tenet of market segmentation is that people have different preferences for products and services, but no individual, at least not a representative one, is totally distinct. Numerous empirical applications of market segmentation have been reported (Bass, Tigert, and Lonsdale, 1968; Blattberg and Sen, 1974; Haley, 1968; Johnson, 1971).

The hedonic demand model (HDM) falls in the tradition of econometric random coefficient models. It is related to

multiattribute research because it presumes that the utility of a product is based on one or more of its attributes. Since different individuals are allowed to differentially weight these attributes in the assessment of a product's utility, HDM shares features with individual differences scaling. Furthermore, the model is designed to work with aggregate databases, such as those which report only market shares, and therefore the orientation of HDM is compatible with market segmentation.

This presentation has three principal sections. Initially, a theoretical overview of random coefficient models is provided. The second section builds on the overview to establish a bridge between HDM and standard consumer research tools. This conceptual bridge should facilitate the adoption of HDM in consumer research. Finally, the third section describes some empirical results derived by applying the modeling orientation to the demand for autos.

Theoretical Overview

Random coefficient models can be characterized by their concern with the aggregate behavior of consumers although assumptions about individual differences are inherent to them. The models concentrate on *how many* consumers would buy a good rather than on *which* consumers would buy it. Traditionally, such models have been intrinsically linear and this limited their application to a wide class of consumer products. More recently, random coefficient models have been applied to the problem of consumers choosing only one among a finite number of items. This modeling orientation builds on economic antecedents which represent the utility of goods and services in terms of a bundle of attributes (Court, 1941; Lancaster, 1966). Empirical implications of this modeling orientation have been explored in various empirical studies (see, for example, Griliches, 1972; Charles River Associates, 1977; Hausman and Wise, 1976).

The Linear Demand Model

The value of the random coefficient approach can be shown by considering its application to linear equations. The demand relationships in linear form can be written as follows:

$$D_i = \sum_k \sum_j \beta_{kj} h_{kj} + \epsilon_i \quad (1)$$

where:

- D_i = the amount of the i th good to be consumed in aggregate,
- h_{kj} = the k th attribute of the j th good including its price,
- β_{kj} = estimated coefficients, and
- ϵ_i = independently distributed stochastic error term with mean zero and constant variance.

The above relationship, modified with demographic variables, is the workhorse of econometric demand studies with aggregate data.

There are several drawbacks to Equation (1). The first is that the coefficients will vary among individuals, thereby leading to biased estimates of the β_{kj} 's if they are assumed to be constant across the population (Theil, 1971). If a product's prices or attributes are changed, then the model will misforecast the change in demand.

To cope with this problem models have been developed which allow the β_{kj} 's to vary across individuals (Zellner, 1966; Swamy, 1974). It may be presumed, for example, that tastes for product attributes are distributed normally. If each β_{kj} is stochastically independent and if the h_{kj} 's are nonstochastic with finite variance and independent of the β_{kj} 's, then the mean and variance of the β_{kj} 's can be estimated with generally available regression methods. Theil (1971) points out that these restrictions are not necessarily innocuous. However, the model is appropriate to a large number of situations where consumer behavior needs to be inferred from aggregate data.

Probability Choice

Suppose that a product is such that consumers have a finite set of options and buy one such item on occasion to the exclusion of others. For example, a household may consider several different makes of autos, but it will usually purchase only one at a time. The time between purchases is usually substantial (e.g., more than a year). Other durable goods, such as refrigerators and televisions, are acquired in a similar fashion.

Now consider the problem of estimating the shares of various brands or models of such a product. It is well known that the linear specification given in Equation (1) misspecifies consumer behavior even if disaggregate data are used (Domencich and McFadden, 1975; Charles River Associates, 1973).

A class of models used to analyze consumer behavior under these conditions is based on the tenets of probability choice (Luce, 1959). They are widely used by transportation researchers (see Stopher and Meyburg, 1976, for a historical development of probability choice models in transportation). The most typical application is the use of the binary or multinomial logit model to estimate the probability of a traveler selecting one of several transport modes to make a trip. From a consumer research perspective, this decision can be generalized to the selection of one product or service over another. The probability of a consumer choosing alternative i (P_i) from n elements can be expressed as:

$$P_i = \frac{\exp(\beta_{ki} h_{ki})}{\sum_{j=1}^n \exp(\beta_{kj} h_{kj})} \quad (2)$$

where:

h_{kj} = the attributes (which are denoted by k) of each of the n alternatives, and
 β_{kj} = weights assigned to the attributes.

Equation (2) is a multinomial logit model, and it describes the probability of choice for alternative i as an S-shaped function of each of the product or service attributes. The sum of the P_i over individuals or households yields the demand, D_i , for the product.

Individual differences are not built into the underlying assumptions of the multinomial logit model. Sociodemographic descriptions of consumers can be inserted into Equation (2) to account for individual differences in alternative selection for cases in which the attributes of alternatives are invariant.

The probability choice framework is an advance but the assumption of constant coefficients is very limiting. To see this, suppose everyone in the population can choose among the same set of products. In a cross section of data, this means that the h_{kj} are constant for everyone. Thus, they have no explanatory power for observed differences in choices among products. Even if we have a time series of aggregate observations where changes in product shares can be correlated with changes in product attributes, we cannot estimate the β_{kj} 's in Equation (2) using standard statistical techniques (see McFadden, 1974b).

Even with the important theoretical advance of probability choice models, the problem of predicting product acceptance cannot be easily solved using aggregate data and assuming constant coefficients in the attributes of products. There are other options such as using special surveys or experiments, both of which may be costly. Alternatively, one can drop the assumption of constant coefficients and use widely available aggregate data. This option is explored below.

The Hedonic Demand Model

The hedonic demand model (HDM) allows using aggregate data to estimate market shares among very similar products. It is based on the theory of probability choice behavior while taking account of differences in individuals' tastes. The following develops the behavioral foundations of the model.

A basic assumption is that consumers select that alternative which yields the greatest utility. The utility (denoted by U) derived by a consumer (denoted by x) confronted with several discrete goods, D_i , and all other goods and services, Z , can be represented by:

$$U(D_i, Z|x). \quad (3)$$

It is useful to require that expenditures on Z and the selected alternative equal a consumer's income, I_x , so that:

$$I_x = D_i P_i + \pi Z, \quad (4)$$

where:

$D_i = 1$ for the selected alternative and 0 for all other alternatives,
 P_i = alternative prices, and

πZ = the price index for all other goods and services.

Therefore, the choice situation being modeled can be represented by:

$$U(D_j, Z|x) \geq U(D_i, Z|x) \text{ for all } D_i, i \neq j, \quad (5)$$

and the budget constraint of

$$I_x = D_j p_j + \pi Z. \quad (6)$$

It is also convenient to assume separability between utility based on D and Z so that the link to product attributes can be shown as:

$$U(h_j|x) \geq U(h_i|x) \text{ for all } i \neq j \quad (7)$$

where:

h_j = the vector of attributes of good j , and

x = the vector of taste characteristics.

Since Z does not vary when different D_i are evaluated, Equation (7) is equivalent to Equation (5) under the assumption of separability.

A further assumption of separability and additivity among the attributes makes it possible to define

$$U(h_j|x) = \sum_{k=1}^m h_{kj} x_k \quad (8)$$

where:

h_{kj} = attributes, such as size, horsepower, and price in the case of an auto, and

x_k = the tastes of a consumer with respect to those attributes.

There are m attributes under consideration.

Different consumers are represented by different x_k . The distribution of tastes across consumers and over attributes can be characterized by multivariate probability density functions.

It is useful for interpretive purposes to normalize the x_k so that the taste coefficient of price for each consumer is -1. This normalization permits Equation (8) to be rewritten as:

$$U(h_j|x) = \sum_{k=1}^m h_{kj} x_k - p_j \quad (9)$$

where:

x_k = marginal utilities which indicate the price a consumer would pay for another unit of the k th attribute.

Even when one product dominates another on all attributes, it might be selected by a small fraction of consumers. In order to simulate this potential occurrence, it is convenient to allow a stochastic error term to be added to the utility function of Equation (9). It is usually assumed that the error term is distributed independently and identically across consumers. With the error term, the utility of alternative j can be represented as:

$$U(h_j|x) = \sum_{k=1}^m h_{kj} x_k - p_j + \epsilon_j \quad (10)$$

As a consequence of this error term, the probability of j being selected over i can be denoted by:

$$\text{prob}[U(h_j) > U(h_i)] \quad (11)$$

$$= \text{prob} \left[\sum_{k=1}^m x_k (h_{kj} - h_{ki}) + p_i - p_j > \epsilon_i - \epsilon_j \right] \quad (12)$$

Therefore, for the fraction of the cases in which the $\epsilon_i - \epsilon_j$ is greater than the quantity on the left of Equation (12), alternative i will be selected even when it is dominated on all attributes by alternative j .

While the ϵ 's are distributed independently according to a scaled Weibull distribution, at the level of individual consumers we have a multinomial logit model. However, the parameters of HDM differ across individuals. It is not appropriate, therefore, to apply the multinomial model directly to aggregate market share data. It is necessary instead to estimate the moments (i.e., the mean, variance, and higher ones if appropriate) of an assumed distribution of taste differences across individuals. As the random coefficient models are normally applied, the distribution of taste differences is not directly observed. The distribution is assumed to follow a suitable density function, such as log normal. The data requirements of HDM are substantially reduced by working with an assumed instead of an observed distribution of taste parameters.

McFadden (1974a) has shown that in this case the probability of an individual choosing good j from among n goods given tastes x_k is:

$$P_j = \frac{e^{[U(h_j|x_k)]}}{\sum_{i=1}^n e^{[U(h_i|x_k)]}} \quad (13)$$

Equation (13) can be used to help derive the mean, μ , and the standard deviation, σ , of consumer tastes by integrating over x_k :

$$P_j(\mu, \sigma) = \int \dots \int \frac{e^{[U(h_j|x_k)]}}{\sum_{i=1}^n e^{[U(h_i|x_k)]}} f(x_k; \mu, \Sigma) dx_k \quad (14)$$

where $f(x_k; \mu, \Sigma)$ is the probability density function for the multivariate distribution of consumer tastes over attributes with mean vector μ and variance-covariance matrix:

$$\Sigma = \begin{bmatrix} \sigma_1^2 & & & 0 \\ & \sigma_2^2 & & \\ & & \ddots & \\ 0 & & & \sigma_m^2 \end{bmatrix} \quad (15)$$

The probability expression of Equation (14) involves a rather complex integral -- its order of integration is the same as the number of attributes. While it is impossible to analytically evaluate Equation (14) except under severely simplifying assumptions, numerical integration is possible. Numerical integration relies on Monte Carlo procedures. $P_j(\mu, \sigma)$ can be approximated by taking the average of many calculated P_j from Equation (14) where x_k is a random vector generated from a multivariate probability density function with mean μ and variance-covariance matrix Σ . The details of the solution algorithm and the specification of functional forms of x_k are discussed at length elsewhere (Charles River Associates, 1977) and they will not be summarized here since they are not essential to the points being made.

Ties to Standard Consumer Research Techniques

Random coefficient models are important for consumer research because of the wide range of topics to which they are relevant and the inherent power of the research strategy. In this section, we describe relationships between standard consumer research techniques and HDM in order to highlight the value of this recent econometric development vis-a-vis the analysis of consumer behavior. In particular, three techniques are compared and contrasted with HDM: multiattribute models; individual differences scaling; and market segmentation.

Multiattribute Models

A common form of the multiattribute model has been described by Wilkie and Pessemier (1973). They write a linear compensatory representation in these symbols:

$$A_{jk} = \sum_{i=1}^n I_{ik} B_{ijk} \quad (16)$$

where

i = attribute or product characteristic,

j = brand, and

k = consumer or respondent;

such that:

A_{jk} = consumer k 's attitude score for brand j ,

I_{ik} = the importance weight given to attribute i by consumer k , and
 B_{ijk} = consumer k 's belief as to the extent to which attribute i is offered by brand j .

Consumer researchers have extensively studied variations of this formulation. The original attitude conceptualizations were proposed by Rosenberg (1956) and Fishbein (1967). The relationships among A_{ijk} , I_{ik} , and B_{ijk} have been examined under different measurement conditions and modeling frameworks.

A gap in the theoretical development of early multiattribute formulations was the nature of the relationship between A_{ijk} and consumer behavior. The link between attitude and behavior is implicit with positive attitudes assumed to correlate with positive behavior, but it is known that better predictors of behavior are available.

The strength of the approach is diagnosis as opposed to prediction. Diagnosis results from the exposure of the salience of different product attributes as seen by consumers. To the extent that managers can change product attributes, they can use multiattribute modeling research to help them improve the salience of their product to consumers.

The utility equation (see Equation (10)) of HDM is defined in terms of coefficients for different attributes, in a similar manner to multiattribute models. However, the attributes, h_{kj} , are direct observations on products as opposed to respondents' judgments about product attributes. The utility concept is directly linked to consumer choice through utility maximization and probability representations (see Equations (13) and (14)). Finally, the taste coefficients, x_k in Equation (10) generally correspond to I_{ik} of Equation (16), but they are estimated from aggregate data on market shares instead of being reported by respondents. Therefore, the random coefficient models do not require data from individual respondents. In the latter sense, they are more parsimonious in their data needs; this reduces the cost of analysis and thus adds to the desirability of HDM.

The theoretical basis of HDM is inherently reasonable, and its relationship to consumer behavior is explicit. Consumers are assumed to select the product with the largest utility to them, and utility is defined as a weighted function of attributes and a stochastic term. The weights for attributes are consumer taste coefficients which are estimated to maximize the likelihood of predicting aggregate market share data across respondents.

Individual Differences Scaling

Individual differences scaling follows from psychological research on perceptions and preferences. The notion is that the differences among individuals in preferences or perceptions can be used to quantify the similarities and differences among individuals. With respect to marketing research, it is assumed that these differences have implications with respect to consumer behavior. Among the models which have been commonly used for individual differences scaling are INDSCAL (Carroll and Chang, 1970), the vector model (Tucker, 1960), and variations of the ideal point model (Coombs, 1964).

There are at least four types of applications for individual differences scaling in consumer research. In common with aggregate multidimensional scaling, the technique finds how product attributes vary among one another from the user's perspective. Beyond this point, individual differences scaling is much more flexible. It is possible, for example, to stratify a sample along one or more sociodemographic variables to study how shifts in perceptions and/or preferences vary across

strata. It is alternatively possible to cluster consumers according to their perceptions and/or preferences and examine shifts in sociodemographic variables over perceptual market segments. When it is more useful to find homogeneous perceptual segments than study variation along one or more prespecified sociodemographic variables, the latter procedure is to be preferred over the former. Both techniques, however, will reveal interrelationships of particular types of viewpoints with sociodemographic variables. A fourth application involves using an individual's weights or saliences for perceptual dimensions as the independent variables in a multiattribute formulation. The dependent variable is usually some indicator of consumer preference or purchase patterns. Illustrations of the above four applications are described in numerous sources (see for example, Dobson, Golob and Gustafson, 1974; Dobson and Kehoe, 1975; Green and Carmone, 1972; Green and Rao, 1972; and Dobson and Nicolaidis, 1976).

Individual differences scaling and HDM have complementary and contrasting relationships to each other. There are no guidelines within HDM to select attributes, but individual differences scaling can be used to highlight product attributes which are salient to major market segments. Physical indicators of these psychologically salient attributes could then be used in HDM. It is possible to use output from individual differences scaling in a multiple attribute representation which parallels that of HDM, but the interpretations of the two representations are substantially at variance. In the case of individual differences scaling, consumer tastes, as denoted by saliences for perceptual dimensions, are the independent variables. These tastes are then weighted to account for indicators of consumer preferences or purchase patterns. HDM, however, uses consumer tastes as weights instead of independent variables. Further, these consumer tastes are linked to behavior via a nonlinear, probability choice formulation rather than the linear, compensatory formulation frequently used with individual differences scaling output.

Both random coefficient models and individual differences scaling relate to market segmentation. The random coefficient models are attractive, in part because they can be estimated on aggregated market segmentation data. For HDM, the aggregate data are market shares for different products, a type of information which is frequently readily available. On the other hand, individual differences scaling will normally require a special data collection effort, but its output can be used to form market segments based on perceptual characteristics of respondents. For product positioning with respect to consumer segments in a broad, qualitative sense, the richness of individual differences scaling may be more useful, but for detailed, quantitative estimates of market shares, HDM may be more useful. In any event, there are opportunities for meaningful consumer research in comparing and contrasting the alternative methodologies.

Market Segmentation

Market segmentation in consumer research is predicated on two key concepts. It is initially assumed that meaningful groups of users of a product or service can be identified. The second concept revolves around the creative assessment of product and/or service requirements for different market segments. These concepts are jointly applied towards maximizing profits through rendering services and/or products which appeal strongly to lucrative market segments.

A variety of criteria have been proposed for assessing whether any particular group of market segments is appropriate for profit maximization. Kotler (1972) notes that it is important for segments to be measurable,

accessible, and substantial. Wilkie and Cohen (1976) remark that "true" segments should be homogeneous within and heterogeneous between groups, useful as a behavioral correlate, and efficient to market from production, distribution, and pricing perspectives. A pivotal aspect of market segmentation is the selection of appropriate variables on which to divide consumers. The term segmentation basis is used to denote a set of variables selected to divide consumers. Three principal classes of bases are sociodemographic data (Carman, 1965; Assael and Roscoe, 1976), consumption patterns (Cunningham, 1955), and individuals' subjective judgments (Haley, 1968; Myers, 1976). A major summary and analysis of segmentation research and theory is provided by Frank, et al. (Frank, Massey and Wind, 1975).

As noted above, HDM is organized around a segmentation structure, namely the market shares for different products. The primary thrust of this modeling orientation is to derive estimates of consumer tastes which are consonant with market share data. This consumer taste information can be used for product planning purposes. Also, market simulations can be performed which reveal the implications of an altered product mix. HDM assumes that the set of salient product attributes are known and that the purpose of a marketing analysis is to study substitution among products. When either of these conditions does not hold, another market segmentation analysis technique may be more appropriate. More traditional consumer research tools for market segmentation are directed at product positioning (i.e., what new product would consumers most like to have) and advertising targeting (i.e., what content should a promotional campaign have and to whom should it be addressed). A potentially useful purpose of the traditional approaches is the evaluation of marketing strategy effectiveness (Assael and Roscoe, 1976). It can be seen, therefore, that traditional consumer techniques and HDM complement each other with respect to market segmentation.

An Application of HDM to Autos

The hedonic demand model was developed in a study of the impact of foreign trade controls on the import share of new car sales (Charles River Associates, 1976). The technique yields predictions of the effects of changes in prices and characteristics of any set of automobile models on the market shares of individual models. The predictions of share changes for individual models are then summed to obtain the predicted change in the share of a class of models resulting from any relative price changes.

The input data used are the price, selected attributes, and new car sales in a given time period of a set of automobile models. The attributes include available characteristics which either contribute to, or are correlated with, the quality of a car. Available attributes data for recent years include both the physical dimensions from Automotive News Almanac and performance data collected by the U.S. Department of Transportation and the U.S. Environmental Protection Agency. The physical attributes data include number of cylinders, headroom, height, horsepower, legroom, length, gas tank capacity, transmission type (automatic or manual), turning circle weight and width. The performance variables used were acceleration and fuel economy (miles per gallon). The sample period was the five-month period between April 1974 and August 1974; this period was selected to include the part of the 1974 model year subsequent to the period of acute gasoline shortage.

The results presented below should be viewed as first-run estimates only. Still, the results seem quite plausible and are very similar both to estimates from time series regressions and to a set of predictions of

the impact of imported car price increases on market shares derived by questionnaire techniques (Market Facts, 1976).

The estimate of the taste distribution for characteristics which was used to derive the share elasticities with respect to relative price changes was based on five attribute variables: volume, passenger area, weight, turning circle, and gallons per mile. Volume is defined as the product of length, width, and height, and is a proxy measure for a combination of total seating capacity and trunk space. Passenger area is computed as the product of headroom and legroom, and represents a proxy for driver and front seat passenger comfort. Utility is positively correlated with volume, passenger area, and weight. Utility is negatively correlated with turning circle diameter (the smaller the turning circle, the more maneuverable the automobile) and with fuel consumption in gallons per mile.

Table 1 summarizes statistical information on the estimated distributions of the marginal rates of substitution between characteristics and price. The distribution of consumer tastes for auto attributes is assumed to be log-normal. The statistics reported in Table 1 were computed by taking exponents of the parameters of the normal distributions of the logs of the attributes. As the distributions are log-normal, the mean and median of the distributions are not the same.

TABLE 1
DISTRIBUTION OF ESTIMATED MARGINAL VALUES OF
AUTOMOBILE CHARACTERISTICS
(DOLLARS PER UNIT)

Characteristic	Median	Mean	Variance in Consumer Tastes	95 Percent Consumer Taste Range ¹	
				Absolute Lower Bound ²	Absolute Upper Bound ³
				(Col. 1)	(Col. 2)
VOL 2	2.3053	7.1149	431.57	.12156	43.717
AREAG	5.1795	5.8383	9.2219	1.9850	13.515
WEIGHT	2.7782	3.1316	2.6532	1.0648	7.2492
TURN	-7.4435	-303.29	152,630,000	-.03581	-1,547.4
GPM	-565.42	-637.33	109,990	-216.70	-1,475.30

Variable Definitions

VOL 2 = (.0001) x (LENGTH) x (WIDTH) x (HEIGHT) (in cubic inches)
 AREAG = (HEADROOM) x (LEGROOM) (in square inches)
 WEIGHT = weight (in lbs.)
 TURN = turning circle diameter (in feet)
 GPM = gallons per 100 miles

¹Range of values of marginal rates of substitution including 95 percent of consumers.

²2.5th percentile of consumer taste distribution.

³97.5th percentile of consumer taste distribution.

The numbers reported in Column (2) of Table 1, the median of the distributions, give the marginal value of an additional unit of the attribute in dollars; the units of the characteristics are defined at the bottom of Table 1. The coefficient attached to VOL 2 indicates that the median consumer is willing to pay \$2.31 for an extra 10,000 cubic inches of volume. The coefficient attached to weight indicates that the median consumer is willing to pay an additional \$2.78 for an additional pound. The median coefficient for turning radius is greater than for VOL 2, AREAG, and WEIGHT, but there is also the most differentiation among consumers on this attribute. Note the extremely large variance of consumer tastes for this attribute in Column (3). The median marginal utility for gallons per mile is the greatest of all the attributes. This coefficient, which was derived from data collected immediately after the oil embargo, shows the extreme sensitivity of consumers to gasoline availability. However, despite the time period for which the model is estimated, there is still substantial variability among consumers on the importance of this attribute.

The upper and lower bounds of the 95 percent confidence interval (see Columns (4) and (5)) indicate the degree of dispersion in tastes for each attribute among consumers. The alternative degrees of variability across attributes reveals the ability of HDM to characterize individual differences among consumers. It should also be kept in mind that the model was estimated on physical attributes data and aggregate market share statistics. In any event, it can be seen that the most widely dispersed values are for the attribute "turning circle." Apparently some consumers place a high value on this attribute for parking and general maneuvering ability, but others have practically no preference for it at all. It is likely that a substantial portion of the variation for gallons per mile reflected different expectations among consumers as to gasoline availability and price. The range of variability for the remaining three attributes is substantially narrower than for TURN and GPM.

Table 2 compares the predicted shares consistent with the utility function estimated in the model with actual market shares of different automobile types. The model was estimated using two different price variables -- the one year old price in August 1974 of 1974 models reported in National Market Reports, Inc., Red Book and the estimated new transactions price of 1974 models. The new transactions price variable was corrected by applying "typical" discount factors for different types of cars reported in the annual automobile buying issue of Consumer Reports (April 1974) to list prices reported in the 1974 issue of Automotive News Almanac. The data reported in Table 2 show that the predicted shares from the model conform fairly closely to the actual shares; the model fits the data well. For example, the actual share for all domestics was .86798 and the share estimated by the random coefficient model with adjusted new car prices was .86183. Predicted import shares are slightly higher than actual shares. There is little difference in model estimates across the two price indicators which suggests the model is robust in the face of varying data quality.

TABLE 2
COMPARISON OF PREDICTED SHARES TO ACTUAL SHARES
BY AUTOMOBILE TYPE, APRIL-AUGUST 1974

	Actual Share	Predicted Share: One Year Old Price	Predicted Share: Estimated New Transactions Price
Domestic Autos			
Subcompact	.08792	.07900	.07767
Compact	.21413	.23299	.23701

All Imports	.13197	.15209	.13852

Summary and Conclusions

A major purpose of this report was to present a recent econometric development which has potential value as a consumer research tool. The historical antecedents and underlying assumptions were initially described. These assumptions were subsequently compared and contrasted with those of three standard consumer research techniques. Finally, an application of the approach to auto demand was summarized. It is clear that HDM parallels the functions of other consumer research techniques, that it requires little data which can be obtained without survey collection costs and time delays, and that

it has the potential to produce accurate results which are subject to rich interpretation.

The logic of HDM is based on a simple assumption of utility maximization at the level of individual consumers. Furthermore, the formulation of this model assumes a multiattribute structure, but it is based on physical product attributes. Individual differences among consumers are represented by taste coefficients for the attributes. These coefficients are estimated in a probability choice framework to be consistent with market share data.

As mentioned above, HDM is multiattribute in structure and therefore has a common link with the Fishbein (1967) and Rosenberg (1956) models. A principal difference between the two approaches is the use of physical attribute data versus subjective judgments in the psychological models. The individual differences scaling models, such as INDSICAL, allow for variations among consumers in a fashion which is similar to HDM. However, neither individual differences scaling nor Fishbein models, as initially proposed, were designed to facilitate the estimation of the probability of consumer choice, but HDM is directed toward this objective. Market share data, a type of market segmentation, provide a basis for the estimation of HDM. In the latter respect, a tie is established to a pervasive consumer research tool.

When the model was estimated on auto market share data, its properties were revealed. It was shown that variability among consumers could be represented. It is important to recall that this variability among consumers is described without a reliance on surveys. Only readily available data, such as market shares for models and physical product attributes, were required. In addition, it was possible to estimate a model representation which accurately fitted the data. This ability to accurately describe variability among consumers while correctly estimating market share data is an attractive property, particularly when it is combined with the minimal data requirements of the random coefficient models.

Further research is justified with random coefficient models on the basis of the results described above. These models can have rational structures which show a relationship between utility and probability choice at the level of the individual consumer. They also have extremely simple data requirements. HDM is compatible with standard consumer research functions. Therefore, its use in marketing studies will achieve normal objectives and concurrently extend the state of the art in consumer research.

Attitude-Behavior Changes in A
Before-After Mode Choice Situation

Abstract

A non-equivalent control group design was utilized in the evaluation of the effects of a high-occupancy reserved lane on the mode perceptions and mode choice behaviors of downtown commuters. Significant behavior and perception change was observed in both the treatment and control groups. The standardized change score analysis suggested that the transportation modification had some effect on perceptions although no effect on behavior was observed.

Introduction

A major objective of current transportation policy is the attainment of a more balanced transportation system through greater use of ridesharing modes. Programmatic efforts to facilitate the use of mass transit and carpooling must be based, however, on knowledge of the causal components of individual decisionmaking and an awareness of the level of transportation modifications necessary to affect behavior. Interviewing the same individuals both before and after transportation modifications have been effected can provide the necessary information regarding the relationships among system characteristics, individual perceptions, preferences and social situations and transportation behavior.

Panel data have previously been utilized in transportation research to evaluate the impacts of major changes in the transportation-related environment. Watson and Holland (1977) interviewed a Singapore sample twice to obtain behavioral information on the effects of an urban auto restraint policy. Skinner (1975) used repeated measurements of travel behavior to assess the effects of increased gasoline prices during the 1975-76 energy crisis. Longitudinal data have also provided information on the reliability of models in forecasting response to new modes (Parody, 1977; McFadden, et al., 1977) and on the relationship between attitudinal structures and behavior in response to transportation innovations (Goss and Shuldiner, 1977; Gilbert et al., 1975). Little information is available, however, on the effects of transportation system management actions (TSM) on the perceptions, preferences and behaviors of individuals.

The relationship of the system to the individual and his social environment is represented in Figure 1. While the figure does not detail a theory of behavior, it does provide a framework for the analysis of potential effects of alterations in the transportation system. It is assumed that changes in the system affect the service provided by the modes which, when communicated to individuals, alters their perceptions. Similarly, it is suggested that changes in personality variables, for example an increase in the value of a clean environment, will change the perceptions of the instrumentation necessary to reach the goal and lead to the development of new behaviors.

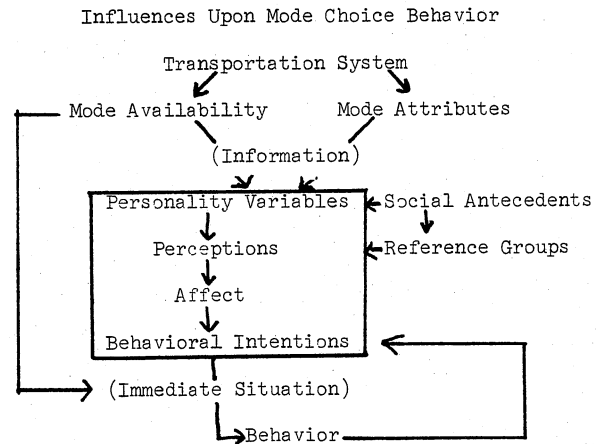

The objective of this paper is to present preliminary findings on the effects of a reserved lane for buses and carpools implemented on the Santa Monica, California, freeway on the mode perceptions and mode choice behaviors for downtown Los Angeles commuters. Changes in individuals residing in this corridor are compared to those observed for a sample of commuters residing

along comparable freeways which also feed into the central business district.

The Design and Methodology

The introduction of a control group is a necessary feature when one is interested in the effects of a transportation modification; otherwise, changes in behavior could also be attributed to extraneous factors operating in the environment. The effects of the modification, or "treatment," are distinguished from general system activities through the comparison of two similar groups, only one of which was exposed to the transportation system changes. In the analysis of social phenomena where similarity of individuals cannot be obtained through random assignment into treatment conditions, the experimental design can be approximated with a "non-equivalent control group design," (Campbell and Stanley, 1963). The similarity of control and treatment groups was obtained, in this case, by sampling within census tracts matched by socio-demographic and travel-related characteristics, (Hartgen and Howe, 1976).

Figure 1

There has been considerable debate as to the statistical technique appropriate for analyzing changes in the non-equivalent control group design. Selection of treatment group based on group differences can result in under-identification of the change model (Linn and Werts, 1977). However, if it is reasonable to assume that any group differences which might confound the treatment with the dependent variable are stationary over time, change score analysis can be applied (Kenny, 1975).

To perform the analysis of treatment effects, the variables are first standardized to correct for possible changes in variance. The time 1 treatment and control group scores for the variable of interest are combined and standardized; the time 2 scores are similarly adjusted. Differences between treatment and control groups are then evaluated with a correlational technique in which the treatment variable is dummy coded and the standardized pre-and-post test scores are correlated with the treatment variable. A significant difference between the pre-test-treatment correlation and the post-test-treatment correlation is indicative of a treatment effect. Significance is determined with the t test for dependent correlations (McNemar, 1969). The t test for related samples is used to evaluate the significance of changes within the treatment and control groups (Bruning and Kintz, 1968).

The Sample and Data

Census tracts within two miles of the Santa Monica Freeway in Los Angeles, California with a high incidence of Central Business District (CBD) workers were identified. These census tracts were matched by socio-demographic characteristics with tracts surrounding alternative freeways which also fed into downtown Los Angeles. Within the census tracts, households were randomly located through reverse telephone directories. Only individuals who worked within the business district were eligible for the home interview. Where a household contained multiple workers, the individual taking the lesser used mode was selected. A supplemental sample of carpoolers observed entering the CBD and bus users located at bus stops was included to ensure representation of these modal groups.

Interviews with 996 individuals were obtained between September 1, 1975 and March 5, 1976; 512 lived in the Santa Monica corridor and 484 were in the control areas. From January - May 1977, attempts were made to recontact the 996 individuals. Interviews were completed for 502 of the Phase I respondents.

Individuals were asked how frequently each month they drove to work alone, drove another person, rode with another and took a bus. Perceptions for each of 3 modes (sharing a ride, driving alone, and taking a bus) were collected for 19 attributes using a seven point semantic differential format. The perceptions were coded such that seven represents the most positive aspect of each attribute. The attribute labels are presented in Table 1.

Table 1
Attribute Labels

Label
1. Comfort
2. Convenience
3. Expense
4. Package space
5. Ease of use
6. Reliability
7. On time arrival
8. Traveltime
9. Vehicular safety
10. Personal safety
11. Destination accessibility
12. Crowding
13. Wait for vehicle
14. Relaxing
15. Weather
16. Waiting in traffic
17. Flexible schedule
18. Extra time
19. Parking cost

The same questions were asked at the two interviews. However, at time 2, individuals were asked to recollect their behavior and perceptions from the period of March through August 1976.

The Treatment

From March 15 to August 8, 1976, the median lanes on the Santa Monica Freeway were reserved for the exclusive use of buses and automobiles carrying three or more persons. No barriers separated the reserved lanes from general traffic, thereby permitting entry or exit throughout the 12.5 miles of the freeway. Preferential freeway access for vehicles carrying two or more persons had been implemented on 12 of 30 ramps prior to the Phase I interviewing although metering rates for the non-bypass ramp lanes were drastically altered at

the start of the diamond lane project. Four new express bus routes were established and four existing bus routes took advantage of the lane. Three new routes were developed to serve the three newly-opened park-and-ride lots and a crosstown feeder service was initiated. Prior to the project, 18 express bus trips were offered every weekday morning, while on the first weekday in August, 74 express buses were in operation. Bus headways were also improved; a policy maximum of 15 minute headways was established during peak hours. Bus prices were increased resulting in an average rise of 20¢ per trip (Billheimer, et al., 1977). On August 11, 1976, the preferential lanes on the Santa Monica Freeway were terminated by court order; improvements in the bus system remained in effect. The freeways in the control areas were not modified during this period, although bus service was improved throughout the Los Angeles region and bus fares were increased in the Southern California Rapid Transit District.

Sample Mortality, Control and Treatment Group Equivalence

Only 50% of the Phase I respondents were reinterviewed at time 2. Thirteen percent of the initial sample refused a second interview; 37% moved and could not be located. Differences between the initial sample and those retained for the second phase suggest some biases exist in the final sample. The individuals who responded to both questionnaires were dissimilar from the original sample in that they were more likely to be older, to have a higher income, to live in a single-family dwelling, and less likely to be black or to have children under six years of age. Additionally, fewer individuals were retained in the control sample (43%) than in the treatment group (57%). The effects of the sample mortality cannot be determined although it is likely that the individuals who were lost from the sample would be more responsive to ridesharing incentives than the older and wealthier travelers.

The individuals who were retained for analysis in the treatment group differed in several respects from the control group. The control group contained a significantly larger proportion of whites, hispanics, and sales workers than did the treatment group. Individuals from large households and dwellers in single-family residences were also overrepresented in the control group. The treatment group contained a larger proportion of blacks and clerical workers. The number and age of children, marital status and the number of licenses and vehicles in the household were not significantly different.

Results: Changes Over Time

Behavior

Individuals were assigned to a mode use category based on use of a mode for 60% or more of the work trips. The three categories of mode use were single-occupant auto (SOA), carpool (CP), and bus (BUS). Where an individual used two modes at about the same rate, he is defined as a dual mode user, an individual who uses three modes for a significant amount of traveling is designated as a mixed mode user. The proportion of trips made in each mode for the user groups at time 1 is presented in Tables 2 and 3. Over 90% of the treatment and control samples used one mode for most of their trips to work. The remainder divided their trips almost equally between two modes.

At time 1, 38% of the treatment group and 58% of the control group used one mode for 100% of their work trips. Almost a majority of the total sample used at least one other way of traveling during a monthly period. At time 2, a larger proportion of the sample had clearly defined an exclusive mode to work; 52% of the

treatment group and 61% of the control group used the same mode every day. A slight increase was also found in the number of people who alternated between two or more modes. In the treatment group, 7% initially used dual modes whereas at time 2, 10% combined modes; in the control group in the percentages are 4 and 6, respectively.

Table 2

Proportion of Trips Made by Mode User Groups in the Treatment Area at Time One

Modal Groups	N	Proportion of Trips by ...

CP-BUS	2	0.0%	50.0%	50.0%
SOA-CP-BUS	0	-	-	-
	<u>N=279</u>			

Changes in the choice of mode to work can be observed in Tables 4 and 5. In the treatment group, 72% of the travelers used the same mode for a majority of their trips at both time periods. Most of the change in the treatment group is due to mode users combining their time one mode with another at time two, or the dual mode users at time one selecting one of those two modes for greater use at time two. Only 13% switched to a mode rarely used at time one. Switching from single-occupant autos was less pronounced than defections from carpools and buses; 19% of those who drove alone at time one switched to carpools, buses or combined modes while 36% of the carpools and 23% of the bus users altered their mode choice behaviors. In the control group, 80% of the respondents used the same mode at both points in time and 13% changed modes radically. Eleven percent of the time one single-occupant auto drivers altered their mode choice behavior compared with 31% of the carpools and 17% of the bus riders.

The small number of dual and mixed mode users necessitated their assignment to a modal group on the basis of the mode used most often in traveling to work. The average mode frequency was then analyzed to determine the significance of changes for time 1 mode-use groups (Tables 6 and 7). In the treatment group, single-occupant auto drivers significantly reduced their use of the mode at time 2 while increasing their use of both buses and carpools. Bus and carpool users significantly decreased the average frequency of use for their respective modes. Carpools more frequently drove alone and took buses at time 2; bus users increased their use of the carpool ($p = .056$). The same pattern

was observed in the control group; mode use groups from time 1 decreased their average use of their respective modes at time 2. Single-occupant auto, bus and carpool users increased their use of the two alternative modes.

Mode choice behavior is based on trial and evaluation of alternative modes for much of the sample; at time 1, 38% of the treatment group and 58% of the control group used a second mode at least once during a monthly period. The single-occupant auto drivers' experience with ridesharing modes was surprisingly high; 75% of the treatment and 73% of the control auto users had taken a bus or a carpool at least once a month. While mode choice behavior changed over time in both treatment and control groups, only 14% of the time 1 single-occupant auto users took a ridesharing mode for more than half of their trips at time 2. This fact combined with the significant level of defections from carpools and buses reaffirms what is already known: ridesharing is not a particularly satisfactory alternative to driving alone for the vast majority of the traveling public.

Contrary to expectations, the mode distribution at time 2 was approximately the same as at time 1. No significant net decrease in driving alone was observed in either the treatment or control groups as a whole although a significant reduction in the frequency of driving alone was obtained for the time 1 single-occupant auto users. This suggests that some travelers who drive alone can be convinced to rideshare. However, the significant defections from the time 1 ridesharing groups indicate that retaining the carpools and bus users to produce a net increase in ridesharing is problematic.

Perceptions

The modal attributes which changed between measurement points are presented in Table 8. The single-occupant automobile attributes which were perceived to change, all changed in the negative direction for both the treatment group and the control group. For the treatment group as a whole, bus travel time, crowding and waiting in traffic improved over time. Carpool attributes of crowding, package space and ease of use changed negatively. Carpool travel time and waiting in traffic significantly improved and were subsequently more positive than those attributes for the alternative modes. Bus safety and cost were perceived more negatively at time 2 in the control group, although waiting in traffic significantly improved over time for the carpool mode.

The changes in perceptions for the total treatment and control groups indicate that some attributes had changed for all mode use groups. In the treatment group, changes are those expected: the attributes of driving alone were worse at time 2, while bus and carpool attribute perceptions of travel time and waiting in traffic improved over time. In the control group, perceptions of the bus and single-occupant automobile were lower at time 2 than at time 1. When the sample was partitioned into subsets in terms of time 1 mode use, some changes in variables which were significant for the total sample were found to be insignificant within any one group (Tables 9 and 10). Furthermore, perceptions of other attributes were found to have significantly altered over time for certain user groups. Within the treatment group, only single-occupant automobile users perceived travel time in that mode to be significantly worse at time 2. No other significant differences were observed in single-occupant auto perceptions of the mode. Bus travel time, bus crowding, bus exposure to weather, and bus waiting in traffic significantly improved although they were still not perceived as strongly positive (4.1). The wait in traffic for the carpool was perceived more positively

at time 2 than at time one. However, the carpool attributes of package space and crowding were perceived to have worsened by single-occupant automobile users in the treatment group. Time one carpoolers believed that at time 2, carpool travel time has significantly improved. Bus travel time and waiting in traffic improved but were still slightly negative (≤ 3.8) while extra time for the bus became marginally positive. Driving alone was considered to be more costly at time 2 than at time 1.

For treatment group bus users, the cost of bus use improved while the reliability of the bus decreased over time. Bus users believed the carpool was less

easy to use at time 2 but the wait in traffic and parking cost of the mode had improved. No significant changes were observed in the bus users' perceptions of driving alone.

Within the control group, single-occupant automobile users believed the ease of use, the ease to the destination, personal safety and waiting in traffic had significantly worsened for driving alone. Attributes for the carpool and bus modes also significantly decreased over time. The carpoolers believed that the carpool mode had increased in reliability; their perceptions of bus safety and cost were more negative at time 2. Control group bus riders believed the bus was

less comfortable at time 2 and more costly than at time 1 and that carpool convenience had decreased between the pre-test and post-test.

Changes significant at (p<.05).

For both the treatment and control groups, changes in single-occupant automobile and bus group perceptions corresponded with behavior. The decrease in use of the carpool by time 1 carpoolers was not indicated by the aggregate perceptions.

Changes in Attribute Importance

Perceptions of mode attributes may change and thereby induce behavior change; it is also possible that the

salience of attributes changes over time and affects behavior. The value that individuals use in determining mode choice may be altered by changes in circumstances or reference groups, because basic motives have changed, because attribute importance is rationalized to correspond with behavior or because an attribute which was "taken for granted" or outside the range of possibility, is altered or becomes available. To evaluate changes in the importance of an attribute in determining behavior, the unstandardized regression coefficients from simple regressions were analyzed (Table 11). Simple, rather than multiple, regressions were used because of known multicollinearity in the data and entry into the multiple regression depends on residual unexplained variance rather than total unexplained variance. A t test was applied to test for significant differences over time.

Within the treatment group, the attributes of arriving on time, vehicle safety and extra time became more important over time in the determination to take a carpool. The increased salience of safety and extra time could be due to the high accident rate on the Santa Monica Freeway and the requirement of three vehicle occupants to use the reserved lane. The increased importance of arriving on time in the decision to use either a single-occupant auto or a carpool may also be due to negative impacts of the reserved lane. Where arriving on time at time 1 had been a matter of personal responsibility in both automotive modes, at time 2 the unpredictable nature of the congestion on the freeway determined whether one arrived on time.

Ease of use in driving alone changed significantly in importance. The media representation of carpools and buses may have served as a negative referent by making that aspect of driving alone even more advantageous or it may be due to unexpected difficulties in use of the mode at time 2. Safety factors were more influential in the determination to take a bus at time 2 than at time 1. Again, the increase in traffic accidents may have highlighted this attribute. Alterations in the importance of parking cost also occurred; the fare increase may have focused individual attention on the lack of a parking cost as a way of rationalizing the cost savings usually attributable to the bus mode. Extra time was found to become more important while crowding decreased in importance. These changes may have resulted from the improvements in bus service which contrasted with what had been available.

In the control group, vehicle safety became more important and personal safety became less important in the determination to drive alone. The reported accident rates on the Santa Monica Freeway may have highlighted an attribute which had little meaning at time 1 and replaced the more traditional perception of the auto as a guarantor of personal safety. Changes in the importance of waiting in traffic, relaxing and exposure to weather in the decision to take a bus may have resulted from the improved bus service on the freeways. The causal structure with respect to the carpool mode changed significantly in the control group. Eight of the 19 attributes became more important over time.

Media coverage of events which occurred between measurements may have aroused interest in the mode and provided information where attitudes were not strongly held. The interview at time 1 may also have stimulated reassessment of the shared ride. Furthermore, trial of the mode would inform individuals about the characteristics of the mode, and if discrepant with expectations would generate reevaluation of the carpool and the value of its attributes.

Importance of the attributes can change through alterations in the external environment and through changes

in individual values, perceptions or behaviors. Individuals may be indifferent to certain attributes at time 1 because they were associated with all 3 modes or were considered necessary or neutral qualities of a particular mode. Where the modes were later differentiated with respect to the attribute or where the attribute was found to significantly change, the individual may reassess its importance. Comparisons between the modes engendered through communications or personal experiences would serve to emphasize the attribute levels associated with usage of a particular mode. The changed reference structure may induce reevaluation of the importance of the characteristics of the modes. Furthermore, changing the importance of attributes may also represent dissonance reduction where behavior and perceptions were not congruent at time 1.

The Effect of the Treatment on Perceptions and Behavior

In order to assess the effects of the reserved lane on mode user groups, subjects in both the treatment and control groups were divided into three categories, on the basis of which mode-to-work (single-occupant auto, carpool, or bus) was most frequently used prior to the modifications in the Santa Monica Corridor. Changes in beliefs and behavior were then analyzed separately for the three groups.

A significant difference between the beliefs in the treatment group vis-a-vis the control group was observed in 15 of the 157 comparisons. These results are summarized in Table 12.

For ten attributes, differences between the control and treatment groups involve significant changes over time in the perceptions of at least one of the groups. The remaining five attributes, while not significantly different from time 1 to time 2 within the groups, display a shift in opposing directions for the treatment and control groups. The difference in the pattern of change suggests some treatment effect. The treatment would be expected to affect bus and carpool perceptions by making them more positive and to reduce the positive perceptions of driving alone. Ten of the 15 perceptual changes are in the expected direction for the treatment group.

For the time 1 single-occupant auto users, the treatment produced a significant change in the perception of the wait in traffic required for carpools. The attribute changed from slightly negative to positive for the treatment group while remaining negative in the control group. For the treatment group, carpool waiting in traffic was more positive at time 2 than perceptions of the wait in traffic necessitated by driving alone or riding in a bus. Most of the remaining perceptions of the attributes of the carpool were less positive than the comparable beliefs about single-occupant autos. No other modifications of carpooling beliefs were significantly different in the treatment group in comparison with the control group.

The single-occupant automobile treatment group perceived that the travel time of the mode had significantly increased from time 1 to time 2, while the control group did not alter their perceptions of this attribute. Both the perceptions of the carpool wait in traffic and the increased travel time incurred in driving alone can be attributed to the changes on the Santa Monica Freeway. However, a significant difference between the treatment and control groups with respect to single-occupant automobile personal safety and ease to destination was unexpected. There was no significant change in the treatment group but the control group perceptions of personal safety and ease to the destination decreased significantly. The actual cause of the change in perceptions for the control group is

unclear and illustrates one problem with the non-equivalent control group design. Any event which affected those living in the control areas but not the treatment zone could result in a confounding of the treatment effect. The treatment group did reduce its frequency of single auto use significantly; however, the control group also reduced its single-occupant auto use by about the same amount. Thus, it is unclear whether the drop

in the treatment group was caused by the policy change and the decrease in the control group by some other factor; or whether both decreases are a product of some other cause.

For single-occupant automobile users, three bus beliefs were found to differ significantly between the treatment and control groups. Bus crowding, waiting for the bus

and exposure to weather were significantly more positive at time 2 than at time 1 for the treatment group. Transportation system modifications which decreased bus headways and increased frequency of bus service in the treatment zones would, therefore, seem to have had the desired effect upon this group. However, changes in the behavior of the treatment group were not significantly different from changes in the control group. Bus use increased for time 1 single-occupant auto users in both samples.

There was a significant treatment effect on the perceptions of the carpool users; the direction of change was, however, contrary to expectation. The treatment group showed a decrease in the ease of use of the carpool mode while the control group found the mode to be improving in its ease of use. This may be a reflection of the reported difficulty in crossing traffic lanes to get to the diamond lane or confusion over the new policy. Perception of crowding in carpools also was less favorable in the treatment group at time 2 and may be due to the need to have at least 3 people in the carpool in order to use the reserved lane. Travel time during rush hour in carpools moved in the desired direction; the treatment group exhibited an increasingly positive perception for this attribute.

The only significant treatment effect on the carpoolers' perceptions of driving alone was a relative increase in the time spent waiting in traffic for the treatment group, while the control group perceived a decrease in waiting time for the single-occupant auto. This is probably attributable to the Santa Monica ramp metering system and the use of ramp bypasses by the carpoolers.

The carpoolers in the treatment group also perceived a significant improvement in bus travel time while the control group perceptions were slightly worse at time 2 with respect to the attribute of the bus. The mean bus use of the carpoolers increased equally in each group.

Bus users in the treatment group considered the carpool to be less easy to use at time 2 than at time 1, and, thereby differed significantly from the control group. Again, this may be attributable to the observed difficulties in accessing the reserved lane. A treatment effect was also observed in the extra time required in driving alone. The treatment group changed positively with respect to this attribute while the control group changed to a less positive perception of single-occupant automobile extra time. Some confusion may have existed with respect to the definition of the attribute; individuals may have changed their parking locations or may be including the extra time required after leaving their car at a park-and-ride lot.

A treatment effect was observed for bus parking cost among the bus users. The more positive belief observed at the post-test for the treatment group is perhaps a reflection of reduced costs for those using a park-and-ride lot. Finally, no significant effect was observed in the behavior of bus users.

No significant treatment effect upon behavior was observed. While significant changes were found in the treatment zone in use of all three modes, behavior change was occurring at the same level in the control group. Several explanations can be offered. First, it is likely that exposure to media and to acquaintances who used the Santa Monica Freeway reserved lane heightened interest in the ridesharing modes and the transportation system in general for the control group. Individuals who were potential ridesharers may have become more aware of their alternatives and availed themselves of the opportunity to try a carpool or bus. Secondly, the definition of treatment as residence in the Santa Monica corridor may be too broad. It is

likely that the reserved lane was perceived as an incentive only for those who could use the freeway for the entire 12.5 miles. Third, the reserved lane on the Santa Monica Freeway was controversial, and consistent threats to its continuation undoubtedly mitigated against the stabilization of attitudes and behaviors.

The changes that were observed in the panel of downtown commuters thus appear to be attributable to a dynamic ridesharing segment of the population for whom increased awareness and availability of the ridesharing mode facilitated the use of the alternatives to driving alone to work.

Conclusions

A significant change in mode choice behavior was observed in both the treatment and control groups over time. In each group, however, only 13% changed to modes with which they had had little experience at time one. In the treatment group, single-occupant auto, carpool and bus users at time 1 decreased their use of their respective modes at time 2. Single-occupant auto users significantly increased their use of the bus and carpool while carpoolers increased their use of the bus and single-occupant auto. Bus users significantly increased their use of the carpool. The same pattern is found in the control group; time 1 mode groups decreased their use of those modes at time 2. Both carpoolers and single-occupant auto users increased their use of the bus at time 2; carpoolers and bus users also increased the use of the single-occupant auto. Both time 1 bus and single-occupant auto users increased their carpool usage.

It is likely that in the process of choosing a mode, individuals try at least one of the alternatives. A considerable number of individuals used two modes about equally in traveling to work. However, those who alternated between two modes at time one had generally selected between them by time two. Furthermore, a majority of the sample used a second way of traveling to work at least once at time one. It appears that most of the Los Angeles downtown commuters are not captive to a mode and that most have experienced at least one of the ridesharing alternatives. The significant defections from the bus and carpool modes suggest a dynamic ridesharing population. Continual promotional and information campaigns are necessary to continue to attract commuters and to thereby replace those who have switched.

Contrary to expectations, the treatment group did not display a large increase in the use of the carpooling mode. Travel counts on the Santa Monica Freeway revealed a 65% increase in carpools and a 300% increase in bus use (Billheimer, et al., 1977). This travel data is derived with respect to all the riders of the freeway, while the survey sample included only downtown workers. It is possible that downtown commuters were already ridesharing in greater proportions than the non-CBD workers or that many who had relocated had significantly altered their travel behavior. It is also likely that the survey sample was not representative of the total population. In the random survey of households the number of downtown workers and their mode to work were obtained; 56% of the total household workers drove alone to work, 20% used a carpool and 24% were bus users. This mode distribution is approximately equal to the mode distribution of the time 1 treatment group that was retained for analysis. It is possible, however, that the background characteristics of the mode users in the sample are significantly different from the population and, therefore, explain the lack of change observed.

The reserved lane on the Santa Monica Freeway appears to have had relatively little effect on the behavior of the downtown commuter sample. Behaviors in the control group were not significantly different than those in the treatment group. However, one of the problems in the analysis is the inability to separate the increased use of the bus associated with express buses using a reserved lane from the mere availability of express buses. Increased bus service in all areas combined with additional express routes on control freeways confounded the analysis. The only conclusion which is indicated is that the reserved lane implemented on the Santa Monica Freeway for five months did not increase carpooling behavior among the downtown commuters. Whether this lack of carpooling behavior can be attributed to the controversial nature of the reserved lane and the continuous discussion of its termination, cannot be determined with the data available.

The importance of modal attributes, as measured by their influence upon behavior, changed over time in both the treatment and the control groups. System modifications, communication, and personal experience with the modes are presumed to have caused the reassessment of attribute salience. Reactions to alterations in service as well as the enhanced comparative evaluation of the attribute levels between modes contributed to the change in the importance of attributes in the mode choice decision.

Perceptions of the modes were also altered in both the treatment and control groups and in general corresponded with the behavior patterns. Significant differences in perceptions were observed in the treatment and control groups. Single-occupant automobile treatment perceptions were found to be more positive than single-occupant automobile control group perceptions of the bus and carpool modes and although the attributes of carpool and bus remained generally less positive than those of the single-occupant auto mode, the magnitude of difference was decreased. It is possible that had all the incentives to multi-passenger vehicle use remained in effect, further behavior changes in the direction of a more balanced mode split might have been attained.

The relationship between behaviors and perceptions of modal attributes can only be determined with individual-level analysis. Further research is required regarding the effects of perceptual consistency and behavior change, changed availability and mode choice, communication flows and mode trial, as well as the determination of the modal attributes which appear to influence behavior.

HALO EFFECTS IN MARKETING RESEARCH: REVIEW AND PROGNOSIS

Neil E. Beckwith, University of Pennsylvania
Harold H. Kassarian, University of California, Los Angeles
Donald R. Lehmann, Columbia University

Abstract

The tendency in rating an object on a particular attribute to be influenced by a general impression is well known. Some of the early psychological studies of this halo effect are reviewed along with more recent work in marketing and consumer behavior.

Introduction

Consumers' ratings of a brand (or other object) on a set of dimensions (attributes or traits) are commonly used in consumer research. Examples include image (i.e., profile) studies, advertising effects studies, and product attribute positioning studies. However, an individual's ratings on an attribute may be determined by many other variables besides cues directly relating to the particular attribute.

In a recent Federal Trade Commission case, consumers' perceptions of a brand of bread were at issue. A complaint of the FTC had alleged that ITT Continental Baking Company had falsely represented Wonder Bread to be superior in nutrition to competing brands of white bread.

It was agreed on both sides that some percentage of the public believed that Wonder Bread stood out in nutrition. One issue was the extent to which specific advertising about the nutritional quality of the brand had influenced these beliefs. The bakery company claimed that the nutritional beliefs about Wonder Bread were influenced by consumers' generally favorable overall attitudes toward the brand (including familiarity, price, and higher levels of advertising) and that this positive overall feeling about the brand in turn influenced the belief that Wonder Bread was nutritionally superior. (Eventually this particular charge was dismissed on other grounds.)

The tendency in rating an object on a particular attribute to be influenced by a general impression is widely recognized.

Concept

Rating responses of an object on a set of attribute dimensions is generally determined as a function of several related aspects. First, it is generally held that some adjustment process exists whereby overall attitude and beliefs about the object on the attributes influence each other, and the individuals' beliefs become adjusted as a result of the overall attitude and other beliefs. This process is neither good nor bad; it exists and must be accounted for.

Second, rating response about the object is influenced not only by true beliefs but also by a variety of measurement effects. This means that a respondent, when rating an object on an attribute, may be responding to stimuli rather than his true belief.

Definitions

Interestingly, within the research community substantial

disagreement exists concerning the definition, importance, circumstances, and even the existence of a halo effect.

Tiffin and McCormick (1965) consider the halo effect to be the domination of all other traits by one particular trait. Krech, Crutchfield, and Bellachey (1962), in a similar vein, point out that if a person is well liked, he will be rated as being very high or positive on all other specific traits. If a person is disliked, perceptions of even his most positive attributes will be downgraded. The perception of the person is influenced by the overall feeling toward that person.

English (1934) many years ago provided a rather general definition of the halo effect as the "tendency in rating to be influenced by general impression or attitude when trying to judge separate traits." This view is broader than that of Krech et al, or Tiffin and McCormick in that haloing is seen as an individual phenomenon and the source of bias is the individual's general (overall) impression or attitude, and includes the rating of any objects.

From a more technical point of view, it has also been common to view the halo effect as the excessive partial correlation between belief ratings (e.g., Symonds, 1925). However, some "natural" correlation between beliefs should be expected even without any halo effect. It is difficult to partition the correlation between the halo and natural components (Bingham, 1939). The Federal Trade Commission adopted a definition in its final opinion in the Wonder Bread case which included three sources of the halo effect: (1) widespread usage, (2) generalized advertising claims, and (3) claims stressing a different attribute (Docket 8860, p. 13).

Related Theories

Various cognitive balance theories (individuals' attempts to maintain beliefs which are consistent with each other) also suggest the existence of halo effects. Heider (1958) points out that if an individual likes both person A and object X, he would expect that his friend, person A, would also like object X. If not, the individual would experience cognitive imbalance—an uncomfortable state. "How can my friend whom I like dislike object X or politician Y or a third person. Either object X is not as good as I thought it to be, or my friend is crazy and not quite as likeable as I thought him to be" (see, e.g., Abelson et al, 1969, Feather, 1964; and Rosenberg et al, 1960).

Festinger (1964) calls this imbalance dissonance, again an uncomfortable state that must be corrected. In this unconscious "correction" process the fact that feelings toward one attribute or person or product can systematically influence another object or attribute is very similar to halo effect from some points of view. Nice people have nice attributes, and less nice people have less nice attributes (see, e.g., Venkatesan, 1973; and Wickland and Brehm, 1976).

As can be seen we have already confused the halo effect defined as "the overall impression influencing specific attributes" with popularity, familiarity, etc. Hence it may be worthwhile to examine what we wish to call halo-like effects.

Halo-Like Effects

A number of other sources of rating bias are similar in spirit to the halo effect, but are actually distinct manifestations.

Other Attribute Effects

Belief about an attribute could possibly influence an individual's rating on another attribute beyond its effect via the overall attitude component. For example, if gasoline mileage was totally irrelevant to some individual's overall attitude, it might still influence his rating of miles per fill-up. Many studies have confirmed that the physical attractiveness of a person influences other persons' ratings of that individual on many attributes, as well as influencing the overall attitude (e.g., Miller, 1970).

Peer Attitudes

An individual's belief response may also be biased by his understanding of his own local peers' beliefs about the object on the attribute or overall attitude. Such peer group conformity influences have been considered by Bourne (1956), Sherif and Sherif (1964), and Siegel and Siegel (1957) among others.

Popularity

Individuals may also be biased by their understanding of the general public's beliefs or overall attitudes about the object, as well as their own local peer groups. Individuals may favorably bias their ratings for well known brands and unfavorably bias ratings for less popular products, for example.

Familiarity

Similarly, individuals may systematically influence their ratings differently for more familiar objects than for less familiar objects. The direction (sign) of such influence is difficult to prejudice, since it would seem to depend upon the general satisfaction level realized during familiarization with the object as compared to the individual's expectations of unfamiliar objects. Koltuv (1962) concluded that the magnitude of halo effects decreases with increasing familiarity; although, James and Carter (1977) did not find a similar result in their recent analysis of 14 students' location preferences.

Cross Sectional Estimation

One of the difficulties in assessing the halo effect is estimating the magnitude of the effect. The most critical problem is estimating the individual's true beliefs.

Cross Sectional Bias

"Halo effect" generally denotes the bias of each individual's belief response. However, measurement problems also exist. Huber and James (1976) pointed out that simply averaging the belief responses across individuals (as in Beckwith and Lehmann, 1975) does not provide unbiased estimates of the underlying locations or values. This is because the objects or alternatives will usually have different fractions of the respondents favoring them. The average of belief responses for the popular objects should be more favorably biased than for less popular objects since more individuals will favorably bias the rating for popular objects than they will for unpopular objects. Researchers have attempted to attenuate this source of bias by separately comparing users and nonusers across brands, for example. Beckwith and Kubilius (1977) have attempted to estimate the true locations of objects to remove this

bias. Also see Bemmar and Huber (1977) for a discussion of the necessity for simultaneous estimation of belief and attitude components.

Correlates of the Level of Halo

Thorndike (1920) originally concluded that the magnitude of halo effects seems to be surprisingly large. Subsequent investigators have attempted to determine which circumstances seem to involve only small or negligible halo effects, and which seem to encourage larger halo effects. There is substantial disagreement among published studies concerning even which circumstances encourage haloing. Thus, the following should be considered to be candidate, rather than proven, circumstances which tend to evidence more haloing:

1. Low familiarity with the objects (Koltuv, 1962).
2. Ambiguous or subjective attributes (James and Carter, 1977; Beckwith and Lehmann, 1975).
3. High perceived popularity or usage of the objects.

In addition, many other circumstances exist which might be expected to influence the degree of haloing. These include:

1. The importance of an attribute. An important attribute might be expected to show evidence of a larger halo effect since the attribute would more strongly influence overall attitude. However, Beckwith and Lehmann (1976) found a slight (but not significant) tendency for halo effects to decrease with increasing attribute importance.
2. Questionnaire wording can affect the degree of haloing (Wilkie, McCann, and Reibstein, 1973).
3. Relative importance of the object or product class.
4. Personal characteristics such as relative intelligence, education, gestalt-proneness, or interest of the respondent in the product class.
5. Promotional strategies employed. Whether the advertising environment primarily uses very general or very attribute-specific communications and claims may influence halo.

Seemingly divergent results have been reported, even for the same product class. For example, the Roper Organization reported that "The lower your gas mileage, the more uncomfortable the seats turned out to be" (Marketing News, 1975). However, Moore and James (1977) found only a very small amount of haloing in 34 students' ratings of automobiles on several attributes, including gas mileage and comfort. We conclude that unraveling the halo-inducing circumstances will not be an easy task, particularly as the focus of inquiry moves to attitude and belief changes.

Summary

Substantial disagreement exists concerning just when and how much haloing occurs. However it seems clear that a serious degree of haloing occurs in at least some circumstances. Until the nature of these circumstances is better understood it is reasonable for researchers to accommodate the possibility of halo effects within any study using belief ratings on attributes. Since the degree of haloing is expected to vary between individuals, individual level analysis would seem to be appropriate, at least until the halo effect phenomena is better understood.

Lastly, it is worth noting that in recent experimental manipulations, subjects were found to halo extensively, even when they had sufficient information to allow for independent assessments on the attributes. Furthermore, the subjects actually believed that the influence ran the other way, i.e., that their assessments on the attributes prompted their overall evaluative rating (Nesbill and Wilson, 1977; Ryan, 1977).

A MEASURE OF HALO

Joel Huber, Columbia University
William James, University of Alabama

Abstract

Several different ways to measure halo are reviewed and a new measure proposed which is logically consistent and simple to implement. The use of familiarity judgments as an intervening variable is proposed as a way to estimate the degree of directional flow in halo judgments.

Introduction

Halo effect appears to be one of those concepts which (like a rainbow) is clear at a distance but dissolves on closer inspection. Halo occurs where affect or preference for an object biases attribute judgments in such a way as to make the judgments more consistent with preference. It may be lamentable, but is certainly understandable and, in certain situations, even quite reasonable. Up close, however, the rainbow fades. It becomes difficult to determine where the edges of halo are; where it exists and where it does not. Its central prerequisite, that changes in affect cause shifts in perception, becomes hopelessly confounded with the alternative explanation, that shifts in perception cause changes in affect. Various definitions of halo, while possessing a degree of face validity, do not allow an unequivocal measure of the strength of the bias due to halo or even its direction. In this study, the use of attributes which have clear physical counterparts, such as size or temperature, allows a relatively independent measure or bias due to halo. It then becomes possible to treat halo as a variable that can be explained by other variables. This begins to move halo effect from the status of a vague explanation to an operationally defined theoretical construct.

Halo has been defined in many ways. These are summarized in Table 1. Much of the work is by psychologists working with personnel evaluation forms. There it is found that a general attitude towards the person being rated, the ratee, results in a corresponding bias in the rating of more objective attributes, such as rated ability to perform a certain task. The measures of halo used have been of four kinds. The first is related to the correlation between attributes, the second to the variance of those attribute ratings for a given subject, the third as an additive interaction between the rater and the object, and the final measure is related to the degree to which preference predicts attribute judgments.

Defining halo as the excessive correlation between attributes goes back to the initial conceptualization of the concept (Wells, 1907; Thurstone, 1920). To the extent that preference causes attribute judgments, it will result in a spurious correlation between the attributes due to a preference factor. Unfortunately, as is pointed out by Bingham (1939), there is a degree of correlation expected even without the halo effect being operative. For example, it is reasonable to expect, for most subjects, that cornering ability and sportiness in automobiles correlate with preference regardless of halo. The problem of determining when the level of correlation becomes excessive has not, and probably cannot, be answered. Taylor and Hastman (1956) use average attribute correlation as a measure of halo to see if different preliminary instructions to raters reduce halo. While instructions as to the pitfalls of halo do appear to reduce the average correlation

TABLE 1
Summary of Operational Definitions of Halo

Definition	Defined On	References	Problems
1. Extra correlation between attribute ratings due to preference factor.	Rater	Wells (1907) Thurstone (1920) Bingham (1939) Koltov (1962) Taylor & Hastman (1956) Keaveny & McGann (1975)	Some correlation is expected. There is no way to determine how much indicates halo.
2. Lack of variance of attributes within object.	Rater and object	Brown (1968) Borman (1975)	Some variance is expected. No way to determine how little indicates halo. Primarily measures subject attention.
3. Additive rater x object interaction.	Rater and object	Guilford (1954)	Attributes must be scaled such that more is better. Contamination effect of factors other than preference.
4. Coefficient of preference predicting belief using average belief as a covariate.	Rater and attribute beliefs	Beckwith & Lehmann (1975)	Assumes average belief is halo free and represents the ultimately "true" belief for the individual.

between attributes, it is impossible to determine whether halo has been reduced or whether raters have merely learned to make artificially independent ratings.

Brown's (1968) definition of halo in terms of attribute variance is based on the notion that a given overall rating will produce correspondingly high or low ratings on the components. If the attributes are coded so that they all produce affective response in the same direction (e.g., more is better), then halo is hypothesized to reduce the variance of the attribute judgments about any given subject. Once again, however, there is no way to tell when the variance is sufficiently high to indicate lack of halo. By pointing out to raters the problem of low variance, Brown (1968) and Borman (1975) are able to significantly increase attribute variance after training, but it is unreasonable to conclude that the change represents less halo effect rather than an artificial scale effect by compliant subjects.

Working across raters, Guilford (1954) defines halo as a rater x object interaction term. By this definition, the preference of a rater for a particular object is

hypothesized to result in a constant added to or subtracted from each attribute for that object. Thus, if a particular rater likes an object, ratings on all dimensions should increase for that subject. There are two things to note about this formulation. First, as with the variance measure, all attributes must be coded in the same direction. Given halo bias, preference for an object will increase ratings on attributes where "more is better", decreasing those where "more is worse". The effect of two oppositely coded attributes tends to lessen or cancel Guilford's interaction term. The second problem is conceptual. We have here defined halo to be the effect of preference on attribute ratings. But preference need not be the only cause of a rater x object interaction. Attributes can themselves have a degree of intercorrelation so that a high rating on one attribute may lead to distorted ratings on other attributes. For example, in rating candidates, if one is considered to be intelligent, he is also likely to be rated higher on many other ratings, thus resulting in a rater x object interaction. To the extent that there are factors other than preference contaminating judgments, Guilford's measure will overestimate the halo effect.

There are, however, two advantages with this formulation of halo. First, even though significant rater x object interaction does not positively indicate the presence of halo, a lack of interaction argues strongly for the lack of halo effect. Second, the method provides a reasonable measure of halo defined in the larger sense of the biasing effect of all attributes, including preference, on each other. This, in contrast to either the correlation or the variance definitions, provides an independent measure of halo which can then be used as a basis to begin to understand the phenomenon.

Beckwith and Lehmann (1975) provide a definition of halo that goes even further towards making the concept operational. While it is not totally clear what their measure is, halo appears to be defined as the coefficient of preference in a regression predicting attribute ratings once the effect of average belief has been removed. This is:

$$B_{ij} = \delta_{j1} B_{ij}^* + \delta_{j2} A_i \quad (1)$$

Where:

B_{ij} = individual's attribute rating of stimulus i by attribute j .

B_{ij}^* = average value across all individuals in study of B_{ij} .

δ_{j1} = effect of average belief on individual beliefs.

δ_{j2} = halo effect of individual preference on beliefs.

A_i = attitude or preference toward object i .

Equation (1) is parameterized across objects rated by a given subject on an attribute. The idea here is that individual belief can be decomposed into two additive components, the first component representing the effect of average beliefs, which is assumed to be relatively halo free; and the second component representing the effect of preference which alters perception through halo. The larger δ_{j2} , the greater halo is presumed to be for that subject.

Beckwith and Lehmann use a system of simultaneous equations and two-stage least squares to estimate the parameters in their system, which, while commendable in principle, resulted in an indeterminate solution. In the case of the Beckwith and Lehmann paradigm, it appears that the coefficients of simple least squares estimation of Equation (1) result in very similar results as the more complex simultaneous system. Thus,

this definition of halo appears, in this instance, to be relatively independent of whether an individual or simultaneous system of equations is used.

Even taking the more simplified form of their model, there are two problems with measuring halo as in Equation (1). The first problem stems from the use of average belief as a surrogate to "true" belief. In doing so the model biases downward the effect of halo when there is considerable agreement across subjects with respect to preference and biases it upward when individual beliefs have a large, but legitimate, individual component.

For example, if different raters have similar tastes in objects, then average beliefs are likely to be contaminated by a kind of average halo effect. Thus, if all raters like a candidate, then it is reasonable that all attribute beliefs will be biased in a direction consistent with this average affect. In this case, the coefficient of A_i in Equation (1) will be attenuated since average attribute measures already contain a large component of individual preference. Thus, the effect of similarity of preference across subjects is to bias downward the measure of halo.

The opposite bias occurs when an attribute has a large, but legitimate, individual component. Consider the attribute of "fit" as it is applied to the preference for a jacket for an individual. To the extent that individual body sizes differ, the average measure of fit of any given jacket is likely to be relatively unrelated to individual preference. A large man will not have a strong preference toward a jacket that has the highest average fit. By contrast, individual fit is likely to be highly correlated with preference and thus lead one to conclude erroneously that there is a strong halo effect with respect to that attribute.

The final difficulty with the Beckwith and Lehmann formulation is making behavioral sense of Equation (1). That is, individual belief is formulated as a weighted combination of average belief and individual preference. But, following a perceptive comment by Johansson *et al.* (1976), it is hard to see how B_{ij}^* can be considered an input to an individual's belief when it is generally not known to the individual. Thus it is nonsensical to assert that Equation (1) represents what an individual could be doing, consciously or unconsciously. Such an average belief might make sense if the individual were asked what he felt the average belief was. Such a solution, however, runs into problems with respect to the direction of causality since a person's perception of average belief may be seriously tainted by their actual belief.

Thus, there are three problems with the Beckwith and Lehmann formulation of halo. The first concerns the identification problems arising from the use of a simultaneous system of equations, the second concerns the bias in halo estimates brought about by the likelihood that average belief is itself contaminated by halo, and the third concerns the behavioral meaningfulness of Equation (1) given that average belief is not typically known to the person making the rating.

A New Concept of Halo

In what follows, a concept of halo is developed that seeks to alleviate or avoid the above problems. Simultaneity is avoided by having all measures simply be correlation coefficients. The use of the average subjects' belief is avoided by using attributes that have clearly defined physical counterparts. This objective measure is then used in place of the average belief. Finally, the problem of using an unknown input in the

belief equation is avoided by defining halo as a function of the extent to which the objective value differs from the individual's belief. Thus the "true" value only enters to define perceptual error and as such is not expected to be known by the individual.

To illustrate the development, data from a study of 14 masters students with respect to their preferences toward 17 cities as sites for their first job is used. They were shown pairs of cities and asked which they would prefer to live in given that work related variables, such as opportunity for advancement, were kept constant. They were then asked how much more they would have to be paid per year to choose the less preferred city. From these dollar differences between pairs of cities, a one-dimensional preference scale was constructed for each subject using a procedure developed by Pessemier and Teach (1966) and described by Huber and James (1976). The process resulted in reliable individual preference scales of interval quality.

Three attributes were chosen for analysis, perceived size, average temperature, and opportunities for spectator sports in the city. These were measured on 10-point Likert Scales. The physical attributes are, respectively, population, average temperature, and the number of major professional sports teams in the city. Since the analysis is made on the basis of univariate relationships, no need was felt to include all determinant attributes. In this case, the attributes were chosen because it was relatively easy to find corresponding physical attributes that could serve as the basis for measuring perceptual error.

Thus the input to the measure of halo contains three elements for each individual: a preference or attitude score for each city, a set of beliefs for each city across three attributes, and finally a set of physical measures that correspond to the beliefs. The particular terms used and their operational definitions are provided in Table 2. Conceptually, halo is defined as the

TABLE 2
Summary of Concepts and Definitions

Concepts	Definitions
A_i Preference	Overall measure of affect towards stimulus i . Standardized within subject.
B_{ij} Psychological Attribute Rating	Perceived measure on stimulus i by attribute j . Standardized for each subject and attribute.
B_{ij}^t Physical Attribute Rating	Physical measure on stimulus i by attribute j . Standardized within attribute.
Psychophysical Transform	Best fitting linear transform predicting psychological attributes given their physical measures.
$B_{ij} = \alpha_j B_{ij} + u_{ij}$	
u_{ij} Perceptual Error	Deviation from perceived attribute of best fitting psychophysical transform.
Y_j Halo	Degree to which preference is related to perceptual error. Measured as the correlation between A_i and u_{ij} .

degree to which preference for an object biases beliefs about that object in such a way as to make them more consistent with the preference. Perceptual error is defined as the difference between the perceived rating of a city

and the best fitting linear approximation given its "true" value. If this residual is positive it means that relative to other cities the individual has judged this city to have a higher rating than is justified given its physical qualities. Halo is then simply the degree to which preference accounts for this perceptual error. This is operationalized as the correlation between the residual of the psychophysical transform and the preference score.

An example may make the logic of this operationalization more clear. Suppose that within the range of cities tested that a person likes warm climates--that being in a warm climate is important. Under halo it is hypothesized that if a person likes a city it will be misperceived to be warmer than it actually is. If correspondingly, less preferred cities are seen to be colder than is justified, then there will be a high positive correlation between perceptual error and preference.

Notice that the direction and the size of the halo coefficient will be a function of whether the attribute is liked and how much it is liked. In the example, if warmth is disliked then those cities that are disliked will be perceived as colder--producing a negative relationship. In a similar way, the importance of an attribute should be related to the actual size of the halo measure. Thus if warmth, or coldness, is very important to an individual then there is more pressure to bring beliefs in line with preferences. One measure of the degree of importance is the simple correlation between preference scores and beliefs. This measure reflects whether in general a high level of preference is associated with a high level of belief.

These two measures, the halo measure and the correlational importance measure are provided in Table 3. The

*Importance (Imp.) is measured as the simple correlation between attribute ratings and preference.

correlations across subjects are greater than .75 for each attribute. Moreover, it is visually clear that even within subjects the two measures covary strongly. Although this relationship is in part due to a computational artifact stemming from the use of preference in both measures, the strength of the relationship makes

behavioral sense and lends credence to this measure of halo.

The relative importance of preference in determining attributes can be looked at from another perspective. For the three attributes, size, spectator sports and warmth, the physical values of these attributes accounted for an average of 61%, 60% and 78% of their variance, respectively. From values of halo in Table 3, it is evident that preference accounts for about 10% of the remaining variance. Thus, halo accounts for a relatively small proportion of the error in attribute judgments. This result, for attributes that have sharply defined physical counterparts, differs from the result of Beckwith and Lehmann study, using more subjective attributes. They found that preference accounts for about 30% of the variance in attribute judgments. This makes sense, the more subjective the attribute, the easier it is for preference to legitimately distort judged attributes. By contrast, the objectivity of a variable like size, or average warmth, makes it more difficult for subjects to distort its value.

Thus, this measure of halo enables one to estimate halo in a way that makes conceptual sense and is simple computationally; for reasons of parsimony alone it is to be preferred to the Beckwith and Lehmann version.

It has two disadvantages. First as operationalized it can only be applied to attributes that have clearly defined physical counterparts. While the method could be used by simply substituting the average subjective belief for the objective measure, such a solution would lead to the problem of average belief contaminated by halo referred to earlier. A partial solution is to develop elaborate psycho-physical transforms that predict the subjective attribute (say, good dating opportunities for a city) as a function of several objective attributes (say, the percent of population that is 18-25 years old and the number of nightclubs per capita).

The second problem is more serious but cuts across all measures of halo presented thus far. This is the problem of the direction of causality. There is an alternative explanation for the results we have presented which we shall call the "random experiences explanation." It will be shown that this accounts for the same results as the halo explanation.

Consider once again the person who likes warm cities. Suppose he erroneously considers a city, say St. Louis, to be warmer than it really is. Given that there is a strong positive affective value attached to warmth, St. Louis can be expected to have greater preference due to the misperceived warmth. Furthermore, the degree of preference bias will be approximately proportional to the degree of positive affective value attached to coldness. Thus, the random experiences and halo explanations account for the same experimental results. In the data provided so far, they are empirically equivalent. The difference between the two is in the direction of causality between beliefs and preference. The correlational methods used cannot determine causal direction. Moreover, it is likely that neither explanation is true to the exclusion of the other, but rather that causality runs in both directions to a greater or lesser extent depending on the subject and the attribute. The next section provides a way to begin to identify the predominant direction of causal flow for different attributes and subjects.

Estimating Causal Direction

If the link between preference and perceptual error is primarily due to the translation of legitimate misperception of attributes into preference ratings, then one would expect this link to diminish as one becomes

more familiar with the objects being judged. On the other hand, to the extent that the halo explanation is correct, selective perception should operate to keep the relationship between preference and perceptual error high even as one becomes more familiar with the stimuli.

In the present study, subjects were asked to specify level of familiarity with each city on a ten-point scale. This can be used to test the halo versus the random experiences explanations by estimating the following equation.

$$u_{ij} = \gamma_j A_i$$

$$u_{ij} = (\gamma_{j1} + \gamma_{j2} \cdot \text{FAM}_i) A_i \quad (2)$$

$$u_{ij} = \gamma_{j1} \cdot A_i + \gamma_{j2} (\text{FAM} \cdot A_i) \quad (3)$$

Where:

u_{ij} = Perceptual error on city i by attribute j .

A_i = Preference for city i .

FAM_i = Familiarity with city i on a ten-point scale.

γ_j = Average effect of preference on error for attribute j , halo effect.

$\gamma_{j1} + \gamma_{j2} \cdot \text{FAM}_i$ = Halo effect taking account of the effect of familiarity.

What is expected under the random experiences explanation is that familiarity will reduce the correlation between preference and error. Thus γ_{j1} and γ_{j2} should have opposite signs. If halo is operant, familiarity should have no effect and the coefficient of γ_{j2} should be zero. Equation (2) can be estimated by changing its form to Equation (3) and simply using regression. This was done for each of the three attributes for the fourteen subjects in the study. Two-thirds of the cases tested did not have significant γ_{j2} terms at a 0.20 level of significance, thus generally supporting the halo hypothesis. Of course, there were only 17 cities in the regression so the power of the test was not very strong. In addition, the correlation between A_i and $\text{FAM}_i \cdot A_i$ results in multi-collinearity which further weakens the power of the test. Since, however, neither hypothesis is expected to be true to the exclusion of the other, the magnitude of the γ_{j2} term can be used to segment subjects on the basis of relative magnitude of the halo effect.

Figure 1 provides the familiarity-adjusted halo level for subjects displaying low halo effects. Notice that for subject 1, preference is negatively correlated with misperceptions of average temperature, but that the degree of this negative correlation diminishes on those cities about which the subject is more familiar. This implies that as cities become more familiar, the perceptual bias due to preference will diminish. Had halo effect been the explanation for the relationship between preference and error, then the slope of the line would have been more nearly horizontal.

Subject number 2 shows a high positive correlation between preference and affective error. This results from a general preference for warm climates so that preferred cities are misperceived in the direction of being warmer. Once again, however, note that the strength of this bias decreases with increased familiarity. In both of these cases, one would hypothesize that these subjects would be receptive to new information about the warmth of the

FIGURE 1
Effect of Familiarity on the Degree to Which Preference Correlates with Perceptual Error

city and it would be reflected in their preference for cities.

By contrast, where the slope is not significant, it can be inferred that preferences are the primary cause of beliefs and that new information is not likely to reduce the bias due to preference. This can be inferred from the fact that for those attributes where γ_{j2} is not significant, increasing familiarity does not reduce error.

In this study, approximately one-third of the attributes resulted in equations which contradicted the halo explanation at a .20 significance level. This implies that while halo is dominant in the majority of cases, there is a significant minority for which random experiences provides a better explanation. Therefore, it is important to make assessments of the relative importance of the two explanations on a case-by-case basis rather than attempting generalizations across all subjects or attributes. Seen in this way, the significance of γ_{j2} represents a descriptive statistic that enables one to group subjects in terms of the degree of appropriateness of the halo explanation. The ability to measure the relative importance of halo has promise as a marketing tool. To the extent that a subject's perceptions are contaminated with halo, it is unlikely that further communication, contrary to this preference, is going to be accepted in an unmodified form. On the other hand, to the extent that marketers can identify those whose perceptual bias is reduced with greater familiarity, it is likely that those individuals will be good targets for marketing communications.

Summary and Implications

In contrast to other definitions of halo, the operationalization presented here is simple and logically follows from the idea of halo as perceptual bias due to preference. While the issue of the direction of causality between preference and beliefs is not completely resolved, the use of familiarity ratings provides a promising technique to identify those cases where the causal flow is predominantly in one direction or the other.

The study suggests several paths for future research. While in this model the physical value is defined as the "true" value of an attribute, other measures are possible. Conceptually, what is needed is that the "true" value approximate the halo free rating the individual would give provided enough time and information. For those variables that have clearly defined physical counterparts, the physical values serve this function well. As mentioned earlier, the average rating across subjects is likely to fail on both criteria; it will

neither be halo free nor approximate the asymptotically true value for most individuals. To generalize the model, what could be done is to expand the psychophysical transform to include several physical components that make up higher-order psychological ratings. For example, multiple regression could be used to predict ratings on sportiness in automobiles as a function of such measurable quantities as width-to-height ratio, cornering ability, as well as dummy variables such as rack-and-pinion steering and disk brakes. Such extended psychophysical transforms would be useful not only in measuring halo, but also in providing guidance to designers attempting to create a sporty car.

Familiarity proved to be a promising variable to discriminate between the halo and the random experiences explanations. In this case, a global familiarity rating on each city was used rather than separate familiarity ratings on each attribute. This oversimplification could result in problems to the extent that subjects are more familiar with one aspect of a city than another. Thus, the model could be improved by including a familiarity or degree of certainty estimate for each attribute.

Finally, experimentation is needed to determine if in fact those who appear to have less halo in their judgments are more susceptible to persuasive communications. If this turns out to be true, then the methodology provided here could become a valuable basis for segmenting subjects in terms of sensitivity to advertising or new information.

HALO EFFECTS AND LOCATION PREFERENCES

William L. James, University of Alabama
Forrest S. Carter, Georgia Institute of Technology

Abstract

The two methods of measuring halo that have been used in marketing were compared and were found to be highly correlated. Some evidence was found to support the hypothesis that halo decreases as preference increases. Halo was not found to increase as familiarity decreases. Halo was found to be a more important source of error than familiarity. Attributes with less clearly defined physical correlates were found to have more halo than those attributes with clear physical correlates.

Introduction

The focus given to attitude research in marketing and the behavioral sciences has led to a renewed interest in halo effects. The halo effect was noticed as early as 1907, but was named by Thorndike (1920). There have been two slightly different ways in which halo has been conceptualized. Tiffin and McCormick (1965) in their classic textbook view halo as the domination of all traits by a particular trait. A more common view is that halo occurs when an overall impression, such as preference, dominates the traits being rated. This latter view appears to dominate in the marketing literature. The concept of halo is important to marketing researchers due to its effect on the prediction of preference, the development of product spaces, and the identification of marketing opportunities. Any time that attribute ratings are collected the researcher must consider the potential impact of halo on the relationships being investigated. Halo might be beneficial if the objective is to predict preference from attribute ratings since it will increase the correlation between the attributes and preference. Halo is, however, detrimental when attribute scores are used to develop product spaces or identify marketing opportunities. It would be a mistake to develop or reposition a product to fit some set of consumer ratings that are heavily influenced by halo. Thus, it is necessary to measure the degree to which attribute ratings are influenced by halo in a given situation. If marketers could identify those consumers who exhibit high levels of halo in attribute judgements it might be possible to determine their susceptibility to advertising and other forms of marketing activity.

Background and Perspective

The first empirical research on measuring halo appears to have been done by Symonds (1925). He used partial correlations between traits to demonstrate that halo raised the correlations of trait ratings by .245 on the average. He speculated that large halo in a trait occurs if a trait is not easily observed or if it is not clearly defined. This line of research led to the view of halo as the excessive correlation between attributes. Unfortunately, as Bingham (1939) points out, some correlation between attributes is to be expected, and there seems to be no clear cut method to determine when the correlation is excessive. This approach usually led to factor analytical solutions where the first factor extracted was assumed to be a measure of overall attitude. The trait intercorrelations were then studied after this factor had been removed. Later research using this definition, such as

Keaveny and McGann (1975), focused on average correlations between attributes and attempted to lower these intercorrelations through instructions and training of raters.

A second approach to the measurement of halo is due to Guilford (1954) who viewed halo as an interaction between rater and object. Guilford (1954) defined several different types of errors which can occur when human raters are used. These errors are halo, leniency error, logical error and rater-trait error. Leniency error is defined as the tendency of a subject to overvalue or undervalue objects in general. Logical error occurs when subjects give similar ratings to objects on traits that appear to the subject to be closely related. Rater-trait error is defined as the tendency of a subject to overvalue or undervalue an object on a particular trait due to a favorable or unfavorable attitude towards the object. An analysis of variance design is then used to test for the rater by object interaction. This definition will overestimate halo to the extent that there are factors other than preference contaminating attribute judgements. An advantage of this approach is that a lack of a significant interaction term indicates the absence of halo.

A third approach to the measurement of halo, used by Brown (1968), focuses on the variance of ratings of an object across attributes. The higher the variance in ratings for an object, the less halo possessed by the object. It is important to note that this approach assumes that all attributes for a given subject are scored so that the subject views more as better. Thus, this approach requires a judicious choice of attributes or the measurement of preference for each subject so that it can be determined whether any recoding is in order for the halo measure. Unfortunately this measure does not indicate how little variance is needed for halo to be present. Wilkie and McCann (1972), and Wilkie, McCann, and Riebstein (1973) were the first to apply this approach in a marketing context. They found, among other things, that instructions could increase variance, that higher variance was found for the most preferred brand than for the other brands, and suggested that low brand familiarity contributes to low variance in ratings. Koltuv (1962) found that as familiarity decreases, halo increases, and that as halo increases the relevance of the trait increases. This is the only approach which has been used by both psychologists and by marketers.

A fourth approach to the study of halo is a regression model by Beckwith and Lehmann (1975) which has only appeared in the marketing literature. Their general findings agree with those from the industrial psychology literature. The most important contribution of this model is that it allows the assessment of the degree of halo exhibited by individual attributes for each subject. This approach views beliefs as being composed of a true belief rating, estimated from average belief scores, and halo error, estimated using preference. The model for an individual subject is given below:

$$B_{ij} = b_1 \bar{B}_{ij} + b_2 P_i + u_{ij} \quad (1)$$

where: B_{ij} is the belief rating for object i on attribute j

\bar{B}_{ij} is the average belief rating for object i on attribute j
 P_i is the preference for object i
 b_{1j} is the importance of the true value of the object on attribute j
 b_2 is the measure of degree of halo for the object on attribute j
 u_{ij} is random error
 All variables are standardized.

Purpose of the Study

The present study follows up on the Beckwith and Lehmann (1975) and the variance approaches. Specifically this paper investigates four areas:

- (i) The relation of the variance measure to both familiarity and preference within a subject.
- (ii) The convergence of the variance approach and the Beckwith and Lehmann (1975) approach.
- (iii) Whether halo is greater for attributes with less well defined physical correlates.
- (iv) Whether halo effects can be separated from misperceptions due to a lack of familiarity.

Data Base

Fourteen masters students rated seventeen cities on nine attributes plus familiarity. Then preference for the cities as places to work was measured using a technique described by Huber and James (1976), resulting in dollarmetric scale values of preference. The attributes were measured on 10 point Likert scales. The cities were selected from a list of 40 used in a pretest. The attributes and the dollarmetric scale were also pretested. In the variance analyses all attribute ratings were rescaled whenever necessary so that for each subject all attributes had positive correlations with preference. The nine attributes rated were: population; spectator sports; opportunities for indoor recreation; opportunities for outdoor recreation; cultural activities; warmth of the climate; pleasantness of the summer; pleasantness of the winter; and snowfall.

Results

- (i) Within subject analyses using the variance measure are presented in Table 1:

TABLE 1

Subject	Preference vs. Familiarity	Preference vs. Variance	Familiarity vs. Variance
1	.46*	.17	.26
2	.28	-.45*	-.18
3	-.22	-.10	.15
4	.42*	.59**	.43*
5	.27	.35	.20
6	-.33	.18	-.31
7	.74***	-.07	-.22
8	-.21	-.09	-.13
9	.33	.57**	.72***
10	.10	-.19	-.39
11	-.07	.10	-.10
12	.41	.42*	.34
13	-.13	-.08	.13
14	.44*	.19	.33

*significant at .10 level (2 tailed test)
 **significant at .05 level (2 tailed test)
 ***significant at .001 level (2 tailed test)

Since there are 14 subjects and only a few have significant correlations a reasonable way to test whether relationships exist is to perform a binomial test. Wilkie, McCann, and Reibstein (1973) found that the lowest preference had the lowest variance, therefore there are 3 correlations out of 14 that are significant at the .05 level for a one tailed test. The probability of 3 or more successes out of 14, given the probability of an individual success is .05, is .0300. Thus, the results are highly unlikely to be random perturbations. Rather, it is reasonable to conclude that a positive relationship exists between preference and variance. To test whether preference and familiarity are positively correlated we find that there are 4 significant positive correlations at the .05 level for a one tailed test. The probability of 4 successes out of 14 is only .0041. Thus it is unlikely that these came about by chance, and it can be concluded that preference and familiarity are positively correlated. To test whether halo is due to misperceptions of the product due to a lack of familiarity we note that there are 2 significant positive correlations at the .05 level for a one tailed test. The probability of 2 successes out of 14 is .1529, and is thus, likely to have occurred on a chance basis alone. Consequently the table does not offer any evidence that for this product there is a relationship between halo and familiarity.

- (ii) The degree of convergence between the variance approach and the Beckwith and Lehmann (1975) approach was assessed by converting the halo measures, b_2 in equation (1), into an overall measure for each subject. The overall halo measure was simply the sum of the absolute values of the individual b_2 . This measure of overall subject halo was then correlated with both the mean variance of a subject's ratings, and with the variance of the variance measure. The correlation of halo with the mean variance was $-.46$ ($p = .095$) and is in the expected direction. The variance of the variance measure was expected to be a better measure since it measured the dispersion rather than the absolute level of variance in product ratings. This variance of the variance measure was correlated $-.65$ ($p = .011$) with halo, and is in the expected direction. Thus, the two different halo measures agree and provide convergent measures of halo.

- (iii) In order to test whether those variables with less clearly defined physical correlates exhibited greater halo, the Beckwith and Lehmann (1975) measure was used. Table 2 shows the mean and variance for halo scores by attribute and by grouping:

TABLE 2

Attribute	Mean Halo	Variance of Halo
Population	.16	.04
Spectator Sports	.16	.01
Warmth of Climate	.14	.01
Snowfall	.15	.02
Indoor Recreation	.35	.06
Outdoor Recreation	.37	.06
Cultural Activities	.26	.04
Pleasantness of Summer	.39	.05
Pleasantness of Winter	.16	.01
4 Physical Attributes	.15	.02
4 Less Physical Attributes	.34	.06
5 Less Physical Attributes	.30	.05

Population, spectator sports, warmth of climate, and the amount of snowfall have clear physical correlates and were pooled for this analysis. Indoor recreation, outdoor recreation, cultural activities, and pleasantness of the summer were pooled as attributes with less

clearly defined physical correlates. When these two groups are compared, the less physical attributes had significantly higher halo scores ($t = 5.03$) at the .005 level. If pleasantness of the winter is pooled with the less physical attributes, the difference ($t = 4.26$) is still significant at the .005 level.

(iv) In an attempt to separate halo from perceptual error, familiarity was added to equation (1). It is assumed that familiarity reflects possible misperceptions due to random nonrepresentative experiences with the object. Table 3 shows the beta weights for a typical subject.

TABLE 3

Halo Versus Random Experiences Explanation

Attribute	Average Score		Preference		Familiarity	
	b	R	b	R	b	R
Population	.83	.96	-.29	-.14	.23	.45
Spectator Sports	.61	.81	---	.35	.42	.77
Indoor Recreation	.44	.22	.55	.88	---	.39
Outdoor Recreation	.29	-.23	.70	.44	---	.39
Cultural Activities	.54	.50	.54	.81	---	.40
Warmth of Climate	-.74	.22	-.32	-.84	---	-.31
Pleasantness of						
Summer	---	-.32	.75	.94	---	.17
Pleasantness of						
Winter	.96	.31	---	-.62	.14	-.08
Snowfall	.62	-.17	.45	.84	---	.27

b = beta weight, listed only if significant at .10
R = structural coefficient

The analysis indicates that familiarity is usually less important than halo as a contributor of error, and that for this product it is not tenable to attribute most of the halo to a lack of familiarity with the cities in the questionnaire.

Conclusion

The most important conclusion is the finding that both the variance measure, used fairly extensively in psychology, and the Beckwith and Lehmann (1975) measure correlate highly. The finding that halo was higher for variables with less clearly defined physical correlates implies that in order to change attitudes prior to trial of a product it may be necessary to focus on those attributes with clearly physical correlates. The low amount of halo found in this study indicates that there is wide variation in the amount of halo in different types of products, and that until more is known about which types of products are heavily influenced by halo each product will have to be investigated on its own.

ECONOMETRIC ESTIMATION OF HALO EFFECT:
SINGLE VS SIMULTANEOUS EQUATION MODELS

Albert C. Bemmaor (doctoral candidate), Purdue University
Joel C. Huber, Columbia University

Abstract

This paper analyzes a single equation model of belief as a function of preference and compares it to a simultaneous equation model. Using statistical tests, this study shows that the single equation model is well specified whereas the simultaneous equation model leads to statistically significant differences in the estimates.

The problem of measurement of halo effect has been extensively dealt with in the marketing literature. In a recent paper, Huber and James present a review of the different operational definitions of halo (Huber and James, 1976). Beckwith and Lehmann use econometric methodology to assess the halo effect (Beckwith and Lehmann, 1975). They analyze individual data on attitudes and beliefs towards television shows. After estimating a single equation model of the effect of beliefs on attitude, they use a simultaneous equation model to eliminate the "intertangled effects" of attitude and beliefs. Their study has given rise to criticism and further research in this area (Wittink and Ness, 1976; Johansson, MacLachlan and Yalch, 1976). The purpose of this paper is to test the Beckwith and Lehmann single equation model of the effect of beliefs on attitude for specification errors, and evaluate the implications of a misspecified model. In the first section, the Beckwith and Lehmann model is described. The second section briefly presents the specification error tests. The third section summarizes the results of these tests. In the last section, we assess the effect of a misspecified model on the parameter estimates.

Beckwith and Lehmann Simultaneous Equation
Model between Attitude and Beliefs

The Beckwith and Lehmann simultaneous attitude-belief model can be represented as follows:

$$A_i = \sum_{j=1}^n w_j B_{ij} + \gamma A_i^* + \mu_0 \quad (1)$$

where

- A_i = individual's attitude towards stimulus i
- B_{ij} = individual's belief towards stimulus i on attribute j
- A_i^* = average attitude of all persons towards the stimulus i
- n = number of attributes

and where the unknown parameters to be estimated are:

- w_j = weight of attribute j
- γ = weight of average attitude A_i^*
- μ_0 being a random disturbance.

The belief equations can be represented as follows:

$$B_{ij} = \beta_j A_i + \gamma_j B_{ij}^* + \mu_j \quad \text{for } j=1, \dots, n \quad (2)$$

where

B_{ij}^* = average belief about stimulus i on attribute j
the other variables being previously defined, and where the unknown parameters to be estimated are:

- β_j = importance of attitude in predicting belief B_{ij} or halo effect
- γ_j = importance of average belief B_{ij}^* to belief B_{ij}

In this paper, we focus our attention on equation (2), the question being: Is (2) well specified? Is it sufficient to estimate halo, or do we need to add (1)? To some extent, we are asking the problem in a direction opposite from that as posed by Beckwith and Lehmann since they consider whether equation (2) should be added to equation (1) in order to estimate the importance weights w_j . However, here, we are not concerned with the estimation of importance weights, but rather concerned with the estimation of halo. We will attempt to show that equation (2) is well specified and therefore is adequate to estimate halo without (1).

Specification Error Tests

The tests which are used have recently been developed by Ramsey (Ramsey, 1969; Ramsey, 1974). These tests detect the following kinds of specification errors: omitted variable, incorrect functional form, simultaneous equation problem, heteroskedasticity and normality of the disturbances. Consider the model:

$$y = X\beta + \mu \quad (3)$$

where y is an $N \times 1$ vector, X is an $N \times K$ matrix of rank K , β is a $K \times 1$ vector of coefficients and μ is an $N \times 1$ vector of disturbances. Ramsey denotes the Full Ideal Conditions assumed when using ordinary least squares estimation method on the model above as: i) the disturbance terms are normally distributed with mean zero and constant variance, and are independent, ii) they are independent of the explanatory variables, iii) the matrix $X'X$ is nonsingular.

In the case of misspecification of (3), these Full Ideal Conditions are violated. The tests consist in analyzing the residuals of the model in order to detect such errors. The five errors considered are broken down into three groups. Group A errors consist of omitted variable, incorrect functional form and the simultaneous equation problem. These errors lead to failure to fulfill the assumption that the mean of the disturbances is zero. Group B errors are those which lead to the violation of the assumption of constant variance of the disturbances, an example of which is heteroskedasticity. Group C errors are those in which the disturbances are not normally distributed so that the distribution of the regression coefficients is affected.

Three tests are used for the analysis: RESET (having a central F distribution), BAMSET (based on a central chi-square distribution) and WSET (whose critical bounds have been defined by Shapiro and Wilk (Shapiro and Wilk, 1965)). RESET is designed to detect Group A errors, BAMSET is used for the detection of Group B errors and WSET for the detection of Group C errors. Further details on these tests are provided by Ramsey (Ramsey,

1974). Ramsey and Gilbert suggest that RESET and BAMSET seem to be independent under BLUS residuals. On the other hand, BAMSET and WSET are not independently distributed under BLUS residuals but do appear so under OLS residuals (Ramsey and Gilbert, 1969).

Under the Full Ideal Conditions, the ordinary least squares residuals are distributed as $N(0, \sigma^2 M)$, i.e., they do not have a scalar covariance matrix. Therefore, an alternative estimator of the vector of disturbances μ can be used to detect specification errors via the analysis of residuals. The BLUS residuals $\tilde{\mu}$ (Best Linear Unbiased Scalar covariance matrix residuals) developed by Theil are such that $\tilde{\mu} \sim N(0, \sigma^2 I_{N-K})$ under the Full Ideal Conditions (Theil, 1965). Ramsey and Gilbert showed that for the case of omitted variable, incorrect functional form and simultaneous equation problem (Group A errors), the use of $y = X\beta + \mu$, $\mu \sim N(0, \sigma^2 I)$ as the true regression model leads to a BLUS residual vector distributed as $N(A'\tilde{\epsilon}, \sigma^2 I_{N-K})$ where $\tilde{\epsilon}$ is a nonstochastic vector the definition of which depends upon the particular misspecification, and A is an $(N-K) \times K$ matrix such that $A'X=0$, $A'A=I_{N-K}$ and $AA'=I-X(X'X)^{-1}X'=M$ (Ramsey and Gilbert, 1969). In the case of heteroskedasticity (Group B errors), i.e. $\mu \sim N(0, \sigma^2 \Omega)$, the distribution of $\tilde{\mu}$ derived from the use of $y = X\beta + \mu$, $\mu \sim N(0, \sigma^2 \Omega)$ as the true model, is $N(0, \sigma^2 A'\Omega A)$. Finally, in the case of nonnormality (Group C errors), the BLUS residuals are such that $\tilde{\mu} \sim D(0, \sigma^2 I_{N-K})$, D being any distribution other than the normal distribution. Comparing the performances of the test statistics using BLUS and OLS residuals, Ramsey and Gilbert recommend the use of BLUS residuals when the primary concern is about Group A errors (Ramsey and Gilbert, 1972). As we are mostly concerned about the problem of simultaneity between belief and attitude, BLUS residuals are used in this study.

Test Results

The data used in this study were collected by Huber and James (Huber and James, 1976). Individual analyses were made on the preferences of fourteen master students towards seventeen U. S. cities as sites for their first jobs. They were shown pairs of cities and asked in which they would prefer to live, given that work related variables such as opportunity for advancement were kept constant. A dollarmetric scale was developed for each individual and used as a measure of preference (Pessemier and Teach, 1966; Huber and James, 1976). Three attributes were chosen for analysis: size of the city, warmth of the climate and opportunities for spectator sports. These attributes were measured on ten-point Likert scales. The results of the tests for the first attribute "size of the city" are presented in Table 1. This table indicates the

TABLE 1
Ramsey test results for the Beckwith and Lehmann model* (size of the city)

Number of rejections (by column) 0 0 1 1

* An r indicates rejection of the null hypothesis of no specification error at the .1 level for a given test. An R in the column labeled DECISION indicates rejection of the hypothesis of no specification error for a given individual using model I because one or more of the test statistics rejected the null hypothesis.

number of times the null hypothesis of no specification error was rejected at an $\alpha = .10$. For each individual, the model is rejected when the null hypothesis of no specification error is rejected by one or more of the tests. These results are indicated in the column DECISION. For the first attribute, the null hypothesis is rejected only once (in favor of the alternative hypothesis of Group C errors). It should be noted that the null hypothesis is never rejected in favor of the hypothesis of Group A errors. Table 2 presents the test

TABLE 2
Overall performance of the Beckwith and Lehmann model for all three attributes

	Number of Rejections of H_0		
	in favor of Group A errors (RESET)	in favor of Group B errors (BAMSET)	in favor of Group C errors (WSET)

Warmth of the climate	2	1	2
Sports Opportunities	0	1	1
Proportion of rejections	2/42	2/42 2/42	4/42

results for all three attributes. In total, the null hypothesis of no specification error is rejected only twice against the alternative hypothesis of omitted variable, incorrect functional form and simultaneous equation problem (Group A errors). Also, for Group B errors, the Beckwith and Lehmann model is misspecified in two cases only. The assumption of normality of the residuals, tested by WSET, seems to be the most critical one, as evidenced by the number of rejections of the null hypothesis. Table 3 indicates the number of rejections

TABLE 3

* An R in any given column indicates that the specified model was rejected when applied to the indicated individual.

for each individual. Except for Individual 4, the Beckwith and Lehmann model seems to be appropriate for at least two attributes out of three. The major result of this analysis is that equation (2) appears to be well specified for most individuals. Despite the fact that

the simultaneous equation model might make theoretical sense, it is contradicted by the empirical evidence with this set of data.

A Monte Carlo analysis of the small sample properties of the tests discussed here is reported in Ramsey and Gilbert (Ramsey and Gilbert, 1972). The basic conclusion is that RESET and BAMSET are reasonably powerful tests against their respective alternatives. The small sample properties of WSET have also been examined by Monte Carlo analysis (Ramsey and Gilbert, 1969). The tests are capable of differentiating between Group A, Group B and Group C errors. However, it is not possible to discriminate between errors within a given group. Hence, the rejection of the model by RESET for two individuals (see Table 2) may not necessarily be due to the simultaneous equation problem but implies the presence of Group A errors in the model. On the other hand, acceptance of the null hypothesis against the hypothesis of a given group of errors implies that all the types of errors comprised in that group are excluded from the model.

Effect of a Misspecified Simultaneous Equation Model on the Parameter Estimates

Summarizing the findings of their study, Beckwith and Lehmann state: "The TSLS regression results indicated that ... for the six belief equations ... the regression coefficients (remained) relatively unchanged from OLS, on average" (Beckwith and Lehmann, 1976). Hence, their model specification does not seem to have much affected the estimates of the halo effect β_j and of γ_j . The TSLS estimates of β_j and γ_j were calculated and compared to the OLS estimates.¹ Table 4 presents these estimates

TABLE 4
Comparison of OLS and TSLS estimates of β and γ for "size of the city" (standard errors in parentheses)

	OLS β	TSLS β	OLS γ	TSLS γ
Individual 1	-.3107 ^a (.348)	.2199 (.489)	1.0627 (.254)	1.0234 (.276)

Individual 12	.0225 ^a (.077)	.1036 (.098)	1.3400 (.143)	1.3512 (.149)
Individual 13	-.0705 ^a (.142)	.1010 (.228)	.7835 ^d (.167)	.8833 (.202)
Individual 14	-.1224 (.055)	-.1198 (.068)	1.0296 (.116)	1.0290 (.116)

¹ In this study, for all fourteen individuals, the range of the identification statistic $W\beta$ is between -4.9033 and .3154. $W\beta$ never being equal to, the structural model is identified for each individual.

^a Difference significant at $\alpha < .01$
^b Difference significant at $\alpha = .05$
^c Difference significant at $\alpha = .10$
^d Difference significant at $\alpha = .20$

for the first attribute, "size of the city". As shown by the results of the t-tests, the differences between the OLS estimates and the TSLS estimates of the halo effect β_j are statistically significant for most individuals. On the other hand, the estimates of the coefficient γ_j of B_{ij} do not change much. The results of the tests of significance of the differences between the two estimates for all three attributes are summarized in Table 5. This table shows that, in contrast to the Beck-

TABLE 5
Results of the tests of significance of the differences between the OLS estimates and TSLS estimates of β and γ for all three attributes

	$\alpha < .01$	$.01 < \alpha < .05$	$.05 < \alpha < .10$	$.10 < \alpha < .20$	Not significant	Total
β	14 (33.3%)	3 (7.1%)	3 (7.1%)	2 (4.8%)	20 (47.6%)	42 (100.0%)
γ	4 (9.5%)	1 (2.4%)	0 (0%)	3 (7.1%)	34 (81.0%)	42 (100.0%)

with and Lehmann results, our estimates of γ_j do not change much, but significant differences occur in the estimates of the halo effect. This means that the TSLS halo estimates cannot be accepted.

As to the attitude equation (1), Beckwith and Lehmann summarize their results by stating: "(T)he attitudes of less than half of the respondents could be explained with positive R^2 's by the TSLS estimated model. We concluded that the linear attribute model is false for at least a substantial fraction of the respondents in this study" (Beckwith and Lehmann, 1975). They argue that "the removal of the halo effect, as in the TSLS estimates, reduced the diagnostic and explanative power of (the attitude equation) for many people" (Beckwith and Lehmann, 1976). It should be mentioned at this point that very small values of the multiple correlation coefficient do not indicate a "poor fit" or lack of significance of the set of explanatory variables in the structural equation. As R^2 is constrained only to the interval $(-\infty, 1)$ large negative values can easily occur, but "negative values certainly do not discredit the model in any meaningful way" (Basmann, 1962; Tomek, 1970). Hence, the Beckwith and Lehmann conclusions seem to be questionable.

In order to assess the robustness of the Beckwith and Lehmann model of the effect of attitude on belief, the "average belief" variable was replaced by the "true" value for all three attributes, and the OLS estimates of the halo effect in the two alternative models were compared. The results which are not reported here show that both estimates are generally very close. On the other hand, the explanatory power of the Beckwith and Lehmann model is generally higher than that of the alternative model. Hence, the effect of the "average belief" variable B_{ij} is to provide an upward bias in the level of explanatory power of the belief equations. This may be partly due to the similar nature of the explanatory variable and the dependent variable.

In conclusion, a single equation model of the effect of attitude on beliefs about cities seems to be well specified according to our test results. Furthermore the

specification of the model - whether a single or a simultaneous equation - seriously affects the halo estimates. A similar type of model testing procedures could be carried out in another context, such as the modeling of the relationship between sales and advertising. In general, these testing methods should prove useful to the assessment of the functional relationships between marketing variables.

A STUDY OF THE AMOUNT OF HALO
IN THE PERCEPTIONS OF AUTOMOBILES

William L. Moore, Columbia University
William L. James, University of Alabama

Abstract

Only a small amount of halo was found in attribute judgments of automobiles using a methodology similar to Beckwith and Lehmann. The amount of halo found in perceptual spaces formed through either attribute or similarity judgments was found to be about equal and low in both cases.

Introduction

Multiattribute models have been used by marketers in an attempt to explain the preferences for objects by the amount of certain attributes that the objects are perceived to possess. While the studies have found that the models generally have good predictive power, a disturbing aspect of these studies has been that respondents have a tendency to rate objects they prefer higher than expected on desirable attributes.

This tendency generally increases the within subject correlation between belief scores on different attributes and it also increases the within subject correlation between the belief scores on attributes and the preference measure. This limits the multiattribute model's value as a diagnostic tool because the dimensionality of the attribute structure of the product class is confounded, as is the analysis of brand strengths and weaknesses. Similarly, if halo effects are present in data used to build perceptual spaces, they will be distorted and attempts to position products in "halo spaces" could be dangerous.

The purposes of the paper are twofold. First, is to study the amount of halo in attribute judgments of automobiles in a manner similar to Beckwith and Lehmann (1975) to determine if their findings are replicated in a very different product category. Second, to compare the amount of halo found in perceptual spaces built with similarity judgments with spaces constructed from attribute ratings.

Background

Psychologists have been aware of the presence of halo for over 50 years (Thorndike, 1920). Much of their work has focused on methods of measuring the amount of halo in trait ratings. This has been done by measuring the correlations between trait ratings (Symonds, 1925; Bingham, 1939; and Keaveny and McGann, 1975) and by measuring the variance of ratings across traits for a given object (Brown, 1968, and Wilkie, McGann, and Reibstein, 1973). A review of their studies is in Huber and James (1976) and won't be repeated.

Beckwith and Lehmann (1975) used a series of regression equations to study beliefs about the attitudes toward television shows. In the first equation they modeled an individual's attitude toward a T.V. program as a function of his beliefs about the program and the sample average attitude toward it

$$A_i = \sum_{j=1}^N \omega_j B_{ij} + \gamma A_i^* + u_i \quad (1)$$

where

A_i is the individual's attitude toward the i th program,

B_{ij} is the individual's belief about the i th program on the j th attribute,

A_i^* is the average attitude toward the i th program,

ω_j is the weight of the j th attribute,

γ is the weight of the average attitude, and

u_i is the disturbance term.

In the remaining equations the individual's beliefs about the attribute levels possessed by a program were modeled as functions of the sample average beliefs about the attribute levels and the individual's attitude toward the program.

$$B_{ij} = \beta_j A_i + \gamma_j B_{ij}^* + u_j \quad j = 1, \dots, N \quad (2)$$

where

B_{ij} , A_i , and u_j are as above,

B_{ij}^* is the average belief about the i th program on the j th attribute, β_j is the weight of individual attitude, and γ_j is the weight of the average belief.

The coefficients of the seven equations (one for attitude and one for each of the six attributes) were estimated using ordinary least squares. These equations were then estimated as a simultaneous system. While the simultaneous system was under identified for some individuals, similar parameter estimates were obtained with the two methods.

Beckwith and Lehmann found that the variation in an individual's beliefs about the attribute levels of a program could be modeled as a function of the sample average beliefs about the attribute levels and the individual's attitudes toward the program. While the regression coefficients associated with the average beliefs were usually larger than the coefficients associated with overall attitudes, they were of roughly the same size. These results indicated that a person's perception of or beliefs about an object can be explained almost as well by knowing what his attitude toward the object is as by knowing what the average perception of the object is.

There has been some criticism of the simultaneous equation methodology and behavioral interpretation (Johansson, MacLachlan, and Yalch, 1976). However, there seems to be little disagreement that there is a systematic relationship between average attribute beliefs, individual attitudes and individual attribute beliefs. This is not to imply that people know what the average beliefs are and that they consciously distort their judgments, but just that there is some systematic variation in individual attribute beliefs.

Data

Judgments on perceptions and preferences for ten automobiles were collected from forty junior and senior marketing students. Each student rated each automobile on ten attributes using a ten point Likert scale. Similarity judgments were also collected on a ten point scale. The ten automobiles and the ten descriptive attributes are given in Table 1.

TABLE 1
List of Brands and Attributes

Brands	Attributes
Cadillac	Gas mileage
Camaro	Style and appearance
Chevrolet Impala	Driver comfort
Ford Granada	Popularity with friends
Mercury Montego	Sensibleness for people on budgets
MG	Power and performance
Mustang	Dealer support
Toyota Corona	Value
Volvo 144	Handling
Vega	Purchase price

Preference measures were collected using Pessemier's dollar metric technique (Pessemier, Burger, Teach, and Tigert, 1971). Each student was asked which one of a pair of automobiles would be purchased upon graduation if he had to choose between those two. Then he was asked how much would the price of his choice have to increase before he would change his decision.

Subjects were first screened on their stated knowledge of the cars in the survey. Then they were screened based on a lack of pattern filling out the attribute ratings. Finally, these preference judgments were converted into the best fitting linear preference scale and only those subjects whose preference judgments were significantly different from random (Bechtel, 1967, Pessemier and Teach, 1970) were kept. Six subjects were eliminated through this screening.

Amount of Halo in Attribute Ratings

The first objective of this study is to determine if the results of Beckwith and Lehmann (1975) were idiosyncratic to the T.V. data, or if these findings are typical of the amount of the halo to be found in attribute judgments of other product classes. In doing this, the individual's beliefs about attribute levels of a brand were modeled as a linear function of the average beliefs about the attribute levels of the brand and the individual's preference for the brand. This is equation (2) above.

These regressions were estimated separately for each individual using OLS. The individual coefficients were aggregated across all the subjects and these aggregate results are presented in Table 2.

TABLE 2
Estimated Coefficients of the Belief Equations

Attribute	Average Belief Coefficients		
	$\bar{\gamma}_j$	$ t $	Number of times significant out of 34
Gas mileage	.855	4.31	34
Style & appearance	.648	2.84	24
Driver comfort	.723	3.66	25
Popular with friends	.441	1.77	12
Sensible for people on a budget	.470	1.77	15
Power & performance	.658	3.55	27
Dealer support	.530	2.01	19
Value for the money	.669	2.80	24
Handling	.654	2.40	17
Price	.633	2.28	21

Attribute	Overall Attitude Coefficients		
	$\bar{\beta}_j$	$ t $	Number of times significant out of 34
Gas mileage	.000	.94	4
Style & appearance	.055	1.23	6
Driver comfort	.027	1.09	6
Popular with friends	.028	.87	1
Sensible for people on a budget	-.105	.59	1
Power & performance	-.001	.79	2
Dealer support	.108	1.03	2
Value for the money	.086	.93	5
Handling	.034	.81	2
Price	.040	.85	4

The average standardized regression coefficients and average absolute values of the t statistics are much larger for the belief variable than the attitude variable for every attribute. In addition to the regression coefficients associated with the average belief measures being much larger, they are also significantly different from zero a much higher proportion of the time in the individual regressions than the coefficients associated with attitude.

In contrast to the Beckwith and Lehmann study, the halo effect appears to be relatively unimportant.

Halo in Product Spaces

If there is a halo effect biasing attribute judgments, then product spaces constructed using either discriminant analysis (Johnson, 1971) or factor analysis (Urban, 1975) would also contain halo. The effects of halo on judgments of overall object similarity has not been researched. However, it has been hypothesized (Beckwith and Lehmann, 1975) that product spaces built from similarity judgments would contain less halo than product spaces constructed using attribute judgments. This hypothesis was explored by constructing both aggregate and individual perceptual spaces then modeling the location of an object along a dimension in the individual space as a function of the object's location on the corresponding dimension in the aggregate space and the individual's attitude toward that object. This gave an equation analogous to equation (2) above.

$$X_{ij} = \beta_j A_i + \gamma_j X^*_{ij} + u_j \quad (3)$$

where

X_{ij} is the location of the i th object on the j th dimension of the individual space,

X_{ij}^* is the location of the i th object on the j th dimension of the aggregate space,

A_i is the individual's attitude toward the i th object,

U_j is the disturbance term, and

β_j and γ_j are regression coefficients.

Similarity Judgments

Similarity judgments for each of the 34 respondents were transformed into individual perceptual spaces using KYST (Kruskal, Young, and Seery, 1973). An aggregate similarity matrix was formed by averaging the pair-wise similarities over all the respondents. This matrix was used to form the aggregate perceptual space. Each of the individual spaces were rotated and reflected to a position of maximum congruence with the average space using a program based on Schönemann's solution to the Orthogonal Procrustes Problem (Schönemann, 1966). Then equation (3) was used to determine the relative importance one individual's preference and average perceptions in modeling individual perceptions.

Attribute Ratings

A reduced space description of the attribute ratings was formed through discriminant analysis. In this application of discriminant analysis, the brands under study were the groups and the discriminant functions were the linear combinations of the attributes that maximally separate the brands in the produce space. The location of the i th brand in the aggregate produce space X_i^* was found by multiplying the matrix, D , whose columns contain the discriminant vectors, times the vector of average attribute ratings B_i .

$$X_i^* = D' B_i \quad (4)$$

Similarly, the location of a brand in an individual product space, X_i , was found by multiplying the matrix D times the vector, B_i , containing that individual's beliefs about the attribute ratings for the brand

$$X_i = D' B_i \quad (5)$$

Equation (3) was used to determine the relative ability of individual preferences and average perceptions to model individual perceptions. These regressions were run for two dimensions in the product spaces for each individual and the results were aggregated across individuals and presented in Table 3.

TABLE 3
Estimated Coefficients of the
Product Space Coordinates

Model	Dimension	Average Coordinate Coefficients	
		$\bar{\gamma}_j$	$\bar{ t }$
Attribute	1	.864	6.47
Similarity	1	.824	5.71
Attribute	2	.743	3.81
Similarity	2	.492	1.81

Model	Dimension	Overall Attitude Coefficients	
		$\bar{\beta}_j$	$\bar{ t }$
Attribute	1	-.04	1.18
Similarity	1	-.102	1.39
Attribute	2	-.119	1.11
Similarity	2	.113	.99

In both methods of modeling perceptions, the average perceptions dominate the effect of preference. Comparing the t statistics, the average beliefs are a stronger influence in the attribute models and the effect of the preference component appears to be about the same in either case. It appears that there is little distortion due to halo in either method of constructing produce spaces and there would be little danger of positioning a product in a "halo space".

Conclusions

While these results aren't necessarily generalizable to the general public or to other product classes, this paper has shown that the amount of halo in attribute models may be quite low. These results also indicate that there may be only a very small danger of positioning some products in halo spaces.

Previous studies have indicated that certain types of attributes may be more susceptible to halo than other types: those without a clear physical analogue (Huber and James, 1976) vague, ambiguous and less important (Beckwith and Lehmann, 1975). Two more types of attributes that may give excessive halo are affective attributes (style and appearance) and the attributes that people have little knowledge of (dealer support).

It is also possible that some product classes generally have a greater degree of distortion due to halo than others. Frequently purchased goods may be routinely purchased without much thought of the attribute levels that different brands possess. When people are asked to make attribute judgments about these products, their responses may be more distorted by halo than their responses about the attribute levels of products that are purchased with more thought. Halo may be more of a problem in product classes where the differences between brands are fairly small, but much less of a problem in product classes with significant differences.

A useful area for future research is a thorough investigation of the amount of halo in attribute judgments of different produce classes. Also, while this study has shown that there is little difference in the amount of halo in attribute and similarity judgments, this topic deserves further study.

EMPIRICAL EVIDENCE OF HALO EFFECTS IN
STORE IMAGE RESEARCH BY ESTIMATING TRUE LOCATIONS*

Neil E. Beckwith, University of Pennsylvania
U. Victor Kubilius (Ph.D. Candidate), University of Pennsylvania

Abstract

Individuals' judgments and responses often reflect many factors, such as their overall attitude toward the object being judged, its popularity, their familiarity with it, etc. These biases are similar to the well-known halo effect—an individual's tendency to bias his responses about an object on any specific attribute by his general, overall (global) impression. This article describes a procedure for estimating locations of the judged objects corrected for these types of halo-like effects.

Introduction

Marketing researchers and psychologists frequently attempt to obtain evaluations or locations of particular alternatives (individuals, objects, concepts, or brands) on particular attributes (traits, factors, variables, or characteristics), as in image studies, attitude models, and product attribute positioning models (Fishbein and Ajzen, 1975; Huber and James, 1977; Rosenberg, et al, 1960). Convenient estimators of these locations are the averages of many individuals' responses on the attribute. However, individuals may commingle their knowledge about the objects on many different attributes, and thereby provide response ratings on each attribute which are biased. Such biases may be due to their evaluations on other attributes, their overall evaluation of the object, its popularity, their usage or familiarity with it, their beliefs about other people's assessment of the object (peer attitude), cognitive dissonance (Festinger, 1957), or consistency maintenance (Rosenberg, et al, 1960). The resulting averages may thereby be biased.

The halo effect is well recognized by psychologists and has been defined as the "tendency in rating to be influenced by general impression or attitude when trying to judge separate traits" (English, 1934). Additional halo-like systematic response biases may be associated with other sources.

We demonstrate a method for obtaining estimates of the locations of objects on particular attributes. We refer to these as estimates of the true or actual location of the objects on the attribute, even though the attribute may be subjective.

Basically, our objective is to use individuals' responses, which indicate their rating of an object on an attribute, to construct an estimate of the unmeasured (true or actual) location of the object on the attribute. We assume that individuals' responses are a function of the (true) location as well as a function of other variables. First, we estimate each individual's response function and then use an iterative technique to estimate the (true) locations of the objects across all individuals.

The store image data which was conveniently available to

*The authors are indebted to Charles D. Goldfine and Karen E. Jakubowski (1977), who originally collected the data and made it available to us for this further analysis, and to Randy Batsell, who critically reviewed an earlier draft.

us has ordinal (ranking) rather than interval (rating) scales on some variables. Since the method we use assumes intervally scaled data, the empirical example is included only for illustration of the methodology. We draw no substantive inferences from it.

Background

The halo effect is well known to psychologists. Thorndike (1920) noted that an individual tends to rate another person on an attribute by his perception of the person on some other attributes. Similar halo-like effects occur in many other circumstances. Bass and Talarzyk (1972) reported that respondents indicated higher average belief scores on attributes for their preferred brands than for less favored brands. Beckwith and Lehmann (1975) demonstrated that respondents also halo their responses when asked to rate television shows as commonly done in the product positioning attribute models. Bass and Wilkie (1973) suggested that the halo effect on indicated brand beliefs may partially explain why importance weights do not seem to add significantly to the predictive performance of such attitude models. In contrast, Moore and James (1977) found halo effects to be relatively unimportant in students' ratings of automobiles. A summary of halo effect research and implications is available elsewhere (Beckwith, Kassarian, and Lehmann, 1977).

Store image studies provide a convenient example of attribute (i.e., trait) measurement problems and are of practical importance since objective measures on many of the attributes are difficult or impossible to obtain.¹

Two recent investigations provided considerable motivation for the present study. Huber and James (1976) pointed out that cross-sectional averages of halo-biased ratings on an attribute are also biased because the alternative objects (such as stores or brands) will generally be favored by different proportions of the respondents. Peterson (1976) found such a haloing effect in six studies of retail store images where average ratings on many attributes were correlated with the market shares of the retailers in their geographic marketing areas. We attempt to obtain less biased estimates of the objects' locations on attributes by considering both relative usage and overall attitudes in the sample of respondents.

Model

In this section we develop an example of a class of models useful for estimating the true (or actual) locations of objects on specific attributes. The example selected is both rather simple and readily extendable to more elaborate functional forms if warranted.

¹Examples of store image studies include those reported by Hawkins, Albaum, and Best (1975-76), Jain and Etgar (1976-77), Kunkel and Berry (1968), Lessig (1972), Linquist (1974-75), May (1971), Sharma and Doyle (1977), and Staples and Lockander (1975-76). Readers are also referred to the Special Store Image Issue of the Journal of Retailing (Winter 1974-75).

As a simple illustration we examine a model having only three components.² First, each object j has an actual location T_{jk} on each attribute k . T_{jk} may be thought of as the true location of the object on the attribute. Respondents may have been exposed to the object, and thereby exposed to cues of T_{jk} (see Castellan, 1973). The analyst is attempting to estimate T_{jk} .

Second, individual i 's evaluation E_{ijk} of object j on each attribute k reflects influences of many other variables besides T_{jk} . For purposes of this example, assume a simple linear transformation:

$$E_{ijk} = b_{i0k} + b_{i1k}A_{ij} + b_{i2k}U_{ij} + b_{i3k}T_{jk} \quad (1)$$

where A_{ij} = individual i 's overall evaluation of object j ,

U_{ij} = individual i 's usage of object j ,

$b_{i \cdot k}$ = individual i 's weighting coefficients,

T_{jk} = location of object j on attribute k .

The $b_{i1k}A_{ij}$ component corresponds to the usual halo effect. The $b_{i2k}U_{ij}$ component is included as an example of other halo-like biasing effects.³

Third, we assume that each individual's response B_{ijk} is a linear function of his evaluation E_{ijk} plus a disturbance e_{ijk} :

$$B_{ijk} = a_{i0k} + a_{i1k}E_{ijk} + e_{ijk} \quad (2)$$

Each individual uses his own linear scaling transformation with coefficients a_{i0k} and a_{i1k} . Disturbances e_{ijk} are independently distributed with mean zero and idiosyncratic variance σ_{ijk}^2 . Basically, this is a linear accommodation of the different response scales which individuals may employ to determine their own responses B_{ijk} based on their own evaluations E_{ijk} .

Substituting (1) into (2) yields the reduced form equation:⁴

$$B_{ijk} = \beta_{i0k} + \beta_{i1k}A_{ij} + \beta_{i2k}U_{ij} + \beta_{i3k}T_{jk} + e_{ijk} \quad (3)$$

The variables B_{ijk} , A_{ij} , and U_{ij} are respondent i 's indicated responses (data). However, T_{jk} , not empirically observable, is to be estimated. A naive estimator of T_{jk} is \bar{B}_{jk} , the average across all i respondents (Beckwith and Lehmann, 1975). However, Huber and James (1976) have pointed out that such an estimator is biased

²The more general linear model is presented at (4). Here we display the special case used as an example.

³In our empirical work we originally attempted to include three separate effects: Store of Last Purchase, Store of Most Frequent Purchase, and Most Convenient Store. However, for most subjects these variables were too collinear. We settled on the single usage measure, Store of Most Frequent Purchase. Similar results were obtained with all three measures of usage except for the Value attribute.

⁴Where $\beta_{i0k} = a_{i0k} + a_{i1k}b_{i0k}$, $\beta_{i1k} = a_{i1k}b_{i1k}$, etc.

because it neglects the differing fractions of respondents favoring each brand. Thus, we elect to estimate T_{jk} cross-sectionally.

Estimation Method

Consider a simple response function for individual i on one attribute k . Dropping the k subscripts for the moment:

$$B_{ij} = \sum_{\ell} \beta_{i\ell} X_{ij\ell} + \beta_{iT} T_j + e_{ij} \quad j = 1, \dots, J \quad (4)$$

where i 's response B_{ij} about object j is determined as a function of L independent intervally scaled variables $X_{ij\ell}$, $\ell = 0, \dots, L$ (including the intercept), and also as a function of the location T_j of object j . The independent variables $X_{ij\ell}$ could include the overall evaluation of the object j (like-dislike), preference, popularity of market share, peer attitudes or i 's belief about them, familiarity, etc. We seek to obtain estimates \hat{T}_j for each $j = 1, \dots, J$. These initial guesses could be chosen arbitrarily. We could use them to estimate all the β s in (4) for an individual i by an ordinary least squares (OLS) regression across the J objects, or perhaps by some other method. If we then examine i 's residuals $R_{ij} - \hat{R}_{ij}$ we would find them to be positive for some objects and negative for others. Assuming $\hat{\beta}_{iT} > 0$, we would then tend to guess that the corresponding original guess about T_j was too small (i.e., too negative) for those objects j with $\hat{e}_{ij} > 0$ and that the corresponding original guess about T_j was too large (i.e., too positive) for those objects j with $\hat{e}_{ij} < 0$.⁵

Instead of using \hat{e}_{ij} s from just one individual to improve the guesses about the T_j s, we suggest that the \hat{e}_{ij} s be obtained for many individuals and that a \hat{T}_j should be increased if $\sum_i \hat{e}_{ij} > 0$ and decreased if the sum of residuals for the object is negative, assuming the $\hat{\beta}_{iT}$ s are generally positive. The scale for \hat{T}_j and $\hat{\beta}_{iT}$ is arbitrary. To resolve this ambiguity, we simply constrain the \hat{T}_j scale to be standardized with zero mean, unit variance, and sign such that $\hat{\beta}_{iT} > 0$.⁶

Thus, this procedure starts from an original set of arbitrary values for the \hat{T}_j s. The β s of the response function are estimated for each individual by OLS. The \hat{T}_j s are then revised. We used the updating rule:

$$\hat{T}_j = \frac{\sum_i [B_{ij} - \sum_{\ell \neq T} \hat{\beta}_{i\ell} X_{ij\ell}]}{\sum_i \hat{\beta}_{iT}} \quad j = 1, \dots, J \quad (5)$$

The procedure is then repeated with the new \hat{T}_j s replacing the previous values until convergence, when $\sum_i \hat{e}_{ij} = 0$. Finally the signs of the \hat{T}_j s are selected such that $\hat{\beta}_{iT} \geq 0$, and the final \hat{T}_j s are scaled to have zero mean and unit variance.

In our example, the procedure converged to the same final locations regardless of the initial \hat{T}_j s arbitrarily selected. Since the procedure estimates (4) for each individual i separately, rather than conjoining them

⁵Of course, we could easily obtain all $\hat{e}_{ij} = 0$ $j = 1, \dots, J$ for any one particular individual i by rigging the \hat{T}_j s. However, we cannot usually find a set of \hat{T}_j s which will drive all $\hat{e}_{ij} = 0$ for many individuals.

⁶In retrospect we feel it might be better to constrain the estimated locations \hat{T}_j to a scale of zero-one, rather than standardizing to zero mean and unit variance. Negative locations seem to make communication of findings more difficult.

into some kind of a big pooled regression, each iteration of the estimation requires only a modest sized regression. Thus, the procedure can be performed on very modest computers, even for very large samples.

Data

The data used in this study were collected by Goldfine and Jakubowski (1977) as part of an advanced study project at The Wharton School, University of Pennsylvania. They investigated the homogeneity of store images and the degree of halo effect upon these store images within a convenience sample of professional women.

Although the methodology is designed to address substantive issues, our purpose here is only to display the methodological procedure. We use this convenient data base as a means of illustrating the application of the procedure. The reader is cautioned to consider this report as only illustrative of the types of results possible. The names of the stores (objects) are included only to facilitate understanding of the procedure.

The sample was obtained mainly on a convenience basis. It consisted of 43 women who resided in the greater Philadelphia area, and were employed in professional/administrative capacities or were studying toward that goal. Some of the respondents were acquaintances of the researchers. Responses from 9 of the women were not used due to missing data or errors. Also, individuals who indicated equal beliefs toward all 10 stores on an attribute were eliminated from analysis of that attribute since regression estimates of their weights were not possible. The 10 stores included diverse types familiar to many of the respondents.

Belief Responses B_{ijk}

The respondents were questioned about the 10 stores on 8 attributes.⁷ The attributes were selected on an a-priori basis. Thus, they are only illustrative of the types of attributes individuals might consider in making store evaluations. Each respondent i indicated her belief B_{ijk} about each store j on each attribute k using a five-point ("Outstanding" = 4, "Unacceptable" = 0) scale which we assumed to be an interval measure. The questionnaire items used to measure two of these attributes, Convenience and Fashionability of Merchandise, were worded such that the individual's differing ideal points (or home/work site) preclude assumption of the existence of a true location of a store on the attribute for all individuals.⁸ In addition, one of the usage measures, Most Convenient Store, also solicited convenience information. Consequently, estimates for these two attributes are not reported here.

Attitude A_{ij}

Each respondent indicated her overall evaluative ranking of each store ("Most Preferred" = 9, "Least Preferred" = 0, no ties). This measure is, of course, only ordinally scaled. However, we used it as if it were an intervally scaled variable for purposes of illustrating the methodology.

Usage U_{ij}

Three different measures of each individual's store

⁷See Table 2 for the list of stores and attributes. The standardized average beliefs \bar{B}_j across all individuals are displayed as \bar{B} in the tables. Raw, rather than standardized, belief, attitude, and usage variables were used in the estimation procedure.

⁸See the Appendix for questionnaire wording.

usage were available: (1) Store of Last Purchase, (2) Store of Most Frequent Purchase, and (3) Most Convenient Store. These variables were coded as dummies (an indicated store = 1, otherwise = 0). Since these three variables measure somewhat different constructs, we would advocate using all three within the analytic procedure. However, in this small set of data, the variables were too collinear to permit their simultaneous inclusion. For purposes of comparison, we included them each one-by-one as a single measure of usage in separate analyses. These usage variables do not meet the interval scale assumption.⁹

While these particular data from a convenience sample are not exactly consistent with the model's assumptions, they are adequate to simply illustrate the methodological procedure.

Illustrative Application

The Quality of Merchandise attribute is used in an example of the procedure. We selected the second operationalization (Store of Most Frequent Purchase) as the measure of usage. Other attributes and the importance of the halo effect are then examined in subsequent sections.

Quality of Merchandise Attribute

In lieu of the yet unavailable locations T_j we selected the cross-sectional averages \bar{B}_j for the initial arbitrary starting point. We then used OLS to estimate $\beta_{i,ks}$ in (3) for each particular individual (one at a time). The 10 stores were used as 10 observations. The OLS estimated coefficients (and standard errors) for one particular individual were:

$$B_{ijk} = -.48 - .03A_{ij} + .28U_{ij} + 1.48\bar{B}_{jk} + \hat{e}_{ijk},$$

(.18) (.07) (.36) (.19)

$$R^2 = .98 \text{ (unadjusted).}$$

This procedure is replicated for each individual in the sample. The resulting residuals do not sum to zero across individuals for each store. For example, here the sum of residuals $\sum_i \hat{e}_{ijk} = .10$ for the first store, Bonwit Teller. Using an updating rule, such as (5), the estimates of T_j s are revised away from \bar{B}_{jk} , and the OLS regressions are then repeated for all individuals. Eventually, the procedure converges to final estimates of the true locations \hat{T}_j . For this same individual the final estimated coefficients (and standard errors) were:

$$B_{ijk} = 1.64 + .15A_{ij} - .28U_{ij} + .92\hat{T}_{jk} + \hat{e}_{ijk},$$

(.23) (.05) (.34) (.13)

$$R^2 = .98 \text{ (unadjusted).}$$

After convergence the sum across individuals of the final residuals is zero for each store, e.g., $\sum_i \hat{e}_{ijk} = 0$, $j = 1, \dots, J$.

Although the analysis yields estimates like these for each individual, such results are too bulky to report in detail.¹⁰ Figure 1 displays the distribution of $\hat{\beta}$ s, standard errors, and t-statistics ($H_0: \beta_{ilk} = 0$) obtained for all 34 individuals. With only 10 objects

⁹For an individual having usage variable value of 1 for only one store, that store is essentially ignored in estimating the individuals' coefficients $\beta_0, \beta_1, \beta_3$, and determines $\hat{\beta}_2$. Some individuals indicated multiple stores.

¹⁰Final R^2 s exceeded initial R^2 s for about half of the respondents on all attributes.

^aUsing the second usage measure (Store of Most Frequent Purchase).

(stores) the standard errors tend to be rather large. Even so, of the 34 t-statistics for $\hat{\beta}_1$, for example, 12 exceeded the critical value 2.447 for 6 degrees of freedom at the 95 percent confidence level. Since it is unlikely that this many estimated coefficients would have $|t| \geq 2.447$ by chance alone, we conclude that β_1 cannot be equal to zero for all individuals, although it could be zero for some individuals. Thus, we conclude that the halo effect cannot be ignored here.

Figure 2 displays the distribution of unadjusted R^2 obtained for these individuals, which ranged from .54 to .98. Averages of these statistics are summarized in the

FIGURE 2

^aUsing the second usage measure (Store of Most Frequent Purchase), R^2 s are not adjusted.

bottom portion of Table 1, column 2. Columns 1 and 3 display similar average results for analyses using the other two measures of store usage: Store of Last Purchase (#1) and Most Convenient Store (#3), in place of Store of Most Frequent Purchase (#2).

The average response \bar{B}_{jk} and estimated true locations \hat{T}_{jk} of the 10 stores on the Quality of Merchandise attribute are displayed at the top of Table 1. Note that the estimated locations \hat{T}_{jk} were very similar to the average responses \bar{B}_{jk} for several of the stores. However, for Nan Duskin, Gimbels, and Wanamaker, the estimated locations \hat{T}_j were noticeably different from the average responses \bar{B}_j . Nan Duskin is one of the less frequented stores; none of the respondents mentioned it as being either the Store of Last Purchase or Store of Most Frequent Purchase. Thus, it is not surprising that the estimated \hat{T}_j is higher than \bar{B}_j for this store. Wanamaker was mentioned in this sample as one of the more frequently shopped stores (although less than Loehmann's). Thus, it is not surprising that the estimated \hat{T}_j is less than \bar{B}_j for this store. Both of these differences are consistent with the notion that average responses \bar{B}_j may be favorably biased estimates of T_j for stores (or brands) having larger market shares.

	S.E.	.3	.3	.3
Average R^2 (not adjusted)		.8	.8	.8

^aThe average responses \bar{B} and the estimated locations \hat{T} are standardized across stores to zero mean and unit variance. The estimated location columns headed 1, 2, and 3 correspond to the three different measures of store usage: 1 = Store of Last Purchase, 2 = Store of Most Frequent Purchase, and 3 = Most Convenient Store.

Value Attribute

The same analysis was performed on the Value attribute generated by the questionnaire item: "Price should be considered in terms of value for money spent." The average responses \bar{B}_j on this Value attribute varied widely among stores. However, the estimated locations \hat{T}_j were roughly similar for all stores except Loehmann's (see Figure 3).

Loehmann's is rather distinct from the other stores. For example, it sells many items with labels excised. Loehmann's had the lowest estimated locations \hat{T} of any store on several other attributes: Quality of Store Personnel, Customer Services, and Store Atmosphere (see Table 2). Readers familiar with Loehmann's may find these estimates plausible, as do the authors.

For many respondents the second measure of usage, Store of Most Frequent Purchase, was highly correlated with \hat{T}_j . This collinearity caused large standard errors for $\hat{\beta}_2$ and $\hat{\beta}_3$ for many individuals. Consequently, for this attribute we used the first measure of usage, Store of Last Purchase.

Other Attributes

Corresponding summary results for the other attributes are displayed in Table 2. For two of the attributes, Quality of Store Personnel and Customer Services, the estimated locations \hat{T} differ quite considerably from the average responses \bar{B} for many of the stores. The procedure converged in between 19 and 58 iterations for all the attributes except Value, which needed 162 itera-

FIGURE 3

Average Response \bar{B}_j and Estimated Locations \hat{T}_j for the 10 Stores on the Value Attribute^a

^aThe average responses \bar{B}_j and the estimated locations \hat{T}_j are standardized across stores to zero mean and unit variance. The average responses for the stores varied between 1.05 and 2.94 on the questionnaire Value scale before standardization. The first measure of usage, Store of Last Purchase, was used.

^aThe average responses \bar{B} and the estimated locations \hat{T} are standardized across stores to zero mean and unit variance. For each attribute except Value, the results were somewhat similar, but not identical, for all three usage measures. Thus, results are only reported for the second usage measure (Store of Most Frequent Purchase) for all attributes except Value. The first usage measure (Store of Last Purchase) was used for Value because of collinearity between \hat{T} and usage measure #2.

tions. The average was 39 iterations before termination (when none of the T_j s changed more than 10^{-7}).

Importance of Halo Effect

In the previous section we concluded that the halo effect cannot be ignored here. The relative importance of the halo effect is indicated by comparing $avg_i(\sigma_{iA} \hat{\beta}_{i1})$, $avg_i(\sigma_{iU} \hat{\beta}_{i2})$, and $avg_i(\sigma_{iT} \hat{\beta}_{i3}) = \hat{\beta}_T$ for each of the attributes (see Table 3).

TABLE 3

Relative Importance of Halo Effect

Attribute	$\sigma_{iA} \hat{\beta}_{i1}$ Attitude (halo)	$\sigma_{iU} \hat{\beta}_{i2}$ Usage	$\sigma_{iT} \hat{\beta}_{i3}$ Location
Quality of Merchandise	.6	.02	.5
Customer Services	.5	-.05	.4
Appeal of Advertising	.6	-.13	.5
Store Atmosphere	.4	.01	.7
Quality of Store Personnel	.5	.07	.3
Value	.5	-.03	.4

The halo (overall attitude) and (true) location components are appreciable and roughly equal for all attributes. The usage component is negligible for all the attributes, evidently because of the low variances σ_{iU}^2 of the 0-1 measure of usage. Comparison between attributes is not possible here because the dependent variable, belief response, was not standardized.¹¹

Caveats

In retrospect, we are now concerned with several issues which were not adequately resolved by this study:

1. Simultaneity—We assumed that none of the right hand variables are determined as a function of the left hand variable. Our estimation is biased if this assumption is false. This type of analysis should be extended to allow for at least the possibility of simultaneous co-determination of overall attitude and the beliefs, perhaps along the lines of Beckwith and Lehmann (1975). Benmaor and Huber (1977) have argued that this specification error may be relatively tolerable, but we have not verified it for this example.
2. Intervals scaled data—We used available rank order data as if it were intervally scaled in order to simply demonstrate the methodology. Instead, intervally scaled data should be used. In addition, the convenience sample of respondents precludes making any substantive inferences from this particular data. However, these data are useful for demonstrating the methodology and illustrating the types of results which might be expected.
3. Individual coefficient nonnegativity—On a-priori grounds, individuals' coefficients $\hat{\beta}_{iTk}$ and $\hat{\beta}_{iAk}$ could be assumed to be nonnegative. By using OLS to estimate each individual's coefficients, we al-

¹¹In retrospect, we should have standardized the data to allow comparisons across attributes.

lowed these estimates to be negative, and many were. A linear programming-based individual estimation procedure might be used instead to obtain estimates constrained to being nonnegative, along the lines of Pekelman and Sen (1974) and Shocker and Srinivasan (1974). This might also reduce the collinearity problem.

4. Statistical properties—We have not demonstrated that the suggested procedure yields estimators T_{jk} which are necessarily no more biased than B_{jk} as estimators of T_{jk} . Presently we only point out that the procedure appears to yield plausible estimates in our example case, and that it seems reasonable to us that the bias will usually be reduced since the procedure explicitly includes effects which would otherwise be "omitted variables," and therefore generally biasing. Also, the OLS single equation standard errors and R^2 s reported for individuals are suspect since T_j is estimated along with the β coefficients.
5. Objective attribute recovery—We have not yet checked the ability of this procedure to retrieve accurate location estimates for attributes with objective physical measures.
6. Computational efficiency—Other computational schema may be found which estimate the true locations more economically. We have not yet attempted to reduce the computational burden of the procedure.
7. Underlying processes—The model, (1) and (2), used for this illustrative example seems to be an oversimplification of the individual's cognitive processes. We hope that other investigators will find this type of analysis useful in developing more complete understanding of such processes.

Summary

A methodology for estimating the location of objects on attributes or traits using individuals' biased response ratings was demonstrated. A procedure like this should be useful for assessing images of objects, such as stores, in image studies, or brand locations in product attribute analyses. The iterative procedure does require a substantial, although not prohibitive, amount of computation. The procedure was demonstrated on an example set of data for purposes of illustrating the methodology and the types of results which might be obtained. However, because the conveniently available data are not completely adequate, we caution against drawing substantive inferences from the example results. They are displayed solely to facilitate description of the methodology. We hope that this work will encourage other investigators to pursue more refined estimators of the unobservable locations or attribute levels of objects.

Appendix

Portions of the questionnaire are reproduced so that readers may judge for themselves the nature of the attributes measured.

Overall Attitude (A_{ij})

We are interested in your overall opinions of the following stores in a very general way. Please rank the stores numerically from 1 to 10 with 1 = most favored, 2 = second most favored, etc., with 10 meaning least favored. [The coding order was subsequently reversed, 9 to 0, for the analysis reported here.]

Store Usage (U_{ij})

At which of these stores did you most recently purchase an article of clothing for yourself? (If none, please specify) [Denoted Usage Variable #1.]

At which of these stores do you most frequently purchase clothing for yourself? (If none, please specify) [Denoted Usage Variable #2.]

Which of these stores do you consider most convenient (i.e., easiest to get to) to either your place of business or your home? (Include branch stores when applicable. If more, please specify) [Denoted Usage Variable #3.]

Belief Responses (B_{ijk})

We are interested in determining your opinions on a number of characteristics for several stores. Please indicate your opinion of each store on each attribute by checking the appropriate space. A short description of these characteristics precedes each section.

A. Quality of Merchandise—This refers only to the materials used in the manufacture of the garment and the garment's construction without any reference to price, fashionability, or any other factors.

B. Price—This should be considered in terms of value for money spent. [Price is referred to as the value attribute in the report.]

C. Quality of Store Personnel—Under this heading you should consider such factors as helpfulness, friendliness, promptness, courtesy, and any other interpersonal dynamic that is important to you.

D. Store Atmosphere—Store atmosphere includes the store's cleanliness, lighting, interior design, background music (if any), and floor plan.

E. Appeal of Advertising—In answering this question, you might consider whether or not the store's ads attract your eye in a newspaper or magazine as well as whether the ads are likely to result in your visiting the store in question.

F. Convenience of Location—(Consider branch stores when appropriate) In this category consider such factors as traffic, parking, proximity to public transportation, how frequently you find yourself in the area where the store is located, and so forth.

G. Customer Services—Customer services include credit availability and terms, return or exchange policies, alterations, rest room facilities, in-store restaurants, or any other particular service that you consider important.

H. Fashionability of Merchandise—In determining the fashionability of a store's merchandise, ask yourself whether the store carries merchandise that you like, not whether the store's merchandise could be featured in a fashion magazine.

Five response categories were provided for each store on each of the above beliefs: "Outstanding," "Highly Acceptable," "Acceptable," "Somewhat Acceptable," and "Unacceptable." These were subsequently coded 4 to 0 respectively.

IDENTIFYING AND DEFINING CONSUMER NEEDS USING HUMAN FACTORS
AND MARKET RESEARCH TECHNIQUES

Thomas Cannon, Design Factors
Dr. Ronald W. Hasty, Colorado State University

Abstract

Consumer need identification and definition are areas whose importance in successfully defining new product concepts, evaluating existing products, and evaluating promotional materials effectiveness has not been fully appreciated by many in consumer research. This paper discusses the significance of these areas in reducing risk and uncertainty in new product development. The application of specific human factors and market research techniques to need identification and definition and the development of specific products using such techniques is discussed.

New Product Development Today

A recent paper (Crawford, 1977) raised the question "Why has the rate of new product success not climbed as a result of the many advances in marketing research technology over the past 25 years?" Crawford cites numerous studies which report failure rates up to 90%. The reasons for such failures range from poor timing, as in the case of the Edsel, to poor planning. However, the most predominant reason for failure, cited by all the studies examined, was "the lack of meaningful superior product uniqueness."

Crawford concludes that while market research techniques may be able to determine what consumers think of products once they are in the market, they are not particularly valuable in the development of truly new products or determining if people will buy the new products before they are introduced in the market.

The authors of this paper take the position that much of the failure to improve the success ratio of new products is traceable to gaps in the conventional product planning process. The major gap results from a lack of techniques suited to systematically identify and define consumer needs. The techniques necessary for these tasks must come from two sources. Those which are useful in consumer need identification come primarily from the field of market research and those suitable for consumer need definition come from the field of human factors research.

Figure 1 shows a typical new product planning process. Stage one is the development of objectives. Stage two is new product idea generation. Stage three screens the ideas for acceptability measured by the objectives set in stage one. Acceptable ideas undergo engineering development in stage four followed by market testing in stage five and commercialization in stage six.

In the process outlined, new product planning is basically a marketing activity. However, engineering and other non-marketing sources normally have responsibility for the generation and development of new product ideas. It is generally accepted in the marketing literature that marketing is responsible for developing idea sources, not ideas, and then coordinating the process required for screening them. (Shocker, 1969 & Larson, 1963)

Planning Process Gaps

The generation of new product ideas is an activity which suffers from a belief that all really successful new

products originate in a flash of creative insight. While such instances are not unknown it is evident that dependence on individual strokes of genius is not an adequate method of meeting the continuing corporate demand for new products. Most knowledgeable individuals would agree with this, yet brainstorming and other methods which attempt to increase the number of such creative flashes, are widely used. Such techniques continue to promote the myth that locked inside every individual is a "bright idea" for a product which would have wide appeal.

What is missing in such approaches is the recognition that any successful new product must be a solution to a consumer need. Once this is understood, it is apparent that the generation of new product ideas should be preceded by (1) the identification and (2) the definition of a need. Logically, only after this is accomplished can solutions to the need be developed through the exercise of creative abilities.

To solve the problem of filling this gap between stages one and two, techniques are needed for developing a specification of those characteristics required to provide consumer satisfaction in accomplishing a given end or task within a specific environment. Four factors must be addressed: (1) the degree of need, (2) characteristics of the consumer, (3) characteristics of the task, and (4) characteristics of the environment.

The degree of need can be defined as the consumers' perception that a discrepancy exists between a condition as it is and as it might be (Smith, 1973). The baseline for determining the degree of such discrepancy is the consumer's present condition. While attempts have been undertaken to make such measurements through the use of motivational research, this type of basic research has been generally neglected by market researchers. This is so, in part, because such measurements are difficult to make without specific analytical tools typically unused by the market researcher.

Utilizing a need characterization methodology to guide the generation of new product ideas can reduce the number of ideas to be screened in stage three to those which offer the greatest potential for satisfying Crawford's requirement of meaningful superior product uniqueness with particular emphasis on "meaningful." The purpose of stage three might be better understood if it were referred to as the screening of need solution concepts. This would keep the focus on an idea's usefulness to consumers and prevent the common mistake of concentrating upon the uniqueness aspect. Most product planning processes use stage three to evaluate concepts to determine if they have the potential to achieve profitability objectives, will result in greater market penetration, and achieve other business management goals. Emphasis on such measures can create an atmosphere in which evaluation of a concepts ability to truly meet the consumers defined needs is neglected.

Market researchers have frequently attempted to attack this problem by using concept testing. This technique attempts to determine if the potential user understands the idea of the proposed product, reacts favorably to it

and feels it answers their need (Luck, 1970). Concept testing, as presently practiced, has not proven to be very reliable in predicting the ultimate success of products (Tauber, 1975). One difficulty with most concept testing is that the consumer is not in a position where evaluations can be made in an educated manner. The consumer has no opportunity to experience the product in the actual use environment, but must make a subjective evaluation based on a verbal or visual representation of the concept. A second serious problem is that all product attributes which are important to the consumer may not be revealed during the concept test because the consumer is not able to predict his or her own behavior in relation to the product over time.

At present, decisions made in stage three are critical because they commit the firm to development in a particular direction thereby excluding alternative courses of action. And this is usually done on the basis of intuition, consensus, and judgment influenced by past experience.

What is missing is a method of allowing potential consumers to evaluate solution concepts and their characteristics in a realistic use environment before the decision to start product development activities is made. Only if this is done can the time consuming and expensive practice of developing products which are not marketable be eliminated. It is a fact that engineering departments are prone to expending resources on concepts which address problems which are not primary to users or in configurations which are not acceptable to users. In addition, the desire to demonstrate technological feasibility often results in solutions which fatally compromise consumer requirements.

Identifying Need With Market Research Techniques

Many existing market research techniques can be readily adapted to identifying various market segments and ranking the segments in terms of profit potential, suitability for existing distribution channels, etc. Identifying specific needs of these market segments can also be accomplished using existing techniques. However, because in the past these techniques have been used almost exclusively for evaluating existing or proposed product attributes, market researchers must reorient their perspective to one which does not focus on the product and its attributes but rather on basic consumer need structures. Research techniques such as depth interviewing, projective methods of word association, thematic application tests, sentence completion, and so forth have provided ways in which information can be obtained from consumers concerning their thoughts and feelings about product characteristics. The task now facing market research is to adapt these proven techniques to provide specific information concerning problems perceived by consumers in their present methods of achieving goals. The authors have utilized such tried and true techniques as in-depth interviews, questionnaires, and focus groups to identify specific areas of need. These and other techniques are also useful in defining with precision the psychological or "felt" needs of consumers.

Defining Physical Needs With Human Factors Research Techniques

Techniques from the field of human factors research provide a complementary capability which allows researchers to answer questions about physical characteristics which are critical to consumer satisfaction. These questions have to do with the range of physical capabilities exhibited by the market segment under consideration, the ways in which consumers presently perform various tasks and the role which environmental factors play in

the accomplishment of tasks. While there are a number of tested human factors techniques which can be utilized to define consumer need, those which are most useful come under the general category of observational methods. In addition to personal observation of consumers the human factors specialist utilizes slow motion and time lapse photography, video recording, and a variety of non-visual recording methods. An example of the latter would be the use of an event recorder to create a record of the sequence, duration, and frequency of a consumer's activities. An extensive amount of human factors research has been done on human capabilities in the areas of vision, strength, hearing, response time, memory, fatigue, and the effects of environmental factors, such as lighting, temperature, sound, etc. These and other factors are directly related to the consumer's overall ability to accomplish goals without encountering problems.

The evaluation of need solution concepts can be accomplished through the use of the human factors technique of physical simulation. Such a simulation is distinct from engineering test models and product prototypes. A physical simulation may employ none of the technology which will be used in the production product. Instead, it utilizes whatever methods allow the product user to be presented with a realistic approximation of the functional characteristics which the product may exhibit in production form. Ideally, a simulation allows modification of the product characteristics to test a variety of configurations. Simulation provides information on the effects of a product's physical characteristics which are most critical to satisfaction. In addition, the probability of error in the accomplishment of tasks while using the product can be examined. This information can be used both to provide for maximum product safety and provide a basis for defense against liability claims.

Introducing human factors and market research techniques into the new product planning process as discussed, is illustrated in figure 2.

The inevitable question is: "How does the new method work in practice?" In an attempt to provide at least a partial answer, the development of an actual product is outlined below.

A Case In Point: The NurturyTM

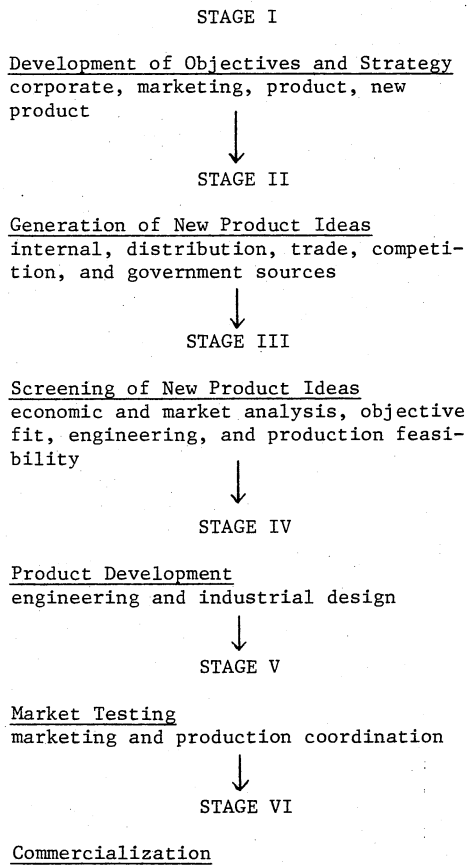

The Nurtury is an infant feeding system which was developed utilizing the process proposed. As a system of products it represents an excellent example of (1) the development of several unique new products, and (2) the development of superior products of a type already on the market. The Nurtury is described in the Appendix.

As discussed earlier in this paper, the first step in the product development process is the identification of consumer need. In the present case, this was accomplished in several ways. First, was the identification of the general area of infant care as a market segment which offered profit potential. An ongoing analysis of basic demographic and social trends in the United States indicated a number of facts which pointed to a potential in this area.

1. A trend to smaller family units which frees disposable income for child care products.
2. Growth of population in the 20 to 39 year age group with an accompanying growth in household formations.
3. An increasing number of first born children in spite of an overall decline in the birth rate.
4. An increase in the average mother's age accompanied by higher educational levels and greater involvement in all facets of child care.
5. The success of firms producing hard goods of the type purchased for first born children in contrast

FIGURE 1

A simplified schematic of the new product planning process. Rejection and feedback loops within and among these stages is implied.

to firms which depended on repeat sales and a high birth rate.

The first step in identifying which of many possible areas within the field of infant care had the greatest development potential was to conduct a series of group discussions with new mothers. Discussions were guided by a moderator from the general topic of infant care problems to specific areas such as feeding, bathing, sleep, mobility, etc. In addition to participating in the discussions, subjects were asked to complete a questionnaire which included listing all infant care products owned and the degree of satisfaction with the products.

The result of these discussions was the identification of home baby food preparation as an area of intense interest for the mothers. The identification of this interest was supported by the finding that 59% of the subjects owned a hand operated baby food grinder which was universally considered an excellent product even though numerous specific problems with its use were cited.

The second step in identifying areas of need in relation to infant feeding was a telephone survey of new mothers to (1) obtain ownership and use information on feeding equipment, (2) determine perceived problem areas, (3) identify preferred characteristics of existing products, and (4) obtain suggestions for improvements in existing products. Each subject was asked specific questions concerning their experiences with the products they

owned. This survey confirmed the need for improved methods of grinding, storing, warming, and serving baby foods. In addition, new areas, such as training aids for drinking and eating were identified.

The final step in the identification of need and the first step in need definition was a literature search. The search served to define existing knowledge concerning the nutritional and safety aspects of home preparation of baby food and provided data on the physical capabilities of infants at various stages of development. The search was supplemented by interviews with pediatricians and pediatric nurses to determine their level of awareness and attitudes toward home preparation. The results of the literature search indicated that underlying the popular interest in home prepared baby food, as revealed by an increasing frequency of publications related to the topic, was a growing body of research which questioned the desirability of feeding commercially prepared foods both from a nutritional and cost standpoint. The chief drawback to home preparation was seen by most professionals as the possibility of contamination during the processing and storage of the food, however, this was not considered an insurmountable problem.

An example of the type of human factors information located concerning physical capabilities of infants was the fact that initial efforts of infants to feed themselves with a spoon are hampered by an inability to perform the combined task of lifting their elbow and rotating their wrist to insert a conventional spoon in their mouth. As a result infants typically invert the spoon while raising it and insert the side of the spoon in their mouth.

Each of the identified areas of need required the application of specific human factors techniques to adequately define exact need characteristics. One of the techniques used to define dimensional requirements for drinking from a training tumbler was an anthropometric survey conducted on a sample population of infants in the defined age group. The survey established the maximum container diameter which could be easily grasped and the most desirable lip design for the tumbler.

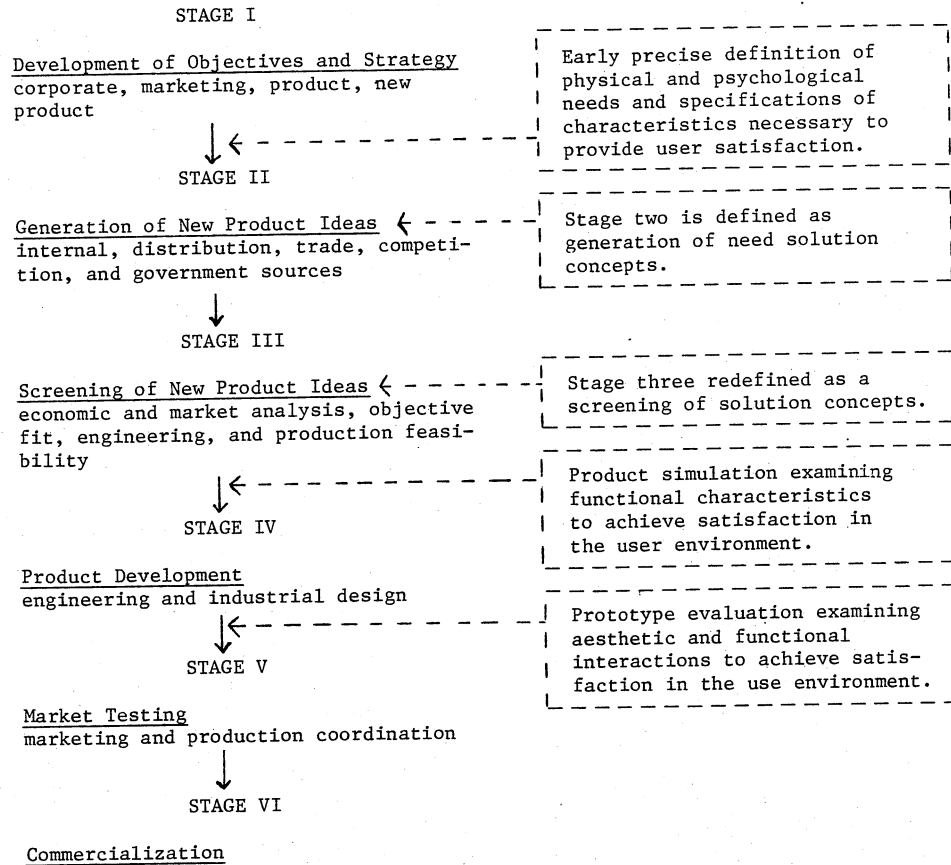

To confirm the information obtained through the literature search and further investigate the existing process of infant feeding a series of observations using slow motion photography were made of mothers preparing and serving baby food in their homes. These films were carefully analyzed to reach an exact definition of problems encountered by individuals using current techniques and equipment.

The problems defined by these studies provided the basis for development of test models or simulations which would allow alternative solution concepts to be realistically evaluated. Each test model was evaluated by fifteen or more mothers and infants for periods of up to two weeks. Subjects were interviewed both before and after the evaluations using detailed questionnaires to define initial perceptions of product characteristics and subsequent changes in perception based on experience with the products. In addition, users were observed and filmed using the test models to aid researchers in the identification of potential problem areas. Depending on the results of the initial evaluations, additional concepts were developed or refinements were made in existing test models. Such modifications were followed by additional user evaluations.

An example of the type of information obtained from observation of the test models in use was the fact that female users of the food grinder invariably applied much greater pressure on the food plunger than was required and as a result often stalled or overloaded the drive motor. This finding indicated that particular attention should be paid to educating the potential user about the

FIGURE 2

INTERJECTING HUMAN FACTORS RESEARCH INTO THE NEW PRODUCT PLANNING PROCESS

proper operation of the product and in addition the grinder should be engineered to meet the actual forces imposed by the user as contrasted with the optimum forces calculated for efficient use.

Conclusion

There are two keys to improving the success ratio of new products. First is utilization of a combination of human factors and market research techniques early in the new product development process to identify and define consumer needs. Second is using these same techniques combined with product simulations to provide consumer input to the screening of solution concepts.

Use of the market research and human factors combine has not been widely exploited and a great deal of refinement and innovation in techniques can be expected. The usefulness of this approach has been demonstrated, however, in the development of a number of products, including those discussed in this paper.

Appendix

The Nurtury™ Infant Feeding System by Teledyne Water Pik is presently being introduced into retail outlets on a national basis. The product consists of three packages containing an electric baby food grinder with accessory items, a baby food warmer and serving tray unit with accessories, and baby feeding helpers including two spoons, a training tumbler, and a bib. Each of the products has characteristics which provide unique

competitive advantages and all of these characteristics were developed to solve problems encountered by mothers and infants in the tasks associated with infant feeding. The primary promotional appeals of the Nurtury are:

1. Mothers can feed their babies the freshest, most natural foods in the world.
2. Babies get the full nutritional value from fresh foods.
3. Mothers save money by turning family food into baby food so there's no waste.
4. Mothers know exactly what's going into their babies.
5. Mothers can easily control the portion size because the Nurtury is specially designed to prepare small quantities of food.
6. Baby food tastes better because it's fresher.

Following are illustrations of each of the products accompanied by promotional copy describing the primary characteristics which make the products unique.

The Nurtury Serving Tray

1. Holds three Storable Servers snugly in place.
2. Has a strong suction cup to firmly grip baby's tray so there's no worry of upsetting.

The Nurtury Baby Food Warmer

1. Evenly warms food to the proper temperature in 10-15 minutes.
2. Automatically maintains temperature so food won't overheat or dry out.
3. Used with the same Storable Servers used for preparing food.

The Nurtury Baby Food Grinder

1. Grinds freshly cooked meats, fruits and vegetables into nutritious baby food.
2. Specially designed to prepare meal-size portions so there's no waste.
3. Comes with three texturizing discs for puree, junior, or toddler.

Storable Servers

1. 4-oz., meal-size, resealable containers for preparing, serving, refrigerating and freezing food.
2. Color-coded for easy identification.
3. Transparent, tight sealing lids.
4. Ounce markings on the side to measure meal-size portions directly into Servers.
5. Stackable, easily portable.
6. Made of durable plastic.
7. Freezer-proof to allow preparation and storage of extra food.

The Overall Bib

1. Covers shoulders, chest, sides, and lap.
2. Pocket catches spills, and pulls open for easy cleaning.
3. Made of durable plastic coated nylon.
4. Drawstring neck opens wide to fit over head. Can be adjusted to fit closely and comfortably around neck.
5. Stain-resistant and easy to clean.
6. May be laundered in automatic washer and dryer.

The Nurtury Nutrition Guidebook

A complete guide to infant nutrition including all aspects of introducing solid foods and solving problems encountered.

Mother's Feeding Spoon

1. Bowl has wide, deep portion in front so mother can feed baby without placing entire bowl in baby's mouth.
2. Food stays on tip of spoon for easy feeding. Allows baby to get more food.
3. Bowl is sized for baby's mouth. No sharp or rough edges.

Baby's Self-Feeding Spoon

1. Holes in the bowl help hold the food on the spoon.
2. Holes help to fill the spoon as baby plays in food.
3. Rectangular shaped bowl and special baby-grip handle let baby eat from the sides of the spoon when held in either hand.

Adjusta-Flo Training Tumbler

1. Locking cap won't come off when dropped.
2. Prevents spills because the Tumbler is designed to roll when dropped so holes are at the top when it stops.
3. Metered flow control adjusts to baby's drinking capabilities.
4. Specially designed lip aids baby's natural transition from sucking to drinking, and allows baby to drink without tilting head back.

INFANT, CHILD AND TEENAGER ANTHROPOMETRY FOR PRODUCT SAFETY DESIGN

Richard G. Snyder, University of Michigan
Lawrence W. Schneider, University of Michigan
Clyde L. Owings, University of Michigan

Abstract

Anthropometry plays an important role in human factors considerations for safe product design, particularly for the 31% of the U.S. population under age 19. This paper discusses two nationwide studies conducted for Consumer Product Safety Commission to obtain center of gravity, linkage, shape and functional body measurement data on 8154 infants, children, and teenagers representative of the U.S. population, for consumer product design, hazard assessment and guidance in establishing requirements or recommendations in standards.

Introduction

For the 77 million individuals under age 19 (Bureau of Census, 1976) representative body dimensional data have been for the most part either non-existent or of little functional value in real-world applications. Yet consideration of body size has a basic relationship to human factors of product safety design. This paper will discuss the data collection problems, techniques, and results of two nationwide anthropometric studies conducted for the Consumer Product Safety Commission (CPSC) by the Highway Safety Research Institute (HSRI), the University of Michigan, from 1972 to 1977 (R.G. Snyder, et al., 1975; 1977).^{1,2,3}

Recent data from the Consumer Product Safety Commission indicate that more than 2 million children are injured each year in accidents involving toys, playground equipment, bicycles, and other child and household products.⁴

The Public Health Service has estimated that toy products alone are responsible for injuries to 700,000 children each year (U.S. Department of Health, Education and Welfare, 1970) and that from 403,000⁵ to 760,000

¹ This study was annually reviewed by, and conducted under standards established by the University of Michigan Medical Center, Committee to review Grants for Clinical Research and Investigation Involving Human Beings, and conforms to the guidelines of the Institutional Guide to Department of Health, Education and Welfare Policy on Protection of Human Subjects.

² This project has been funded with federal funds from the United States Consumer Product Safety Commission under contract number CPSC-C-75-0068. The content of this publication does not necessarily reflect the views of the Commission, nor does mention of trade names, commercial products, or organizations imply endorsement by the Commission.

⁵ Consumer Product Safety Commission National Electronic Injury Surveillance System (NEISS), 1973.

(Pascarella et al., 1971) children require medical attention each year from bicycle accidents. While a large proportion of these fatalities or injuries are due to causes beyond the control of the product designer, evidence is accumulating to document that many accidents to children are a direct result of poorly or improperly designed commercial products.

A toy or household product may be physically unsafe for many reasons (e.g. sharp edges, points and protrusions, faulty mechanisms, etc.), but a primary factor which has general application to almost all products is concerned with the physical dimensions and features of the product and its components as they relate to the physical characteristics of the user or other individuals who may come into contact with the product. For example, how large or small should holes and spacings in toys, furniture slats, railings, and appliance ventilation covers be so that infants and children do not get their hands, fingers, and heads stuck or injured? How should strollers, high chairs, and tricycles be designed to prevent accidents due to instability? Or, what should be the dimensions of bicycles and bicycle hand brakes, school desks, school bus seats, playground equipment, etc. designed for use by children of specific ages and/or body sizes? Answers to these and many other questions require that a complete and reliable source of the physical characteristics of infants, children, and youth be available to designers, engineers, and other groups concerned with establishing guidelines and standards for the manufacture of these products.

An example of the type of anthropometric data required to answer functional design problems is demonstrated by the question of crib slat spacing. For three to six-month old infants what distance between slats will safely restrain them? Since no applicable data were available in the literature, in 1972 an infant population sub-study was designed to take 11 measurements (Snyder, et al. 1972). It was determined that the most critical body measurement was that of buttocks depth, measured from the maximum protrusion of the buttocks to the anterior surface of the upper legs. Findings from the study, which also included limited *in-situ* tests, indicated that the expected 90% of the population at a confidence level of 95%, lies between 2.9 inches and 4.7 inches for 4½ to 6½ month old infants and 2.9 inches to 4.4 inches for 2½ to 4½ month old infants. These were viewed as conservative as they were taken with pressure transducers on soft tissue in a relatively non-compressed condition. Since inter-slat distances, particularly on older cribs, were found to be as high as 4 inches, it was obvious that a design change was necessary. The CPSC subsequently established the standard as 2-3/8 inches (Federal Register, 1973).

As of 1972 a source of reliable and consistent data providing measurement statistics for both traditional and functional anthropometric measures for a sample representative of the infants, children, and youth in the United States was not available. This was surprising in view of the fact that some 800 studies in the literature were found to provide child measurement data (Snyder et al., 1973; reprinted 1975). This comprehensive review of the literature on child and infant anthropometric data revealed that while a large number of studies had been

conducted, the type of measurements needed for most safety applications were actually non-existent.

A large number of these studies were longitudinal (rather than cross-sectional) surveys designed to study the growth of a fixed population over a period of time using only a few basic measures such as height and weight. All the studies were limited in that they either used specific populations, selected age ranges, or only a few measurements, and did not consider differences due to region of the country, race, and other environmental and socio-economic factors likely to affect the sizes of children. Even if these factors had been considered and if all the measurements necessary had been taken in one study or another, differences due to measurer technique, definitions in measurements, and differences in age groupings would make it impossible to compile these data into one common source of reliable and consistent information. Additionally, many growth studies as recently as Marshall and Carter (1975) have found that children today are taller and larger than children their same age in past generations. Since two-thirds of the 35 most complete studies encountered had been made prior to 1960, it is questionable how representative much of these data may be of the current population of U.S. children.

This point was emphasized in a 1975 study conducted jointly by physical anthropologists from several organizations attempting to evaluate masterbody forms for 3-year and 6-year old child dummies for the Federal Aviation Administration (Young et al, 1975) and National Highway Traffic Safety Administration (Reynolds et al, 1975). It was found that of 98 body dimensions determined to be necessary for describing the external morphology of a child test manikin, 68 were not available in the literature. For example, the shape of the torso at the nipples is described by circumference, breadth, depth, and height from seat pan, but only circumference and depth measurements had been previously taken. Unfortunately this work was conducted before data were available from the initial CPSC Study. Problems related to anatomical considerations for the design of child restraints, another application where anthropometric data were needed, has been outlined by Burdi et al (1969).

Objectives

The purpose of the two studies conducted for CPSC was to provide anthropometric data of both a functional and traditional nature to describe the sizes, shapes, body linkage, selected functional measures, and seated and standing centers of gravity for a population of infants, children, and teenagers representative of the 48 conterminous United States. Tasks involved determining the measurements most required; the experimental design; designing, constructing, and testing unique advanced anthropometric instrumentation including mini-computer systems and entirely new center of gravity devices; collection, reduction, and analysis of the required dimensional data; and finally, tabulation and representation of the data in a format most useful to persons concerned with designing or establishing guidelines and standards for children's products, taking into consideration the potential functional applications.

Methods

This study was undertaken as a multi-disciplinary team effort with co-investigators representing specialties in physical anthropology, bioengineering, pediatrics, computer engineering, industrial and operations engineering and biostatistics. In addition, advisory consultation with other scientists occurred as the study progressed.

To establish the numbers of various types of infants and children to be included in the sample, the initial study

utilized U.S. Census and HEW data to project a sample of 4000 subjects whose racial and socio-economic characteristics matched the proportions of those characteristics in the total U.S. population. While the 1972-1975 study involved 41 measurements on infants and children from age 2 weeks to 13 years, the 1975-1977 study expanded this data base to also include 13 to 18 year olds (a population for which little data were known), and expanded the number of measurements to 87.

To assure the national representativeness of school-age subjects, a sample of schools was selected from a national list available from the third round of a study of youth fitness completed in the Department of Physical Education at the University of Michigan. The selection process used in the youth fitness study has been described in detail in Reiff, et al. (1968). The U-M Survey Research Center maintains demographic and socio-economic data on a national sample of geographic-political units representative of the U.S. population. Utilizing this sampling frame as a base, a smaller sampling frame was conducted for the anthropometric study. It consisted of random selection of eight central-city areas, 10 suburban areas, and 31 areas outside large metropolitan areas. The next step involved random selection of one school district within each of the sampled areas. Finally, specific schools in those districts were randomly selected, using a ratio of two elementary schools to one intermediate school to one senior high school. Because of scheduling and space problems, some schools originally selected did not participate in the measurement study. However, every effort was made to select matching schools from the same area.

Measurements and Measurement Strategy

Traditionally, anthropometric measurements have been devised to describe human variation in body morphology, body proportions, and changes in size attributed to growth, race, and other variables of interest to anthropologists. These dimensions were taken to describe the linear distance between two landmarks (heights, breadths, and depths) or around a body segment at a prescribed level (circumference). In today's world, however, this classical approach to anthropometry is not sufficient to answer questions relevant to the interaction of man with a multitude of man-made environments. While the traditional anthropometry measures are still important as they describe differences between individuals and populations, the differences must also be considered as a part of a man-machine system. Thus a systems approach to anthropometry was used as a general guiding principle. Consideration was also given to the probability that another study of this magnitude would not be likely in the near future and it was thus essential to provide the maximum amount of information possible within the budget and time limitations and to identify those measurements that would be of most interest and usefulness to the greatest number of potential users.

The result of these considerations was a list of 87 measurements shown on the following page. Traditionally, all measurements are made on every subject in the survey sample. However, because time available per subject was limited to 15-20 minutes so as to assure school and subject cooperation, this permitted obtaining only about 40 measurements per subject. The strategy adopted was to obtain the 22 Core measurements (Group I) on all subjects, plus Group II, Group III, or Group IV measurements sequentially, on every third subject. Thus, 42-45 measurements were taken on each subject, and the sample sizes for measurements in Groups II, III, and IV are one-third as large as for Group I.

The key factor in this approach was to select measurements for Group I that correlate highly with measurements in the other three groups. Because the core measurements were taken on every subject, and each of the

non-core measurements correlates highly with one or more of the core measurements, this provided a means of checking the representativeness and comparability of the non-core sample populations. Statistical comparisons of measurement means in selected core measurements and age groups showed that there is no significant difference between the samples for Groups II, III, and IV.

To avoid any systematic association of measurements with subjects in a particular age group or region of the U.S. all measurement sets were taken equally at all measurement sites. To accomplish this, the combination of measurement sets (I + II, I + III, I + IV) were done sequentially.

Measurements, Age 2-19

I. Core Measurements. Weight, Stature, Head Circumference, Chest Circumference, Waist Circumference, Hip Circumference, Upper Arm Circumference, Forearm Circumference, Upper Thigh Circumference, Calf Circumference, Foot length, Foot Breadth, Hand Length, Head Breadth, Shoulder Breadth, Shoulder-Elbow Length, Elbow-Hand Length, Maximum Hip Breadth (sitting), Buttock-Knee Length, Knee Height, Erect Sitting Height, Head Breadth.

II. Shape Measurements. Chest Height, Waist Height, Hip Height, Chest Breadth, Waist Breadth, Neck Circumference, Natural Waist Circumference, Wrist Circumference, Ankle Circumference, Calf Circumference, Ankle Breadth, Calf Breadth, Upper Thigh Depth, Wrist Breadth, Forearm Depth, Upper Arm Depth, Neck Breadth, Head Length, Eye Height, Thigh Clearance, Maximum Thigh Breadth (sitting).

III. Linkage Measurements. Vertical Arm Reach, Frontal Arm Reach, Lateral Arm Reach, Step Height, Suprasternale Height, Iliocristale Height, Iliospinale Height, Trochanteric Height, Gluteal Furrow Height, Sphyrion Height, Tibiale Height, Bispinous Breadth, Clavicale-Acromion Length, Acromion-Radiale Length, Radiale-Styilion Length, Biacromial Breadth, Hip Breadth at Trochanter, Supine Stature, Supine Sitting Height, Standing Center of Gravity, Seated Center of Gravity.

IV. Head, Face, and Hand Measurements. Bizygomatic Breadth, Maximum Frontal Breadth, Mouth Breadth, Nose Length, Lower Face Height, Face Height, Head Height, Tragon to Back of Head, Tragon to Top of Head, Ear-Sellion Depth, Bitragon Breadth, Ball of Fist Circumference, Maximum Fist Breadth, Maximum Fist Depth, Thumb-Crotch-Middle Finger Length, Middle Finger-Thumb Grip Length, Thumb Length, Index Finger Length, Middle Finger Length, Middle Finger Diameter, Index Finger Diameter, Thumb Diameter, Minimum Hand Clearance.

Infant Measurements. Since infants (age range two weeks to 24 months) do not have mature skeletal and muscular systems and cannot perform movements required for most of the functional measurements, a separate set of 34 measurements was compiled and used for these subjects. These were:

Weight, Crown-Sole Length, Crown-Rump Length, Head Circumference, Head Breadth, Head Length, Shoulder Breadth, Shoulder-Elbow Length, Upper Arm Circumference, Elbow-Hand Length, Forearm Circumference, Wrist Circumference, Hand Length, Hand Breadth, Minimum Hand Clearance, Maximum Fist Breadth, Thumb Diameter, Middle Finger Diameter, Chest Circumference, Chest Breadth, Waist Circumference, Waist Breadth, Rump-Sole Length, Rump-Knee Length, Hip Circumference, Hip Breadth, Mid-Thigh Circumference, Mid-Thigh Depth, Knee-Sole Length, Calf Circumference, Ankle Circumference, Ankle Breadth, Foot Length, Foot Breadth.

Data Collection

In the 1972-1975 study, measurements were made at 71 schools, clinics, and day care centers in 8 states. The 1975-1977 study included measurements obtained at 104 locations in eight regions (20 states) by two teams. In the latter study, one consisted of two males, the other of two females. Team members were selected for their ability and experience in working with children and teenagers. They received extensive training and supervised practice before commencing the field work. Several members were fluent in Spanish which was important in some schools particularly in the Southwest where English was a second language. In some cases materials to parents were printed in both Spanish and English. The process of obtaining approval from school authorities and parents, and of scheduling specific grades and classes, usually required considerable preliminary contacts. Ordinarily the school superintendent was approached by letter and then telephone. The request was presented to the school board for approval and then principals of schools in that district were contacted. Often the team coordinator visited the schools to explain the study to teachers and students, using an 18-minute film (University of Michigan, 1975) produced during the previous CPSC-sponsored study. After it was decided that a school would participate, an explanatory letter, consent form, and demographic questionnaire were distributed to parents of children in school grades selected to participate. The entire process of obtaining approval, informing teachers, parents, and students, and obtaining signed consent forms usually required about two months. When schools were closed during summer vacations, subjects were measured at summer camps.

The primary sources for subjects two to five years old were nursery schools and day care centers. Nationwide, infants were the most difficult age group to obtain, and additional sources for infant subjects were The University of Michigan Well Baby Clinic and a pediatric clinic in Pontiac, Michigan.

Instrumentation

An important aspect of this study was the design, fabrication and use of a portable mini-computer system for automatic retrieval of measurement data. Figure 1 illustrates this system and shows the NOVA 1220 computer system including 24 K of memory, 2 LINC type drive units 16 channels of A/D input, a signal conditioning and power supply package for processing instrument signals and activating device transducers, and an interactive display system consisting of keyboard, terminal and video display.

Figure 1

The Automated Anthropometric System

Four different automated measuring devices were interfaced with the NOVA computer system and utilized in the measuring process. These have been reported in detail by Snyder, et al. (1972; 1975), and Owings et al. (1974 a; 1974 b; 1974 c).

While computerized techniques have been suggested and explored previously (Garn, 1962; Prah1-Anderson, 1972; Bullock, 1974⁶), the automated anthropometric system described is believed to be the most extensive systematic use of automated anthropometry, the first such use of the NOVA mini-computer data acquisition system, and the first practical portable computerized means of obtaining center of gravity measures on both infants and children.

For measuring linear distances (i.e., breadths, lengths, depths, heights) the automated caliper or anthropometer was used. These instruments are illustrated in the drawings of Figure 2. GPM (Siber Hegner & Co. Ltd) anthropometers and calipers were modified to provide electrical readout of length by means of a 10-turn potentiometer connected to the moving blade by a pulley and

Figure 2

Modified sliding calipers and modified anthropometers showing potentiometer, pulley and cable system, and pressure transducer.

cable system. A miniature pressure transducer (Königsberg Model P21) mounted in the special plexiglass blade provided a means of standardizing measurements on soft tissue. Body linkage and head, face, and hand measurements were taken using removable pointed extensions of different lengths. A button in the stationary plexiglass blade activates the measuring process on each device.

A third automated device shown in Figure 3 was used for measuring various body circumferences. This consists of a standard steel measuring tape wrapped around a pulley which is attached to the shaft of a 10-turn potentiometer. The tape is wrapped about the particular body segment being measured and clipped back on the tip of the aluminum tape guide. Tension is provided by a coil spring located inside the pulley and the measurement is sensed by the computer upon depressing the plastic but-

ton with the thumb or index finger.

Figure 3

Modified girth device for electrical readout of circumference measurements.

Two devices were designed for measuring whole body center of gravity, one for infants and one for children and teenagers up to 250 pounds. The principal of operation is the same for both and is illustrated for the larger device in Figure 4. The subject is placed in either the supine standing or sitting position on a rigid platform supported by three precisely calibrated load cells. Outputs of the load transducing cells are amplified before entering the A/D unit of the computer. By sensing the load cell readings with the subject in position and with the device empty, the computer calculates the location of the center of gravity relative to a known reference plane.

Figure 4

Center of gravity device with subject in supine standing (upper) and supine sitting position (lower).

Two complete systems including computer, measurement instruments, TV display, and center of gravity devices were assembled and transported throughout the United States by the two teams in Dodge Maxi-vans as illustrated in Figure 5.

Other devices used for taking other functional measurements include a hole template for measuring finger and thumb diameters, hinged plexi-glass hole boards for measuring hand clearance (Figure 6) and a grip rod with pivoting extension for measuring functional grip dis-

tances (not shown). In order to standardize and facilitate the positioning of the subjects for various measurements, a portable table and adjustable foot rest

Figure 5

Maxi-van used to transport anthropometric equipment.

platform were designed and used with each measuring system (See Figure 1).

Figure 6

Hole template for measuring finger diameter and hinged plexiglass hole boards for measuring hand clearance.

The entire measuring process including sequencing through the measurement data sets, calibration of automated instruments and pressure transducers, recording of subject demographic information, retrieving and recording measurement values from the various automated devices, checking measurement values relative to subject age and stature, and calculating subject center of gravity was controlled by a computer program called "MAP" or Michigan Anthropometric Processor.

Data Handling, Editing, and Analysis

At the completion of each geographic location data tapes were returned to HSRI for transfer to a file on the Michigan Terminal System (MTS). Interim editing took place during the course of the study by listing measurement values according to subject age and visually checking for bad data. Final editing was accomplished when data collection was complete by using two routines written for the HSRI PDP 11/45 system.

A program called X-VAL, obtained from anthropologists at Wright Patterson AFB, was used to search for extreme measurement values in designated age groups. Subjects

were grouped by data set, sex, and age intervals of one year each, and the program listed the ten smallest and ten largest values for each measurement along with statistics of the distribution (e.g., mean, standard deviation, skewness). Visual inspection of the data was then used to search for subject numbers with unreasonable measurement values and a complete listing of the data on these subjects was produced. From this listing a decision could be made as to whether to delete or leave the value in question.

A second procedure used to edit the data was multiple regression analysis. This involved establishing a linear relationship between one measurement variable and several other measurement variables. For example, one might attempt to establish a linear relationship of weight with stature, chest circumference, and waist circumference [weight = f (stature, chest circ., waist circ.)]. Once a relationship was established, measurement values which fell outside the predicted value, plus or minus specified error tolerances, were edited appropriately. This procedure allowed for editing points which were incorrect but which still fell within two standard deviations of the mean measurement value for a given age range (i.e., they are not extreme values).

Sample Population Characteristics

The composition of the sample population of measurement subjects by race and sex is shown in Table 1. As the table shows, 50.7 percent of the subjects were male, 49.3 percent were female. As for ethnic identification, 86.5 percent of the subjects were identified as White, 11.0 percent as Black, .9 percent as Oriental, .1 percent as American Indian, and 1.5 percent as Other (mixed or unknown).

Every effort was made to ensure the ethnic, geographic, and socioeconomic representativeness of the sample. However, biases resulting from self-selection factors due to the voluntary nature of final subject measurements were recognized.

Table 1

Sample Population by Race and Sex

Results

The anthropometry and center of gravity measurements for 8,154 infants, children, and teenagers were obtained, collated, and analyzed in these two nationwide CPSC studies. For detailed information concerning the resulting data the basic reports (Snyder et al, 1975; 1977) must be referred to. The final report of the most recent study presents the measurement results for 34 measurements of infants from two weeks to 24 months old, and for 87 measurements of children and teenagers from two through 18 years old. For each measurement, tables present the summary statistics for males, females, and combined sexes in 16 age groups, including sample size (N), mean, standard deviation, minimum measurement, 5th 50th, and 95th percentiles, and maximum measurement. Also presented in tables and graphs are the bivariate relationships for selected functional measurements with stature and weight. The linear regression coefficients and constants given in these tables provide for predicting these functional measurements on individuals or groups for which only stature and weight are known.

To illustrate the results and functional nature of the measurements, results for five of the measurements are presented in the Appendix. These measurements in order of presentation are stature, weight, frontal grip reach, distance from thumb crotch to tip of the middle finger, and seated center of gravity as a percent of sitting height.

It is worth noting that since publication of the final reports several new and diverse applications of these data have been made known to us. For example, requests for these data have been made by a foreign government relative to child restraints, a major aerospace company relative to wrist dimensions, a manufacturer of medical x-ray phantoms for facial data, a U.S. assistance program for application to nutritional problems, several toy manufacturers, an automotive manufacturer relative to child dummies, a group concerned with design of school bus seats, and several other government agencies. While no single study can fulfill all the needs of all users it is the authors' hope that this body of new data made possible by the major technical advances in instrumentation of the automated computerized anthropometry system, will provide the user with basic functional, shape, and linkage data necessary for improved product safety design.

Appendix

STATURE

Subject stands erect with head oriented in the Frankfort Plane, arms hanging at sides. With an automated anthropometer, measure the vertical distance from the standing surface to vertex (top of the head).

FRONTAL GRIP REACH

Subject stands erect with feet together, back to wall, grasping the handle of the grip device in right hand. The anthropometrist holds the subject's right shoulder against the wall as the subject extends right arm to maximum horizontal grip reach. With the pointed blade of an automated anthropometer, measure the horizontal distance from the wall to the most distal point on the handle of the grip device.

THUMB CROTCH-MIDDLE FINGER LENGTH

Subject extends right hand and fingers with palm up, thumb away (abducted) from hand. With an automated sliding caliper, measure the distance from the crotch of the thumb to the tip of middle finger parallel to the fingers. A constant correction factor for the caliper blade offset is added to the measurement.

SEATED CENTER OF GRAVITY

Subject lies on back on the CG device with legs placed over the adjustable support so that the knees form a 90° angle, the buttocks are firmly against the reference plane, and the upper legs are approximately 90° to the torso. The arms are placed at the sides. The horizontal distance of the center of gravity from the buttocks reference plane (D_2) and vertical distance of the center of gravity from the CG platform (D_3) are computed. The horizontal distance is reported as measured and as a percent of supine sitting height [$(D_2/\text{supine sitting ht}) \times 100$]. The vertical distance is also reported as measured and as a percent of buttock-knee length [$(D_3/\text{buttock-knee L}) \times 100$].

Abstract

The Human Factors Section at the National Bureau of Standards was recently involved in the evaluation of a Lawn Mower Safety Standard for the Consumer Product Safety Commission. This report describes the results of three studies performed in conjunction with this effort as related to blade contact injuries and the implementation of a dead-man control requirement.

Introduction

The Human Factors Section at the National Bureau of Standards (NBS) has provided support to the Consumer Product Safety Commission (CPSC) during the development and evaluation of a power lawn mower safety standard. Part of this support took the form of providing CPSC with data concerning how lawn mower users interact with power mowers. Three empirical studies were performed to assist CPSC in resolving specific questions concerning requirements in the proposed safety regulation based on a report from Consumers Union (Consumers Union, 1975).

In October 1974, CPSC accepted the offer of Consumers Union of United States, Inc. (CU) to develop a standard under Section 7 of the Consumer Product Safety Act [15 U.S.C. 2056(b)]. The CPSC received a proposed standard from Consumers Union in July 1975 (CU, 1975). In May 1977, CPSC published in the Federal Register (CPSC, 1977) a proposed safety standard based on the CU proposal with modifications and additions made by the CPSC staff.

CPSC estimated that there were 178 000 power lawn mower-related injuries in 1975. Costs associated with these injuries are estimated to be in excess of 73 million dollars. According to the National Electronic Injury Surveillance System, operated by CPSC, over half of the injuries resulted from body contact with the lawn mower blade (CPSC, 1976). In an attempt to reduce the number of blade contact injuries, the CPSC included two requirements in the proposed safety regulation which directly relate to blade contact.

The first requirement, intended to protect feet from blade contact, describes a region under the lawn mower housing through which the blade cannot pass. This is accomplished by using an anthropometric foot probe in a performance test. The second requirement is for a "dead-man" control which must be continuously activated by the mower user in order for the blade to operate. The "dead-man" control is primarily intended to protect hands and fingers from blade contact. The three studies reported here, all performed during the evaluation phase of the standard development process, deal with these two requirements.

The first experiment addresses the problem of describing the region under a mower housing through which the blade should not pass. This was accomplished by a comparison of three available foot simulator probes with a sample of potential lawn mower operators' feet, especially with regard to dynamic characteristics.

The second experiment provided data to answer the question "How long after the dead-man control is released should the blade be allowed to rotate?" Alternatively, one might ask "How long does it take an operator to move from the handle location to an area of potential contact with a moving blade?"

The third experiment is related to the prospect that consumers might intentionally defeat the dead-man control. To meet the proposed standard the blade may be stopped either by means of a blade clutch/brake system with the engine continuing to run or by engine shut-down. If this latter method is employed to stop the blade, lawn mower users would likely be required to restart their mowers repeatedly throughout a period of use. The CPSC has suggested that this inconvenience may encourage consumers to defeat the dead-man control unless the mower is easy to restart. This experiment, therefore, was designed to provide CPSC with data which can be used to objectively define the subjective judgment of easy-to-restart for pull-started lawn mowers.

Complete technical details and data from the three studies can be found in the NBS reports on the individual studies (Ramey and Persensky, 1977; Pezoldt and Persensky, 1977; Persensky and Ramey, 1977).

Study I. Evaluation of Anthropometric Foot Probes

The foot probe test developed by CU for inclusion in the proposed mandatory lawn mower standard makes two major assumptions: first, that the probe or foot simulator is representative of the feet of the population of lawn mower users; and second, that the probe test determines potential for foot contact with the blade.

NBS evaluated the adequacy of available generic foot probes, emphasizing a comparison between the probes and the dynamic characteristics of the feet of potential lawn mower users. The probes used in the study were: the Consumers Union (CU) proposed probe, adapted from an Underwriters' Laboratory probe; the United Kingdom (UK) probe, designed by the British Standards Institute; and the American National Standards Institute (ANSI) probe.

The apparatus used in the study (Figure 1) consisted of two parts. First a camera and strobe were mounted on a platform focused on a gray-on-black measured-graph backdrop. The film used produced positives for immediate examination and negatives for future analysis and was capable of multiple exposure. The second part of the apparatus was a frame with a movable metal partition 15 cm wide which could be adjusted to allow vertical openings of 6 to 10 cm in 1 cm increments to simulate different lawn mower housing heights.

The subjects in the study included 127 males and 74 females ranging in age from 9 to 66 years. Foot length data for these subjects were compared to those collected by other researchers for specific populations. This comparison demonstrated that the present sample was representative of the range of potential operators' foot sizes. No determination however, could be made of the representativeness of the distribution of foot sizes.

FIGURE 1
EVALUATION OF ANTHROPOMETRIC
FOOT PROBES TEST APPARATUS

After putting a white nylon stocking (to increase image contrast) over their right foot, subjects were instructed to:

Insert their right foot under the metal panel as far in and to the left as comfortable, keeping the foot flat on the base. Then,

Rock back on the heel of the foot, lifting the front of the foot as far off the base as possible, curling toes upward, yet keeping the foot as far in as possible.

Keeping the front of the foot elevated and toes curled up, pull the foot out from under the partition until the base of the toes contacted the metal panel.

At each of the three positions described above a picture was taken, creating a triple exposure print and negative as graphically depicted in Figure 2.

FIGURE 2
EVALUATION OF ANTHROPOMETRIC FOOT
PROBES REPRESENTATIVE RAW DATA

Triple exposure photographs, one at each of the three housing heights (i.e., 6, 8 and 10 cm), were taken both with shoes on and shoes off. This procedure resulted in six triple exposure photographs, one exposure at each of the three positions described above, for each participant.

The negative photographs were used for data reduction. Measures were taken for the point representing the height of the longest point of each of the three positions and the point corresponding to the length of the highest point at each position. (Position 1 was foot flat on floor; Position 2 was foot raised and toes curled; and Position 3 was base of toes contacting the partition.) There were, therefore, two sets of coordinates for each position, or a total of six per negative (housing height). The same procedure was repeated for each participant at each housing height both with shoe on and shoe off--a total of 36 sets of coordinates per participant. The same three positions were measured for each of the three generic foot probes and for a shoe probe made by affixing a shoe on the end of a length of wood. The shoe probe was constructed from a 95th percentile size female's shoe.

Horizontal and vertical insertion distances for the generic probes, the shoe probe, and the foot data were used to develop safety envelopes for each housing height. Figure 2 shows the measurement points used to develop the safety envelopes. Figure 3 is a composite envelope at a housing height of 10 cm for each of the three generic probes (CU, UK, ANSI), the shoe probe, and the 95th percentile foot data.

FIGURE 3
 COMPOSITE SAFETY ENVELOPE FOR THREE GENERIC
 PROBES, A SHOE PROBE AND THE 95TH
 PERCENTILE FOOT DATA AT 10 cm HOUSING HEIGHT

Of particular interest is the fact that, of the three generic probes, only the UK probe passes through the space above the plane of the housing opening. However, none of the probes approaches the vertical insertion distance achieved by the 95th percentile foot data. This region, above the housing, is of primary importance in providing foot protection since mower blades are located above the plane of the bottom of the housing. Although the CU probe exceeds the other generic probes and the foot data in terms of horizontal insertion distance, it does not provide any additional foot protection over that provided by the UK probe since the mower blade rotates above the lower edge of the housing.

In addition to comparing safety envelopes derived from the aggregate foot data with the generic probe data, a comparison of each individual's data was made with each generic probe to determine the percentage of participants who would be completely protected by each generic probe and by the shoe probe. These data indicate that at least one point of each individual's foot movement data falls outside the safe area defined by each of the generic probe envelopes. Therefore, a lawn mower which satisfies the criteria of any of the generic foot probes would not completely protect any of the participants in study. The shoe probe performed somewhat better than the generic probes. However, as shown in Table I, this probe would not

provide the magnitude of protection which would be obtained from a probe designed from the 95th percentile foot data.

TABLE I
 PERCENTAGE OF SAMPLE COMPLETELY PROTECTED
 BY SHOE PROBE AND BY A PROBE DESIGNED
 TO 95TH PERCENTILE FOOT DATA

Sample Condition	Housing Height (cm)		
	6	8	10
% Protected by Shoe Probe			
With Shoe	14	14	46
Without Shoe	1	1	14
% Protected by 95th Percentile Probe			
With Shoe	77	82	74
Without Shoe	80	78	73

Clearly, there is a serious problem with all of the existing generic probes, as shown by comparison of the individual data with the generic probe data. It seems clear that further research should be performed toward the development of a more adequate probe.

Study II. Time-to-Blade-Access

Several recommendations have been made for the maximum allowable blade stopping time, that is, the time from release of the dead-man control until the blade comes to a complete stop. The power mower industry, through the Outdoor Power Equipment Institute (OPEI), suggested a stopping time of seven seconds (OPEI, 1975). Consumers Union recommended a three or four second stopping time based on a study employing college students (CPSC, 1977). The National Bureau of Standards had previously recommended a blade stopping time of one second, based on data reported by the University of Iowa (Porter, Jones, and Persensky, 1974). In view of the inconsistency among these recommendations, CPSC requested NBS to perform a basic empirical study of operator movement time to provide an ergonomically sound recommendation for blade stopping time for walk-behind power mowers.

Of critical interest is the time it takes a lawn mower user to move from the operating position at the handle to a position of potential blade contact. Participants in this study were tested using a reaction time device which was designed to measure mower users' approach times to various points representing areas of potential blade contact. The test apparatus (Figure 4) permitted measurement of reaction time--or time to release a simulated dead-man control at the onset of a cue light and, more importantly, movement time--or the time from the release of the dead-man control to activation of one of five switches as surrogates for blade access areas.

FIGURE 4
TIME-TO-BLADE ACCESS TEST APPARATUS

The subjects' task was to move from the handle to the appropriate switch designated by a cue light, then depress the switch by hand. The distances of the switches from the handle were at intervals of 25.0 cm from 50.0 cm to 150.0 cm. The shortest and longest distances were based on the distance of the closest rear wheel and furthest front wheel, respectively, as measured on a sample of existing lawn mowers. The 100 subjects tested (64 males and 36 females) ranged in age from 16 to 62 years. Each received five trials at each distance on a randomized schedule. Subjects were instructed not to rush to strike the switch plates, but rather to walk at a normal rate.

Blade-area access-time data are summarized in Table II. Analyses of these data reveal that, as expected, there are no statistically significant differences in reaction time as a function of movement distance; however, movement time increases with movement distance. Average movement times observed in this study ranged from 0.6 sec. to 3.3 sec. The median movement times at the shortest and longest distances were 1.4 and 2.2 sec., respectively. Clearly, however, a "worst case" strategy seems more fitting when recommending an appropriate blade stopping time. That is, the selected time should protect significantly more than half of all users. Table II also presents percentile information for movement time to each of the five simulated blade contact areas. Inspection of the table suggests that a blade-stopping time of 0.7 second would protect all but five percent of the sample from potential contact with the rotating blade at the shortest distance tested.

TABLE II
TIME-TO-BLADE-ACCESS: REACTION
AND MOVEMENT TIMES (SEC)

	Movement Distance (cm)				
	50.0	75.0	100.0	125.0	150.0
Reaction Time					
Median	0.5	0.5	0.6	0.6	0.6
Range	0.3-1.2	0.3-2.0	0.3-1.1	0.3-1.3	0.3-2.0
Movement Time					
Median	1.4	1.5	1.8	2.0	2.2
Range	0.6-2.7	0.6-2.8	0.7-3.0	0.8-3.3	0.9-3.0
5th Percentile	0.7	0.8	0.9	1.1	1.2
95th Percentile	2.2	2.5	2.8	3.0	3.2

The time data generated in this study reflect only direct movement time from the handle to areas of potential blade contact. In the absence of any data to the contrary, however, it must be assumed that in the worst case lawn mower operators do, in fact, move directly from the operating position to an area of potential blade contact. Unless other movement scenarios can be established, a more valid movement time criterion cannot be determined.

Study III. Ease of Pull

This study was designed to provide CPSC with data based on subjective judgments, which can be used to objectively define "easy-to-restart" for pull-started power lawn mowers. Many factors are involved in establishing criteria, among the more important of which are:

- the force of pull required to start the engine;
- the distance through which a pull must be made;
- the average number of pulls required per engine restart;
- the number of times the engine must be restarted during the mowing period; and
- the time interval between restarts.

In addition to these factors, which are all external to the individual starting the mower, a number of human characteristics are of at least equal importance. To the obvious factors of age, sex and physical condition, must be added the kinesthetic and proprioceptive feed-

back cues experienced when pulling the starting cord and the connotations placed upon the terms "easy" and "hard."

This study did not attempt to explore all of these factors. The data generated by this effort, therefore, cannot be construed as providing a definitive answer to the question "What is easy to restart?" Rather, the present study attempts to define easy to pull under experimentally controlled conditions. In psychological terms, the problem becomes one of determining the relationship between physical stimuli and the psychological responses to such stimuli. In this case the stimuli are the forces which are exerted on a simulated pull-start mechanism and the responses are subjective judgments about the ease or difficulty involved in applying these forces.

Two simulators were designed and built for use in this study (Figures 5 and 6). The simulators were operationally identical with the exception of the locus of pull. Pulls on the "housing" simulator were executed from a height typical of several current lawn mower designs, i.e., 38 cm (15 in). The "handle" simulator was designed to be pulled from a position on the handle, 83 cm (33 in) above the ground. Although most current lawn mowers are more similar to the housing simulator, lawn mowers incorporating a dead-man control may have the pull handle located in an area similar to that on the handle simulator.

FIGURE 6
EASE OF PULL TEST APPARATUS
HANDLE SIMULATOR

The simulators permitted pulls similar to those experienced when pull-starting a power lawn mower. Pulls could be made through four distances and the difficulty (resistance) of pulls could be manipulated by the experimenter. Difficulty of pull could only be controlled in a very gross sense by manipulating an adjustable cylinder on the simulator engine; the actual force applied was determined by the participant. Measurement of the forces applied when pulling the start cord was accomplished by incorporating a load cell in the pull handles. These load cells were interfaced with a digital readout, peak load indicator. Peak force (i.e., the maximum force exerted at any point in the pull) was measured to the nearest pound (4.45N). Forces required to actually start the engine could not be determined since neither gasoline nor spark plugs were present in the simulators.

The subjects' task consisted of making 36 pulls at one of the simulators on each of four consecutive days. Each day the subjects were provided with a different length cord which determined the distance through which they were to pull. The distances through which they pulled were approximately 46, 61, 76, and 91 cm (18, 24, 30, and 36 in). The order in which subjects were assigned to the various distance categories was randomly determined. Subjects were instructed to pull the "starting" cord in the same manner they would to start a lawn mower. Immediately following each pull, subjects were requested to judge whether that pull was easy or hard. A forced choice paradigm was employed, requiring subjects to judge each pull as either "easy" or "hard." No intermediate responses were allowed. Participants were instructed to consider the simulators as "perfect lawn mowers," that is, they would start on every pull. In fact, of course, the engine never started. Subjects made six pulls in a five minute test period, followed by a rest period of approximately 10 minutes. Six test periods were completed each day by each subject.

A modified staircase method was employed to determine compression ratio adjustments to the simulator after each pull. Generally, if a subject judged a pull "easy", the compression ratio of the simulator engine was increased one unit for the next pull. If a pull was judged "hard," the compression ratio was decreased. Some variation in this procedure occurred in an attempt to assure that subjects pulled over a broad range of forces. After each pull, the judgment about the pull, either "easy" or "hard," and the peak force exerted during the pull were recorded. Peak force, rather than any measure of force over time, was employed for several reasons. First, peak force proved simple to measure. Second, pilot tests showed the measure to be capable of discriminating between pulls judged easy and pulls judged hard. Finally, peak force was felt to be the most easily adaptable to test method development.

A total of 5,372 pulls were made from the handle position and 5,009 pulls from the housing. For most analyses, the peak force measures of primary interest were the maximum forces judged easy (Easy_{max}) and the minimum forces judged hard (Hard_{min}) for each subject. For purposes of analysis, peak forces were grouped in 22N (5 lbf) categories.

With one exception, there were no statistically significant differences for either Hard_{min} or Easy_{max} as a function of the distance of pull. The peak forces, therefore were combined for all four pull distances. Tables III and IV show the cumulative distributions (number and percent) of Hard_{min} and Easy_{max} for males and females using the handle and housing simulators respectively. These data are shown graphically in Figure 7 for female subjects using the handle simulator.

Figure 7 provides the basis for defining "easy to pull" under the conditions of this study. The cumulative percentages of Hard_{min} and Easy_{max} displayed in this figure define the lower limit of "hard to pull" and the upper limit of "easy to pull" respectively for females pulling from the handle position. Similar figures, not presented here, have been constructed for males using the handle simulator and for males and females using the housing simulator. For any given percentage of the sample, the Hard_{min} line defines the minimum peak force which was judged hard. Similarly, the Easy_{max} line defines the maximum peak force which was judged easy for any specified proportion of the sample. These two functions may be viewed as providing conservative (Hard_{min}) and liberal (Easy_{max}) definitions of the peak forces considered to be easy to pull. Inspection of Figure 7 reveals the very large difference between the "liberal" and "conservative" estimates of easy to pull. This difference reflects the large variability in judgments of easy and hard both between individuals and within a single individual. This variability was evident for males and females using both the handle and housing simulators.

It was recommended that a "conservative" stand with regard to determining a force value for easy to pull be adopted by CPSC. This was suggested so that the greatest percentage of the population could "easily" restart lawn mowers and so that the incentive for defeating the dead-man control would be reduced. In practice, this would mean determining the peak

force by using the Hard_{min} distribution for females and selecting the sample percentage at 80 percent or greater. That is, the value for pulls from the handle position should be approximately 140N (31 lbf).

This study does not, nor was it intended to, answer the question of why one judgment is "easy" and another "hard." Neither does it provide a definitive answer to the question of what is easy to restart. The data generated in the study do, however, provide a practical basis upon which a policy decision regarding the upper force limit for "easy to restart" can be based.

The three studies reported here provide empirically based answers to specific questions which have arisen during the development of a proposed safety standard for power lawn mowers. As a result of these studies, the following recommendations have been made to CPSC:

1. In lieu of development of a new foot probe, the United Kingdom probe should be used for testing compliance with the standard since, of available probes, the UK probe most closely approximates movement of human feet under a lawn mower housing.
2. Based solely on the elapsed time from release of the dead-man control to finger access to areas of potential blade contact, a maximum of 0.7 seconds should be allowed for blade stopping.
3. The peak force necessary to restart a lawn mower with a handle mounted pull cord should not exceed approximately 140N if restarting is to be considered easy by a substantial portion of lawn mower users.

All of these recommendations have been made with certain qualifications. However, the three studies reported here do provide data which should be considered when CPSC makes policy decisions in these matters.

CHILDREN'S CONCEPTIONS OF MEDICINE:
THE ROLE OF ADVERTISING¹

Thomas S. Robertson, John R. Rossiter and Terry C. Gleason
Center for Research on Media & Children, The Wharton School

Abstract

This paper examines three important studies concerning children's orientations toward health and proprietary medicines and the relative impact of advertising on children's beliefs, attitudes, and proprietary medicine usage patterns. The report on the Wharton study is the first data emanating from this recently-completed project.

Overview

An issue of some consequence in the formulation of broadcast regulatory policy is the impact of medicine advertising on children. This issue was heightened in 1975 by a petition to the Federal Communications Commission emanating from the Attorneys General of nineteen states. In their petition the Attorneys General requested a ban on medicine advertising on television between 6:00 a.m. and 9:00 p.m. (Attorneys, 1975).

The substance of this petition was not so much that exposure to medicine advertising leads children to consume medicine, since consumption is presumably mediated by parents, but that exposure to medicine advertising induces receptive attitudes toward medicine-taking. Concern was voiced that such attitudes later become manifest in increased consumption and perhaps over-consumption, or dependency, on these products in adulthood.

The Attorneys General request for a ban on broadcast advertising of proprietary medicines before 9:00 p.m. was subsequently denied by the Federal Communications Commission on the grounds of lack of evidence for the effects suggested:

"... in the absence of empirical evidence to support the claim of a causal connection (between misuse or abuse of drugs and televised advertisements of over-the-counter drugs) it would be unreasonable and arbitrary for (the Commission) to accept the idea that otherwise lawful advertising should be prohibited" (FCC, 1976).

The purpose of this paper is to review three key studies relevant to the issue of advertising's impact on children's conceptions of medicine. In particular, we will focus on some initial results of a study just completed at Wharton, the objective of which is to provide the missing evidence concerning the link between advertising and medicine conceptions. A point of clarification is in order first, however, concerning children's exposure to proprietary medicine advertising. Industry self-regulation codes prohibit the advertising of medicines on "children's programs" (National Association of Broadcasters, 1974). However, these codes apply only to programs "initially designed for children" -- that is, those shows which are concentrated on Saturday mornings. Most children's viewing, however, is to non-children's programs. Among the top fifteen shows viewed by children, only three are shown in time periods covered by the NAB children's codes and 85% of children's viewing is to non-children's programs (Adler, 1977).

Research Evidence

There is little systematic research evidence on the effects of medicine advertising on children. Most research concerning advertising and drug products has focused on teenagers, rather than children, and has been concerned with illicit drug use, rather than proprietary medicine use.

The most significant studies to-date are twofold. The first is a study by Milavsky, Pekowsky and Stipp (1975-76) of NBC focusing on television drug advertising and its relationship to proprietary and illicit drug use among teenage boys. The second is a study by Atkin (1975) of Michigan State University, addressing the effects of television advertising on fifth, sixth, and seventh grade children. In this paper we also want to present initial results from the recently-completed Wharton study, which examines the impact of proprietary medicine advertising among third, fifth, and seventh grade children.

The NBC Study

This is a study of teenage boys utilizing a longitudinal panel design. The basic thrust of the research is to relate television viewing to reported usage of proprietary drugs and illicit drugs. The strength of this study is the measurement of television viewing, which is then combined with Broadcast Advertisers Reports, Inc. data which tracks commercials appearing on programs. Thus, the researchers were able to derive a drug advertising exposure measure indicating the total number of advertising seconds for proprietary medicines to which each boy was exposed. This procedure is described in detail by Milavsky, Pekowsky and Stipp (1975-76).

The NBC research findings indicate a positive, but relatively weak relationship between exposure to proprietary advertising and reported usage of proprietary medicines. This relationship is accentuated in homes where there are many proprietary drugs around the house.

By contrast, the NBC research finds a negative relationship between drug advertising exposure & reported usage of illicit drugs -- a finding similar to that of Hulbert (1974) in research with college students. Illicit drugs, however, are not our concern in this paper, nor is there advertising for illicit drugs.

The Atkin (Michigan State) Study

The Atkin study is based on data collected from a sample of 256 fifth, sixth, and seventh grade children selected from schools in urban, suburban and small town areas in Michigan. The basic thrust of the research is the examination of the relationship between television advertising exposure and a relatively rich set of dependent variables concerning children's beliefs, attitudes, and usage patterns for proprietary medicines.

The strength of the Atkin research is in his conceptualization of a set of interesting mediating variables affecting any proposed advertising exposure-medicine usage relationship. The weakness of the Atkin data,

in our opinion, is his measure of "medicine advertising exposure," which was constructed by multiplying amount of viewing to a limited set of television programs by the child's reported frequency of attention to four specific medicine commercials.

Atkin's results may be summarized in terms of the following medicine advertising exposure relationships, all of which are based on sixth-order partial correlations--controlling for grade, sex, social class, scholarship, child's frequency of illness, and parent's approval of medicine use.

- Population incidence of illness. Children with high exposure to medicine advertising perceive that people are more often sick ($r = .14$) and that they more often take medicine (.14).
- Belief in medicine. High medicine advertising exposure correlates with the child's belief in the quickness of relief after taking medicine (.10).
- Illness anxiety. Children with high exposure to medicine advertising worry more about getting sick (.14).
- Approval of medicine. The relationship between medicine advertising exposure and the child's approval of medicine is .12.
- Medicine efficacy. Children with high medicine advertising exposure are more likely to report feeling better after taking medicine (.12).
- Medicine usage. There is a general lack of relationship between medicine advertising exposure and medicine usage (.03).

In general, these results suggest that medicine exposure does, to a certain extent, influence the child's conceptions of illness and medicine. These relationships tend to be accentuated somewhat among the smarter children (as measured by scholastic performance) and among the higher social status children. Other variables such as age and sex of the child, parental attitudes toward medicine, or the child's frequency of illness all show inconsistent patterns.

Neither the NBC nor the Atkin study begins to settle the issue of proprietary medicine advertising's impact on children's medicine conceptions. A major fault characterizes both studies: the reliability of the measures is not reported. Correlations between unreliable measures can be seriously attenuated. Although both studies employed multi-item measures of medicine advertising exposure which are likely to be quite highly reliable, the reliabilities of the "effects" measures are unknown. The unreliability problem is particularly acute in the Atkin study (the only study with children as subjects) where single-item measures were employed. The consequence of unreliability is to produce lower correlations than might have been obtained with reliable measures. The possibility remains that the impact of medicine advertising on children is substantially larger than previously reported.

The Wharton Study

The Wharton Study was conducted in order to present a more conclusive investigation of children's conceptions of medicine in relation to various socialization factors that may be contributory. Exposure to televised medicine advertising was one of these factors.

The sample consisted of 673 children in approximately equal numbers from the third, fifth and seventh grades (ages 8 to 12). The sample ranged from

disadvantaged to upper-middle class families. Approximately equal numbers of boys and girls were interviewed at each grade level. The medicine advertising exposure measure was constructed in the same manner as in the Milavsky et al. NBC study. A random sample of 35 television shows was taken, excluding school hours and late night programming (past 11:30 p.m.). Children were asked to indicate how often they had watched each program on the last four occasions preceding the interview. Broadcast Advertisers Reports were then consulted to determine the number of medicine commercial minutes appearing on each show over the reporting period. The shows were weighted by the medicine advertising count and by viewing frequency, then summed to derive an overall measure of medicine advertising exposure. Reliability for this measure was 73.²

The "effects" variables for this study consisted of: 1) Belief in the efficacy of over-the-counter medicines, 2) Affect toward (liking of) over-the-counter medicines, 3) Intention to take over-the-counter medicines when symptoms occur, 4) Request frequency to parents for over-the-counter medicines, and 5) Usage frequency for over-the-counter medicine. Two additional variables comparable to the Atkin study were also examined -- the child's perception of the population's incidence of illness and an illness anxiety measure.

Each "effects" variable was measured by five self-rated items. These items comprised five categories of over-the-counter medicines: headache remedies, stomach remedies, cold remedies, cough remedies, and vitamin preparations. Reliability coefficients computed over the five items for each variable were: Beliefs .81, Affect .81, Intentions .75, Requests .76, Usage .52, Population Incidence .59, and Illness Anxiety .84.

Results. The findings are shown in Table 1, including the zero-order correlations and the fifth-order partial correlations. The variables controlled for (generally similar to Atkin) are grade, sex, social class, child's illness level, and parental supervision of medicine use.

In general, the magnitude of relationships is similar to Atkin, suggesting a somewhat tenuous association between medicine advertising and the several "effects" variables. The results may be summarized as follows:

- Medicine advertising exposure shows a zero-order correlation of .11 (significant at .01 level) with beliefs in the efficacy of medicine but only .04 at the fifth-order level.
- The relationship builds slightly when medicine advertising exposure is related to affect toward medicine (.14 zero-order and .07 fifth-order partial correlations).
- The relationship improves again when medicine advertising exposure is related to intent to take medicines when ill (.17 zero-order and .10 fifth-order).
- The strongest relationship holds between medicine advertising exposure and reported requests for medicine when ill (.24 zero-order and .18 fifth-order).
- When medicine advertising exposure is related to usage, the zero-order correlation is only .07 and the fifth-order .00.

² Reliability was computed using Cronbach's coefficient α (Cronbach, 1951). This measures the internal consistency of a series of items used to define a variable (see also Rossiter, 1977). The size of α reflects the degree to which the set of items comprising a test is oriented toward a single underlying dimension.

Table 1

Correlations Between Medicine Advertising Exposure and Children's Medicine Conceptions

Variables	Zero-order Correlations	Fifth-order Correlations*
Belief in the efficacy of Medicine	.11 ^b	.04
Affect toward Medicine	.14 ^a	.07 ^c
Intent to Take Medicine	.17 ^a	.10 ^b
Requests for Medicine	.24 ^a	.18 ^a
Medicine Usage	.07 ^c	.00
Population Incidence of Illness	.00	-.10 ^b
Illness Anxiety	.22 ^a	.13 ^a

* Controls for grade, sex, social class, illness level, and parental supervision of medicine-taking.

a Significant at .001 level

b Significant at .01 level

c Significant at .05 level

- The relationship between advertising and the child's perception of the population incidence of illness is .00 (zero-order) and -.10 (fifth-order).

- Finally, the medicine advertising exposure/illness anxiety relationship is .22 (zero-order) and .13 (fifth-order).

Interestingly, there is an absence of an advertising/usage relationship. However, requests for medicines to parents represents the critical response measure for children's consumer behavior. This is because parents execute most purchasing for children (especially for medicines) and requests, therefore, should be regarded as the "response" over which the child has control. Analysis of the advertising exposure/requests relationship indicates that it is moderate (.18 fifth-order) and highly significant in a statistical sense (.001 level).

Conclusions. What have we learned at this early stage of our analysis? Generally, television advertising of proprietary medicines has a rather moderate effect on children's beliefs, affect, intentions and request behavior. Interestingly, the effect increases as we move from beliefs to requests (fifth-order partials of .04 versus .18). There is no obvious impact of television advertising on actual usage of medicines. Apparently, usage behavior is a function of other factors, most particularly illness level and parental mediation.

In order to understand children's conceptions of medicines, television advertising as an explanatory factor must be placed in the context of a multi-mediational model of effects. The examination of such an enriched model will comprise the next phase of our analysis. In particular, we wish to understand the family mediation process and the role of multiple information sources in affecting children's conceptions of medicine.

CONSUMER BEHAVIOR AND NUTRITION: PREVENTIVE HEALTH PERSPECTIVES

M. Venkatesan, University of Oregon

Abstract

There is increasing interest in consumer behavior and nutrition. However, the present attempts are inadequate inasmuch as they follow the "curative" approach. What is needed is a "preventive health approach." Such an approach recognizes that changing consumer nutritional habits is a long-term phenomenon. A brief summary of the current state of our knowledge in this area is provided and suggestions for future research are outlined.

Ever since the Federal Trade Commission issued a proposed Trade Regulation Rule on food advertising aimed at regulating the claim and information contained in the advertisements for food products, considerable attention is being devoted to consumers and nutrition. Much of this attention has been directed in the forms of suggestions -- some of which resulted from recent studies -- towards the formats in which such information should be provided [Kendall, 1977; Scammon, 1976], the type of information that should be provided [Bettman, 1975], and the attributes of such information [Quelch, 1977]. Other studies have concentrated on the current level of knowledge and the use of such knowledge by consumers [Jacoby, 1976, USDHEW, 1974, 1975].

It is interesting to note that these flurries of activities did not deal with the reasons for the attempts of the Federal Trade Commission and others to provide nutritional information. The current attempts at disclosure are based on the belief that there is nutritional deficiency among consumers and is based on the findings of three major studies, viz., The Ten State Nutrition Survey [1972], First Health and Nutrition Examination Survey (HANES) [1974] and the USDA Survey of Dietary Levels of Households in the United States [1965]. There are unresolved controversies surrounding the interpretations of the findings from these three studies and the segments of population to which such findings properly relate. Irrespective of these difficulties, the philosophy behind the TRR of the Federal Trade Commission, and therefore, of the studies that have attempted to research and suggest ways in which to communicate the nutritional information have all taken a "curative" approach to the problem. That is, a "malnutrition" problem is perceived to exist among consumers and therefore the researchers are suggesting "cures" to the policy makers. It is clear that our studies of consumer knowledge of nutrition [Jacoby, 1976] and their use of such information and our suggestions [Bettman, 1975, Scammon, 1976, Venkatesan, 1977] have all been influenced by this "curative" perspective of the problem of nutritional deficiency among consumers. In short, we have taken the same approach as much of the medical practitioners and which has come under increasing criticism. The reason for this can be traced to lack of clarity in our thinking with regard to nutrition and consumer behavior and our haste to apply our "consumer behavior approach" to this area of human behavior and assuming the results will be similar to buying behavior research for a variety of products and services.

We have finally come to understand that in order to affect the behavior of consumers in the area of nutrition, we have to be concerned not with the "curing" aspects of nutritional deficiency, if any, but with the

preventive health behavior aspects of consumer behavior. It is becoming increasingly clear that more and more consumers are exhibiting concerns about food additives, ingredients of food products, trace minerals, etc. reflecting an interest in prevention. We, as a society, are becoming more convinced that prevention is both simpler and cheaper than cure in all aspects of our behaviors. There is increasing emphasis on prevention of every kind -- medical, occupational, environmental, and nutritional. For purposes of this paper, preventive health behavior for consumers in the nutritional area can be defined (with a slight modification of the existing definition of health behavior of Kasl and Cobb, 1966) "as any activity undertaken by a consumer who believes himself/herself to be healthy, for the purpose of preventing nutritional inadequacies.

In general, there are two types of prevention activities that can be undertaken by individuals, viz., passive prevention and active prevention. Passive prevention does not involve any active participation by the consumers to get prevention. An example of such prevention might include fortification of all food products with required levels of vitamins, minerals, etc., or elimination of all additives/ingredients (and even products) which are not fully tested and which are suspected or even remotely linked to some cancer producing agent. As is obvious, passive prevention measures will not, for the most part, involve the consumer. However, such passive preventive measures are not feasible because providing fortification of food products becomes prohibitively expensive. Secondly, much is not known about the long term effects of such fortification efforts. Thirdly, not all of the individuals require the same level of nutrition intake.

Much of our problem in the nutritional area (deficiency, obesity, etc.) are "self-imposed" such as excessive eating, eating of junk foods and improper diets, etc. Nutritional knowledge and use of such knowledge in the choice and consumption of nutritionally beneficial food products fall under "consumer behavior," as such activities involve consumer awareness about nutrition and relating such knowledge to foods and food products and consumption of such products relate to consumer choice processes. Here, our understanding of consumer behavior and applying it to nutritional settings might be of help to both the producers of these products and to the policy makers. Thus our concern is with consumers' active prevention behavior and that implies that the individuals have specific things to do, some of which might affect and/or change their life styles. That is, consumers are fully expected to actively participate to gain benefits of prevention. Even if such preventive measures are taken by consumers, there is no guarantee that any illness or deficiency will be prevented for the individual nor can it be claimed that such prevention may lead to elimination of any disease, etc.

The active prevention notion in the nutritional area involves social change concepts, that is, changes in the life styles of individuals over a long period of time and deliberate intervention programs may become part of change strategies. Some claims have been made that such social changes can be brought about by "social marketing." [Kotler and Zaltman, 1971]. We do not currently have ample demonstrations or empirical

evidence of success in this area. There are also a number of ethical and public policy considerations in any attempt to implement active prevention measures by consumers in the nutritional area. There are still controversies regarding the RDA levels that are set as guidelines and there will be problems in policy makers attempting to suggest not only consumption of specific foods (eggs vs. beef, etc.) but consumption of specific brands of food products.

Current State of Our Knowledge

The Food and Nutrition Surveys (1974, 1975) of the Food and Drug Administration are the most comprehensive studies to date. By and large, these two surveys indicate that a substantial proportion of consumers are knowledgeable about the concept of "well-balanced diet" and only a small proportion of consumers have indicated that they were not getting a well-balanced diet and this was not due to any lack of awareness on their part, but that it was due to other reasons such as "fussy eating" and too much time spent away from home and the like. The Red Book surveys (1974, 1976) also indicated that a very high proportion of their respondents are aware of the basic food groups, and recognized the need for well balanced meals and the like.

If the awareness level is high, why then is their consumption behavior presumably not consistent with their awareness? For one thing, none of the national surveys have found any serious concern or perception of a serious problem with nutritional deficiency. Most consumers are concerned with obesity and other similar problems. Bauman [1973] correctly identified the reasons for lack of concern when his surveys found that most housewives believed that they were serving their families with a variety of basic foods over a period of time, which they believed will achieve nutritional balance. The second reason Bauman attributed for nutritionally inadequate eating habits is the breakdown of traditional three-meals-a-day pattern of eating behavior and the growing tendencies of families to eat more meals away from home. Another reason advanced by some is that while there may be general awareness of nutrition, the need for well-balanced diet and the like, consumers generally lack information on specific nutrients. Their problem is compounded by the fact that consumers have difficulties connecting their already meager knowledge of specific nutrients with the food products in general and with specific brands of food products in particular. There may also be a confusion factor, as Lachance [1973] observed:

The consumer wants a balanced diet, but the confusion over how to attain it is fantastic. Not only are there more foods to choose from, but we nutritionists have contributed to the confusion. One can take any one of several college level textbooks on nutrition to learn that the good sources of protein, several vitamins, and minerals are organ meats (e.g., liver), egg, milk, cheese, etc., only to advise in a separate chapter or article that to avoid heart disease one must limit the intake of -- you guessed it -- organ meats, milk, eggs, certain cheeses, etc.

Finally, as the surveys have repeatedly found that the unshakeable belief among consumers seems to be that one can get enough nutrition from eating a variety of foods from the supermarket and this contributes to the problem of consumer education. There are other reasons and there are a number of studies that point out problems and difficulties in attempting to change the eating habits of consumers. [For a summary of these studies and a critique, see Kendall, 1977].

Proposal for Research

Research in how consumers make choices of food products in the supermarket is very sketchy and much less is known about how they combine their nutritional information with actual choice of branded products. It is obvious that food choices are not the same as brand choices of food products. The recent research studies that deal with consumers evaluative criteria for food products and with attributes of food products and the type of information that needs to be provided are all concerned with way "ought" to be provided and not with how and why consumers make their choices of food products the way they do. For example, we know very little about the criteria consumers seem to use in choosing brands of food products. Bayton [1968] has reported that he had found from his research in the purchase of food products that consumers had the following parameters, which he grouped into seven categories:

I. Nutrition Parameters

1. Body growth needs
2. General health needs (rather than specific health needs)
3. Vitality; energy
4. Energy "carry-through" (concern over longlasting energy)

II. Economic parameters

5. Price, per se
6. Value (what you get from the money)

III. Sensory--aesthetic Parameters

7. Taste-aroma-appearance complex
8. Refreshment (especially "coolness" relief of thirst)

IV. Personableness Parameters

9. Personableness-in-general (lively; good complexion, bright and sparkling eyes; general attractiveness)
10. Sex personableness
Males--vigorous, athletic; masculinity
Females--lovely complexion; nice figure, femininity

V. Appropriateness (suitability to my kind of person or to given situations)

11. Religious-cultural appropriateness
12. Age--group appropriateness (milk for children, coffee for older ages)
13. Status-group appropriateness (class-relatedness of some foods)
14. Social setting appropriateness (family privacy; intimate friends, special guests; restaurants)

VI. Convenience

15. Convenience in purchasing; availability
16. Convenience in storing
17. Convenience in preparation
18. Convenience in serving
19. Convenience in consumption

VII. Health apprehensions

20. Weight apprehension
21. Cardiac apprehension
22. Contamination apprehension (pesticides, bacterial, animal medications, atomic fall out)
23. Allergies

There is not much research evidence available on these parameters. However, it is clear that jumping to conclusions or extrapolations from findings on the use of nutrient labeling to the whole area of nutrition and consumer behavior is both imprudent and premature. Secondly, changing or influencing consumer behavior in this area, as pointed out earlier, is a long-term problem. In a study [Wilson, 1972] attempts were made to educate six families, on a longitudinal basis, on nutrition information. The resultant improvements in their food habits was minimal. Thus, quick solutions and grandiose short-term suggestions are not likely to succeed in changing the behavior of consumers. What is needed is a program of painstaking experimental research for a long period and implementation of the research based approach by policy makers will in all likelihood increase the chance of maximum benefit at least cost for the society and enhance the nutritional well being of our society.

ENVIRONMENTAL PROTECTION FOR THE NON-SMOKER:
CONSUMER BEHAVIOR ASPECTS OF ENCOURAGING NON-SMOKING

Lawrence H. Wortzel, Boston University
Roberta Clarke, Boston University

Abstract

It is becoming more widely recognized that cigarette smoke is harmful to non-smokers, yet there has been very little study of the ways in which non-smokers can protect their environments from smoke. This paper reviews and recasts studies on cigarette smoking to bring their results to bear on the problem of non-smoker environmental protection. It also offers some ideas for both research and action.

Introduction

The existing research and related literature on cigarette smoking can be broken down into three major categories. The first category, which makes up the bulk of the literature, details and seeks to prove the physical and health-related damage experienced by those individuals (and experimental animals) who smoke cigarettes. The second category of literature, somewhat less substantial in nature, directly addresses the smoke and those who would wish to influence the smoker not to smoke. This literature is concerned with the smoker's own good.

It is the third category, however, which this paper addresses. In this category is literature which seeks to educate the non-smoker about how to prevent the smoker from lighting up a cigarette in the non-smoker's presence for the non-smoker's good. There are, at present, few studies and little literature dealing with this topic. However, we believe that this category will soon become more actively studied for several reasons.

First, while it has long been widely accepted (at least on the cognitive if not the affective level) that cigarette smoking is harmful to the health of the smoker, only recently has it been recognized that smoking can also be deleterious to the health of the non-smoker who is in close proximity to smokers. Scientific evidence that cigarette (as well as pipe and cigar) smoke is harmful to the non-smokers who are exposed to it (U.S. P.H.S., 1972) points to such harmful effects as eye and nose irritation which is immediately apparent but transitory; children particularly are sensitive to these effects (Lugnette *et al.*, 1970). Of a more lasting nature, however, is the possible increased probability of lung cancer and emphysema, neither of which is apparent to the non-smoker at the time of exposure. In fact, many non-smokers, unless they are specifically allergic to cigarette smoke, have probably been relatively unaware of the long term hazards of smoke from others' cigarettes.

However, this situation can be expected to change. There are significant efforts being made to inform non-smokers of both the short and long term hazards of exposure to smoke. The American Lung Association, for example, publishes a pamphlet, Second Hand Smoke, the majority of which is devoted to explaining the dangers of smoke. This pamphlet also briefly suggests some defensive actions which non-smokers can take to protect their environments. Moreover, Action on Smoking and Health (ASH) offers bumper stickers, buttons and small message stickers which either promote non-smoking or request that the reader not smoke. GASP (Group Against Smokers'

Pollution) of Massachusetts, another consumer activist anti-smoking, exists to publicize the hazards of second-hand smoke and to support legislation aimed at insuring non-smokers' rights.

The ultimate solution to the second hand smoke problem may be the enactment and vigorous enforcement of anti-smoking legislation. Indeed, significant progress has been made in this direction, with the establishment of "no smoking" sections in airplanes and (some) restaurants as well as "no smoking" regulations in some public places. But, in the short term, the smoker must still defend against smoke in many of the environments in which he or she finds himself or herself.

A second and related reason why we expect this area (the protection of the non-smoker's air rights) to become more heavily researched is that the growing emphasis on preventive health care has made us all more aware of personal health risks and more active in seeking to maintain our health. Why jog, for example, to fill our lungs with clean air and then breathe others' smoke?

As noted previously, whatever smoking-related health education literature there was existed primarily to educate the smoker to the dangers of smoking. This literature is essentially passivist with regard to whatever health risks smoking presented to the non-smoker. However, preventive health care education is now beginning to extend itself to educate the non-smoker in smoking-related preventive care; that is, how to prevent smokers from smoking near you. The growing activist stance in non-smoker preventive care is certain to have an effect upon future research in this area.

While there is not much literature directly on the topic of non-smoker environmental protection, there is a considerable body of literature, some of which has been reviewed, (Fishbein, 1977) which can be considered as having some relationship to this anti-smoking problem; however, the literature has never been examined from the non-smokers point of view. If the literature has been reviewed in any kind of action format, that format has been one aimed toward either encouraging non-smokers not to start or encouraging smokers to stop (permanently). The question here is a much more temporary one; it is concerned only with encouraging non-smoking for short or finite lengths of time in specific places. Thus, the primary emphasis is on identifying consumer behavioral reasons that are amenable to immediate attack.

This paper, therefore, deals with the short-run (non-legislative) problem of activist non-smoker environmental defense: how the non-smoker can defend whatever environment he or she is in and only for the length of time he or she happens to be in that environment. The paper relies upon consumer behavior analysis as a basis for selecting marketing tools and promotional context which can be effectively used to inhibit smokers in distinct situations.

The studies which have been reviewed fall into two broad areas: 1) internal cues: smoking and personality/social behavior characteristics, and 2) external cues: factors which trigger the smoker to light up a cigarette. Both

areas will be discussed; included in the discussion are suggestions for strategies and tactics that might inhibit short term smoking. The format will be first to review the studies and then to suggest action strategies. This review will be in no sense exhaustive as the authors' own reasonably exhaustive review indicated a considerable degree of redundancy in the literature. Therefore, only a representative group of studies deemed to have actionably useful findings will be reported here.

In addition to the literature on psychosocial correlates of smoking, there is also a literature on physiological correlates. Some of this literature (Schachter, 1977) presents evidence that cigarette smoking produces physical dependency if not addiction. This literature will not be addressed here; while a recognition of the role that physiology plays may be significant in inducing an individual to stop smoking permanently, there is not any strong evidence that physical symptoms are so intense as to prevent smokers from postponing a smoke for a finite length of time. The review begins, therefore, with internal cues.

Internal Cues: Personality and Social Behavior Characteristics

There have been quite a few studies covering the relationship between smoking and personality and various social behavior characteristics. None of these studies have demonstrated that any of the factors that were studied actually caused smoking; however, their presence may offer some clues to the non-smoker who wishes to take action.

Review of Studies

A number of studies examine the motivations for and correlates of smoking among adolescents, since many smokers begin smoking during adolescence.

Adolescents begin their smoking in a peer-group atmosphere which they perceive as accepting of smoking. In a national study including both smokers and non-smokers conducted in 1975 by Yankelovich, Skelly and White, over 80% of teenaged boys and girls said they usually think of teen-agers as smokers, and 67% said they usually think of teachers as smokers. This indicates that teen-agers believe smoking was an activity accepted by both their peers and their school authority figures. (U.S. Dept. of HEW, 1977). Perhaps the most insightful description of adolescents' motivations for smoking is offered by Neeman & Neeman, who comment:

It is possible that the act of smoking itself is, in part, a component of the communication process, namely an "emblem" or display: the blowing out of a plume of smoke has been likened to the display of a peacock's plumes, decoded as an emblem of status or dominance vis-a-vis peers of the same or opposite sex, communicating the smoker's toughness, independence, and a precocious type of sexual maturity, and conveying social acceptance and recognition. Smoking also provides a means of offering or accepting social contact. (Neeman & Neeman, 1975)

These comments are well supported and sex-differentiated by data from the survey conducted by Yankelovich *et al.*, which was referred to earlier. This survey concluded that cigarette smoking among teenaged boys was associated with social uneasiness, the desire to be popular with girls and demonstrating one's masculinity. Girls, on the other hand, do not see smoking as a social asset, but rather as a sign of a rebellious independence, and a somewhat defiant social maturity. For example, a much larger proportion of teenaged girl smokers, as compared to non-smokers, said they drink alcohol and had had

sexual relations (U.S. Dept. of HEW, 1977).

Studies have also been conducted among college students. Some of these studies have used general personality inventories to try and differentiate between smokers and non-smokers. Schubert gave the MMPI, along with measures of tobacco usage to two samples of college students, totalling 1270 respondents. His results were not consistent between the two samples when these results were analyzed in terms of traditional MMPI categories. There was no consistent personality differentiation between smokers and non-smokers. However, an item analysis did indicate some constant differences. Smokers' self-descriptions indicated they were more likely to be bored, impulsive and thrill-seeking, to behave in a socially unacceptable fashion, to ascribe this trait to others and to have masculine traits. These characteristics were described generally as arousal-seeking (Schubert, 1965).

These findings were both reinforced and extended by a later study using 517 male college students as subjects and the Boston University Personality Inventory as the instrument. Heavy smokers (as compared to non-smokers) were more impulsive, defiant and danger-seeking. These results also were reported as suggesting that smokers used smoking as a means of warding off manifest distress conditions such as tension, irritability and boredom (Jacobs & Spilken, 1971).

There is also some evidence that adult smokers have considered their behavior as deviant but not defiantly so. As early as 1966, 45% of all smokers (then currently smoking) interviewed in a National Survey agreed that "cigarettes are morally wrong." (Nuehring & Markle, 1974). During the years between 1966 and 1974, the authors argue, many smokers have become 'repentant deviants' (as opposed to the younger defiant deviant) who admit the reprehensibility of their actions and by doing so gain license to persist in smoking. But the more mature smoker has integrated smoking into his or her personality and/or into his or her psychomotor behavior. When one becomes an established, regular smoker, smoking becomes a means of telling others about oneself, but the acts associated with smoking become habitual and autonomic. Possibly, in fact, smoking becomes an idiosyncratic behavior akin to foot tapping, pencil twirling, nail biting and the like (Dunn, 1973).

Action Implications

These findings present some intriguing yet contradictory possibilities for action. However, if non-smokers are to take these actions, they would have to do so as a group as the action possibilities might best be defined as media advertising in public places. The content of this advertising could be communicated by individual non-smokers as well, but less successful results would be expected.

The opportunities for action in terms of "advertising" would differ between more experienced vs. newer smokers, especially if the newer smokers and teen-agers or college students. Among more experienced smokers, the general tenor of messages should be (1) to emphasize that smoking in that particular place is deviant behavior and that the only way to repent is not to smoke and (2) to raise consciousness that one is smoking in that place if one does so, since smoking for some individuals is so habitual that they are at a conscious level momentarily unaware that they are smoking.

On the other hand, messages such as these should cause young, newer smokers, especially males, to light up a cigarette. These messages would reinforce deviant (smoking) behavior among this group since teen-aged male smokers are defiant deviates; moreover, raising consciousness about the act of smoking raises the impor-

tance of the situation as an opportunity to display one's masculinity or one's social maturity as the case may be. Therefore, it should be more effective instead for advertisements to portray smoking in such environments as unmasculine, socially immature and a sign of social weakness. Unfortunately, this type of advertising (which would probably be communicated in print through buttons, brochures, posters and youth newspapers, given the higher cost of broadcast media) is not likely to be very effective principally because of the importance of the peer group in guiding smoking behavior.

In summary, the studies of personality and social behavior characteristics suggest a possible line of attack for producing non-smoking behavior among experienced mature smokers but a considerably less attractive line of attack for younger, less experienced smokers. Since specific attitudes and behavior are usually better predictors of action than the generalities discussed in the above studies, it is possible that in the future more specific research could direct us toward more effective action.

External Cues: Factors that Trigger Smoking among Smokers

There have been several studies focusing on relationships between smoking and various external cues. First, we will examine those studies with indirect action implications, followed by studies that indicate action directly. This second section will also rely to some extent on non-academic literature and information provided by anti-smoking groups, as such material considerably broadens the action possibilities open to the non-smoker.

Review of Studies-with Indirect Action Implications

Shapiro *et al.*, studied 750 smokers to determine what links, if any, existed between environmental events and "lighting up." They found that it was usual for smokers to smoke on specific occasions although these occasions varied across people. There were, however, some situations that were popular among all smokers. These were situations that were stressful, required concentration, or were relaxing (Shapiro, *et al.*, 1977). In these situations, individual smokers originally began to smoke to reduce negative affect or to cope with an unpleasant or stressful situation. For others, smoking was initiated to experience or to increase the experience of positive affect, excitement, relaxation and enjoyment associated with the situation. Over time, however, what is experienced by the individual in many such situations is neither enhanced nor dampened by smoking, but instead the specific situation becomes a strong cue to smoke and the individual does so without becoming aware that he or she is doing so (Tomkins, 1966).

Herman, using eating behavior as an analogy, divided smoking cues into external (situational, such as other people smoking) and internal (deprivation of cigarettes). He conducted an experiment using approximately 100 college students as subjects in which internal and external cues were manipulated for both light and heavy smokers. He found that heavy smokers were affected primarily by internal cues (although they were not insensitive to external cues), while light smokers were affected by both internal and external cues (Herman, 1974). It would seem fruitful to explore further the relationship between smoking and external cues since these are "marker-controllable" variables. There is further evidence that external cues are important in the situations with which we are concerned.

The nature of external cue situations may differ across social classes. Meyer *et al.* point out that many blue collar jobs, for example, prescribe or proscribe the amount of smoking that can take place during work. White

collar workers, on the other hand, are usually free to smoke on the job (Meyer *et al.*, 1973). Thus, blue collar workers may be exposed to many fewer external cues than are white-collar workers and therefore may be differentially (either more or less) sensitive to external cues. Thus, Herman might have had different results had he used blue collar workers instead of college students.

There has been some attempt to identify some of the specific situations providing external cues that trigger smoking. Hochbaum, early on, pointed out that smokers link smoking with entering a room where there are people or with seeing someone else smoke (Hochbaum, 1965). Foss reports on a study of 87 present and former smokers; both groups smoked primarily in social situations or social gatherings; 54% of present smokers and 79% of former smokers reported having done so (Foss, 1973). Both Hochbaum and Foss, however, say that the overt act is simply a manifestation or expression of some less apparent but deeper feeling such as anxiety or inadequacy.

In summary, while both internal and external cues influence smokers' behavior, much smoking is done in social situations in which external cues are present in abundance. These cues may serve to trigger smoking, for example, by reminding the smoker of the anxiety inherent in the situation. There is also evidence that people continue to smoke in situations that no longer produce affect, thus suggesting that cues can simply produce smoking behavior for no other reason than the presence of the cue.

Action Implications

With respect to external cues, essentially there are two smoker populations to be considered: those for whom smoking in a given situation produces affect and those for whom the situation is merely a cue, and no affect is produced. The action implications are different in each situation. Where affect is produced, the goal of action is to modify the affect, providing substitute sources of gratification or relieving anxiety as indicated. Where there is no affect present, it would seem that the goal of action is simply to make the smoker aware that he or she is smoking for no particular reason.

The action problem is more difficult when the smoker is motivated primarily by affective cues. Perhaps, the best that can be done is for the non-smoker to recognize the motivation and simply ask for delay.

Review of Studies that Indicate Action Directly

This section of the paper departs slightly from the previous format in that action ramifications will be discussed with the studies or will be suggested independent of experimental data. Non-verbal action possibilities will be discussed first followed by direct verbal communication strategies.

Two relevant studies deal with behavior under the presence or absence of specific external cues, essentially suggesting non-verbal active strategies. These two will be reviewed first.

One such study found that women (but not men) were more likely to smoke when in proximity to others who were smoking (Tryon *et al.*, 1977). The other concerned college students' smoking in a classroom without ash trays. Students refrained from smoking either because of fear of criticism from the instructor or because of guilt about dropping ashes on the floor (Ritter & Holmes, 1969).

These two studies suggest some specific actions. The first study suggests that the non-smoker probably needs

to keep as much territory as possible around him or her smoker free; if a woman is more likely to smoke when in proximity to other smokers, she may want to do so when juxtaposed between the non-smoker and a group of smokers. Obviously, this also suggests segregating all smokers from the non-smoker rather than intermingling smokers and non-smokers. The second study, besides indicating the obvious strategy of ash tray removal, argues that in the non-smoker's own environment, placing an expensive-looking rug where visitors sit could silently inhibit others from smoking (but at some risk).

Commercial programs which help smokers to stop smoking also want to protect their successful graduates from having to deal with smokers. Their recommendations for non-verbal action included not only the removal of ash-trays and matches, but also the wearing of anti-smoking buttons (which they point out may label the button wearer as a fanatic or "nudnik" but are also to some extent successful in temporarily postponing smoking behavior). The balance of the studies to be reviewed deal with specific communication content of various types, each of which suggests some possibility for action.

Horn & Waingrow have proposed using mastery as a motivation to get people to stop smoking. They argue that, for some people, inability to keep control of themselves is more frightening than the health hazards attached to smoking. Thus, presenting smoking as out-of-control behavior may motivate some smokers to give it up (Horn & Waingrow, 1966). Such a strategy might be dubious over the long-term, but for short periods of time could be an extremely effective bit of personal selling. The non-smoker could ask the smoker, "are you so out-of-control that you have to smoke right now?"

Another stop-smoking motivation might be humiliation. Premack posits that it's acutely humiliating to be identified as belonging to an interdicted class (Premack, 1970). To the extent that smokers view themselves as deviants and are really contrite about their position, it can be speculated a humiliating message might work, "Gee, I didn't think anyone in your position would smoke smoke...". However, the success of such a message might depend also on the relative status of the smoker and the non-smoker.

Anti-smoking consumer groups and smoke-ending programs have developed a grocery list of actions which non-smokers might take to protect themselves from second hand smoke. However, some of these groups take pains to point out that non-smokers must first believe they have the right to take these actions against smokers before they will do so. Therefore, the groups believe the first step is to educate the non-smoker as to his or her rights. This has been done by (1) indicating to the non-smoker that smokers are now a minority (46%) of the U.S. population, in a country of majority rule and (2) educating the non-smoker to the dangers he or she may be inflicting on him or herself by breathing second hand smoke. Second hand smoke contains such poisonous substances as ammonia, benzene, carbon monoxide and hydrogen cyanide. The anti-smoking groups' contention is that if the non-smoker recognizes the risks of breathing second hand smoke, he or she is more likely to take an activist stance in attempting to prevent smoking in her or his immediate area.

These groups have also raised the question of whether non-smokers as a group should also attempt to educate smokers about the dangers of second hand smoke. All communications from non-smoker to smoker all likely to be more effective if the smoker is able to appreciate the physical and psychological irritation which smoke causes to the non-smoker.

The communications suggested by anti-smoking groups which a non-smoker may use to temporarily prevent nearby smoking tend to fall into three categories: courtesy,

empathy and medical. Courtesy communications such as "Please don't smoke," or "Could you wait until we are off the elevator before you smoke" are viewed as sometimes effective but also sometimes hostility-arousing as the smoker may believe this his/her rights are being trodden on.

The empathy communication, which tends to be a good deal more personal, is best used by a previous smoker who has stopped smoking permanently (or by a non-smoker who is willing to lie). The message is basically "Please don't smoke right now. I am a former smoker and being so close to someone who is smoking makes me extremely uncomfortable (makes me feel like smoking, makes me anxious, etc.) If you could just wait until I'm gone..."

However, the literature of the anti-smoking groups seems to favor the medical communication which clearly indicates a negative physical effect suffered by the non-smoker due to the smoker's smoke. Complaints of eye and nose irritation or of general allergic reactions to smoke may produce the desired results. However, the stronger the medical complaint, the greater the likelihood of non-smoking behavior, according to the anti-smoking groups. Thus, complaints of emphysema and asthma by the non-smoker to the smoker appear to be the most effective in postponing smoking behavior.

Finally, if all else fails, one may look to Powell and Axrin. They studied the effect of electric shock on cigarette smoking; they found that the effects of shock worked in the short run, as the number of cigarettes a smoker in this experiment smoked were a function of the intensity of the electric shocks he received (Powell & Axrin, 1968). Perhaps, as a last resort, timid non-smokers should install electric chairs in their offices.

Conclusions

Modifying smokers' behavior, even for short periods of time, is a rather complex process and one that should be tailored both to the situation and to the smoker. It appears that group action on the part of non-smokers is likely to be effective only in the short-run. Soon, for example, if individual non-smoker action increases, smokers might start carrying their own ashtrays; moreover, their willingness to believe that the coughing non-smoker next to them has emphysema will decline as the number of self-proclaimed emphysemics increases.

In any event, there are significant opportunities to do research on the subject.

Abstract

Mass media have considerable potential for affecting health behavior. The pervasiveness of mass media and the exposure levels of broad segments of society suggest that mass media may be an important information source regarding health and a relevant socialization force regarding health attitudes and behavior. Nevertheless, research evidence indicates that most mass media campaigns oriented toward changing health care habits fail. The objectives of this paper are to analyze why health care campaigns fail and to derive generalizations for more effective use of mass media by health care professionals.

Overview

The role of mass media in affecting knowledge, attitudes, and behavior toward health care may be thought of in terms of the following two dimensions.

1. Mass media may impact health knowledge, attitudes and behavior both in a deliberate sense through "campaigns" that are specifically designed for such impact, and in an unintended or "incidental learning" sense through material that contains health-related information, but which is not specifically intended to impact health knowledge, attitudes or behavior.
2. In both cases, mass media may act either as a "change agent" or as a "reinforcing agent" -- that is, media may function in such a way as to change knowledge, attitudes and behavior or to confirm existing behavior patterns. In these respects, the role of mass media in affecting health care is similar to their role in affecting knowledge, attitudes and behavior toward other products and services.

Campaign Versus Unintended Effects

Mass media campaigns are intended to communicate certain health care information with a view toward change in health habits. Examples include anti-smoking, seat belt usage, lower cholesterol, and hypertension identification campaigns.

Mass media may also have unintended effects in the sense that the average viewer is exposed to a regular diet of "medical" shows on television and also to large numbers of commercials for proprietary medicines. The learning from such programming and commercials may be in the form of "misinformation" and may not be compatible with good health habits. A national study by the Louis Harris Organization (1973), for example, concluded that mass media were second only to the individual's physician as a source of health information. Furthermore, much of the health information absorbed from television is likely to be under low involvement conditions and, therefore, processed without evaluation.

A logical question then is whether mass media depict an accurate profile of health, illness, and the value of medical services, drug products, or medical treatment. Some social critics suggest that mass media depict a distorted and stereotyped view of these topics with consequences for people's health beliefs,

attitudes and behavior and for their probabilities of accessing the medical system under specified conditions. For example, to what extent does advertising for proprietary drugs convince people to search for simplistic solutions to medical symptoms that may be indicative of more serious problems? To what extent does cigarette advertising help people to deny or sublimate the medically dangerous effects of smoking?

The extent to which mass media either positively or negatively impact health is an important empirical question requiring systematic evidence to resolve. One study of television programming found that 30% of the health-related information was "useful" while the remaining 70% was inaccurate or misleading or both (Smith, 1972). This may suggest the magnitude of the potential problem, although this study is only one isolated piece of research evidence. Another study by Frazier et al. (1974) of dental health advertisements concluded that 43% of the information is inaccurate, misleading, or fallacious. The hypothesis may well be that mass media act more to misinform than to educate people about health and appropriate health habits.

Change Agent or Reinforcing Agent

The potential of mass media communications in the health care arena is generally phrased in terms of their promise for changing habits and life styles. However, the history of communication research indicates that the most persistent finding is that mass media act mainly to reinforce existing attitudes and behavior.

The ability of mass media to effect change is actually a function of a number of factors and requires certain conditions which we will develop later in this paper. Basically, however, the probability of change tends to be a function of how much commitment people have to existing behavior patterns. Under high commitment conditions, as is frequently the case in health care, bringing about change may indeed be a difficult undertaking. This is likely to be the case since health behavior is frequently rooted both in long term reinforcement patterns and in support by the individual's social environment. (In some special cases physical and psychological addiction patterns may also be a factor with which to contend.) A look at the evidence on health care campaigns supports the statement that most health care campaigns do not succeed among large numbers of intended subjects. The literature is replete with discouraging case studies.

- Obesity. In summarizing the evidence on obesity, Stunkard (1975) sets forth five propositions: (1) most obese people do not enter treatment, (2) of those who do, most drop-out, (3) of those who remain, most do not lose much weight, (4) of those who lose weight most will regain it, and (5) many of those entering treatment pay a high emotional price. Nevertheless, Stunkard registers considerable hope based on behavior modification programs, which recently have improved the treatment of obesity. He implicitly rejects mass media as an important force in changing behavior.
- Smoking. Anti-smoking campaigns have had limited success, at best. Cigarette consumption has not

declined, despite communication campaigns and public policy initiatives protecting non-smokers. In fact, it is increasing among teenagers, especially among girls. However, there has been a change toward consumption of lower tar and nicotine cigarettes. Perhaps the consequence of messages about lower tar and nicotine cigarettes has been to convince smokers that smoking is becoming safer.

On the other hand, one potentially successful anti-smoking campaign was initiated, when counter-advertising messages were shown on television under the equal time provision of the Federal Communications Commission. Possibly the combination of smoking and counter-smoking commercials presented together acted similarly to a two-sided communication; however, it is unlikely that mass media counter-advertising alone accomplished the job.

Seat Belts. In a review of research on seat belt usage campaigns, Leon Robertson et al. (1974) report a general lack of positive results. These authors then initiated a well-controlled experimental study using split-cable television whereby one audience received messages advocating seat belt use and a matched audience on the other half of the cable did not receive messages. After a nine month period tracking actual seat belt usage behavior, the authors could only conclude that: "The campaign had no measured effect whatsoever on safety belt use" (p. 1077).

Community Fluoridation Programs. Despite endorsement by the United States Public Health Service and the Surgeon General, controlled fluoridation of community water supplies has more often been rejected than accepted by voters. Between 1950 and 1969, 1139 communities voted on fluoridation; the issue lost in 666 communities and won in 473 (HEW, 1970). One part of the difficulty is the complexity of the fluoridation issue and another part is voters' susceptibility to the fear appeals used by opponents.

Health Maintenance Organizations. Despite the advantages claimed for the HMO concept, enrollment campaigns have met with limited success--with a few notable exceptions (primarily the Kaiser plan). Perhaps the HMO concept is not as desirable as its advocates claim (Glasgow, 1972) or perhaps the benefits to consumers are not readily apparent and communication campaigns have underestimated the difficulties of changing medical behavior patterns.

Heart Disease. The most encouraging results on a mass media campaign are from the Stanford study conducting a program to reduce susceptibility to heart disease among residents of three communities. Instructional programs used in conjunction with mass media have documented attitudinal and behavioral changes in diet and cigarette smoking. The role of mass media alone in one community on a delayed continuity basis is almost as effective as the personal instruction-mass media combination (Maccoby and Farquhar, 1975). The cost-effectiveness of this campaign, however, is very much in question.

campaigns fail. These reasons may be summarized as follows:

1. Most health care campaigns operate without explicit objectives or with inappropriate or unrealistic objectives, probably because they are based on an inadequate understanding of the way mass communications work, and on an inadequate understanding of the marketing requirements of the "product" being promoted.
2. Most health care campaigns are non-programmatic; they are short-run, one-time efforts, while the behavior change they are designed to induce must continue in the long run.
3. The beneficial effects of the recommended behavior change are not immediately apparent to the consumer, and perhaps never will be.
4. Most health care campaigns fail to identify market segments within the total audience who require different communication approaches in line with their specific needs.

Setting Objectives and Assigning a Role to the Mass Media

It is not sufficient to seek knowledge change or attitude change without a mechanism for also achieving behavior change and it is difficult for the mass media to achieve behavior change. For example: most smokers have knowledge of the ill effects of smoking and many have a negative attitude toward smoking. Therefore, presenting them with more knowledge as to the negative effects of smoking is unlikely to have much impact. Instead, a communication campaign must be linked to a behavior change mechanism other than mass communications (such as behavior modification group enrollment) if the campaign is to be successful. But behavior change even so induced is unlikely to persist in the long run unless its beneficial effects are continuously reinforced, since the beneficial results from the behavior change are not apparent in the short run and since there may also be some gratifications attached to the previous behavior.

Although non-smoking is a regularly repurchased "product," this is a different marketing situation from the usual consumer packaged goods situation in which advertising is used to achieve trial, and in which reinforcement from use of the product is a significant force in accomplishing continuing use of the product. An important function of mass communications in changing health behavior must be to reinforce new behavior, since use of the "product" is insufficient reinforcement in itself. Fortunately, this is a role which mass media have continually demonstrated an ability to perform well. Nevertheless, behavior change must be accomplished first, and by means other than mass media.

As we have noted, most health campaigns are short-run, start and stop efforts, with little long-term systematic and programmatic planning. Yet, changing health is likely to involve both multiple channels of persuasion and regular long term reinforcement. In summary, people must be moved through a decision sequence which is likely to take some significant amount of time and different means of persuasion may have complementary and cumulative impact, and may be necessary to achieve persistent behavior change.

Segmentation

Most health care campaigns try to reach everyone. Yet, not all segments of the market are as likely to change and different segments may require different incentives for change. It is incumbent on the change

Why Health Campaigns Fail, and How to Help Them Succeed
Analysis of the foregoing and other campaigns indicates that there are some basic reasons why most health care

agent to specify the market segments likely to be receptive to change and to expect that different messages focused on different needs may be effective with different demographic and psychographic segments.

Examination of needs by segment may be mandatory. For example: smoking provides gratification for smokers; it fulfills certain needs. These needs may relate to anxiety patterns or may be tied to social interaction patterns (Wortzel and Clarke, 1977). Programs to help reduce smoking, we might argue, should help find alternatives for the continued satisfaction of these needs. Basically, if we are to change health we must do so in line with people's needs. It does little good to scare people, insult people, etc., except under certain extreme conditions. Changed health patterns must be shown to be in line with the audience's self-perceived needs.

Segmentation is also critical if mass media are used to support a campaign in which behavior change has been accomplished by other means. Reaching the yet unchanged will be wasteful, if not counter-productive in light of possible future efforts. It is essential to reach the changed in order to reinforce the behavior changing mechanism.

Conclusion: Principles for Health Care Change

Following is a set of tentative propositions for the successful design and implementation of health care campaigns.

1. Mass media communication by itself may be effective in initiating change, but generally only if the change sought is minor and consumers have low information needs. This is seldom the case in health care.
2. Mass media communication will generally be most effective at an early point in the health decision change process whereas personal sources will generally be most effective later in the decision change process.
 - a. Mass media communication objectives, therefore, must be tied toward encouraging people to access the professional health care system, or to sensitize them to other sources of communication.
 - b. The peer and professional system will constitute the subsequent supporting mechanism necessary to bring about actual change.
3. It is the cumulative effect of a communication campaign that eventually results in behavior change.
 - a. This indicates the need for repetition and reinforcement over time. Reinforcement of health change is a particularly important role for mass media.
 - b. This indicates the need for multiple information sources which play complementary roles -- including advertising, personal selling, peer support, and professional intervention.
4. Peer sources (personal influence) will be a particularly important source of legitimation and "reality testing" when the benefits of change are not obvious or cannot be demonstrated in the short run. This is likely to be the case in much of health care.
5. Communication campaigns for health care -- even when they make use of donated public media time

and space -- are not free. The real cost is the opportunity cost if the communication campaign could have been more successful.

6. A health care communication campaign must explicitly recognize the problem of selective perception -- that those who see the message may be those who are already concerned about the issue and engaging in recommended change activities.
7. A communication campaign may have to provide support for change within a family or peer group context. Obesity, for example, may be tied to family diet habits and change may depend on family involvement.
8. Communication messages must be keyed to the needs of the market segment being reached. It is necessary to offer positive alternatives and not simply to denigrate the individual's existing health habits.
9. Low returns should be expected in a communication campaign. Most advertising and persuasion seeks small levels of change -- in the range of 3 to 5 percent of the audience per year. Mass conversion in the short-run is indeed a rare phenomenon.

A REVIEW OF FORMAL THEORIES OF CONSUMER SOCIALIZATION

Deborah L. Roedder (student), Northwestern University
Nicholas M. Didow (student), Northwestern University
Bobby J. Calder, Northwestern University

Abstract

Consumer socialization research presently overrelies on Piaget's work as a source of theory. There is a need to bring other formal theories to bear. However, in using other theories researchers must be aware that socialization theories vary along a number of dimensions. This paper provides a framework for comparing formal theories. Three classes of theories are described in terms of this framework.

Introduction

As an area for empirical investigation, consumer socialization has largely developed in response to public policy issues surrounding children. Under the rubric of consumer socialization, research has mostly focused on age-related differences in children's attention perception, and evaluation of television commercials (e.g. Wartella and Etna, 1974; Ward, 1972; Ward, Levinson and Wackman, 1972; Blatt, Spencer, and Ward, 1972). Some attention has also been directed toward the interaction between parents and children in purchasing situations and the influence of the family in contributing to the development of the child's consumer skills (e.g. Ward and Wackman; Ward, Wackman and Wartella, 1977).

Since the focal point of research has been similarly public policy questions, the theoretical development of consumer socialization has proceeded in a rather ad hoc manner. Most investigators have adopted Piaget's theory of cognitive development as an explanatory framework. There has been little questioning of the suitability of Piagetian theory to the explanation of advertising effects, let alone its usefulness as the sole approach to investigating the wide range of phenomena which should be included under consumer socialization.

While there has been occasional criticism of the reliance on Piagetian theory (e.g. Calder, Robertson, and Rossiter, 1976), there has been almost no work exploring alternative theoretical sources. To date only Robertson and Feldman (1976) have addressed this critical issue.

As a starting point toward a more complete theoretical approach, Robertson and Feldman (1976) suggest that the area of consumer socialization should be divided into component problem areas which can then be matched with various theoretical approaches. They argue that available theories, such as learning theory and psychoanalytic theory, should be analyzed according to their problem orientation and utilized for the particular research problem under investigation.

As a blueprint for theoretical development, however, Robertson and Feldman's proposal offers a rather limited, unidimensional analytical framework. Although the proposal documents the overreliance on Piagetian notions and correctly identifies the need for incorporating alternative theories into consumer socialization research, the basis for analyzing these alternative approaches is limited to problem orientation. However, since the classical approaches to socialization were developed and extended by researchers in different disciplines, the resulting theories differ on a multi-dimensional basis. The theoretical formulations vary

not only in problem orientation, but in their basic orientation regarding socialization as a phenomenon.

The following discussion provides a multi-dimensional framework for analyzing alternative formal theories. The analytical framework developed is then used to compare these classes of formal theory. The objective is to go beyond problem orientation to specify more precisely the relevance of formal theory to consumer socialization research.

A Multi-Dimensional Framework for Analyzing Formal Theories of Socialization

The selection of a particular formal theory directs, and thus limits, the questions which a researcher can pose and seek to answer. This selection should be made with full appreciation of the dimensions upon which formal theories of socialization vary.

These dimensions are identified and organized here in a framework consisting of the following major categories: (1) the "process" orientation; (2) the "content" orientation; and (3) the "goal" orientation. These three categories and their specific dimensions are summarized in Figure 1 and explained in the discussion which follows.

FIGURE 1
Analytical Framework for Interpretation
of Formal Theories of Socialization

PROCESS ORIENTATION

passive view of the individual	_____	active view of the individual
external control over socialization	_____	internal control over socialization

CONTENT ORIENTATION

socialization viewed as cumulative	_____	socialization viewed as transitional
socialization emphasized through childhood	_____	socialization emphasized through life
emphasis on individual difference	_____	emphasis on group commonalities

GOAL ORIENTATION

descriptive focus	_____	explanatory focus
complete approach to socialization	_____	fragmentary approach to socialization
decision processes	_____	all processes

Process Orientation. Socialization theories differ in how they depict the basic process of socialization. After a review of the socialization literature, Zigler and Child (1969) suggest that one of the most fundamental

differences with regard to current theory is the view of the individual as a passive or active participant in the socialization process. One can view socialization as a process whereby social forces are applied to an individual or as a collaboration between society and the individual. A related issue concerns the control over the progression of socialization. That is, whether external conditions exert control over socialization or whether internal processes largely determine the progress made in socialization.

Content Orientation. Although the majority of socialization literature focuses on children and adolescents, some attempt has been made to study socialization at later stages in the life cycle (cf. Brim, 1966). In terms of our analysis, formal theories vary in their ability to encompass socialization processes at different stages in the temporal life cycle.

Another distinction can be drawn between perspectives that approach socialization as either cumulative or transitional in nature. Cumulative approaches assume that socialization follows some definitive path, that is, what has been learned in the past is a pre-condition or contributes heavily to future socialization. In contrast, transitional approaches view the socialization process as a less progressive movement from a beginning to an identifiable end.

A final content difference in formal theories is their emphasis upon individual differences versus group homogeneity in the socialization process. Although this dichotomy is most apparent in psychological approaches as opposed to sociological/anthropological approaches, some distinction is still possible in the viewpoints analyzed here.

Goal Orientation. The most visible difference between theories in terms of goal orientation is the focus of the conceptualization in terms of an explanatory versus descriptive approach. The descriptive approach tends to identify changes in the individual as a result of socialization, whereas the explanatory approach concerns itself with the actual process of change.

A less definitive distinction can be drawn between theories that offer a complete approach to socialization as opposed to those that offer only a fragmentary perspective. In this analysis, a complete approach is described as one capable of explaining the socialization process across a wide variety of situations. Fragmentary approaches are theories which provide a description or explanation of the process in limited contexts.

The final dimension is decision orientation. That is, whether or not the process of socialization involves the conceptualization of the individual as a decision maker.

The dimensions within each of the three major categories of the framework are more fundamental than any orientation toward specific kinds of problems. We will attempt to show that these dimensions have important implications for consumer socialization research. Three important classes of formal theory are analyzed in turn using the dimensions. These classes of theories are selected by the authors because, in the case of cognitive development theory, prominence in extant investigations of consumer socialization or, with regard to the latter two classes, because of their promise for future research. Other, more marginal theories (e.g. social anthropology, psychoanalysis, psychoanalytically oriented social anthropology, normative-maturational, genetic and constitutional) are described in Zigler and Child (1969).

The orthodox position of cognitive development theory is best represented by the work of Jean Piaget (cf. Piaget, 1950; Piaget, 1968; Piaget and Inhelder, 1969). Piaget's theory of cognitive development is based in his paradigm of the intellectually mature human. To Piaget the fully developed person represents a paradigm of universal order and equilibrium between the interactive parts and the individual as a whole (Maier). Thus, development is a function of the drive for equilibrium and equilibrium depends on activity and experience. The active view of the person continuously interacting with the environment in search of equilibrium is the basic Piagetian model. This interaction, which is controlled primarily by the individual, identifies previously unknown contradictions and absences in the cognitive structures of the person (Zigler and Child, 1969). The person seeks a balance with the environment, yet such a balance can only be obtained by a new equilibrium through the processes of assimilation and accommodation.

In this view, the environment of the neonate is initially undifferentiated. How the social and ideational environment becomes differentiated for an individual in cognitive development is a result of the socialization of the person (Maier, 1969) or the manifestation of phylogenetic drives as experienced during the formative cognitive years of early life. The person seeks to adopt, or to find equilibrium in the environment, by assimilation of events into the cognitive structure, while simultaneously accommodating the cognitive structure to the requirements of the events (Calder *et al.*, 1976). The interpretation of the events as one would conceive them (assimilation) and the modification of the cognitive structure by the actual event (accommodation) are complementary cognitive processes. The interaction of these two processes over the stages of cognitive development is the source of the summary description of Piaget's theory of the person as "ever changing, ever the same."

The content of cognitive development theory hypothesizes a cumulative view of changing cognitive structure and behaviors, as opposed to any transition content. Piaget's concern for cognitive development spans the chronological range from birth to cognitive maturity, which usually occurs in late adolescence. The emphasis is upon the typical individual, rather than individual differences, groups, institutions, or cultures.

Cognitive development theory hypothesizes "unity in continuity" (Maier, 1969, p.4) in both quantitative and qualitative behaviors. Existing cognitive structures and behaviors are highly dependent on previous ones. The developmental schedule of Piaget represents a cumulative series of sequential phases in which each later phase is related to previous acquisitions. The qualitative differences in the person's cognitive processes are differentiated into Piaget's multiple stages (cf. Piaget and Inhelder, 1969). These stages of different cognitive processes do not vary in sequence. One's progress through the stages may be accelerated or retarded only somewhat by various environmental factors of socialization (Kohlberg, 1971). Another perspective of this cumulative process is that it represents a continuous unfolding of generalization and discrimination, with each cognitive structure representing to some degree a repetition of the structures of previous stages in a slightly different form (Maier, 1969). This unfolding continues until the point of developmental maturity. Cognitive developmental maturity is achieved in most cases in the mid-to-late adolescent years (Piaget and Inhelder, 1969).

Piaget focuses on the development of cognitive thought, or the intellectual aspect of personality development,

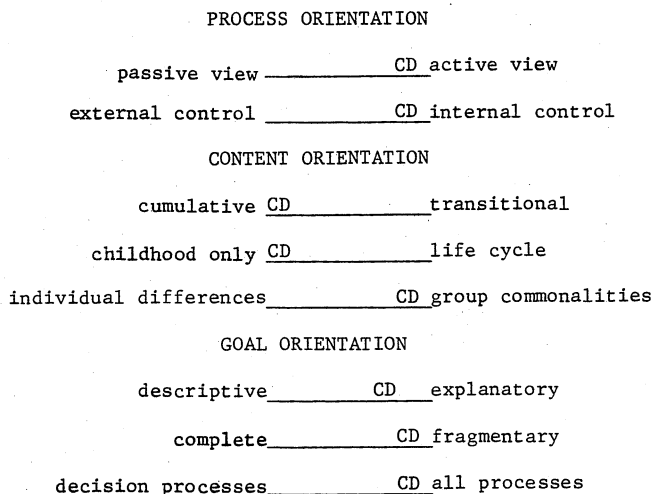

as opposed to affective or behavioral development. In this respect Piaget's theory of cognitive development is not intended to be a complete explanation of the concepts one would include in the nominalogical network of socialization.

The theory of Piaget is a description of marked developmental changes in cognitive processing over a fixed succession of stages (Zigler and Child, 1969). These changes include both qualitative reorganization of cognitive processes over the stages and the emergence of new cognitive structures in each stage. Developmental changes are different from maturational changes. The former reflect sociopsychological changes, while the latter represent only biological changes and organic growth. The successive stages of cognitive development are identifiable by developmental phases of readiness and acquisition, not by maturational phases or chronological time intervals (Maier, 1969). From the chronological perspective, however, the age at which a child achieves a particular stage is a function of previous cognitive ability and subsequent experiences (Reese and Lipsett, 1970).

The focus of Piaget's theory of cognitive development is not necessarily that of decision-making. Rather, Piaget is concerned with the individual's competencies and limitations with regard to comprehension of a situation. Cognitive development theory does not directly focus on normative choice situations which are one of the concerns of traditional consumer socialization research. On the contrary, the emphasis of Piaget is on those constructs of cognitive processes which are related to general, hypothetical levels of intellectual development.

The boundaries of cognitive development theory identified by the analytical framework in Figure 2 are cause for concern in many respects. The most severe limitation of Piaget's theory is its restricted emphasis upon childhood and early adolescence. By strict adherence to this perspective, we deny many areas of potential interest throughout an individual's life, such as consumer socialization issues connected with stages of family formation and dissipation, the development of family consumer "decision-making styles," and the "retirement community." If notable changes in consumer behavior occur within the individual's lifetime, a theory of consumer socialization should be capable of encompassing such phenomena.

FIGURE 2
Summary of Analysis of Cognitive
Development Theory (the symbol CD
positions the theory on each dimension)

A related problem concerns the viewpoint of consumer socialization as cumulative in nature. This of course stems from Piaget's perspective of cognitive development as occurring in stages towards the final goal of the individual's equilibrium with the physical world. For the purposes of an adequate formation of consumer socialization, it seems appropriate to include transitional learning in the theoretical perspective. Certainly we cannot ignore the identity transformations that individuals undergo during their lifetime, which have implications for changing consumer perspectives. An example is the transformation from a teenager to a bachelor to a husband to a retiree. Because Piaget is interested in the physical environment, it also becomes problematic to deal with the symbolic content marketing phenomena, such as product images.

The adaptation of Piaget's cognitive development theory in consumer socialization research focuses investigation upon the child's limitation in sensation and cognitive perceptual ability. Cognitive development theory addresses long-term sociopsychological changes. It is of marginal help in explaining the specifics of cognitive responses (Calder et al, 1976), short-term fluctuations (Robertson and Feldman, 1976), or the affective aspects of intelligence and behavior (Robertson and Feldman, 1976).

Finally, Piaget's theory does not address the question of discriminative interpretation of the environment and does not explicitly view the individual as a "decision-maker". The child is viewed as searching to understand the environment. Perceptual boundness is included in the analysis, yet the individual's selective processing of information is characterized as a cognitive deficiency rather than a decision process that is so important in an information processing perspective. Only if one recognizes the limitations of process, content, and goal, can Piaget's theory of cognitive development be of benefit in consumer socialization research.

Traditional Learning Theory

Almost all definitions of socialization share at least one common element. This general element is variously expressed in verb form as "acquires," "develops," or "transmits". What the element means is that socialization results in a relatively permanent change in the behavior of an individual. The generic term for the relatively permanent change is "learning". Where the unanimity of "learning" is lost, though, is with regard to the differences in process, content, and goal of the various formal theories of learning.

This section reviews the general characteristics of formal connectionist learning theories and formal cognitive learning theories. Each theory individually and in combination makes a substantial contribution to understanding the general area of socialization. Because of the breadth and all-inclusive nature of the construct of learning, some authors suggest that socialization is synonymous with a social learning process. This perspective combines psychology, sociology, and anthropology into the traditional research of socialization (Goslin, 1971).

Hill (1971) argues that the field of learning theory may be initially divided into connectionist theories and cognitive theories. Learning theories in the connectionist tradition are represented by the stimulus-response contiguity theories of Watson and Guthrie and by the reinforcement theories of Thorndike, Skinner, and Miller. The theories of Lewin and Tolman represent the traditional cognitive positions. More contemporary connectionist shifts toward the cognitive positions are represented in theories by Spence and Mowrer. Cognitive social learning theories are formal attempts at synthesis of the

two historic divisions.

Hill (1971) identifies the boundaries of the division of connectionist and cognitive when one theory is taken independently of the other to explain learning in humans. On the one hand, when dealing with humans it is probably myopic to refer to all learning in the connectionist mode of the increased or decreased probability that certain responses will occur. Human responses can only be understood in the context of beliefs, attitudes and goals. Likewise, the pure cognitive mode, such as Lewin's life space, omits any interactive mapping between the environment and the life space of the individual. It is the lack of holism of the first perspective and the inoperable nature of the second perspective which are addressed by a third group of synthesis theories such as cognitive social learning (cf. Mischel, 1973; Mischel, 1976; Bandura, 1971).

Process for connectionist learning theory is the behavior change which results from classical conditioning and operant conditioning. Learning by classical conditioning happens first. It occurs before the child has the capabilities of language and classification. After language development begins, learning by operant conditioning involving problem solving, decision-making, and other cognitive contingency skills, is feasible in addition to continued involuntary classical conditioning (Reese and Lipsett, 1970).

Connectionist learning theories differ from cognitive learning theories along the several process dimensions. In general, connectionist theories view the process as one which is externally controlled and which occurs as effectively if the person is active as it does if the person is passive. Cognitive learning theories conversely view the person as an active participant in the process. For them, internal cognitions and beliefs have a significant personal impact on the process.

Within the connectionist perspective classical conditioning stimulus-response theories address learning situations in which the outcomes are dependent on externally imposed reward contingency schedules. In this perspective an external agent has complete control over the process. Instrumental conditioning theories focus on learning which occurs due to rewards and punishments which result from active behavior of the person (Reese and Lipsett, 1970). In both instances the control process of reward or nonreward is external to the person involved in the learning situation.

The cognitive perspective hypothesizes cognitive representations and active manipulations involving contingencies which may be quite complicated. In the traditional cognitive learning theories the representations and contingencies are subject to influence from external sources, but the learning process is itself dominated by the person.

Generally, learning theory has no temporal limitations. Relatively enduring changes in behavior which may occur at any age are the focus of the content. The one modification to this statement reflects the cognitive developmental stage theories (cf. Kohlberg, 1971), which are incorporated within some of the more contemporary cognitive-developmental learning theories. These theories are thus focused more on learning in the pre-adolescent years, the years during which the cognitive processes of the person proceed through the fixed hierarchical sequence. Social learning theories are also broad enough to accommodate variations at different developmental levels (Zigler and Child, 1969).

Learning theories vary with respect to whether the content is cumulative or transitory. Connectionist learning theories may be imposed at any point in any phenomenon. The more cognitive learning theories, and especially those which also include developmental

aspects of cognition, are more cumulative in content. Cognitive social learning theories, Mischel's for example, require a cumulative idiographic content understanding in order to make any reliable predictions of behavior.

Connectionist learning theories focus exclusively on group commonalities of learning. Contiguity theorists and reinforcement theorists are concerned with the general conditions under which the response will become more or less probably. Early cognitive theorists likewise address commonalities of cognitive representations and contingency development. Contemporary cognitive social learning theory is idiographic rather than nomothetic. The researcher is thus able to investigate and seek to understand individual differences in learning which are contained within the theoretical perspective of the phenomenon. Bandura and Walters (cf. Zigler and Child, 1969), for example, recognize that different cognitive contingencies and available social models within a single age stratum result in considerable interindividual variations.

The final area in which characteristics of learning theory are considered is that of the goal of the theory. Formal learning theories are attempts at complete theories of explanation which are not limited solely to decision-making phenomena.

In the perspective of learning theory all behavior, purposeful or not, is synonymous with learning. In this view, all socialization is synonymous with social learning in a general sense (Goslin, 1971). The difficulty with this idea is that each of the two major areas of traditional learning theory, connectionist and cognitive, are found to in fact be incomplete theories when taken independently. The synthesis positions of cognitive social learning theories are thus intuitively appealing. The controversy, though, centers upon the lack of existing assessment techniques to provide consistent, meaningful measures of the theoretical constructs when they are applied to substantive areas like consumer socialization. In this sense even the synthesis positions currently fall short of their goal.

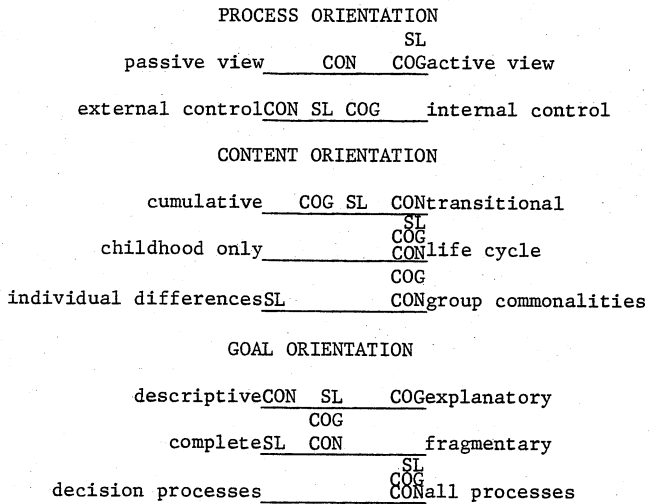

Mischel (1973) argues that a complete formal theory of behavior processes must be inclusive of aspects of the person, the situation, and the interaction of the person and the situation. His cognitive social learning theory involving person variables of cognitive competencies, encoding strategies and perceptual constructs, symbolic exchange expectancies, differential personal values, and self-regulatory internal and external goals and plans is an encompassing attempt at a complete theory of explanation and prediction. Operationalizing the constructs of Mischel in substantive socialization areas presents quite a challenge, however.

Learning theories, even with their inherent boundaries as identified in the analytical framework of Figure 3 should be very useful in many substantive areas of socialization research (see Zigler and Child, 1969, 465-468). Hopefully, our discussion renders the range of these theories clearer.

Interaction Theory

A great deal of theorizing and empirical work in sociology and social psychology could be subsumed under the general heading of "interaction" theory. For the purposes of this analysis, the discussion of interaction theory will center around symbolic interaction and role theory. It is indeed difficult to make distinctions between these two perspectives, since many role theorists reflect a symbolic interactionist viewpoint in some form or another. However, most role theory departs somewhat from symbolic interaction. It reflects

FIGURE 3
Summary of Analysis of Learning Theories
(the symbols CON, COG, SL position

learning theories respectively)

a partially deterministic viewpoint different from symbolic interaction.

Symbolic interaction theory attempts to explain how an individual acts or thinks in relation to an environment which is symbolic as well as physical in nature. Man is characterized as actively seeking and learning meaning, values, and behaviors through interaction with others. The individual learns about himself through encounters with other people and learns to "predict" the behavior of others by taking the role of another individual (individual other) or taking the role of a number of persons acting together in some group or society (generalized others).

Role theory has adopted the notion of Mead's role-taking in the symbolic interaction process as its point of departure and major focus of elaboration. The general proposition of most role theorists is that overt behavioral and attitudinal phenomena can be codified into meaningful categories called roles. From this starting point, role theorists have developed quite divergent conceptualizations - the idea of role has been used to denote prescription to norms and demands, enactment and involvement in role performance, overt and covert processes, and behavior which the individual initiates versus that which is directed toward the person (Biddle and Thomas, 1966). The more social psychologically oriented theorists have described social interaction by the mutual sharing of role expectations whereas many sociologically oriented theorists have tended to use role concepts in describing an individual's integration into society.

On the basis of this brief description, it should be clear that most interaction theory stresses an active view of the individual in social processes. Symbolic interaction theorists have been consistent in their view that the individual constructs the "world as taken for granted", the symbolic environment, through interaction with other people. Role theorists have been somewhat less consistent in viewing the individual as an active participant. Some observers (e.g. Linton, 1947) present the view that roles are externally constructed without any individual input. Other writers also see roles as socially structured, yet stress the importance of the individual's participation in learning, performing, and discriminating roles in the process

of socialization. An extreme position in terms of the individual's participation is presented by Turner:

"The idea of role-taking shifts emphasis away from the simple process of enacting a prescribed role to devising a performance." (Turner, 1962, p.23.

In terms of external control, symbolic interactionists recognize that the individual's environment is an integral influence in the process of learning and interaction. However, they strongly resist the notion that individuals or things in the environment control the behavior or the socializing individual (Blumer, 1962).

In contrast, some of the proponents of role theory see the process as a limited form of social determinism - focusing more on social influences. The behavior of the individual is formed by the sanctions, rules, and demands of others in addition to input from the individual regarding his own understanding and prescriptions of what his behavior should be (Biddle and Thomas, 1966). Other writers, most notably Sarbin and Allen (1968), totally reject any suggestion of a conformity theory and reflect the symbolic interactionist emphasis upon individual input and activity.

In terms of generality, both symbolic interaction and role theory are capable of studying socialization throughout an individual's life. Both viewpoints recognize that the individual changes group affiliations and confronts new environments in the course of a lifetime. With regard to the symbolic environment, man is constantly creating and changing meanings:

"Socialization continues throughout life in another sense: the society and its groups are constantly creating new meanings and values: (Rose, 1974, p. 147).

Role theorists are even more explicit in their concern for socialization issues throughout the life cycle. Some roles are characterized as being nonrepetitive in nature - in effect, they are "stages" in the life cycle. Other roles that are successively enacted, such as wife and mother, must also be learned at different stages in the life cycle.

Both interactionist positions also share the view that socialization is more transitional in nature than cumulative. Although general skills are needed for effective role enactment and interaction (such as cognitive and motor skills), the specific skills are usually learned at the time the individual enters a new role situation (the obvious exception being anticipatory learning). As Sarbin and Allen (1968) note, most of the general skills are learned in childhood and contribute to later role learning. But, the specific skills learned for a particular role are usually not transferable to another position - especially roles that are nonrepetitive in nature. Successive roles to be learned do not usually build upon each other and may often conflict.

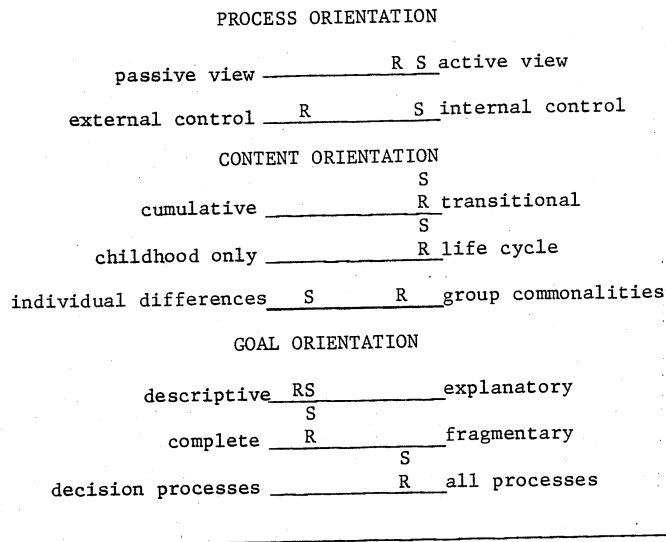

Regarding aggregative emphasis, role theorists tend to look more towards group (in this case role) characteristics than do symbolic interactionists. Roles are usually perceived to be structured by some measure of group consensus; however, role expectations do differ between individuals in the same position. For symbolic interactionists, the interaction process proceeds through a "definition of the situation" agreed upon by the participants; for role theorists, this is accomplished through the sharing of role expectations.

Although these interaction approaches appear to offer rich conceptualizations for socialization processes, they fail to adequately explain the learning processes

involved in socialization. Symbolic interactionists have been more interested in dynamic and developmental processes than role theorists who focus largely on description and structures. The sparse amount of work which deals with role learning suggests that individuals develop conceptions of role enactment through social learning processes, both incidental learning and explicit coaching (Strauss, 1966).

Interaction theories thus offer an active view of the individual. They treat socialization throughout the life cycle, and within many contexts (see Figure 4).

FIGURE 4
Summary of Analysis of Interaction Theories
(the symbols R and SI position role and symbolic interaction theories respectively).

Conclusion

We have developed a framework for the interpretation of formal socialization theories and have positioned three classes of theories within the framework. Analysis of the theories reveals marked variation along the dimensions of the framework. Selection of formal theories for consumer socialization research must thus be viewed as more complex than a unidimensional choice dictated by a problem orientation. Rather, theory selection requires careful consideration of the multidimensional nature of theories. Although a theory may seem applicable on one dimension, it may also dictate the researcher's view of socialization on other dimensions.

The diversity of theories of socialization indicated by our analysis also points up the weakness of an off-the-shelf approach to explanation in consumer socialization research. Ultimately, the goal must be to contribute to the development of theory. This can best be done by comparing the explanatory power of existing theories.

CHILDREN'S CONSUMER INFORMATION PROCESSING: REPRESENTATION OF INFORMATION
FROM TELEVISION ADVERTISEMENTS

Ellen Wartella, The Ohio State University
Daniel B. Wackman, University of Minnesota
Scott Ward, Harvard University and Marketing Science Institute

Abstract

This paper considers several conceptual and methodological issues involved in examining how children represent TV information in their memory system. It is suggested that researchers examine children's constructed memory for advertising information as well as their verbatim memory for commercial elements. The kinds of interpretations and connections children make regarding the nature of the advertised product and its relationship to other similar products are proposed as ways in which children might "construct" meaning for the advertised information. Furthermore, the paper discusses how to measure children's memory for advertisements and suggests that both recall and recognition measures should be used. This is to insure that researchers do not underestimate young children's processing abilities.

Introduction

Models of adult consumer information processing have tended to distinguish those processes involved in viewer reactions to television advertising from those mental processes involved in product choice situations (Hughes and Ray, 1974). The activities of selecting, interpreting and making sense of advertising information are referred to here as representational processes since they concern how advertising information is represented in the child's cognitive system. This paper will focus on several conceptual and methodological issues surrounding the way investigators model children's representation of information from television advertising stimuli.

The notions presented here are an extension of previous work adopting a cognitive developmental perspective on children's consumer information processing by Ward, Wackman and Wartella (1977). The basic model of information processing outlined in this previous research has relied heavily on Piaget's theory of cognitive development to suggest major dimensions along which children younger and older than middle childhood vary. Perhaps best-known of these dimensions is that of perceptual boundedness: younger children's tendency to focus on the perceptual and surface characteristics of products and advertisements (Wartella and Ettema, 1974; Ward and Wackman, 1973). We have viewed these dimensions of cognitive growth and the general cognitive abilities available to children as "rules for processing information" at various levels of cognitive development (Kohlberg, 1969).

This initial conceptual model followed rather strictly Piaget's theory and was useful in isolating the general distinctions among grade school children's knowledge about TV advertising and products. For instance, between kindergarten and sixth grade, children acquire greater understanding of the purpose of advertising; they tend to select both more and varied kinds of information when recalling a television commercial and describing a product, and gradually use multiple attributes when comparing brands of a product group (Ward, Wackman and Wartella, 1977; chapters 3 and 4).

In our current research, our interest is to go beyond these general dimensions of children's consumer information processing and elaborate more fully various as-

pects of how children represent information from specific TV advertisements. Our research is still strongly cognitive developmental in perspective but less closely aligned to strict Piagetian formulation.

Watching Television as an Information Processing Task

In our previous research we examined children's information processing transituationally; i.e., the same mental processes intervening between the input of a stimulus and the child's output of a response were assumed to occur both in the television viewing situation and in product choice situations. Consequently, we tended to focus on information processing activities which were similar in both task situations. For example, information selection from an advertisement was operationally defined as recall of elements in a commercial; and information selection about products was operationally defined as the kind of attributes children focus upon when they are asked to consider buying a new product (Ward, Wackman and Wartella, 1977). For purposes of describing general characteristics of children's thought about the consumer environment, this conceptual and methodological approach proved useful, as suggested above. However, in order to increase conceptual clarity of those activities involved in consumer information processing, it seems advisable to examine these two task situations independently. In this way, more specificity in points of divergence and similarity between the two processing tasks can be examined.

Furthermore, as Dawes (1975) points out, any model of information processing is necessarily circumscribed by the task being modeled. In particular, problem-solving tasks might best be viewed as conceptually distinct from non-problem solving tasks (Berlyne, 1970). While many of the same mental activities are involved in both situations, the tasks posed for the child information processor are probably much different.

For instance, a major distinction between the television viewing situation and the product choice situation is the degree to which each task is problem-oriented, where in the child is seeking information to reach some solution or decision, such as a product choice. It would seem reasonable to assume that in most instances when young, grade-school children sit down in front of a TV set and watch a commercial there is little "planfulness" involved in how they select information and little "intention" to seek information to use in a purchase decision. This assumption is based on the evidence of relatively low comprehension of the purpose of advertising by grade school children and only moderate awareness of TV advertising as a source of new product information across a wide range of products (Ward, Wackman and Wartella, 1977).¹ Such directed and planful use of

¹ For instance, among kindergarten, third and sixth grade subjects surveyed, only four percent, 15 percent and 38 percent respectively, indicated that they recognized the selling motive when they responded to the question: Why are commercials shown on television (Ward, Wackman and Wartella, 1977; Table 4-4, p. 60). Further, when these same children were asked to name sources of new product information for toys, clothes and snack

television advertising probably occurs only rarely, and most likely at particular times during the year, such as Christmas time when children are seeking gift ideas (Caron and Ward, 1975). On the other hand, when children are asked to "choose" a cereal at the store or are given money to spend on a product of their choice, the information processing task at hand involves directed thinking activities and intentional use of information to solve a problem, i.e., to "buy" the product that best satisfies the child's needs or desires.

This is not to say that children don't use information which they have learned from television commercials to reach a purchase decision; indeed, there is evidence that television viewing influences product requests at Christmas time (Robertson and Rossiter, 1977). This suggests that viewing TV advertising may directly affect product choice by influencing the child to buy a particular product, i.e., by raising the salience of product X above all other brands of a product group. Alternatively, TV advertising may influence the child's strategy for approaching a product decision, by suggesting certain attributes of brands in a product class to be considered, i.e., suggesting that the child buy the brand of a product class that has the most of attribute X (Wright and Barbour, 1975).

However, the crucial point is that television advertising most likely enters product decision-making tasks sometime after viewing the television advertisement even if during TV commercial viewing the child's desire for a product is raised. This suggests that we should examine children's memory of what they have seen and heard from television commercials since it is what they have stored and retrieved from memory which will influence their processing activities at the time of product decision-making.

We are interested here, then, in exploring how the information presented on the television screen is stored and retrieved from the child's memory system. Rather than focus on models of information processing which are directly problem-solving task-oriented, such as Newell and Simon (1972) and Pascual-Leone (1969, 1970), we have chosen to examine models of memory development for further conceptualization of how children select, interpret and comprehend TV advertising information.

Representation of Information in Memory

The view of memory adopted here distinguishes between two types of memory: episodic memory, or memory for a specific event which occurred at a specific time and place; and semantic memory, or the accumulated knowledge one has acquired about the world (Brown, 1975). Piaget and Inhelder (1973) refer to the former as "memory in the strict sense" and the latter as "memory in the wider sense." Episodic memory involves memory for directly experienced occurrences, the actual input or verbatim recollection of experience and "for discrete perceptual instances that are distinct and separable from the larger unit in which they occur" (Brown, 1975; p. 136). Thus, episodic memory is usually what is referred to as verbatim memory for a television commercial or program, as it involves remembering the elements of the television commercial. On the other hand, Brown (1975) notes that semantic memory involves "memory for meaningful systems of units in context." Such memory is constructive and holistic, and it is memory for the gist of a narrative or story, such as the overall "message" a viewer constructs from a TV commercial.

foods, fewer than one-third of the kindergarteners, and only about one-half of the third and sixth graders mentioned TV commercials (Tables 4-2; p. 57).

Further, as Brown (1975) points out, no particular interaction with an environmental stimulus is totally one type of memory experience or the other for a child; aspects of both episodic and semantic memory are involved whenever a child interacts with the environment. Children's semantic memory system, in the broadest sense their acquired knowledge about the world and their attendant cognitive abilities, skills and language, helps determine what they will "remember" about any specific episode or occurrence, i.e., it influences children's episodic memory:

"What the head knows has enormous effect on what the head learns and remembers. . . Older individuals will presumably store, retain and retrieve a great many inputs better or differently than younger ones, for example, simply because developmental advances in the content and structure of their semantic or conceptual systems render these inputs more familiar, meaningful, subject to gap filling or otherwise more memorable for them. (Flavell, 1977; p. 189)

This perspective maintains that memory is a constructive process. Memory "involves an imaginative reconstruction or construction built on extant knowledge" (Brown, 1975). Both at the point of storing and retrieving information from memory, the subject is constructing and reconstructing an internal representation of that information to be remembered (Paris, 1975).

One result of this constructive aspect of memory is that children attempt to integrate information they remember to comprehend the "gist" of the stimuli presented. Paris (1975) reviews several studies in which children in second and fifth grade were presented with a series of sentences which told a story. Later the subjects were given a series of sentences to read, some of which they had actually read earlier, some of which were new but preserved the meaning of what they had read, and some of which were new sentences that did not preserve the meaning. Paris reports that the children consistently confused the original sentences with those new sentences which preserved the correct meaning of the narrative. This finding (which has also been found for memory of pictorial stimuli) suggests that children integrate semantic information to construct a holistic meaning of that information. They go beyond the information given to integrate ideas and form inferences. Further, as this research points out, children's integration of information is sometimes at the expense of correct recognition of information they had actually seen or heard.

The perspective on memory outlined above has a very basic implication for research on children's information processing of television advertisements: researchers should examine more than verbatim or episodic memory for particular elements of commercials, such as brand name or product attributes mentioned. Examination must be made of the kinds of inferences and connections children make when integrating the advertised information into their semantic memory system, i.e., what overall message do the children take away from the commercial? As Paris' (1975) work suggests, even in the absence of children's faithful and accurate retrieval of specific elements from an advertised message, these children may still "remember" some constructed or integrated meaning from the message. It may be this "constructed meaning" from the message which children recollect from the advertisement during product decision-making situations.

In our current research, we are exploring several ways in which children might go beyond the information given in the TV commercial, including: (1) by drawing connections between the product and themselves, such as how they can use the product or what will happen to them after buying the product; (2) by making comparisons

between the product advertised and other brands of that product class, such as how game X is the same as or different from other games the child has played; (3) by making inferences about the people and activities shown in the commercial to arrive at inferred attributes of the product. Researcher attention to such connections and inference-making should further elucidate cognitive characteristics of children's representation of TV advertising information. This is particularly the case since past research on information processing of advertisements has primarily examined children's selection and recall of commercial elements (Ward, Wackman and Wartella, 1977).

A second implication of memory research for consumer information processing studies concerns the kind of developmental differences in processing activities which may be observed. Verbatim memory of commercial elements and constructed memory for the commercial's meaning may not show the same type of developmental effects. Brown (1975a, 1975b) argues that where memory tasks involve primarily episodic memory, the researcher should expect a "levels difference" on the measure of memory retrieval. For instance, various research studies have indicated that as children grow older they recall a greater number of elements (Ward, Wackman and Wartella, 1977); thus the level of recall performance increases with age. However, where memory retrieval tasks engage primarily the semantic memory system, Brown predicts that the researcher will find a pattern difference, some interaction of developmental level with the task variables. For instance, one might predict a "patterns difference" in the type of inferences children in grade school make about the television commercial message. Considering that children younger than middle childhood have been shown to have difficulty making comparative judgments about objects (Cellerier, 1972), such children might be less likely than older children to make connections between the product advertised and other brands of that product class. Older children might be more likely to make multiple kinds of connections and inferences about the advertising information.

This discussion of the kinds of constructed meanings children might make of advertising information and the types of developmental effects which might be hypothesized for children's representation of advertising information should serve to illustrate the relevance of memory research for conceptualizing children's consumer information processing. Furthermore, the literature on memory development has implications for the methodologies employed to measure processing activities.

Measures of Representational Processes

Measurement of children's memory for television advertising information has typically employed open-ended recall measures (Rossiter, 1975; Rubin, 1972; Ward, Wackman and Wartella, 1977). Furthermore, researchers have focused primarily on verbal memory to the neglect of visual memory (Rossiter, 1975). Although the particular modality used to code information in memory is still open to debate (cf. Bransford and McCarrell, 1974; Brown, 1975; Piaget and Inhelder, 1973), it seems reasonable to allow for the possibility of multiple forms of representation--visual, verbal and imaginal. As Rossiter (1975) has suggested, multiple memory codes should be measured.

The issue of how best to measure retrieval of information from memory may be a thornier issue than previous research has acknowledged. Particularly, more attention should be paid to the distinctions between recall and recognition memory. While researchers may tend to think of recall and recognition questions as measurement tools, recall and recognition activities also constitute types

of retrieval activities for the subject being interviewed. Moreover, recall and recognition memory place different task demands on the subject for actively retrieving information from memory.

Recognition involves external memory cues for the child, such that there is already something present in immediate experience to assist the retrieval process. There are no such external cues present in recall memory. In recall, the subject has to do more of the retrieval job himself: "recall is the more difficult process as it demands regeneration in the absence of the stimulus" (Brown, 1975, p. 111). Piaget (1968) and Brown (1975) have proposed that there is a developmental progression in the development of these retrieval activities, such that recognition memory develops earlier in the child than does recall memory. Several studies provide evidence that recognition is a more efficient memorial process than recall for children younger than middle childhood (A.L. Brown, 1975b; Ritter, et al, 1973; Kobasigawa, 1974). This research literature suggests that both recognition and recall measures should be used to examine young children's memory for television advertising information. It may be the case that previous research has underestimated what children are learning from television advertising. In our current research we are exploring this possibility.

A series of experiments are in preparation to examine kindergarten and third grade children's information processing of several specially produced commercials for hypothetical brands of candy and game products. A post-viewing questionnaire is under construction to measure children's recall and recognition of both discrete visual and verbal elements of the commercials and various kinds of inferences and connections children might make to integrate the commercial information. The general question strategy is to begin each type of question with a recall measure (e.g., "What product did the commercial show you?") and then to follow that open-ended recall question with a series of multiple-choice recognition items (e.g., "Was it: a) a raisin candy b) a chocolate covered raisin c) a chocolate covered peanut?"). Through a revolving sequence of recall and visual and verbal recognition measures we are attempting to tap children's episodic and semantic memory for the product advertised and the TV commercial narrative message.

Pretest data collected in Columbus, Ohio on 18 kindergarten and 12 third grade children's episodic memory for advertised information about a chocolate covered raisin candy are presented on the next page. Recall and recognition measures were made after one TV commercial exposure. Children's memory for the type of product advertised, brand name, and two attributes mentioned about the candy was measured, first by a recall measure and then if the answer was either incorrect or incomplete, by a recognition measure. As the table indicates, third graders show better memory overall of the advertised product than do kindergarteners, particularly when recall measures are employed. However, when recognition measures are used, the number of kindergarteners "remembering" the commercial elements improves considerably. Although these data refer to episodic memory, we are also utilizing recall and recognition measures to examine

2 Piaget (1968) introduces an intervening retrieval process called reconstruction memory which occurs when the child is presented with the elements of a pattern he was previously shown and is then asked to reconstruct the correct pattern from the elements. Piaget suggests that the developmental sequence of memory development moves from recognition to reconstruction to recall memory. Reconstruction memory seems less useful as a general measurement tool for advertising research and thus has been ignored here.

children's semantic integration of the advertised information.

Table 1

Number of Children Recalling or Recognizing Information About a Chocolate Covered Raisin Candy After One Exposure to a TV Advertisement for that Product

	<u>Kindergarten</u>	<u>Third Grade</u>
<u>Memory for Product Type</u>		
Recall Measure	6	12
Recognition Measure	$\frac{8}{N = 18}$	$\frac{-}{N = 12}$
<u>Memory for Brand Name</u>		
Recall Measure	3	10
Recognition Measure	$\frac{9}{N = 18}$	$\frac{2}{N = 12}$
<u>Memory for Primary Product Attribute</u> (raisins have vitamins)		
Recall Measure	3	7
Recognition Measure	$\frac{7}{N = 18}$	$\frac{1}{N = 12}$
<u>Memory for Secondary Attribute</u> (# of candies in box)		
Recall Measure	-	5
Recognition Measure	$\frac{5}{N = 18}$	$\frac{-}{N = 12}$

The suggestion that recognition measures provide better estimates of children's verbatim memory for commercial messages is a rather obvious statement. Surprisingly, such recognition items are rarely employed. If the goal of the researcher is to identify optimally how much of the commercial message children do store in memory, then recognition measures should be used.

One argument which might be advanced for not using recognition measures rests on an implicit assumption regarding how advertised information is used in children's product decision-making. If it is assumed that information which can be recalled, i.e., self-generated without external cues, has the greatest impact on subsequent decision-making, then recognition memory of a TV advertisement would seem relatively unimportant. Alternatively, if it is assumed that children's product decision-making at least sometimes occurs in situations - where children do have cues to remind them about the advertised information, e.g., product choices which occur in stores, then recognition memory for advertised information may be relatively more important in product decision-making. However, until we know more about how

and where children do reach decisions about product choice, and the kinds of situational factors which are present during decision-making, it is difficult to assess the validity of these alternative assumptions. Our current research strategy is to measure both recall and recognition memory since we are interested in assessing how much of the advertised information children do store regardless of which retrieval strategy is used in subsequent decision-making.

To summarize our position, we believe that research on children's information processing of television advertisements can be informed both conceptually and methodologically by considering the development of memory activities. Greater attention should be paid to semantic memory or how children integrate advertising messages into their general knowledge system. By examining how children construct meanings of the advertised information and represent that meaning in their memory system we hope to acquire greater understanding of how children use advertising information in subsequent product decision-making. This research perspective should lead to greater specificity in conceptualizing and measuring children's information processing activities.

THE EFFECTS OF TV MESSAGES FOR HIGH AND LOW
NUTRITIONAL FOODS ON CHILDREN'S SNACK AND
BREAKFAST FOOD CHOICES

Marvin E. Goldberg, McGill University
Gerald J. Gorn, McGill University
Wendy Gibson, (student) Stanford University

Abstract

This study investigated the capacity for food messages developed for television to influence the nature of children's snack food and cereal selections. In a controlled experiment, children were exposed to varying numbers of commercials for highly sugared snack foods and cereals, or Public Service Announcements (PSA's) for less sugared, nutritious fruits and vegetables. In addition, a 24 minute edition of the 'Fat Albert' program starring Bill Cosby called 'Junk Food' was utilized. After exposure to one or another of these stimuli, children were presented with a number of snack food and cereal choices. Exposure to the Fat Albert program (even when it was interrupted by the commercials for snack foods) was most effective in reducing the number of highly sugared foods selected and increasing the number of fruits and vegetables selected. Exposure to the PSA's or the snack food commercials was also capable of creating differences in the foods selected by the children. These differences were noted even though children in all the conditions were aware of which foods were "healthy" or "unhealthy".

In April 1977, the consumer activist group, Action for Children's Television (ACT) petitioned the FTC to prohibit the advertising of candy to children on television. At just about the same, the office of Research and Analysis of the New York State Assembly made virtually an identical recommendation to the New York State Legislature related to the advertising of all heavily sugared products to children (Mauro and Feins, 1977).

The focus of the discontent with present advertising practices revolves around the postulate that given their relatively underdeveloped cognitive abilities, young children are likely to be unduly influenced by the more than 20,000 TV commercials that they are exposed to each year (Adler et al, 1977); the majority (55%) of which are for either breakfast cereals or snack foods (Gussow, 1972). ACR (1977) has cited evidence from associations such as the American Dental Association and the Society for Nutrition Education to document the fact that frequent sugar consumption in the form of the typical pre-sweetened breakfast cereals and snack foods usually advertised on TV contributes especially to tooth decay in children, as well as other potential physical problems such as obesity. While there seems to be relatively little controversy regarding the potentially negative effects of an overconsumption of sugar and sugared products, what appears to remain an issue of greater contention is the establishment of a causal link between exposure to children's TV advertising for sugared snacks and breakfast foods and subsequent attitudes and behavior regarding these food products.

Correlational evidence (Clancy-Hepburn, Hickey and Nevill, 1974) is suggestive of such a link, as is observational data (Atkin, 1975; Galst and White, 1976), and experimental evidence (Goldberg and Gorn, 1977; Poulos, 1975). These notwithstanding, a recent summary of the research in this field concludes that the nature and extent of these effects is not clear and that much re-

mains yet to be assessed (Adler et al, 1977).

While the majority of both policy-makers and researchers have tended to focus on the degree to which TV commercials affect children adversely, consideration has more recently also been given to the manner in which TV can be used to encourage positive or pro-social behavior, including sound dietary habits in children. Thus a variety of groups have been involved in developing Public Service Announcements and program material that encourage children to eat nutritious foods such as fruits and vegetables and to moderate their intake of highly sweetened snacks and cereals they see advertised on TV (see Society for Nutrition Education, 1975). The White House Conference on Food, Nutrition and Health (1970) specifically recommended that the President establish a permanent task force to formulate a mass-media nutrition education program. More recently the New York State Office of Research and Analysis recommended in their report (March, 1977) that stations be requested to air PSA's emphasizing proper nutrition for children, to be paid for by a tax levied on all broadcasters as a function of their advertising revenues. These efforts suggest that at least these policy makers and other interested parties believe there is a link between the material children are exposed to on TV (messages featuring either low or high nutritious foods) and their subsequent attitudes and behavior.

Research has documented that: very young children in particular are most likely to believe television commercials (Ward and Wackman, 1973); are most likely not to understand disclaimers (Atkin, 1975), and are least likely to understand the sales intent of the commercials (Rubin, 1972; Robertson & Rossiter, 1974). Thus television may have an especially strong impact on the very young, with the potential to maximally influence their food habits which for these children may not be as yet fully formed.

One of the most elaborate nutrition education efforts via the mass media is a series of programs called "Mulligan Stew". It includes a series of six half hour films integrated with written teaching materials that attempts to get children to learn the various nutrients associated with the four basic food categories. An experiment evaluating the effectiveness of this program revealed that it was successful in communicating the nutritional information but was, on the whole, unable to get the children to change their consumption behavior (Jenkins et al, 1975).

The present study sought to test the potential of TV as a medium for influencing children's snack and breakfast food preferences. The 30 second message - either Public Service Announcement for highly nutritious foods or commercials for less nutritious foods was one vehicle used. The second was a 24 minute program entitled "Junk Food", one of a number of issues treated by a series called "Fat Albert" starring Bill Cosby who notes:

What this series attempts to do is harness the natural interest (enjoyment of cartoons) and act as a conveyor of learning to instill an awareness of life and develop codes of behavior.

Employing animation as the primary medium to teach its (Fat Albert's) goals differs from Sesame Street and the Electric Company in that its emphasis is upon the affective development of young viewers (1976, p. 60-61).

It was anticipated that exposure to these materials, insofar as they made the various foods attractive and salient, would serve as cues to the children and encourage the selection of either more or less nutritious foods, as the case might be. It was also considered likely that an entire program devoted to nutrition would be more effective than the 30 second PSA's. The increased time would not only direct attention to nutritional issues for a longer period of time, but potentially ought to allow for greater creativity in developing a meaningful theme.

In a further effort to vary the degree of exposure to messages for more or less nutritious snack and breakfast foods, conditions were developed in which the number of PSA's or commercials either approximated the number permitted per half hour by the NAB Code or was double that number.

Method

Subjects

The twin objectives of utilizing children who were as young as possible, yet at the same time could respond to simple paper and pencil measures resulted in the selection of a sample of first grade children.

Subjects were drawn from three Northern California-Bay area schools, about one mile from one another. The communities surrounding the schools were part of the same upper-middle class suburban area and were essentially indistinguishable from one another. In all, there were seven first grade classes in the three schools (three in one school and two in each of the remaining two schools). Total enrollment in those classes was approximately 175 of whom 122 or 70% participated in the study, (having returned signed permission statements from their parents). Subjects were randomly allocated to one of eight conditions (described below). At each school, assistants would draw a randomly selected subset of children from different classes and take them to a room where the experiment was conducted. Typically seven or eight would then watch one of the following professionally videotaped and edited programs.

Independent Variables

1. "Yogi's Gang", a 24 minute animated cartoon program provided the context for a 30 second commercial for each of the nine food products listed below. These were typically inserted, two at a time at five appropriate points in the program, for the total of 4.5 minutes of commercial time; an amount roughly corresponding to what children typically see in a half hour on childrens TV (N.A.B. Code, 1975). Commercials were for: Mounds Candy Bar, Lollipop Lifesavers, Crackerjacks, Hershey Candy Bar, Blow Pops, Milky Way Candy Bar, Kool-Aid, Sugar Crisps, and Fruity Pebbles.
2. "Yogi's Gang" plus the commercials for the nine food products, each repeated once for a total of 9 minutes of commercial time. These were inserted three at a time at six points during the program.
3. "Yogi's Gang" plus eight Public Service Announcements (for a total time of 4.5 minutes) stressing the values of eating fruits, vegetables, milk; and suggesting moderation in the use of candy bars,

sugared cereal and other sugared snacks. (The majority of these were selected from among those produced under the direction of the Bay area Committee on Children's Television; two produced by ABC were taped off-air). One or two of these Public Service Announcements were inserted at the same five points in the program as in condition 1.

4. "Yogi's Gang" plus eight Public Service Announcements each repeated once (for a total time of 9 minutes). These were inserted two or three at a time at the same 6 breaks as in condition 2.
5. A 24 minute "Fat Albert" program entitled "Junk Food". This is an animated childrens cartoon aired weekly on CBS, starring Bill Cosby. The program depicts "Fat Albert" and his friend "Slim" who eat only Junk Food (mostly non descript candy). This leads to a toothache for Slim followed by an anxiety producing visit to the dentist. This convinces Fat Albert, but not Slim, to turn to good healthy foods. Finally, Slim having skipped meals in favor of junk food is so weakened that he is responsible for losing the "big" football game. Most of the program is animated, with Bill Cosby appearing occasionally to underline a point made in the course of the animated cartoon. The theme of the program generally is: "This is Bill Cosby coming at you with music and fun and if you're not careful you may learn something before it's done."
6. The Fat Albert "Junk Food" program with the eight Public Service Announcements described above - each repeated once for a total of 9 minutes. In essence this condition represented the maximum message with regard to eating highly nutritious foods. The PSA's were typically inserted three at a time at six points in the program; (because of limitations of time and subject population we were unable to run this condition with the eight Public Service Announcements shown once only; i.e. for a total of 4.5 minutes).
7. The Fat Albert "Junk Food" program with the nine 30 second food commercials described above for a total of 4.5 commercial minutes. These were typically inserted two at a time at five points in the program. (Because this program was originally aired on CBS during Saturday morning, this condition comes close to replicating reality; i.e. what children viewing the program off-air would actually have viewed: the "Junk Food" program with its message to moderate candy and sugared product intake, ironically along with commercials for several examples of these sugared products.
8. A control group not exposed to any program at all. (Although the focus of this study was on the direct comparisons permitted by the groups described above, it was decided to incorporate this group to establish "baseline" data, as well as to assess the comparability of children in each of the three schools used in this study).

Dependent Variables

Following the program the children were involved in a four-five minute discussion of their favorite TV programs so as to break any momentary set that the program material might have established. At that point the children turned to the questionnaire that was used to obtain the dependent measures.

Subjects were first asked to indicate if they were a boy or girl and were then shown the first of a series of 3' x 2' boards each divided by lines into six of the six rectangles so that a child saw six actual snack foods

mounted on a board. Following consultation with nutritionists, three of the six foods were selected because they represented "healthy" highly nutritious snacks and the remaining foods were selected because they represented snacks that would be "unhealthy" and low in nutrition if over-eaten at the expense of other more nutritious foods. The first board had the following three snacks considered as highly nutritious: banana, peanuts, raisins; and three sugared snacks considered as less nutritious: Mounds Candy Bar, Jelly Beans and Lollipop Life-savers. The first page of the questionnaire had a pictorial representation of the food sketched on the page in the same location as on the board and identified in writing as well. The experimenter reviewed the items on the board in front of the children and subsequently on the first page of the questionnaire and made sure they recognized the correspondence between the board and the questionnaire page. No problems were encountered in this regard throughout the experiment.

The experimenter then structured the situation for the children's selection of the snack foods by indicating the following:

Now I want you all to pretend something. Let's pretend that your Mommy and Daddy were going away on a holiday, and they asked me to babysit for you while they were gone. Now I don't know the kind of foods you would want while they were gone. So suppose I said here are six snacks - you can eat three of them. Now you can tell me which three you would want by putting a big X through the three snacks on your page you would want most.

After they had indicated their three choices the experimenter removed the first board and revealed a second board with a second set of six snack foods; once again with three foods considered highly nutritious (apple, carrots, orange) and three considered less nutritious (Crackerjacks, chocolate "stars" and Ju-Jubes). The experimenter introduced the second board by suggesting:

Now let's suppose it was the second day I was babysitting for you while your Mommy and Daddy were away on a holiday. And again, because I didn't know the kind of snacks you like, I said here are six snacks and you can pick three of them to eat today.

After the children had once again made their three choices, the experimenter went on to the choices for the "third day of babysitting" (pear, cheese and crackers, fruit cocktail-snack cup; Hershey Candy Bar, Malted Milk Balls and Blow Pops) and then the "fourth day of babysitting" (strawberries, peaches-snack cup, raisins; Milky Way Candy Bar, Hershey Chocolate Kisses, Gum Drops).

It is important to note that in each set of six foods one or two of the sugared candy products were among the ones advertised in the commercial conditions, while one or two were more akin to the non-descript sugar products used in the Fat Albert program. Among the 3 more nutritious snacks presented in each set, one or two were among those featured in the Public Service Announcements while one or two were not.

Following the four boards of snack foods the experimenter went on to introduce two boards consisting of breakfast foods:

O.K. now what about breakfast. I wouldn't know what you would want for breakfast so you would have to tell me. Let's see, you could have:

Once again the six choices presented on the board consisted of three foods selected with the help of nutritionists: milk, orange, eggs and toast; and three considered less nutritious: Kool-aid, Super Sugar Crisps and Fruity Pebbles (sugared cereal). These foods were pictorially represented in the same fashion in their questionnaire and here too, the children were asked to "put an X through the 3 foods you would want for breakfast". Once completed, the children were provided with a second set of breakfast choices consisting of the same more nutritious alternatives (milk, orange, eggs and toast); and Cap'n Crunch, Frankenberries and Kool Aid as the less nutritious alternatives. (Only the cereals were changed in an effort to provide the same reasonably realistic breakfast choices in each set). While the four cereals are all roughly equally popular, the first two (Sugar Crisps, Fruity Pebbles) were among the nine advertised products in the commercial conditions while the latter two (Cap'n Crunch, Frankenberry) were not.

The second set of questions focused on the children's level of awareness of the healthy or unhealthy nature of each of the foods they just had seen on each of the six boards (four sets of six snack foods plus two sets of six breakfast foods). After all the children's choices had been made, the experimenter returned to the first board of snack foods and asked the children to turn to the next page of their questionnaire which once again included a pictorial representation of the foods corresponding to the first board. In this instance, however, each food had a "smiling face" with the word "good" and a "frowning face" with the word "bad" immediately below it. The experimenter indicated:

Now I want to ask you a different kind of question. Let's think about Do you think are good for you and healthy or bad for you and not healthy? If you think are good for you and healthy put a big X through the happy face that says good for you. If you think are bad for you and not healthy then put a big X through the sad face that says bad for you.

Now what about? Are good for you and healthy or bad for you and unhealthy? Put an X through the happy face that says good for you and healthy or an X through the sad face that says bad for you and unhealthy.

The experimenter continued in this way for each of the foods on each of the remaining boards.

At the conclusion of the entire set of questions, where time permitted, the experimenter engaged in a group discussion with the children, asking questions such as: why they had made choices they did; what they thought could be done given the "we all sometimes eat things that are not healthy for us."

Results

The children were able to select a maximum of either three more nutritious or three less nutritious foods on each of six boards, making a maximum of 18 possible in either direction. The control group selected a mean number of 10.2 less nutritious foods (and 7.8 more nutritious foods). As indicated in Table 1 these figures are very similar for the children in each of the three schools suggesting comparability on this key dimension.

TABLE 1

Mean Number of Less Nutritious Foods Selected by Children at Each School

School	N	\bar{x}	S
A	10	9.7	4.9
B	5	10.8	4.8
C	5	11.0	4.4

Initial examination of the mean scores revealed no significant difference between the groups exposed to either 4.5 minutes of PSA's ($\bar{x}=8.67$) or 9 minutes of PSA's ($\bar{x}=8.73$) in the context of the Yogi's Gang program. The difference between those exposed to either 4.5 minutes of commercials ($\bar{x}=12.12$) or 9 minutes ($\bar{x}=13.14$) was almost as small and equally insignificant. Given the similarity of data in the two groups exposed to Public Service Announcements and the similarity of data in the two groups exposed to commercials, it appeared more parsimonious to combine each pair in further analysis. [In fact, the similarity of the results with repetitive exposure parallels several earlier studies suggesting that repetition does not further change short term attitudes much beyond the impact of the initial exposure (Goldberg and Gorn, 1974, 1977)].

An analysis of variance conducted with the four original conditions and the two merged conditions described above, revealed highly significant overall differences ($F=9.62$, 5, 116 df, $p < .001$). Table 2 presents the means for each of the six groups in ascending order.

TABLE 2

Mean Number of Less Nutritious Foods Selected

Independent Variables	\bar{X}	S.D.	N
Fat Albert	2.87	4.03	15
Fat Albert & P.S.A.'s	5.60	5.78	10
Fat Albert & Com'ls	6.06	4.04	16
Yogi's Gang & P.S.A.'s	8.70	6.71	30
Control	10.70	4.55	20
Yogi's Gang & Com'ls	12.58	4.04	31

Post Hoc Newman Keuls analyses suggested the following significant differences between particular groups. Children exposed to Fat Albert selected significantly fewer less nutritious foods ($\bar{x}=2.87$) than those exposed to Yogi's Gang and PSA's ($\bar{x}=8.70$), who in turn selected significantly fewer than those who were exposed to Yogi's Gang and commercials ($\bar{x}=12.58$). The control group fell between the latter two ($\bar{x}=10.20$) but was not significantly different from either.

As might be expected, children who viewed Fat Albert with commercial insertions selected a somewhat greater amount of the less nutritious foods ($\bar{x}=6.06$) than those who viewed the program uninterrupted ($\bar{x}=2.87$) but this difference was not significant. Similarly, but perhaps more surprisingly, adding 9 minutes of PSA's to the Fat Albert program also tended to increase the number of less nutritious foods selected (5.60) but, again, not to a statistically significant extent.

In sum, while Fat Albert by itself was significantly more effective than Yogi's Gang plus PSA's in reducing the number of less nutritious foods selected, inserting commercials or Public Service Announcements into Fat Albert tended to reduce the effectiveness of the program to the level of Yogi's Gang plus PSA's. Nevertheless, children in each of these latter conditions still selected

ted significantly fewer less nutritious foods than the controls or those in the Yogi's Gang plus commercial condition.

An analysis of variance performed on just the 4 sets of snack food choices considered together was equally significant ($F=10.69$, 5, 116 df, $p < .001$). Post Hoc analysis revealed essentially the same pattern of results as were obtained for the total set of foods.

While the overall analysis of variance was also significant for the 2 sets of breakfast foods considered separately ($F=4.32$, 5, 116 df, $p < .001$), Post Hoc Newman Keuls revealed only one significant difference: the group seeing Fat Albert selected significantly fewer less nutritious breakfast foods ($\bar{x}=1.53$) relative to either the control group ($\bar{x}=3.45$) or the groups exposed to Yogi's Gang plus commercials ($\bar{x}=3.87$).

The second set of questions asked children to indicate whether each of the 36 foods they were presented with was "good for you and healthy" or "bad for you and not healthy". Very few errors were made in response to this question. In fact, the mean number of errors for all 122 subjects was 2.62. The overall analysis of variance revealed no significant differences between the groups ($F=1.12$, 5, 116 df, $p > .05$).

Discussion

The results of this study suggest that the type of snack and breakfast foods children select may be a function of the type of food messages they are exposed to on TV. Those who viewed material stressing the attractiveness and value of eating more nutritious foods (Fat Albert, PSA's) selected significantly more of these types of foods than those who viewed commercials stressing the attractiveness and value of eating less nutritious foods.

The Fat Albert program "Junk Food" was more effective than the PSA's in reducing the number of less nutritious foods selected. A number of explanations may be provided for this finding. For one, the unique constellation of creative factors associated with the Fat Albert program in general, and with Bill Cosby it's star in particular, is probably responsible in large measure for the program's effectiveness.

By contrast, at least some of the PSA's seemed less imaginative, slower moving etc. Of course, a program format with 24 minutes allows for the development of themes with antecedent events leading to subsequent consequences, while the 30 second PSA's make this approach difficult if not impossible. The question remains still, how effective could the Fat Albert approach be in a thirty second PSA?

The evidence in this study suggest that the degree of effectiveness of the various TV messages was not a matter of mere minutes of exposure. Doubling either the number of minutes of PSA's or the number of minutes of commercials had no increased effect on the children who were exposed to the messages. Further, adding 9 minutes of PSA's to the Fat Albert program did not enhance it's effectiveness. In fact, the number of less nutritious foods selected increased in this condition, even if not significantly so. Observation of the children in this condition suggested that the redundancy of the messages contained in the nine minutes of food PSA's added to the 24 minute "Junk Food" program resulted in the children paying little attention to the TV by the end of the sequence. This type of viewer satiation has been observed among adults who are overexposed to TV commercials (Greenberg and Suttoni, 1974) and among children as well (Goldberg and Gorn, 1974, 1977).

While Fat Albert appeared most effective in reducing the number of less nutritious foods selected, it should be emphasized that the Public Service Announcements were also able to significantly reduce this number (and concomitantly to increase the number of more nutritious foods selected). Of course real-life insertion of these PSA's would likely occur together with other commercials many of which might well be for candy, chocolate and other sugared foods. The impact of such "mixed" TV exposure remains to be tested. However, it is interesting to note that the real-life condition of Fat Albert with sugared snack and breakfast commercials inserted throughout the program was still effective in significantly reducing the number of less nutritious foods the children selected.

It is evident that at least this sample of children knew which foods were more nutritious and which were less so. Nevertheless, this appears to have made little difference with regard to the foods they actually selected (something often observed with adults as well). Changes in food choices appear to have developed as a result of what Cosby (1976) calls "affective education" rather than cognitive education. The latter approach is often typified by schools which:

.... often concern themselves solely with the development of cognitive skills, leaving the development of the affective domain to the parents. In doing so what they overlook is the total development of the child (Cosby, 1976, p. 61).

Fat Albert is a human hero who children can empathize with as he struggles with value conflicts and peer group problems. The program themes explore the intangibles of values and ethics, influencing behavior and feelings. It is attitude formation (Cosby 1976, p. 33).

Using Fat Albert or the PSA's to increase the attractiveness and salience of the more nutritious foods seems to have served as a cue that led children to develop more positive attitudes towards these foods and to consider them more actively and positively than they otherwise might have. Similarly the primary purpose for exposing children to snack food commercials in the course of the experiment was to make these foods also more salient. The appropriate directionality of the differences between the control and commercial groups suggests that this goal was accomplished. It may be noted that because the "control" group would typically have been exposed to the same commercials during their normal viewing hours they did not constitute a "control" in the strict sense of the term. Thus, while the groups exposed to food commercials selected a larger number of less nutritious foods than did the control group, it is not surprising to note that this difference was not significant.

The possibility of demand characteristics inducing change in an advocated direction is an everpresent problem in experimental design. In this study, the fact that the Fat Albert program was more effective than PSA's would seem to argue against an explanation of results based on demand characteristics. The experimenters' intentions in each condition should have been equally clear and had both groups responded on the basis of demand characteristics they both should have changed approximately equally, which was not the case. The experimenter also tried to eliminate any momentary set the children may have had after the program by interposing a 5 minute irrelevant discussion between the program and the questions the children were asked. While this diversion could have been longer, it should be noted that children's response sets have generally been found to change particularly rapidly (Mischel, 1972).

Indeed their excitement in expressing their attitudes about their favorite TV programs (the focus of the intervening discussion) strongly suggested that they had moved away from any initial set they may have developed during the TV program.

With regard to demand characteristics, it is also important to note that a number of studies have observed that young children do not understand the motives and intent behind TV commercials (e.g. Robertson & Rossiter, 1974). As a result, they are not likely to be moved to hypothesize what is expected of them in an experiment, as a function of the messages to which they are exposed. Utilizing young children in an experiment, in many regards ensures a relatively "naive" population.

This study considered sugard snack foods and sugared breakfast cereals as belonging together toward one end of the low-high nutritious spectrum. Indeed, at least anecdotal evidence suggests that many children treat sugared breakfast cereals as snacks rather than breakfast foods thus blurring the distinction between the two. Nevertheless, there may be good reason to treat the two types of foods separately. For example, the role of cereal in a balanced breakfast is a complex issue and one that perhaps could be addressed more comprehensively than was the case in this study. In fact, the Fat Albert program contained only one very brief reference to breakfast cereals and only one of the PSA's dealt with breakfast cereals. This suggests that an increased focus on breakfast foods in this study might have resulted in greater differences with regard to breakfast food choices. However, the results provide some evidence counter to this hypothesis. The one PSA that did deal with breakfast cereal was much more explicit with regard to the problems associated with sugared cereals than the Fat Albert program was, yet only the children who viewed Fat Albert selected fewer less nutritious breakfast foods relative to the control group or those seeing Yogi's Gang plus commercials. The relative absence of significance with regard to the breakfast food choices in this study may be more readily understood by examining the dependent measures. The inclusion of only two sets of breakfast foods provided a relatively reduced range of potential responses. Moreover, the repetition of all the alternatives except the cereals further constrained the range of possible responses. In sum, future studies that treat breakfast foods and sugared snacks separately could encourage greater specification and elaboration with regard to both the independent and dependent variables.

The general discussion that followed the administration of the questionnaire suggested that children may well consider the issues raised during the experiment with much more specificity than the global "good-bad" "healthy-non healthy" measure that was obtained. For example, when asked what people should do if they were constantly tempted to "eat things that were not good for them" responses included the following: "they should try and avoid the aisles in the supermarket with all of these foods"; "they should brush their teeth after each snack"; "they should try to get good things like fruit inside the chocolate". Thus when pressed further, children appear to be able to treat the nutritional issue in a more multidimensional manner. In fact, while the global awareness of whether foods are or are not nutritious may not be predictive of actual choice behavior, the more specific cognitions children have, or can be taught to have, may be more useful as predictors in future research.

Footnotes

1. The cooperation of many individuals at the Institute for Communication Research, Stanford University, in

particular Don Roberts, is gratefully acknowledged. The assistance of Doreen Croft, Carol Goldberg and Laurel Ward was also appreciated. Thanks are due to Sally Williams of the Committee on Children's Television, San Francisco; Lou Scheimer and Norman Prescott of Filmation, Reseda CA and Lee Hambleton of CFCF-TV, Montreal for much of the TV materials provided.

2. While Kool-Aid may seem to be an unusual breakfast alternative, in fact, it has been found (e.g. Jenkins et al, 1975) that a small but significant proportion of children do drink Kool-Aid or Pop for breakfast.

PSYCHOMETRIC CHARACTERISTICS OF BEHAVIORAL PROCESS DATA:
PRELIMINARY FINDINGS ON VALIDITY AND RELIABILITY

Jacob Jacoby, Purdue University
Robert W. Chestnut, Columbia University
Wayne D. Hoyer (student), Purdue University
David A. Sheluga (student), Purdue University
Michael J. Donahue (student), Purdue University

Abstract

Along with verbal protocols and eye movement techniques, a family of behavioral process methods have recently been introduced to study pre-decision information acquisition and usage. Various questions may be raised in regard to these methods, including those relating to validity and reliability. Data are presented here regarding the validity and reliability of behavioral process methods. A fuller report will be provided in Jacoby and Chestnut (in preparation).

Introduction

As noted elsewhere (Jacoby, 1976, p. 5), all that is usually required for a measure or measurement approach to gain acceptance in that consumer research community is for an investigator to describe and use the measure in a single published study. As long as the measure or approach has a certain degree of face validity -- and oftentimes, even if it does not -- it tends to be uncritically accepted.

This uncritical attitude has led to a profusion of operational measures for virtually all of our core constructs. As an example, Jacoby and Chestnut (in press) identify 55 different brand loyalty indices in the published literature and came across several others in the unpublished proprietary literature. The problem, as Kohn and Jacoby (1973) demonstrated in regard to operationally defining innovators, is that different measures of the same construct, when applied to the same subject population, often produce conflicting results. Under these circumstances -- namely, a welter of different definitions which yield contradictory results -- it becomes exceedingly difficult to compare and integrate findings from different investigations. The end result is that consumer research is being strangled by its poor measures and progress in understanding consumer behavior is thwarted. Clearly, we must begin to devote greater empirical attention to describing the psychometric properties of our measures and measurement approaches, particularly the validity and reliability of said measures and approaches. This becomes especially true where we have the possibility of rejecting such measures before they can establish a toehold and proliferate.

Having advocated this in general (Jacoby, 1976; Jacoby and Chestnut, in press), it would be hypocritical if we did not apply this logic in our own research. In particular, since 1972-73 (see Jacoby, 1975a) we have been involved in the development and extension of an empirical approach for the purposes of identifying pre-decision information acquisition. An overview of approximately 20 studies in this series is described in Jacoby (1977) and theoretical underpinnings have been outlined in Chestnut and Jacoby (1977a). More recent developments include: several papers published or in press (Jacoby, Chestnut, and Fisher; Jacoby, Chestnut, and Silberman; Sheluga and Jacoby); completed studies on concept learning (Donahue and Jacoby, in preparation), attribution theory (Major and Chestnut, in preparation), and salesman influence in life insurance purchases

(Chestnut, 1977); an illustration of its application to health care services (Chestnut and Jacoby, 1977b); the completion of a monograph on consumer nondurable purchases (Jacoby and Chestnut, 1977); and an on-going project for the Federal Trade Commission (Jacoby and Chestnut, in progress). Much of this work is now being integrated into a single volume (Jacoby and Chestnut, in preparation).¹

The approach has also stimulated acceptance and usage by others. Examples from academia include: Bettman (e.g., Bettman and Kakkar, 1977), who was introduced to the approach during a 1975 visit to Purdue and through his participation as a consultant (Bettman and Jacoby, 1976) on the Jacoby and Chestnut (1977; Jacoby, Chestnut, Weigl, and Fisher, 1976) project; Van Raaij (1977a,b), who became acquainted with the approach through a colloquium (Jacoby, 1975b) at the University of Tilburg in May of 1975; and investigators in Mannheim, West Germany where the senior author spent the summers of 1975 and 1976 as a visiting scholar (see Raffée et al., 1976). Further, a variety of commercial applications emanating from this research program have been developed and refined, and are now being offered by the Opinion Research Corporation of Princeton, New Jersey.

Given the burgeoning interest and activity in this approach, it is incumbent upon those who utilize it to begin supplying data regarding its psychometric properties. The present report focuses on validity and reliability, bringing together some unpublished data from several investigations which bear on these issues.²

Validity

Addressing validity requires an understanding of the basic kinds of behavioral process (BP) data generated and how these relate to the criteria available. Reduced to its essential core, the BP approach provides data regarding (1) information acquisition behavior -- the information acquired prior to arriving at a decision (which may be further decomposed into the depth, content, and sequence of information acquisition), and (2) choice behavior -- the identity of the option selected when the decision is reached. Validity

¹An approach similar to ours, was independently arrived at by Payne (e.g., 1976).

²The data on a third psychometric property, sensitivity, will not be detailed in this report. Suffice it to say that BP is believed to provide much greater sensitivity, especially in regard to the sequence of information accessing and usage. Particularly in a crowded product category (where there may be 20 or more different purchase options and 30 or more items of objective information for each), it would seem beyond the capabilities of most people to be able to accurately recall the precise amount, identity, and exact sequence in which information was accessed and used.

assessment in these two cases assumes different forms because of the nature of the criteria available.

In the case of information acquisition behavior, there is no external "true value" criterion to serve as a standard and against which we can compare our data. That is, we have no way of crawling into the person's head and directly measuring the information that he acquires in vivo when arriving at a decision in the "real world." Thus, regardless of whether we solicit data using traditional verbal reports (via questionnaire or interview, e.g., "Tell me what information you are acquiring and which information you are ignoring when you make your breakfast cereal purchase decision"), employ verbal protocols (e.g., Bettman, 1970), use a behavioral process approach, or employ an eye tracking procedure (e.g., Russo and Rosen, 1975), we have no ultimate criterion (or "true value") against which to evaluate our data. This is reflected in Figure 1 which depicts verbal reports (VR) and behavioral process (BP) as alternative approaches for assessing actual pre-decision

FIGURE 1
Relationships Existing Between Verbal Report and Behavioral Process Measures of Behavior (Either Information Acquisition/Usage or Choice) and Actual In Vivo Behavior

information acquisition. Since we have no way to determine actual information acquisition during real world decision-making, relationships 1 and 2 are not ascertainable. What is measurable is the relationship between the verbal report and BP approach, Relationship 3. This is termed "convergent validity" and represents the necessary first step for demonstrating construct validity (see Campbell and Fiske, 1959; Nunnally, 1967).³

In contrast, in the case of choice behavior, both verbal reports of choice (e.g., "I usually buy Rice Krispies") and the identity of the option selected at the end of a BP simulation are potentially verifiable against an external criterion. That is, if Mrs. Jones says she usually buys Rice Krispies (in response to soliciting a VR), or ends up selecting that brand in a BP simulation, then (at least in theory) it is possible to verify this fact. Hence, all three relationships depicted in Figure 1 are potentially ascertainable for choice behavior.

Information Acquisition Behavior

Convergent validity represents the degree to which different operational measures of the same concept yield comparable results (Relationship 3 in Figure 1), i.e., "a confirmation by independent measurement procedures" (Campbell and Fiske, 1959, p. 81). Data on the convergence between VR and BP measures of information usage are available from several investigations. The earliest example comes from a study conducted during the spring of 1973. In this investigation, Jacoby, Szybillo, and Busato-Schach (1977, p. 213) report a median correlation

³The various types of validity and their relationship to each other are discussed in Jacoby and Chestnut (in press, Chapter 4).

of .37 (between verbal reports of typical information usage behavior and the order in which these types of information were accessed in a BP simulation) for students reaching a brand choice decision under a Brand Names Present (BNP) condition, and .53 for students arriving at choices under a Brand Names Absent (BNA) condition.⁴ A replication conducted two years later in Germany (Raffée et al., 1976) reveals slightly higher coefficients when VRs of typical usage behavior were correlated with actual usage/non-usage in the BP task: a median of .63 in the BNA condition and .61 in the BNP condition (see Jacoby, Hefner, Schöler, Grabicke, and Raffée, 1976, p. 9).

Probably the most comprehensive evidence on convergent validity was obtained in an investigation (Jacoby and Chestnut, 1977)⁵ which employed sociodemographically heterogeneous samples of residents from Tippecanoe County, Indiana, three different test products, and a much more advanced and sensitive BP methodology than was used in the two above-cited investigations. Table 1 presents the data for the information dimensions used by

⁴The Brand Names Absent (BNA) manipulation is used to reduce the impact of relevant information in memory on information acquisition behavior. In essence, it makes the BP simulation comparable to a situation in which the subject is confronted with a set of purchase alternatives consisting entirely of "new" brands.

⁵This study, hereafter referred to as the NSF investigation, was supported by a grant from the National Science Foundation (GI-43687).

the 456 (out of the 615) subjects in this study who were information seekers. (N.B. The other 149 subjects made their brand choices on the basis of seeing only the brand names of the 16 available brands and did not acquire any additional information prior to arriving at their decision.) As can be seen, the median Spearman coefficients (between self reports of typical information accessing behavior and behavior displayed in the BP decision task) across all information dimensions in the five samples ranged from a low of .22 to a high of .33. Again, values were higher for the BNA than for the BNP condition. Since analysis of the depth of search for these subjects (see Table 8 discussed below) revealed that the mean number of different information dimensions considered prior to making their purchase decisions was 3 to 4 in the BNP condition and approximately 7 in the BNA condition, median Spearman coefficients were identified when only the five most heavily considered dimensions for each of the five samples were considered. These coefficients are: .29 for breakfast cereal; .55 for margarine, BNP; .37 for margarine, BNA; .45 for headache remedies, BNP; and .40 for headache remedies, BNA. Thus, convergent validity seems to be higher (near .40) if attention is limited to frequently used dimensions. Also of interest, for the first time, BNP coefficients are higher than their BNA counterparts.

In sum, three findings are noteworthy in regard to the convergent validity between VR and BP measures of information acquisition/usage. (1) In general, it would appear that the information people say they typically acquire and the information they actually do acquire in a behavioral process simulation tends to be positively related, but only to a small degree. Coefficients of Determinance (r^2) reveals that only between 5% to 40% of the variance is explained. If we omit the two samples using an earlier and less sensitive BP variant of methodology, the remaining Coefficients of Determinance based on full samples and all available information dimensions all fall below 12%. (2) Higher correlation coefficients are obtained when brand names are absent relative to when they are present. This makes considerable sense since, when brand names are present, the individual may be accessing information from memory as well as from the external information environment. Unfortunately, BP procedures can only directly assess information acquired from the external environment. When brand names are absent, all brand-specific information must be acquired from the environment. Thus, without memory to rely on, there should be a greater correspondence between what people say is important to them and what they pay attention to (i.e., access) in a BP simulation. (3) Higher coefficients are obtained for the more heavily accessed information dimensions. Again, this makes considerable sense: people can be expected to less accurately recall accessing infrequently used rather than frequently used information -- especially for low-priced nondurables where much of the information is of a relatively trivial nature.

Several additional comments should be made in regard to the low ($r = .2$ to $.3$) correlations obtained between VR and BP indicants when all available information is included and the newer methodological variant is used. First, these coefficients could have been negative, in which case we would have had a major dilemma on our hands (i.e., since there is no available external criterion, which of the two measures do we say provides the "reasonably correct" picture?). On the other hand, these two approaches could have yielded indicants that were in very high agreement (say, $r = .8$ or $.9$). In such a case, it could be argued that the BP measures do not provide much unique coverage and (given that they are more difficult, expensive, time-consuming, etc., to collect) should therefore be dispensed with. From this perspective, coefficients in a low to mid positive range (i.e., $.3$ to $.7$) would seem to be optimal.

Even granting this argument, the obtained coefficients still show a relatively low degree of relationship and suggest that the measures do contain a fair share of error. However, these low coefficients also seem to be at least partially attributable to factors above and beyond unexplained error. In responding to the VR measure, subjects may have indicated what their behavior may have been like at an earlier point in time but, perhaps (aided by memory), they no longer do. Further, the VR measure asked respondents to indicate what they do "in general," i.e., across purchase instances. In contrast, the BP situation examines only a single instance. As argued elsewhere (Jacoby and Chestnut, in press) in regard to brand loyalty, if we are trying to describe a person's customary behavior, then sampling considerations suggest that we need to consider his behavior across several rather than a single test instance. Stated in a somewhat different form, the two assessments (i.e., VR and BP) were measuring slightly different things: the VR measure asked the individual to indicate what he did in general, whereas the BP measure considered only a single instance. In a similar vein, the BNA condition and the VR data also address somewhat different things. Whereas both the VR measures and BP-BNP condition attempt to reflect and examine the external information environment as it exists in the real world,

the BNA condition, through the very absence of familiar brand names, does not. Again, to the extent that different things were being addressed by the two measures (i.e., VR and BP-BNA), we would expect this to be reflected in a lowered correlation. Thus, considering the various actual and potential influences on these coefficients, the values obtained seem quite reasonable and in line with what might have been expected.

Choice Behavior

Both BP and VR methods may be used to collect choice data. Important questions are: (1) just how much agreement exists between these two approaches (Relationship 3 in Figure 1), and (2) how accurate are BP-derived estimates of actual choice behavior (Relationship 2) relative to VR-derived estimates of this same behavior (Relationship 1)? Respectively, these are questions of convergent and criterion-related validity.

Data regarding both types of validity comes from the three BNP samples in the previously noted NSF investigation (Jacoby and Chestnut, 1977). In a fashion similar to numerous other investigations, each subject was asked to recall the names of all brands in the product category he had purchased during the preceeding 12 months, and to then estimate the percent of purchases he devoted to each of these brands. The sum of the estimated percent of purchase for each brand was then divided by the total *n* in each sample to arrive at an aggregated VR estimate of each brand's market share for this sample. Since brands other than those included in our simulation were recalled (e.g., according to Time magazine [1976, p. 61]): "there are no fewer than 156 brands" of breakfast cereal available in American supermarkets and our study considered only 16 of those with the largest market shares), the VR market share estimates cumulated across all brands in our investigation sum to less than 100%. The proportion of time each brand ended up being "purchased" at the end of the BP simulation task represented that brand's BP-derived market share.

Since BP estimates were based upon only those 16 brands provided in each of the decision simulations, these estimates summed to 100% for each product category. In contrast, the VR market shares for 198 subjects across the 16 brands of breakfast cereal used in the investigation cumulated to 69.3%; the 16 brands of margarine had a combined VR market share (across *n* = 107) of 52.3%; and the 16 brands of headache remedy had a combined VR market share (across *n* = 104) of 90.6% (see Table 2). Let us consider the results for each of these products while bearing this point in mind.

The Pearson *r* calculated between the BP and VR market share estimates for breakfast cereal was .48. Two factors are relevant to an evaluation of this coefficient. First, due to an oversight, when subjects indicated that they had purchased Raisin Bran during the preceding 12 months, the interviewers had not been instructed to probe with a follow-up question in order to determine just which brand (Kellogg's or Post) was involved. Hence, the VR data for these subjects could not be counted for either of these brands and were therefore omitted from the calculation of the VR market shares. (The BP data suggest that most of these purchasers would have specified Post.) Second, Quaker 100% Natural had recently been introduced into the market area and had not had sufficient time to have been purchased with any great regularity during the preceding year. There is thus reason to believe that the VR estimates of market share for the year were not an accurate reflection of purchase probabilities existing at the time of the investigation. When these 3 problem brands are removed from the set of 16 test brands, the Pearson coefficient increases to .73 (*p* < .01). With only the two Raisin Bran's removed, the coefficient increases to .64.

The Pearson coefficient for margarine is a highly significant .83. However, a problem exists similar to that for breakfast cereal. If a respondent recalled Blue Bonnet but did not differentiate just which Blue Bonnet was meant, these data could not be used in calculating the VR market share estimates. With the three Blue Bonnet brands omitted, the Pearson Coefficient decreased to .57 (*p* < .05).

The VR and BP estimates for headache remedies seem to be in fairly high agreement, and a Pearson product moment

correlation between the two was highly significant ($r = .98$). The high (90.6%) percentage of VR market share estimates entering into this correlation probably makes it the most dependable one of the three samples.

It should be acknowledged, however, that the obtained correlations, while moderately high (see Table 3), are based on only 16 (or 13) sets of figures so that changes in 2 or 3 pairs of figures would be sufficient to exert dramatic impact on the coefficients obtained. Second,

TABLE 3
Correlations between VR-Derived and BP-Derived Market Share Estimates

Product	Number of Brands	Cumulative VR Market Share	r	p
Breakfast Cereal (N = 198)	All 16	69.3%	.48	$\approx .06$
	14 (-2 Raisin Bran)	63.0%	.64	$< .02$
	13 (-2 RB & Quaker 100% Natural)*	57.1%	.73	$< .02$
Margarine (n = 107)	All 16	52.3%	.83	$< .001$
	13 (-3 Blue Bonnet)*	34.1%	.57	$< .05$
Headache Remedies (N = 104)	All 16*	91.0%	.98	$< .001$

* = Adjusted for confounds (i.e., considered to provide the best estimate).

we are again confronted with the problem that the VR measure assessed behavior over a series of purchase instances whereas the BP indicant was based on only a single instance. Finally, it should also be noted from Table 3 that the cumulated VR market share estimates (when adjusted for confounds) for a given product appear to be positively related to the strength of the relationship manifested between VR and BP estimates -- the greater the amount of VR market share included in our BP test situation, the higher the relationship between the two estimates.

The NSF investigation also supplied relatively crude data regarding Relationship 2 in Figure 1. Readers familiar with this research from earlier reports (e.g., Jacoby, 1975a; Jacoby, Chestnut, Fisher, and Weigl, 1976; Bettman and Jacoby, 1976) may recall that subjects were provided with "cents-off" coupons which they were later able to apply toward purchases of their test product. Breakfast cereal and margarine subjects received five such "30¢-off" coupons, with three of these being good only toward purchases of the brand they had selected at the end of their BP choice task. The other two coupons were good toward the purchase of any brand in that product category, be it the one they had selected in the BP simulation or another. The coupons were valid for a period of four months from the date that the individual participated in the study.

An indication of predictive validity is obtained by addressing the following question: To what extent was the brand selected in the BP task predictive of the brand later purchased (Relationship 2, Figure 1)? Table 4 provides data pertaining to predictive validity for the two margarine conditions. While the vast majority of people redeemed at least one coupon (90% in the BNP sample and 83% in the BNA sample), considerably more coupons were redeemed for the BNP sample (64%) than for the BNA sample (51%). (The data for BNP are comparable to those obtained with breakfast cereal, where 89% of the subjects redeemed at least one coupon and 67% of all coupons were returned.) This pattern of coupon

TABLE 4
Coupon Redemptions for Margarine

	BNs Present			BNs Absent		
	Pos- sible	Actual	%	Pos- sible	Actual	%
Subjects redeeming coupons	107	96	90%	110	91	83%
Designated coupons redeemed	321	216	67%	330	170	52%
Undesignated coupons redeemed	214	128	60%	220	113	51%
-BP selected brand	214	52	24%	220	12	5%
-other 15 brands	214	76	36%	220	101	46%
Total coupons redeemed	535	344	64%	550	283	51%

redemptions suggests that the coupons had value for the subjects, and providing five such coupons most probably generated a realistic degree of task motivation, as was intended. Unfortunately, using designated coupons as a manipulation of motivation meant that validity data based on these coupons would be confounded. Moreover, while redemption of the undesignated coupons provides somewhat cleaner data, they are nonetheless affected by the fact that each subject also possessed three designated coupons and these might have influenced how he used his undesignated coupons.

Notwithstanding these problems, Table 4 reveals the following pattern: (1) A higher proportion of coupons were returned by the BNP (as compared to the BNA) subjects, both overall and for the brand they selected in the BP task. This is not surprising since 72% of BNA subjects chose a brand at the end of the BP task which they supposedly didn't purchase (according to an independent VR assessment). The motivation for these subjects to redeem their coupons could be assumed to be low. (2) In contrast, BNA subjects used a higher proportion of their undesignated coupons to redeem unselected brands. (3) Approximately 10% of the undesignated coupons returned by the BNA sample was for their selected brand, while this figure was 40% (24/60) for the BNP sample. The 10% figure for the BNA sample is only slightly higher than the 6.125% that could be expected to have selected their favorite brand in the BP choice task (i.e., there being 1 out of 16 chances of selecting this brand). The 40% figure for the BNP sample is just about what one might have expected given that these subjects already possessed three coupons valid only for their selected brands (and might have therefore chosen one other brand for the sake of variety) and also because the weighted mean VR brand loyalty score for this group was 48 on a 100 point base, indicating that slightly less than half their purchases were devoted to their most often purchased brand in that product category.

Reliability

The key theme of reliability is that of consistency in response. Such consistency can be examined at various levels. As applied according to the traditional approach, an attempt is made to hold virtually everything constant in regard to the assessment except the fact that assessment takes place at two different points in time. That is, the same measuring device (or approach) is applied to the same individuals, in regard to the same stimuli, in the same testing environment, by the same test administrator, etc. However, to be able to generalize, one must also explore consistency in response across different subjects from the universe of

all possible subjects of concern, different stimuli from the universe of all possible stimuli of concern, different testers, different environments, etc. That is, according to an increasingly influential contemporary interpretation, traditional reliability assessment expands into the quest for generalizability (see Cronbach, Gleser, Nanda, and Rajaratnam, 1972).

This paper describes data relating to several points along this consistency continuum. First examined is the consistency of response within the same subject across two different points in time with respect to the same decision. Next, we consider the consistency of response within the same subject across qualitatively different decisions. Finally, we consider the consistency of response across different subjects and different decisions.

Further, while the section on validity considered both information acquisition and choice behavior, hardly any relevant data have been collected regarding the reliability of choice. Hence, our attention is generally confined to pre-decision information acquisition, particularly the depth (i.e., how much?) and sequence (in what order?) of such information acquisition.

Same Subject, Same Decision, Cross-Time Consistency

One fundamental form of traditional reliability is test-retest reliability -- that is, will the same measurement procedures administered at two different points in time to the same individuals and under the same conditions yield identical (or nearly identical) results? Naturally, this assumes no relevant change during the period intervening between the first and second assessment in the item(s) being assessed. Another basic variety of traditional reliability is parallel form -- that is, to what extent do alternative or equivalent forms of an instrument (or, in this case, a measurement procedure), when applied to the same content, yield comparable results?

Preliminary answers to these questions come from a study in which 71 undergraduates were asked to arrive at a "blind date" choice from among 8 hypothetical options, each described along 15 information dimensions. Approximately half this sample was re-tested after a ten-minute delay during which they were engaged in an interpolated activity; the other half was re-tested approximately one week later. Further, some subjects were given the identical information, with only the labels designating the alternatives being changed (either from letters to numbers or vice versa), while other subjects were confronted with entirely new information for eight different blind dates. The Different condition reflected parallel forms reliability, while the Same condition represented test-retest reliability.

Table 5 indicates the number of subjects in each condi-

TABLE 5
Within Subject, Within Decision (Test-Retest and Parallel Form) Consistency

	Immediate		Delayed	
	Same (N=17)	Different (N=25)	Same (N=17)	Different (N=12)
No. of items acquired	.67***	.91***	.27	.69**

Type 3 transitions	.69***	.89***	.45*	.85***

tion and correlations obtained. In general, these coef-

ficients reveal a pattern of high test-retest reliability for the Immediate retest condition, particularly when Different rather than Same stimuli were employed. Also, and as might have been expected, coefficients were generally lower under the Delayed condition. However, they are quite comparable to the test-retest reliabilities obtained for a set of VR items collected for comparison purposes from the these Delayed retest subjects (see Table 6). These latter data suggest that the Delayed/

TABLE 6
Consistency in VR Responses for Subjects in the Delayed Retest Condition

	Same	Different
1. What is your current status with respect to members of the opposite sex? (check one)	.73***	.50*
<input type="checkbox"/> Married		
<input type="checkbox"/> Formally engaged		
<input type="checkbox"/> Going steady with one person		
<input type="checkbox"/> Currently dating two or more people on a regular basis		
<input type="checkbox"/> Not currently dating anyone		
<input type="checkbox"/> Never had a date with a member of the opposite sex		
<input type="checkbox"/> Other (please specify) _____		
2. For your answer in question 1, how long has this been the case? _____ months.	.26	.71*
3. How often do you date? Approximately _____ times per month.	.47*	.55*
4. Have you <u>ever</u> had a "Blind date?" <input type="checkbox"/> Yes <input type="checkbox"/> No	.01	.58*
5. If yes, approximately how many times? _____	.90***	.86***
6. (Pre-Task) Even if you have never had a blind date, make believe you were going to go out on a date with someone you never met before. What would you say the chances would be that you would have a good time? (Response options consisted of a modified 11-point Juster scale; see Engel, Kollat, and Blackwell, 1973, p. 363).	.29	.81***
7. (Post-Task) From the information you have now, what probability would you say there was that you would have a good time if you went out with this person? (modified 11-point Juster scale)	.14	.71**

Same subjects might have been somewhat strange. In particular, consider the coefficients for items 2 and 4. Additional data are being collected to clarify this issue.

The two Same cells provide our only indication of the consistency of choice (in contrast to the consistency of information acquisition behavior, which we have been considering up to this point). For any given blind date selected at t_1 , the probability of selecting this same date at t_2 was 1 out of 8 (or .125). Twelve out of 17 (71%) subjects selected the same date on the Immediate retest, while 5 out of 12 (42%) did so for the Delayed retest.

Consistency within the Same Subject across Different Decisions

Thus far, our published reports have considered pre-decision information acquisition for individuals making purchase decisions. However, as suggested by the study above, the BP approach is applicable to other types of decisions as well. One attempt to explore the psychometric properties of the approach involved having the same subjects arrive at three qualitatively different kinds of decisions: purchase one of eight brands of toothpaste; select one of eight (hypothetical) individuals as a blind date; and, choose (vote for) one of the eight candidates on the 1976 U.S. Presidential primary ballot in Indiana. The number of information dimensions for each task was 17, 15, and 6, respectively.

Attention is confined here to the (Brand) Names Absent conditions for the following reasons. First, while the matrix of information used for the toothpaste and political candidate decisions was "real" information (in the sense of actually being available in the environment), this was the only condition possible in the case of the blind dates, where the different alternatives were all hypothetical. Second, when names are present, respondents can rely upon the information they have in memory regarding each of these different options. As a result, we are unable to determine just which information is accessed and considered relevant (since information may also be retrieved from long term memory). Further, since each subject probably had different past experiences with respect to the various toothpastes and candidates, a BNP condition would introduce too many uncontrolled and potentially confounding factors. Finally, when the identity of the choice options is known (as in BNA), a large proportion of subjects (e.g., 36% to 46% in the NSF investigation, see Table 7) do not access any information from the external environment. Thus, (Brand) Names Absent was used to insure that subjects engaged in at least some information acquisition behavior.

Table 8 provides the relevant data for the 31 subjects on 3 depth and 2 sequence variables. All 15 Pearson co-

efficients were positive, highly related (median $r = .57$), and statistically significant -- 14 at beyond the .01 level and 11 of these at beyond the .001 level. Thus, there seems to be a high degree of consistency in the depth and sequence of information acquisition within subjects who arrive at qualitatively different types of decisions.

Consistency across Different Subjects and Different (but comparable) Decisions

Finally, the NSF investigation (Jacoby and Chestnut, 1977) provides data regarding consistency across heterogeneous decision tasks. The 615 subjects in the 5 samples were interviewed over a 2-year period (1975-76) by more than 12 different interviewers. Respondents reflected a cross-section of Tippecanoe Co. (Indiana) residents above the age of 18 and were representative in terms of age, education, and total family income. All had been "qualified" in advance as users of all three

TABLE 7
Cross-Subject, Cross-Decision Task Consistency

	Brand Names Present			Brand Names Absent

Type 4 transitions	.20	.16	.16	.24	.25

test products.

Table 7 presented the relevant data for six depth, six content, and four sequence variables. The depth variables are fundamental and need no further explanation. The content variables cover the three information dimensions common to all three test products. The sequence variables are those which we developed in 1974 and have been using ever since. Readers are directed to Jacoby, Chestnut, Weigl, and Fisher (1976) for a more detailed description of these indices. Given the many possible configuration of values that the data could assume, inspection of Table 7 reveals an exceptionally high degree of consistency, particularly when one considers the three groups nested under BNP as one comparison set, and the two groups under BNA as another.

Discussion

Appearances (i.e., the many tables of data presented) to the contrary, we have here only touched the tip of the data iceberg. Space limitations do not permit a more exhaustive presentation of data or discussion of findings. Based upon what we have been able to present, however, the tentative findings may be summarized as follows:

1. The convergent validity between VR and BP assessments tend to be in the order of .2 to .4 for information acquisition behavior and range from .48 to .98 for choice behavior. One would expect such greater agreement in regard to a single global act such as choice relative to agreement on the more molecular behavior of information usage. One way to look at this finding is to say that the BP approach has more unique variance to contribute in the study of information acquisition behavior.
2. With respect to reliability, BP measures of information acquisition behavior tend to be quite consistent:
(a) across time for different subjects, different interviewers, and different (but comparable) decision tasks;
(b) within the same person, across different decision tasks; and
(c) within the same person, for the same decision task, across time (i.e., under both immediate and delayed re-test conditions). Further, BP measures seem to be at least as reliable as VR indicants. While we would agree that this assertion is based on little data, the fact of the matter is that not much data have been supplied in the consumer realm to establish the reliability of our traditional VR measures. As examples, based on a comprehensive review of more than 300 studies in the brand loyalty literature, Jacoby and Chestnut (in press) found only two studies which provided reliability data. Similarly, a fairly thorough review of the hundreds of articles comprising the advertising research literature published during the seven years spanning 1968-1974 revealed only two studies bearing on the test-retest reliability of VR measures used in that domain (Jacoby, 1976, p. 6).

Considerable additional evidence bearing on the validity and reliability of BP measures has already been collected and is being supplemented by ongoing research. These data, which include consideration of other types of validity and reliability, will be more thoroughly examined in Jacoby and Chestnut (in preparation). The primary function of this manuscript has been to provide some of the preliminary empirical evidence which suggests that BP measures demonstrate satisfactory validity and reliability and deserve a place in our methodological armamentarium. Obviously, considerably more evidence must be adduced to substantiate this assertion; we are proceeding with this task.

SUBJECTS' INFORMATION PROCESSING IN
INFORMATION DISPLAY BOARD STUDIES

David C. Arch (student), University of California, Los Angeles
James R. Bettman, University of California, Los Angeles
Pradeep Kakkar, University of Pennsylvania

Abstract

The processing carried out by subjects in information display board studies is examined. A theoretical analysis of the display board task, a review of relevant prior research, and a pilot study using prompted protocol data to attempt to understand subjects' display board usage behavior are reported. The results suggest that curiosity and exploratory behavior may be widespread. Implications for further use of the display board method are considered.

Introduction

Several researchers have recently utilized information display boards to study how consumers acquire information (e.g., Jacoby, 1975, 1977; Jacoby, Chestnut, Weigl, and Fisher, 1976; Bettman and Jacoby, 1976; Payne, 1976a, b; van Raaij, 1977a, b; Bettman and Kakkar, 1977; Capon and Burke, 1977). The typical approach used in these studies has been to present information to consumers using an information display board, essentially a matrix array (with attributes as rows and brands as columns, for example). That is, each row of the board would be labelled with an attribute name for the product of interest, such as price, net weight, or unit price. Each column would be labeled with the name of a particular brand or alternative. In some studies real brand names were used (e.g., Jacoby, Chestnut, Weigl, and Fisher, 1976; Bettman and Jacoby, 1976); in others hypothetical alternatives were presented (e.g., Payne, 1976a, b). In each cell of the matrix there is a pocket or other device for holding information cards. These information cards have the appropriate brand and attribute information for that cell printed on their reverse sides. The subject is asked to choose a brand after selecting as many information cards as desired from the display board, one at a time. As each card is selected, the subject can turn the card over and read the information contained. The sequence of cards selected is then the major data of interest.

These card sequences can be analyzed in many ways. The typical approach has been to consider both how many cards were selected, and also the structure of the transitions between pairs of cards. Two general acquisition strategies used by subjects emerge from such analyses: processing by brand (examining cards for one brand, then moving on to another brand, etc.) and processing by attribute (examining cards for several brands for one attribute, then moving on to another attribute, etc.).

The display board method described above has been used to study the relationships of acquisition strategy to brand loyalty and consumption frequency (Jacoby, Chestnut, Weigl, and Fisher, 1976); effects of information presentation format on acquisition patterns (Bettman and Kakkar, 1977); effects of degree of perceived risk, amount of information, and presence of memory aids (Capon and Burke, 1977); effects of information load (Payne, 1976a, b); consumer choice heuristics (Bettman, 1977); and other phenomena related to consumer information acquisition (e.g., see Jacoby, 1977). Thus the technique has proven useful. However, the implications of some recent research lead to disquieting questions about what subjects are actually doing while acquiring information in display board studies. Accordingly, the

purpose of this paper is to examine the available evidence characterizing subjects' information processing in display board studies to raise some of the questions these research results suggest, and to assess the validity of the method in light of this evidence. Three sources of evidence are considered below: a theoretical analysis of the characteristics of the display board task; a review of prior research; and a preliminary report of results of a pilot study designed to examine subjects' processing.

A Theoretical Analysis of the Display Board Task

Newell and Simon (1972) have suggested that one can learn a great deal about the processing used by individuals in carrying out a particular task by examining the constraints imposed by that task. A consideration of what a task requires for successful completion can yield important insights into how behavior must be structured to be adaptive in that particular task environment. This theoretical consideration of task properties is termed a task analysis (see also Bettman, 1977). A brief task analysis for the information display board method is now presented.

We focus in the following and throughout the remainder of the paper on display board tasks where real alternatives are used, i.e., where actual brand names are available to the subject. This implies that various strategies are possible for the subject, including the use of memory to supplement or replace examination of the board. Different problems may arise when brand name is not available or if hypothetical alternatives are used (e.g., prior knowledge may not be as great an influence on processing), but consideration of such problems is beyond the scope of this paper. Several aspects characterizing the display board task with known brand names are now considered: the interaction with memory; format considerations; how information is accessed; the types of acquisition possible; the effort required for acquisition; and the obtrusiveness of the method.

Subjects bring some prior knowledge to the task if known brands are used on the display board. This prior knowledge may interact with acquisition. The subject may acquire less from the board and use more information from memory; the subject may check up on information in memory by acquiring the relevant information from the board; the subject may acquire information from the board to see if it looks plausible given what is in memory (i.e., may check up on the experiment); and so on. Thus, memory can impact not only how much information is acquired, but also the purposes underlying some observed acquisition sequence. This interaction of the information acquired with that in memory needs to be examined more closely.

The matrix format used in display board tasks allows either brand or attribute processing to be carried out easily. However, almost all real world information acquisition settings place considerably more constraints on processing. Shelf displays, package information, and many ads are organized by brand. That is, information

is presented separately, for one brand at a time. Thus brand processing would be easier than attribute processing. In addition, display boards present the subject with a very well-structured, comprehensive, and organized information display. Although some real world displays are also well-organized (e.g., a table in Consumer Reports), in most cases consumers must piece together information from several different sources, presented in different fashions, perhaps on different attributes for different brands (e.g., acquiring information from television commercials or from manufacturers' brochures). The implication is, therefore, that the format and organization of the display board task does not place the same constraints on acquisition as do most real world environments. For more discussion see Bettman (1977).

The accessing of information also appears to differ between display board tasks and actual consumer information displays. In the display board task, subjects can only acquire one piece of information at a time: acquisition is sequential. In looking at a package or some other displays, however, consumers can see several pieces of information at the same time: acquisition can be (essentially) simultaneous. For example, in examining a nutritional label on a cereal package, a consumer can see the general pattern of the nutrient percentages simultaneously.

Display board tasks tend to focus on intentional or goal-directed information acquisition. That is, for a consumer to acquire a piece of information in a display board study, he or she must specifically pull out a card from the board. This may be contrasted with a consumer's scanning a package visually and "happening" to see some piece of information. This more serendipitous type of acquisition is not possible with display boards, but may be very characteristic of actual information acquisition.

To examine another related property of display board tasks, let us assume that the display board and some visual information display (e.g., a package label or a table) contain the same information. Then the effort required to obtain information from the display board may be relatively high compared to visual search of the other information display. That is, in the display board task, the subject must remove the various cards desired, rather than simply scanning the display. This analysis would also imply that information acquisition would potentially be much slower for display board tasks than for visual search of the same information displayed in a table or on a label. Thus less information in total might be selected in display board tasks than in cases where a package or other display were visually examined. Use of information in memory might also be more widespread in display board tasks than in visual search, due to the greater effort involved in directly examining information from the board (Russo, 1978a), as compared to the effort involved in visual search.

Several of the aspects discussed above can now be brought together to analyze the relative difficulty of acquiring information from a display board or from some real world display. The matrix format and well-structured, comprehensive nature of the display board would tend to make acquisition easier from the board. The greater effort and time required for acquisition from the board and the limitation to sequential rather than simultaneous access would tend to make acquisition from the board harder. Therefore, the difficulty of the display board as compared to some real world display would depend upon which of the above factors is stronger. Some actual information displays would be harder than the board (e.g., cases where information was not available in one place, but had to be pulled together by the consumer, where the information was presented in different formats for different brands, and so on). Thus format and the availability of information in a comprehensive

and well-organized display might dominate the effects of how information could be accessed. On the other hand, some actual displays would be easier than the board (e.g., if the same information available on the board were displayed in a Consumer Reports table or on a package label). In this case, the relative ease of visual search compared to choosing cards would dominate the format factor, since the format and organization would be essentially the same for both displays. Even in these cases, however, simply comparing the relative difficulty of the display board and some real world acquisition setting can be misleading, because the factors underlying the difficulties encountered in each task may be very different, as the above analyses demonstrate.

Finally, display board methods are very obtrusive. Subjects may think that the information they acquire is being carefully monitored, and therefore may try to select more "rational" pieces of information. The analyses above suggest that there may be some biases in the display board task. We now turn to an examination of selected prior research using display boards to determine if these studies can shed further light on subjects' processing during such tasks.

Prior Research on Subjects' Processing in Display Board Tasks

Three areas of research which have implications for the type of processing carried out by subjects in display board tasks are considered below: effects of information presentation format; comparison of display board and eye movement acquisition results; and effects of time pressure.

Information Presentation Format Effects

As noted above, display board tasks, with their organized matrix format, may make some kinds of processing (e.g., attribute processing) easier than in actual choice environments. Bettman and Kakkar (1977) tried to directly study the impact of format on acquisition. Subjects were 150 housewives, divided equally into three groups. One group (Matrix) received information on cereals in the standard matrix display board format. A second group (Brand) received information in separate booklets for each brand, and a third group (Attribute) received separate booklets for each attribute. Thus the Brand group's format should encourage brand and discourage attribute processing, with the opposite true for the Attribute group. The results were strongly supportive of the predictions. Subjects in the Brand group used almost exclusively brand processing, and subjects in the Attribute group used attribute processing extensively. Subjects in the Matrix group used both brand and attribute processing.

These results suggest that major variations in display format can have a strong impact on acquisition. They also suggest that the matrix format used in display boards may allow or encourage different acquisition strategies than those characteristic of some real world environments. Thus the theoretical format bias discussed above has empirical support.

Comparing Display Board and Visual Package Search

Several of the theoretical analyses above implied that there might be important differences between acquisition from a display board and visual search of a package or some other information display. It was suggested that if the same information were available from the board and from a visual display, then more information might be acquired and acquisition might be faster for visual search. Van Raaij (1977a, b) reports a study which directly compared display board and visual search

behavior.

In Van Raaij's study (1977b), the same twenty housewives participated in an eye movement study and then in a display board study four months later. The same thirteen alternative brands of coffee were used in both studies, each characterized by four attributes. In the eye movement study, actual product packages with the four attribute values affixed to the sides were examined by the subjects, and their eye movements were recorded. The display board study used a standard matrix display. Van Raaij examined both brand name present and brand name absent conditions; only the brand name present study is considered below.

Several suggestive results were obtained. First, subjects acquired more information in the eye movement study (26.2 versus 15.7 different items -- these figures do not count examining the same piece of information more than once as a separate acquisition). Second, of the pieces of information they selected, subjects examined 51.4% twice or more in the eye movement study, but there was no reacquisition in the display board study. These two findings provide support for the notion that acquisition during visual search may in many cases be more accidental, a result of scanning the package, while acquisition from a display board tends to be intentional or consciously goal-directed.

A third finding was that the acquisition sequence measures were very similar for both studies, with more brand processing evident. Finally, the choice times were greater in the display board conditions than in visual search. Hence, more information was examined per unit time in visual search than in the display board study (Van Raaij, 1977a). The results described above imply that there may be some major differences between visual package search and acquisition from a display board in situations where the same information is available on both the display board and the package.

Effects of Time Pressure

Bettman and Kakkar, in an unpublished study, examined the effects of time pressure on acquisition in a display board task. Subjects were 150 housewives, equally divided into three conditions, all using the same display board task for breakfast cereals. In the first condition (No Pressure), subjects were given no instructions about the time they might take to complete the task. In a second condition (Full Time Asked), subjects were told that, on average, other subjects took two minutes to complete the task. They were then asked how much time they would need, and were given the full amount asked for (the average time asked for was 114 seconds). In the third condition (Half Time Asked), subjects were also told that other subjects took two minutes and were asked how much time they would need (the average time asked for was also 114 seconds). However, this group was then told that due to the number of subjects to be run, only half the time they asked for could be allowed.

The results were somewhat surprising. As expected, the time taken to choose a brand differed across the three groups ($p < .001$). The No Pressure group took 108.5 seconds, the Full Time Asked group 69.7, and the Half Time Asked group 45.3. However, there was not a significant difference in cards taken ($p = .147$) although there was a trend in the expected direction (No Pressure - 7.4; Full Time Asked - 6.5; Half Time Asked - 5.1). There were significant differences in time taken per card ($p < .01$), with the Half Time Asked group taking the least time and the No Pressure group the most. One other unexpected result was that although the Half Time Asked group felt more hurried than the No Pressure group, the Half Time Asked and Full Time Asked groups

did not differ in feelings of being hurried or being under time pressure. Finally, the acquisition sequence measures (types of transitions) did not differ across groups.

These results seem to imply that subjects adapted to the attempt to impose time pressure by simply speeding up their processing. This may mean that subjects could speed up because they were checking up on things they already knew. If this were the case, it might raise serious questions about subjects' goals for examining information in display board studies. However, it might also mean that subjects were processing in a fairly leisurely fashion in the No Pressure and Full Time Asked groups, and that there was a good deal of "slack" time available. Hence, subjects might have been able to speed their processing easily, without really burdening themselves. This speeding up observed could be a method generally used to adapt to tasks when time available for processing is decreased. If time pressure were made quite severe, subjects might not be able to adapt by speeding up, and might have to resort to other strategies (e.g., restricting the brands and attributes they examine). However, Bettman and Kakkar apparently did not impose this much time pressure with their manipulations.

The theoretical analyses and review of prior research have indicated that there may be some serious biases or problem areas in display board tasks. The major issues appear to be: (1) The impact of prior knowledge about the alternatives on acquisition from the board; (2) Impacts of format on acquisition, with some evidence that display board formats may encourage or allow different kinds of processing than some kinds of real world environments; (3) Apparently substantial differences between display board and visual search acquisition, including how much information can be simultaneously accessed, whether acquisition can be accidental or is more goal-directed, how much time is taken, and how often information is re-examined; and (4) Impacts of time pressure on acquisition.

The above discussion has presented only an aggregate view of subjects' processing in display board tasks, and the picture is complex. It is still very difficult to characterize what subjects are actually doing while they are acquiring information from a display board. In particular, there is very little direct knowledge of the goals underlying subjects' information acquisition or of the effect of subjects' prior knowledge on acquisition. Thus there is limited hard evidence about details of subjects' processing, although there are many possible hypotheses (not necessarily mutually exclusive). For example, subjects may be (1) Acquiring information as they would in a store; (2) Checking to see if the information in the display board is the same as they think it should be (i.e., seeing if the experimenter is "tricking" them); (3) Exploring brands they know very little about, or exploring brands used previously but not currently; (4) Using the opportunity to "educate" themselves about their current brand; and so on.

An exploratory study was carried out by Arch and Bettman to attempt to gain some more detailed insights into subjects' processing. Preliminary results of that study are now reported.

An Exploratory Study of Subjects' Processing in Display Board Tasks

The study used two main approaches to try to increase understanding of subjects' processing. First, an attempt was made to measure prior knowledge for the brands used. Second, prompted protocols were obtained from subjects after they had selected their information cards.

Method

Subjects were ten female shoppers, ranging in age from 18 to 49. They were recruited by interviewers in a shopping mall and asked to answer some questions about consumer products. They were told this would take about 20 minutes, and were paid for their time.

Subjects were led by an interviewer into a partitioned area within the mall, where they answered questions about frequency of purchase and familiarity with breakfast cereals. Subjects were then asked to fill out a Brand Characteristic Summary, in an attempt to gather fairly structured information about prior knowledge. The Brand Characteristic Summary was a table with eleven characteristics (attributes) for cereal listed along the rows, and ten brands of cereal listed along the columns (thus there were 110 cells or boxes in the table). The subject was instructed to put a 1 in those boxes corresponding to characteristics of brands that they knew a lot about and would not need to check in the store; a 2 if they knew a little or a fair amount but would want to check it in the store; a 3 if they knew almost nothing but would want to check; and to leave the boxes blank for those brands and characteristics they would not want to check even if they knew little. This task was designed to elicit what pieces of information subjects might check while in the store shopping, so that the information acquired later in a display board task could be compared to it. There may be some bias in the Brand Characteristic Summary task, in that subjects may overstate what they know and what they claim they would want to check in the store. This is discussed more fully below.

Since subjects were later to be given a display board task for cereals, some intervening tasks were included between the Brand Characteristic Summary and the display board to diminish possible attempts at consistency by subjects trying to appear "rational." Accordingly, subjects also filled out some questions and a Brand Characteristic Summary for steam irons. Then the subjects went to another table where they tried samples of lip balms and answered several questions about these samples.

Subjects were then given a standard display board task for cereals, using the same attributes and brands as in the Brand Characteristic Summary. No subject connected these two tasks in post-task debriefings. After completing the display board task and choosing a brand, subjects answered several questions about their reactions to the task (e.g., certainty they had made the best choice, confusion with the task, whether they felt they behaved the same as in the store, which brands of cereal they purchased most frequently). While the subject was doing this, the interviewer took the sequence of cards selected by the subject from the display board, and put X's in the boxes of a new Brand Characteristic Summary table for those cards selected.

After the subject finished the questionnaire, the interviewer gave her the deck of cards she had selected and the table marking those cards, and told her that the X's on the table represented the cards chosen. The interviewer then asked the subject to go through the deck of cards in the order they were originally selected and to talk about what was going through her mind when she first took these cards. This verbal report, which was tape recorded, has been called a prompted protocol (e.g., Russo and Rosen, 1975), prompted by the sequence of cards taken. Such prompted protocols are related to, but not the same as, protocols taken simultaneously, during the actual acquisition task itself (e.g., Payne, 1976a, b). Prompted protocols differ from simultaneous protocols in several ways. First, since the prompted protocols are taken after the display board task has

been completed, there are no problems with the protocol's interfering with or biasing the acquisition behavior observed. Second, the prompted protocols have proven useful in other studies (Russo and Rosen, 1975) at providing a somewhat more structured view of the processing undertaken than is usually obtained with simultaneous protocols. However, there is also potentially a major disadvantage to prompted protocols, in that, since they are not taken while the behavior is occurring, there is more danger of rationalization or retrospection about "why I did that" (Nisbett and Wilson, 1977). On balance, it was felt that the somewhat more structured view provided by prompted protocols and the fact that the acquisition behavior would not be biased were more overriding concerns in the present study.

Following the prompted protocols, the interviewer took out the original Brand Characteristic Summary and compared that to the cards taken, asking the subject about selected differences (e.g., items marked with a 1 on the Brand Characteristic Summary (know a lot, don't need to check) but then acquired, items marked with a 2 or 3 (know some or a little, need to check) but later not acquired, and so forth). This was also tape recorded.

The description of the procedure is lengthy. To summarize, the major data available are measures of purchase frequency and familiarity, Brand Characteristic Summary information, the sequence of cards selected from the display board, reactions to the display board task, prompted protocols taken after the display board task, and some probes for differences between the Brand Characteristic Summary and display board tasks. One can then examine characteristics of the display board acquisition patterns, characteristics of the Brand Characteristic Summary data, the relationship between the Brand Characteristic Summary measures and the information acquired from the display board, and the prompted protocol data.

Results

Display Board Results. In the aggregate, the display board results agree with prior research. Subjects selected an average of 10.2 cards, or roughly 9% of the 110 available. Subjects' acquisition sequences were classified, using the criteria in Bettman and Kakkar (1977). Seven subjects used brand processing, two used attribute, and one used another strategy. This agrees with the Bettman and Kakkar results, which showed that more experienced shoppers tend to use more brand processing. Subjects also seemed reasonably certain they had made the best choice (a mean of 5.2 on a 7-point certainty scale) and claimed that their behavior on the display board task was very much like their in-store behavior (a mean of 6.2 on a 7-point scale with endpoints 1 = Not at all like I behave in the store and 7 = Exactly like I behave in the store). This latter result should certainly be viewed with some scepticism, since subjects' responses may be biased upward by desires to please the experimenter, i.e., to let the experimenter know they were cooperative.

Brand Characteristic Summary Results. Subjects claimed to have a good deal of prior knowledge in the Brand Characteristic Summary. On average, subjects checked 18.1 items with a 1 (know a lot, wouldn't need to check); 22.4 items with a 2 (know some, would want to check); and 28.8 items with a 3 (know little, would want to check). Thus subjects marked an average of 69.3 items of 110, or 63%. Also, subjects claimed they would check in the store 51.2 (the sum of the 2 and 3 responses) of 110 items, or 46.5%.

Comparing the Display Board and Brand Characteristic Summary Results. At the aggregate level, it is obvious that subjects claimed in the Brand Characteristic

Summary that they would check a great deal more information than they actually did examine in the display board task -- 51.2 items (46.5%) in the Brand Characteristic Summary versus 10.2 items (9%) in the display board task. In addition, not all of the cards selected in the display board task correspond to responses of 2 or 3 (know some or a little, want to check) in the Brand Characteristic Summary. In fact, of the average of 10.2 cards taken from the display board, 3.6 were items checked with a 1 (know a lot, don't need to check) in the Board Characteristic Summary; 2.8 were items checked with a 2 (know some, want to check); 2.6 were checked with a 3 (know little, want to check); and 1.2 were blank (don't want to check). Thus subjects actually selected cards for a higher percentage of the items they had marked with a 1 (and hence said they wouldn't need to check) than for items they had marked with a 2 or 3 (and hence said they would want to check).

These results show that subjects sometimes do not acquire information in the display board task, even though they claimed they would in the Brand Characteristic Summary. Subjects actually acquired at least one card in the display board task for 51% of the attributes and for 44% of the brands they checked in the Brand Characteristic Summary.

The results also indicate that subjects acquire information they earlier claimed they would not need to examine. Those cases where subjects marked items with a 1 in the Brand Characteristic Summary and then selected the corresponding cards in the display board task were examined, using subjects' tape recorded responses to the interviewers' probes. Subjects' stated reasons varied. Some of these instances simply appear due to unexplained inconsistency in the subjects' responses; some appear to be due to subjects' checking items to see if the information is what they believe it to be; and some are due to subjects' checking attributes that they feel they know for their store, but which might vary from store to store (e.g., price). One other reason appears which is quite interesting, and which may shed some light on the differences between the Brand Characteristic Summary and display board results. Subjects may say they know a lot and don't need to check when they know a characteristic's general level -- e.g., they know protein content is 'high.' They may then later check that item to refine their knowledge, to find out that 'high' protein is 10 grams. Thus 'knowing' a lot may mean knowing general ranges to the subject, not knowing an exact amount.

The discussion above amply documents that there are substantial disagreements between subjects' claims in the Brand Characteristic Summary and their acquisition behavior in the display board study. There are several possible reasons for this. First, it may be that the Brand Characteristic Summary task encourages overstatement of intended search, since this appears rational. Second, the Brand Characteristic Summary, as asked, may not have been seen by the subjects as being specific to their own shopping behavior. That is, rather than responding with what they would actually want to check if shopping for cereal in the store, subjects may have responded with what they might check if they were to consider some brands in the future, or what they might check if they had time. On the other hand, subjects made many comments in the protocols characterizing the display board task as a shopping task (which of course does not necessarily mean it was really treated that way). Although the evidence is scanty (mostly subjects' comments), the second reason seems more likely.

Insights from the Prompted Protocol Data. The contents of the prompted protocol data were judged by the authors. In our future research on this topic, with more subjects, independent judges will be used. Thus these

preliminary results are only suggestive. The prompted protocol data suggest two main findings. First, there seems to be a great deal of exploratory or curiosity-based information acquisition in the display board task. Subjects spent a good deal of time checking on brands they had previously purchased but no longer bought, saying they did this because they were curious about what these old brands were really like (this occurred for five of ten subjects). Subjects also spent time exploring new brands they knew little about (for four of ten subjects). One of these subjects said, "I didn't know too much about the cereals I did check. That is why I was going through them..." Finally, subjects also used the display board task to explore or educate themselves about their current favorite brand (for five of ten subjects). Thus there is curiosity about brands previously bought, relatively unknown brands, and the consumer's current brand. In many of the cases where exploratory behavior was observed, there appeared to be little explicit comparison of alternatives carried out.

A second finding is that some display board acquisition appears to be aimed at checking on the experiment (this may have occurred for three of the ten subjects). As one subject stated, "I wondered what your card was going to say."

Discussion

The results of the exploratory study suggest two broad areas for discussion: how to measure prior knowledge, and how to interpret the curiosity findings.

The discrepancies noted above between the display board and Brand Characteristic Summary tasks suggest that more work needs to be done on the measure of prior knowledge used. One must first distinguish between general knowledge (protein is high) and specific knowledge (protein is 10 grams). Subjects appear to interpret the Brand Characteristic Summary as asking for general knowledge. The Brand Characteristic Summary may have failed as a good measure of this general knowledge because subjects did not relate it to their actual shopping behavior, but responded more with what they might do sometime. Thus, one might strengthen the Brand Characteristic Summary by being very specific, attempting to tie it to shopping behavior (e.g., asking subjects to indicate what they would do in the store the next time they shopped for cereal, or what they did the last time). One might try to validate such a measure (and the display board findings as well) by measuring actual search behavior, perhaps in an artificial store setting, but this may be very difficult. For specific, as opposed to general, knowledge, one may have to test actual values. It is not clear whether measures of general or specific knowledge would be more related to acquisition behavior.

The curiosity findings in the display board task are intriguing. They may, of course, be spurious. One could argue that this exploratory behavior is a result of low involvement with the task. Subjects may decide that they are in an experiment, they might as well get something out of it, and that the situation is one which is well-suited for learning about new brands, old brands, or one's current brand, since an array of information is available. On the other hand, these findings could be real. There is very little evidence about exploratory behavior in actual choice situations, a major gap in consumer research. However, subjects claim that they treated the board like a shopping situation. Although this is weak evidence at best, the exploratory behavior results seem definitely worth pursuing.

Overall Discussion

Three sources of evidence about display board tasks have been considered: theoretical arguments, prior research,

and the preliminary study reported above. The evidence itself is very hard to characterize; however, some conclusions seem warranted. First, display board tasks appear to have some serious biases, which may limit the range of phenomena they can be reasonably used to study, but also possess some strengths for researching other areas. For example, display board tasks may be very useful for researching curiosity-based or exploratory behavior, a phenomenon which has proven extremely difficult to research. Also, display board tasks may be very suited for studying the goals consumers develop for information acquisition. That is, the consumer may set up some goals for search, for what information to examine. The information acquired in a display board task may relate to these goals, since intentional or goal-directed search is largely what is observed.

Display board tasks, because of their biases, do not seem as suitable for some real world visual search tasks. As noted in the Van Raaij (1977a, b) findings above and in the theoretical task analysis, the display board task diverges from some visual search tasks in many crucial respects. In particular, the above arguments imply that display board tasks may not be appropriate for studying acquisition of package information, especially where fairly complete information is available on the package. As a specific example, results of display board studies might be particularly misleading for drawing public policy implications about providing package information. One major aim of providing information on a package may be to have consumers learn about that information over time by "accidentally" acquiring it while scanning the package. As noted earlier, display board tasks do not allow for this type of phenomenon to any great extent. Thus actual acquisition of information over time and its eventual impact may be severely understated by results of display board studies. Eye movement analyses seem best suited to studying most visual search tasks (Russo, 1978a, b).

One final comment seems necessary. Both the display board task and eye movement studies suggested above are obtrusive tasks. There is probably a consumer research counterpart to the Heisenberg Uncertainty Principle: one cannot measure process without impacting that process. Thus process methodologies will have impacts; the problem is to understand those impacts.

EYE FIXATIONS CAN SAVE THE WORLD: A CRITICAL EVALUATION AND A COMPARISON
BETWEEN EYE FIXATIONS AND OTHER INFORMATION PROCESSING METHODOLOGIES

J. Edward Russo, University of Chicago

Abstract

Eye fixations are described and evaluated as a type of process tracing data. Several examples illustrate their use, in both laboratory and consumer settings. This method is compared with four alternatives: chronometric analysis, information display boards, input-output analysis, and verbal protocols. Each method is evaluated on seven performance attributes ranging from validity to equipment cost. The resulting ratings are summarized in a single table. Each method is seen to have unique advantages, so that no one method dominates and no one method should be shunned. The use of joint methodologies is strongly advocated. Eye fixations and verbal protocols are especially complementary methods.

Introduction

The phenomenological base of the information processing paradigm is the sequence of cognitive events that occur between stimulus and response. The ascension of this paradigm in consumer research has shifted the theoretical concern from states to processes and the empirical focus from the output of a process to data that can identify the process itself. To identify the sequence of events that constitute information processing, new methodologies have been developed and old ones elaborated. The goal of this paper is to describe one of these methodologies, the recording of eye fixations, and to compare it to the most popular alternative techniques.

Process Tracing Data

The available methodologies can be classified as process tracing or otherwise. All process tracing techniques rely on intermediate responses to provide evidence of ongoing cognitive activity. These responses occur during the performance of the task, prior to the availability of the task's output. Process tracing methodologies include the recording of eye fixations, verbal protocols, and information display board techniques. Input-output analysis and chronometric analysis are examples of methodologies that do not rely on a trace of the process.

The intermediate responses that constitute the process trace can be either naturally occurring behaviors, like eye fixations, or they can result from additional instructions, like verbal protocols. There are many possibilities in both categories. For example, natural overt behaviors include the use of external memory, such as writing intermediate computations for later retrieval. Instructed behaviors include, besides verbal protocols, the category of subgoal markers. For example, when choosing from several brands, consumers can be required to mark each brand as it is eliminated. These overt eliminations provide a trace of the progress of the choice task. The potential range of process tracing observations is very large. Only a few of these possible data collection techniques are now in use in any of the behavioral sciences.

Eye Fixations

For humans the most efficient means of obtaining information from the environment is through eye fixations.

Fixation points are located very accurately, and the intervening movements of the eyes are very fast. For example, a typical 5-6 deg. movement requires about 30 msec. This means that during typical tasks, only 5% of the time is devoted to eye movements, while useful fixation time accounts for the other 95%. The speed and accuracy of the visual system are unrivaled by other human sensory systems.

Eye Fixations as Information Acquisition Responses

When using eye fixations to trace cognitive processes, one limitation must be kept in mind. Eye fixations are information acquisition responses. Rarely are they anything else. This means that using them to identify cognitive processes is like using only the tip to judge the shape of an entire iceberg.

Cognitive processing can be partitioned into two types of activity, the acquisition of information and the operations that are performed on this input. Any strategy for performing a cognitive task, such as consumer decision making, will exhibit a characteristic pattern of information acquisition and internal computation. The task of the researcher is to identify the consumer's strategy from only what is observable. The internal computation is not observable, and neither is any information that is retrieved from memory. It is mainly when the guiding strategy calls for external information that observable behavior is produced.

For a researcher to infer the underlying cognitive strategy from a sequence of eye fixations, the task environment must be structured around the acquisition of visual information. Even then this inference is seldom an easy task, and it is sometimes impossible. However, cognitive psychologists and other behavioral scientists have had some notable recent successes in eye fixation analysis (e.g., Just and Carpenter, 1976a). These data are becoming more useful as we understand better how to interpret appropriate subsequences of fixations and as process-oriented theories become available to guide the examination of these data.

Collecting Eye Fixation Data

There is no single best way to collect eye fixation data. Many different techniques are available. These techniques differ widely in convenience, price, subject restraint, and other relevant attributes. Each of the recording methods has characteristic advantages that can make it well suited to some experimental situations but not to others. For example, to gather pilot data, direct observation of the subjects' eyes may provide enough accuracy at a low cost. For a confirmatory study involving detailed stimuli like package facings, a more precise, computer-controlled eye position sensor may be needed.

Simple Observation. Direct observation methods are the least complicated way to collect eye fixations. Typically, a video recording of the subject's face is made during task performance. At some later time, this recording is coded into a sequence of eye fixations by combining knowledge of the stimulus display with a subjective determination of the subject's direction of gaze. The latter task can be time consuming, especially if many subjects are involved. It is also susceptible

to a trade-off between reliability and accuracy. The primary advantages of direct observation techniques are minimal set-up and equipment costs. (The only equipment needed is a video tape recorder and playback monitor.) Furthermore, using this method, eye fixations can sometimes be recorded unobtrusively. For example, a one-way mirror can be used to separate the video camera from the subject (Van Raaij, 1976a; Russo, 1977a).

Precise Recording. If large amounts of precise eye fixation data are needed, a computer-controlled system is essential. Such a system consists of two major components: an eye position sensor and a laboratory computer for recording and analyzing the fixations. These systems can be quite expensive, but they offer great accuracy and efficiency. With appropriate software, a print-out of the location, duration, and sequence of eye fixations is available immediately (Loftus, Mathews, Bell, and Poltrock, 1974). Furthermore, on-line analysis of eye fixations offers exciting possibilities for altering the visual display as a function of where the subject is looking. For examples of such systems and their use, see Just and Carpenter (1976b) and Reder (1973).

Further Reading

The preceding brief overview of eye fixation methodology is necessarily selective. The following readings are recommended to readers seeking more detail on the recording and analysis of eye fixations.

A forthcoming volume by Senders, Fisher, and Monty (1978) contains an up-to-date survey of the use of eye fixations in cognitive psychology and several applied disciplines. In spite of an emphasis on military applications, this book is highly recommended. Included in this compilation is a paper by the present author that analyzes in detail the relation between eye fixations and underlying cognitive strategies (Russo, 1978). Also recommended is a similar, but earlier, volume by Monty and Senders (1976). The classic reference work on the eye is a six-volume collection of papers edited by Davson (1962-1975). Particularly relevant is the chapter on eye movements by Alpern (1969).

For a review of data collection methods and apparatus, a recent comprehensive survey by Young and Sheena (1975a, b) is available. The simpler, less expensive methods are reviewed by Russo and Mathews (1975). Just and Carpenter (1976b) describe a complete eye movement laboratory and its use. Examples of software systems that are used in computer-controlled eye fixation recordings are provided by Conery, Smith, and Russo (1974), Reder (1973), and Goode and Russo (1971).

Examples of the Use of Eye Fixations

The best way to explain the methodology of eye fixations is by example. Two complementary applications have been selected from the author's personal experience (Russo and Rosen, 1975; Russo, 1977a). Both focus on the multi-alternative choice process, first in a setting characteristic of experimental psychology and then in a consumer setting. When examining these examples, the reader is urged to consider the general problems of interpreting eye fixation sequences, rather than the specific interpretations presented. These general problems include validating an interpretation and isolating the relevant cognitive units of behavior.

Multialternative Choice

Eye fixations were used by Russo and Rosen (1975) to expose the strategies used in multialternative choice. The subjects were college students and the choice sets were always six used cars. The cars were described by

three alphanumeric attributes, make, year, and mileage; no pictures were used. A preliminary measurement of utility permitted the construction of choice sets of uniform difficulty both within and across subjects. The eye fixation sequence from a typical trial is presented in Table 1. These data include refixations only; the initial fixation on each alternative was controlled by the stimulus display.

In analyzing this sequence of fixations, the goal is to link these information acquisition responses to an underlying cognitive strategy. The aspect of these data that first strikes an observer is the pattern of alternation between two alternatives. There are four such alternating chains of fixations, marked in Table 1 by vertical brackets. They range from a minimum of three to six fixations in length. This pattern of eye fixations suggests a series of pair comparisons. That is, it suggests that the subject's strategy for multialternative choice is to partition the table into a sequence of pair comparisons. Over twelve subjects, about 64% of refixations were in pair comparisons, with only one subject exhibiting less than 50%.

The interpretation of an alternating sequence of three or more fixations as a pair comparison may have face validity. But how can the researcher be certain that this interpretation is correct? Two validation procedures were used. First, verbal protocols were collected, and these data were examined for statements that confirmed the interpretation of eye fixation sequences. When the alternating pattern included four or more fixations, a 95% confirmation rate was obtained. That is, for 95% of the longer alternations, the subjects explicitly stated that the two fixated alternatives were being compared. When there were only three fixations, an X-Y-X pattern, the confirmation rate dropped to 69%. This suggested that some of the briefer alternations did

not indicate the occurrence of pair comparisons. On average, 83% of the fixation alternations were accompanied by explicit statements of comparison. Since the verbal protocols could not be expected to be complete, this confirmation rate is a lower bound.

A second validation procedure relied on the prior measurement of the utility of each of the six alternatives. A strategy of pair comparisons implied that evaluation took place within these alternating patterns of eye fixations. However, evaluation might also have taken place during the remaining "single" fixations. Figure 1 implies that this was not the case. All evaluative processing took place in the pair comparisons.

FIGURE 1

RELATIVE FREQUENCY OF REFIXATIONS BY UTILITY RANK

To understand Figure 1 consider the following: whenever evaluation is taking place there should be a sensitivity to the utility of the alternatives. The higher the utility of an alternative the more attention (number of fixations) should be received. This predicted pattern holds only for the pairs. The singles show no sensitivity to utility, indicating that no evaluative processing took place during these fixations.

Both procedures for validating the interpretation of the eye fixations required the use of additional data. First, verbal protocols directly confirmed the hypothesized interpretation. Second, a series of outputs of the evaluative process were transformed into utility ranks, which had a uniquely predicted relation with the eye fixations. Validation procedures are almost always examples of the convergent use of two methodologies for examining the same phenomenon.

Behavioral Units versus Cognitive Units

This example illustrates a critical step in the analysis of eye fixations. Subsequences of eye fixations, namely alternations of three or more fixations, were interpreted as single cognitive units. Although the behavioral unit

was a single eye fixation, the cognitively meaningful unit was a group of eye fixations. It is essential to aggregate the behavioral units into the appropriate cognitive unit (see Just and Carpenter, 1977a). Consider the interpretation of fixation durations. In this experiment great effort was expended trying to interpret the durations of individual fixations, especially within a single pair comparison. No success was achieved, however, because these single fixations did not represent complete cognitive units. In contrast, the durations of the pair comparisons yielded important insight into the subjects' strategies.

Another way of emphasizing the importance of identifying cognitive units is to consider what happens when they cannot be found. The early literature on reading contains many examples of extensive recording of eye fixations, often with primitive equipment and great labor cost. For an example, see Kolers (1976). These studies relied on summary statistics, such as the location, frequency, and mean duration of the observed eye fixations. Although such measures are informative about reading performance (e.g., good readers need fewer fixations), they say little about the reading process, i.e., the process of comprehension. As in many other situations, an adequate theory of the process is necessary before any progress can be made in meaningfully interpreting the observed behavior. In short, the "fishing expedition" approach to research is particularly risky when the eye fixation methodology is being used.

Consumer Decision Making

An eye fixation analysis of consumer decision making has recently been completed (Russo, 1977a). Typical shoppers made purchase decisions in a simulated supermarket setting. The subjects' faces were videotaped through a one-way mirror; they were not aware that their eye fixations were being recorded. The results of a typical trial are shown in Figure 2. A schematic diagram of one array of products is shown. The numbers denote eye fixations listed in order of occurrence. The data are hypothetical, but realistic, and are representative of the major characteristics of the 138 actual fixation sequences.

^aThis is the brand/size usually purchased and the one chosen during this decision.

The results of this study will not be summarized here. A few findings, however, serve to illustrate the use of the eye fixation data. The choice process was partitioned into three stages: overview, comparison and checking. The first and last stages were identified primarily by the absence of repeated fixations. In Figure 2, the fixations covered by these stages are: overview, 1-6; comparison, 7-22; and checking, 23-25.

The comparison stage was characterized by pair comparisons. That is, the same alternating pattern of fixations (X-Y-X ...) that was found by Russo and Rosen (1975) occurred during the comparison stage of the consumer decision process. In the preceding example there are three such alternations: 7-8-9, 14-15-16, and 20-21-22. Overall, 50% of the comparison fixations were accounted for by pair comparison alternations. There is an interesting twist connection among these pair comparisons. About two-thirds of them involve the usual brand. Consumers seem to anchor their pair comparisons on their habitual choice. Competing alternatives are directly (pairwise) compared to this standard.

One other finding from this study is relevant to the eye fixation methodology. On over 50% of the trials, the shoppers continued to look at the products on the shelves after they had selected and stated their choice. In Figure 2, the four fixations shown in parentheses, (26) through (29), are typical of this post-decisional pattern of looking. These fixations tend to be located on items that have received little or no attention during the decision process. About 80% of the post-decisional fixations were devoted to brand/sizes never previously looked at or fixated only once before. This is an example of the eye fixation methodology exposing part of the process that would probably not have been revealed by any other method.

Comparison Among Methodologies

In this section, five major methods for identifying cognitive strategies are compared. The methods are evaluated only on their ability to expose cognitive strategies. This evaluation ignores all other experimental goals, such as predicting the output of the process or determining memory structure. First, the five methodologies are described. Then seven performance attributes are presented on which each of the methodologies is evaluated and compared with the others. This entire section is summarized in Table 2, to which readers, if they choose, can turn immediately.

Methodologies

The previous discussion of eye fixations will not be recapitulated here. Instead, we move to the four alternate methodologies that are to be evaluated.

Chronometric Analysis. This method relies upon the total time required to complete a process. This time is typically recorded for many trials within an appropriate experimental design. By comparing the mean response times for different experimental conditions, the nature of a cognitive process can be investigated. This is especially true if the process can be described as a sequence of stages or subprocesses. This technique is most effective for brief tasks, those less than a few seconds in duration. Its use is more problematical for longer tasks like purchase decisions. This technique has seen very little use in consumer research. For an introduction, see Gardner, Mitchell, and Russo (1978); also see Johnson and Russo (1978).

Information Display Boards. In this method, stimulus (product) information is available in an array of pockets on a large board. The subjects reach into a pocket to draw a card which contains the desired information. This method is representative of most techniques that trace a

process through a sequence of overt information acquisition responses. The major exception is eye fixations. The important difference between information display boards and eye fixations is acquisition effort. Whereas an eye fixation typically requires 230 msec. to deliver the requested information (Russo, 1978), a manual reaching response takes about ten times longer.

Input-Output Analysis. This label refers to all methods that rely exclusively on the output of the cognitive process as their data base. By carefully designing the stimulus input, an analysis of the output can reveal processing detail. For example, various heuristics for judgment have been exposed only by analyzing the judgments themselves (Tversky and Kahneman, 1974). See also Lichtenstein and Slovic (1973) and Tversky (1969). Because the method of input-output analysis relies on such a narrow data base, it is not always successful in revealing the underlying process. For example, compare Slovic and MacPhillamy (1974) with Russo and Doshier (1976). Input-output analysis is easily the most common experimental method in behavioral science and should be contrasted with the newer process tracing techniques.

Verbal protocols. A verbal protocol is generated when subjects think aloud while performing an intellectual task. That is, subjects are required to verbalize what they are thinking as they perform the task. This procedure should be differentiated from introspection, in which trained subjects are asked to observe and explain their own internal processes. For a discussion of this distinction, see Payne, Braunstein, and Carroll (1977). The collection of a concurrent verbal protocol should also be distinguished from retrospectively collected protocols. A concurrent protocol avoids many problems associated with protocols that rely on memory (Nisbett and Wilson, 1977). The most important point about verbal protocols is that they are difficult to analyze formally. This is true even for the most structured tasks like logic, chess, and cryptarithmic (Newell and Simon, 1972). They have been successfully analyzed in relatively few consumer experiments (however, see Bettman, 1970; and Payne, 1976).

Performance Attributes

Seven attributes have been selected on which the performance of the five methodologies is to be judged. This list represents the necessary compromise between efficiency and completeness. Others may find some eighth attribute more important than one listed here, especially in a particular application. The seven fall into three broad categories: quality of the data, breadth of applicability of the method, and cost.

Data Quality. The success of any methodology for identifying cognitive strategies depends on its ability to reveal the process in detail. The more detail, the better. A lack of detail must be compensated by repeated trials within complex experimental designs.

If detail roughly corresponds to the quantity of data, then informativeness represents an aspect of data quality. This attribute describes the amount of information conveyed by a single datum, such as the output of a process or one eye fixation. Informativeness also includes some notion of interpretability. The more easily interpretable the data, the more informative.

Just as important as either detail or informativeness is validity. The recorded observations must be a valid indication of the underlying process. They should not be easily censored or distorted as a reaction to the experimental situation. One test for potential invalidity due to reactivity is the question: Can subjects successfully conceal any or all of their strategy from an experimenter who relies on "Method X"?

Breadth of Applicability. To be useful a method should be applicable in a range of experimental settings. These include natural consumer environments, such as the supermarket or at home in front of the TV, as well as laboratory settings.

Breadth of applicability can be limited by the obtrusiveness of the method. Certain situations that are particularly susceptible to experimental reactivity require unobtrusive recording. Would shopping decisions be performed normally if shoppers knew that their eye fixations or total decision time were being recorded?

Costs. The ease of use, or convenience, of a method is important, especially if many trials are to be collected. Note that convenience includes data analysis as well as data collection. Thus, detailed observations like eye fixations are difficult to use, more because of the effort required to analyze them than to collect them.

The last attribute is the cost of equipment, both in dollars and the time necessary to set up an operating system. For example, an eye movement laboratory is costly both because the equipment can be expensive and also because a software system can take considerable time to develop.

Evaluation by Methodology and Attribute

Each of the five methodologies is evaluated on each of the seven performance attributes. A five-category ordinal scale is used: excellent, very good, good, fair, and poor. The values are intended to be consistent within attributes. No comparisons across attributes are implied by the ratings. Relative importance among the attributes depends upon the particular research problem and can be expected to vary greatly. The thirty-five ratings are summarized in Table 2. An explanation of these ratings follows.

Ability to Reveal Process Detail

1. The total duration of the process by itself cannot provide much detail. This is especially true for the relatively long processes associated with typical consumer tasks. In certain circumstances, however, detail can be obtained by performing more sophisticated chronometric analyses on the durations from a complete, prop-

erly designed experiment. For a discussion, see Gardner, Mitchell, and Russo (1978) or reviews in the psychology literature (Chase, 1977; Pachella, 1974).

2. This is the most detailed of the process tracing methods. An interesting comparison with verbal protocols is reported by Newell and Simon (1972, pp. 310ff). They claim that adding eye fixations to their standard analysis of verbal protocols increased the precision of the process trace by about 50%. This comparison is flawed by the reliance of the eye fixation analysis on a prior description of the process derived from the verbal protocols. Further, one of the authors of this study has since claimed that "verbal protocols provide . . . data at densities comparable to the densities of eye fixation records" (Simon, 1976, p. 261). On the other hand, the Newell and Simon data were recorded in a very structured task, cryptarithmic, using highly educated subjects. Both factors enhance the amount of verbal information that can be generated. In contrast, the detail available from eye fixations is present even in less structured tasks, such as viewing advertisements, and even when representative consumers serve as subjects. Overall, the detail provided by verbal protocols is very good, but not as great as that provided by eye fixations.

3. Information display boards reveal less detail than is commonly assumed. Consider a simple measure of detail like the observation rate. This is the total number of observations divided by the total time of the process, expressed in observations/min. The estimate of this rate for the information display board method is derived from data reported by Jacoby and Chestnut (1977). For comparison purposes, the rate for eye fixations is obtained from Russo (1977a). This latter study is similar to Jacoby and Chestnut's. They both used representative shoppers making realistic purchasing decisions from an array of real brands. However, there were differences in the display presented to the subjects. Whereas the stimulus for Jacoby and Chestnut was an information display board (brand and attribute array), Russo used actual product packages on shelving that simulated a supermarket setting. The reported mean observation rates are 4-5 acquisitions/min with the information display boards¹ versus 49 eye fixations/min. Thus,

¹The lower bound of four acquisitions/min may be high. This value was based only on the 61% of the subjects who

TABLE 2

A COMPARISON OF FIVE METHODOLOGIES FOR CONSUMER INFORMATION PROCESSING RESEARCH

Method	Performance Attributes						
	Data Quality			Breadth of Applicability		Cost

Verbal Protocols	5. v. g.	10. exc.	15. fair	20. exc.	25. poor	30. good	35. v. g.

the density of observational detail is almost ten times less for information boards than for eye fixations.

Van Raaij (1976b) used an information acquisition response that is intermediate in effort between a reaching response and an eye fixation. His subjects reached for an actual product package which displayed four information attributes on the four sides. Compared with an information display board, Van Raaij's reaching response is no more effortful and possibly less so. And without any further reaching, the subjects could acquire three additional attributes by turning the package in their hands. Given this level of acquisition effort, one would expect an observation rate between those of information display boards (4-5 observations/min) and eye fixations (49 observations/min). The value calculated from Van Raaij's data is 14 observations/min.

Because a reaching response is relatively effortful, subjects can be expected to adopt strategies that minimize the use of this type of information acquisition. For example, rather than reacquire the same value a second or third time, they tend to memorize these values. When needed again they are recalled, which is much quicker than a second reaching response. The problem is that, since recall is internal, it is unobservable. This defeats the purpose of the method, to provide a detailed trace of the choice process. In the information display board studies by Jacoby and his associates, reacquisition rate never exceeds 7% of all acquisitions (Jacoby and Chestnut, 1977; Jacoby, Chestnut, Fisher, and Weigl, 1976). When Van Raaij used the information board method he found a zero reacquisition rate (Van Raaij, 1977). In contrast to these low values, the reacquisition rate for eye fixations is much higher. Russo (1977a) reports a rate of 56%; i.e., 56% of all eye fixations were re-fixations. Van Raaij (1976a) also recorded eye fixations but required a simple, manual manipulation of packages. For this information acquisition response, the reacquisition response was 35%. As expected, this value is intermediate between the information display board rate (< 7%) and the pure eye fixation rate (56%). Caution must be used in interpreting these data because differences in the stimulus display make reacquisition rates not precisely comparable. However, such large differences indicate that at least some difference would remain if identical stimulus display could be used across all methods.

The danger in all this is that because information display boards yield a relatively sparse trace of the process, they may lead to different views of the subjects' strategies. Using a detailed eye movement trace, both Russo (1977a) and Van Raaij (1976a) report that subjects use pair comparisons to directly compare among alternatives. In contrast, Jacoby and Chestnut (1977, p. 94) conclude that their subjects' information "search seems to be of very shallow depth." Arch, Bettman, and Kakkar (1978), use verbal protocols to provide insight into information display board behavior. They report that "there seems to be a great deal of exploratory or curiosity-based information acquisition in the display board task." These contrasting inferences from the two methodologies suggest that the danger of sparse data yielding different conclusions is real.

In summary, information display boards require an effortful acquisition response, more effortful than the eye fixations on which shoppers mainly rely in natural settings. This increased effort encourages the use of strategies that conceal much of the detail of information acquisition.

searched the information board at all (when brand name was given). The data reported by Jacoby and Chestnut (1977, Tables 6-10) do not permit a revised calculation of observation rate based on all subjects.

4. Input-output analysis was not intended to provide detailed observation of the process. This method relies entirely on one observation, the output of the process. Only with repeated observations in an appropriate experimental design can a cognitive strategy be inferred. For a notably successful instance, see Tversky and Kahneman (1974). However, important parts of the strategy, if not its entire detail, can sometimes be exposed; see, e.g., Slovic, Fleissner, and Bauman (1972) or Slovic (1969).

5. Verbal protocols reveal more detail than any method except eye fixations. Although quantitative comparisons are problematical, the observation rates of the two methods can be compared, just as they were for eye fixations and information display boards. Newell and Simon (1972, pp. 310ff) formally analyze a verbal protocol, transforming it into a series of "productions." These are the smallest meaningful cognitive units within their theory. They report a rate of 19 productions/min. When the associated eye fixations are analyzed, in conjunction with the verbal protocol, the rate increases to 28 productions/min. This comparison is biased in favor of eye fixations because they have the benefit of a prior verbal analysis. However, it has the rare advantage of comparing two different types of data on the same criterion.

Verbal protocols are difficult to compare to eye fixations because these two types of data are so different. The strength of verbal protocols is their ability to reveal larger strategic concepts. These larger concepts are easier to verbalize than details like the purpose of an individual eye fixation. Subjects do not verbalize many details either because they are not aware of them or reporting them would slow down performance intolerably. An indication of how much more detail is available than is spoken can be obtained from results reported in Russo (1977b). A standard concurrent verbal protocol was compared to a new technique called prompted protocols. A retrospective protocol is collected while subjects are prompted by a replay of their sequence of eye fixations. Based on three different tasks, the prompted protocols averaged over twice as many words as the concurrent protocols. When coded for specific informative statements, the prompted method yielded about 75% more statements than a concurrent protocol. This additional information in a prompted protocol illustrates the details that are otherwise not reported, but would seem to be captured by an eye fixation sequence.

In summary, in spite of the difficulty of directly comparing verbal protocols with nonverbal data, the evidence consistently suggests that verbal protocols do not provide as detailed a process trace as eye fixations. Nonetheless, verbal protocols still provide very good detail and are clearly superior to the other three methods on this attribute.

Informativeness

6. Response times are directly interpretable and are, in this sense, informative. It may take many of them to provide a complete picture of the underlying process, but each response time is still clearly informative.

7. Eye fixations are inherently informative only in so much as characteristic patterns of fixations can be isolated. The individual fixations are usually not interpretable. Of course, with an adequate theory of the process, an eye fixation sequence can become very informative, but the existence of such a theory is not presumed for the typical research problem.

8. The sequence of acquisition responses provided by the information display board method suffers from the same difficulties as eye fixations. In addition, because the response rate is lower, there is less oppor-

20. A major advantage of verbal protocols is that they can be collected in almost any setting. It is almost as easy to record shoppers talking in a supermarket (e.g., Bettman, 1970) as in a controlled laboratory situation. Because a relaxed, comfortable subject generates better protocols, it can be argued that the method works better in natural field settings than in the laboratory.

Unobtrusiveness

21. Because of the need for speed-accuracy instructions and appropriate measuring apparatus, chronometric methods tend to be very obtrusive. It is difficult to insure uniform task performance without making subjects aware that their response times are being recorded. However, unobtrusive recording is possible, usually by hidden observers using stopwatches.

22. Eye fixations can be recorded unobtrusively (e.g., Russo, 1977a; Van Raaij, 1976a; Monty, 1975). However, the experimenter must pay a price in either more expensive equipment or more costly manual analysis.

23. Information boards are necessarily obtrusive. The special stimulus display means that subjects know their behavior is being observed. On the other hand, it ought to be possible to construct a display very similar to an information board that would simulate the information array in a natural setting. Unobtrusive observation of information acquisition should then be possible. This author is not aware of any such studies.

24. Unobtrusive recording is easiest for the input-output method. The only response that has to be recorded is the output. However, when used for process analysis, a highly structured experimental design is usually needed. This design can be difficult to conceal from subjects.

25. There is no way to ask subjects to think aloud without obtruding into their natural behavior. There are just not enough subjects who normally go around talking to themselves.

A major distinction between verbal protocols and the other four methodologies is that only the former requires an extra response. Subjects must simultaneously perform a second task, to generate a coherent verbal description of the thoughts that occur to them while completing the primary task. The existence of this second task is not only obtrusive, but raises the larger question: does generating a verbal protocol alter the primary process in important ways? Most experimenters believe that the answer is negative; however, there is little, if any, direct empirical support for this conclusion.

Ease of Use

26. The recording of response times is relatively easy, although standardized procedures should be followed (see Sidowsky, 1966). The data analysis is similarly uncomplicated.

27. Some eye fixation methods are easy to use, but most require either complicated recording procedures or effortful data analysis. Unlike the other methodologies, there is such a wide range of techniques for recording eye fixations that one can almost always trade off such desiderata as accuracy, ease of use, and unobtrusiveness.

28. A major advantage of information boards is that they are very easy to use. Large numbers of subjects can be conveniently run without special selection or training (see Jacoby and Chestnut, 1977).

29. In special situations, recording the output of a process can become complicated. In general, however, the

input-output method is very easy to use.

30. Verbal protocols are considered relatively easy to use, because a verbal report is such an easily accessible response. This impression is too optimistic for two reasons. As many a well-intentioned experimenter has found out, analyzing the protocols can prove problematical. A formal analysis is effortful and probably restricted to highly structured tasks (see Newell and Simon, 1972). And even "formal" analyses require enough subjective interpretations, that marked disagreement among data analysts is possible (Haines, 1974). A second problem is that many subjects, especially those with less education, do not generate an acceptable protocol when requested. The classic protocol studies of Newell and Simon use graduate students as subjects. This writer's experience is that typical shoppers provide sparse, self-conscious protocols. A training procedure is required before representative consumers can generate verbal protocols that are informative.

Equipment Price

31. For the accurate control of stimulus exposure and recording of response duration, relatively expensive tachistoscopes are normally used. Alternatively, a laboratory computer can control shutters or a CRT display. Less expensive recording devices can trade off cost for accuracy. Even a simple stopwatch can be very effective.

32. Basically, eye fixation equipment is expensive. Furthermore, it often requires other equipment, like a laboratory computer, or special facilities, like light-sealed rooms with electrical shielding. On the other hand, the eager but impoverished researcher can use simple video recording or can construct his own device for only a few hundred dollars (e.g., Russo and Mathews, 1975). It is hoped that the example discussed earlier (Russo, 1977a) will expose how low the financial barrier to recording eye fixations can be.

33. Information boards are inexpensive, durable, and easy to maintain. This can be especially advantageous to the researcher who wants to trace information acquisition behavior without making the commitment required by eye fixation technology.

34. The equipment needed to display stimuli and to record output varies with the nature of the task. Usually, however, the cost is minimal.

35. To collect verbal protocols, a good microphone and an adequate audio recorder are needed, with a transcriber for typing. Although this equipment can cost several hundred dollars, it may already be available to most consumer researchers or can be rented for a small fee.

Joint Methodologies

A catalogue of the strengths and weaknesses of individual methodologies leads to the consideration of the concurrent use of two or more methodologies. There are two modes of joint use: parallel and interactive. Methods are used in parallel when two sets of observations are recorded and neither set of data is changed from the situations where it alone is observed. In the interactive situation, the observations themselves are determined by a joint methodology. They differ from the data generated by either single method. Both cases are considered below.

Parallel Joint Methodologies

Parallel joint methodologies are a natural way to minimize the shortcomings of one method. For instance, where eye fixations have only a fair rating on informativeness, verbal protocols are excellent. In the con-

tunity for patterns of responses to occur and to repeat themselves. Because of a preference for recall over re-acquisition, stimulus components are seldom viewed more than once. This further inhibits the development of characteristic patterns of responding.

9. The informativeness of the output of a process is usually very good. A shopper's chosen brand, the rated importance of an information source, or the amount of product knowledge that can be recalled are all informative and easily interpretable responses. Of course, a single output response cannot inform the entire process; but a suitable pattern can.

10. Verbal protocols provide more information per datum than any of the other methods. Indeed, their preeminent advantage is that they usually provide their own interpretation. That is, at the same time that verbal protocols trace the process, they also explain it. This self-interpretability is unique. Self-interpretability is particularly advantageous when the research is exploratory, i.e., when there is no well-founded theory to guide the investigation of the process of interest.

Validity of the Recorded Observations

11. Chronometric analysis is susceptible to two threats to validity, a trading-off of accuracy for speed and a heightened level of motivation. In order to assure uniformity across all trials, subjects are typically given explicit instructions about speed and accuracy. This means that they are made aware that their performance is being timed. Such awareness may cause faster or more consistent performance than might be the case if subjects could be observed unobtrusively.

12. The validity of eye fixations is excellent. Since people are typically unaware of these movements, they are difficult to alter or censor. Because of the apparatus usually employed to measure eye fixations, reactivity is a potential problem. However, the evidence suggests that subjects soon forget that their eye fixations are being recorded, i.e., that eye fixation recording does not alter the ongoing cognitive process (e.g., Gilbert and Gilbert, 1942). If reactivity is still worrisome, there are methods for unobtrusively recording eye fixations (e.g., Van Raaij, 1976a; Russo, 1977a).

13. The validity of the information board methodology is problematical and unknown. On the face of it, one would expect it to be very good. However, total reliance on reaching response is unrealistic and this may alter at least some aspects of the cognitive process (e.g., the rate of repeated acquisition). It is also worrisome that the stimulus environment is so different from natural shopping settings. Clearly, what is needed is a validity check on the method. Ideally, the information board results should be compared with information acquisition in natural shopping settings.

Van Raaij (1977) reports results that approximate this ideal comparison. The same shoppers chose in the same product category using both naturalistic packages and an information display board for the identical package information. Van Raaij reports marked differences in the observed behavior, including the total amount of information acquired and the reacquisition rate. The number of brands considered averaged 10.4 of 13 when packages could be picked up and examined, but only 6.6 of 13 when subjects had to use an information display board. These differences suggest that subjects' behavior in the information board situation may differ in important ways from that in a natural shopping setting.

14. The validity of the process output is good. This method does not receive a higher rating because it is usually possible for the subjects to alter their output

(and the strategies that generate them). Social desirability or just reactivity to the experimental situation can change the process. Of course, if the output is recorded unobtrusively, the validity of the method is excellent. The problem is that a complex experimental design is almost essential if input-output analysis is to expose a cognitive strategy. Such structured designs are difficult to conceal from subjects.

15. Recall the test: "Can subjects successfully conceal any or all of their strategy from the experimenter who relies on Method X?" Applying this test to verbal protocols results in no better than a "good" rating for validity. Of course, the problem is worse if the protocols are retrospective (Nisbett and Wilson, 1977). In this case, a "fair" rating is in order; and experimenters should try to construct a validity check. Even with concurrent protocols, however, there is an irresistible tendency for subjects to "clean up their act," i.e., to describe a more coherent or thorough strategy than normally occurs. In addition, subjects are not aware of many details, such as quick checks, sidetracks, brief interruptions, etc. These behaviors are not included in the verbal protocol, further creating an overly positive picture of the cognitive process.

Range of Experimental Settings

16. Because of the need for specific speed-accuracy instructions and for accurate measuring equipment (reaction time clocks, tachistoscopes, etc.), chronometric methods tend to be restricted to laboratory situations. Response times can be recorded in the field, although simpler, less accurate apparatus must be used.

17. Eye fixations are the least transportable of all the methodologies. Only if video recording is used (which requires a lengthy hand analysis) can they be used in the field. Eye fixations have been recorded from shoppers in a simulated supermarket setting (Russo, 1977a). However, this writer knows of no recordings of actual supermarket behavior. (This could be accomplished with one or more small concealed video cameras with wide angle lenses, but considerable effort would be required to analyze the data.)

A portable eye fixation recording apparatus has been developed and used extensively by Mackworth (see Thomas, 1968). Subjects wear a helmet that carries both the eye position sensor and a video camera. The camera records the scene in front of the subject (i.e., the camera "sees" what the subject sees). The apparatus then superimposes on the video recording a bright spot that indicates the point of regard within the visual scene. This apparatus is not only transportable, but permits the use of dynamic stimulus displays, such as moving scenes, TV advertisements, etc.

Overall, the range of settings where eye fixations can be recorded is almost unlimited. The relatively low rating for this methodology reflects the difficulty of attaining this flexibility. This difficulty translates into a greater cost of equipment or the increased difficulty of data analysis.

18. Information display boards are easily transportable. Jacoby has used them in a specially designed trailer parked in a shopping center for easy recruitment of consumer subjects (Jacoby and Chestnut, 1977). This method will always be somewhat laboratory-bound, however, because it requires a special stimulus display. This is the only method that does not permit naturalistic product displays.

19. From the viewpoint of its technology (apparatus, etc.), this is the simplest method. It is very easy to transport to field situations.

sumer choice study reported earlier (Russo, 1977a) it was not clear that the eye fixations would be easily interpretable, so a concurrent verbal protocol was collected. These data were used to partition the process into stages (overview, comparison, and checking). In addition, they provided insight into the specific product attributes that subjects considered (e.g., price, size, ingredients, packaging, etc.). It was not possible to identify the relevant attribute(s) from the eye fixations on a package.

More complex use of several methods is entirely feasible. Russo and Doshier (1976) explore the binary choice process by using eye fixations, verbal protocols, input-output analysis, and response times. Payne and Braunstein (1977) use verbal protocols, response times, and a computer-controlled information acquisition procedure that resembles information display boards. For a further discussion of parallel joint methodologies, see Payne, Braunstein, and Carroll (1977).

Interactive Joint Methodologies

An interactive joint methodology is as much the creation of a new method as it is the joint use of two standard ones. For example, Reder (1973), Rayner (1975), and Just and Carpenter (1976b) have all developed systems for changing a visual display contingent on where a subject is looking. This is an interactive joint use of input-output analysis and eye fixations. Another example is prompted protocols (Russo and Rosen, 1975; Russo, 1977b). A retrospective verbal protocol is prompted by a replay of the sequence of eye fixations. The verbal protocol can be prompted by other behavior, including the sequence of acquisitions from an information display board (Arch, Bettman, and Kakkar, 1978). Prompted protocols are an example of the interactive, joint use of eye fixations (or information display boards) and verbal protocols.

The possibilities for interactive joint methodologies are almost limitless. This is an exciting research area, both for solving current data acquisition problems and also for generating new forms of data that will yield insight never before possible.

Summary and Conclusions

The eye fixation methodology has important advantages not found in other methods. These process tracing data offer excellent detail and validity. The drawbacks to this method are primarily practical considerations like cost, transportability, and ease of use. Although these drawbacks cannot be ignored, there are trade-offs that can permit the recording of eye fixations at low cost or in natural settings or unobtrusively. The main advantage of this method, however, is the high quality of the data, which is, after all, the best reason for using any research method.

Verbal protocols are remarkably complementary with eye fixations. An examination of Table 2 reveals that no method is more different from eye fixations than verbal protocols. This suggests that the disadvantages of one can be compensated by the strengths of the other. Prompted protocols are one illustration of this. They preserve the informativeness of verbal protocols while adding the detail of eye fixations. In general, it is suggested that any researcher using eye fixations would benefit from the simultaneous use of verbal protocols. These methods naturally complement each other.

This review has been less sanguine about the use of information display boards. In several respects they generate data of low quality that seem to differ from that found in natural situations. The problem is the high effort associated with a reaching response. If this effort could be reduced, methods very similar to infor-

mation display boards could provide adequate data quality at low cost. A computer-controlled information display is one way in which this might be accomplished (Payne and Braunstein, 1977).

The main conclusion of this comparison of methods is that no one method dominates. Each one has its own set of advantages. The choice of a method depends on the specific experimental situation. Generally, the use of joint methodologies can make up for the deficiencies in one method. If this paper yields one firm recommendation, it is that researchers make greater use of the opportunities and advantages of joint methodologies.

VERBAL PROTOCOLS AND DIRECT OBSERVATION
OF SUPERMARKET SHOPPING BEHAVIOR: SOME
FINDINGS AND A DISCUSSION OF METHODS

John W. Payne, Duke University
E.K. Easton Ragsdale, University of Chicago

Abstract

A prime characteristic of the information processing approach to the study of behavior is the use of methods that are capable of providing detailed observations of the course of behavior over time (Simon, 1976). Examples of such process tracing techniques are: the collection of verbal protocols, monitoring information acquisition, and response time recording. The purpose of this paper is to discuss some of the benefits and some of the problems associated with the use of one process tracing technique--verbal protocols, to investigate consumer decision behavior. In particular, the use of verbal protocols to study consumer decision making in supermarkets will be illustrated.

Verbal Protocols

The collection of verbal protocols is conceptually a straightforward method of obtaining process data. The subject is simply asked to give continuous verbal reports, "to think aloud," while performing the task of interest. The verbal protocol is then treated as a "record of the subject's ongoing behavior, and an utterance at time t is taken to indicate knowledge or operation at time t " (Newell & Simon, 1972).

Distinguishing Protocols from Other Verbal Data

The collection of verbal reports is an old idea in psychology. It is also an idea which has generated considerable controversy. Because there is an apparent parallel between verbal protocols and other types of verbal data, I want to stress a few of the distinctive features of the process tracing technique of verbal protocols. First, unlike the earliest introspective techniques, subjects under the process tracing strategy are naive about the theoretical constructs of interest to the researcher. Second, in collecting verbal protocol data the subject is not asked to theorize about his behavior. Instead the subject is asked "only to report the information and intentions that are within his current sphere of conscious awareness" (Newell & Simon, 1972). The researcher, not the subject, does all the theorizing about the cause and consequences of the subject's knowledge state. Third, unlike the traditional way in which verbal reports have been collected--after the response, verbal protocols are collected during the actual performance of the task. While answers to the questions, "What are you doing right now?" may be misleading, they are likely to be considerably less misleading than later descriptions of how the task was performed. Later descriptions allow much more opportunity for the subject to mix current knowledge with past knowledge, making reliable references from verbal reports difficult.

This last distinction is crucial, for the controversy of what subjects can verbally report has reemerged many times. Nisbett and Wilson (1977) recently argued that people have little or no ability to directly observe and verbally report upon higher order mental operations that result in a response of some kind. While the research they review is impressive in supporting their argument, the fact that the evidence is derived entirely

from verbal reports collected after the response limits its relevance for evaluating the process tracing technique of verbal protocols. On the other hand, the evidence from years of research on human problem solving behavior does indicate that verbal protocol data can serve as a valuable basis for model building. Obviously, more research is needed to determine the levels and amounts of information about cognitive processes that can be provided by verbal protocols collected in various task environments.

Using Protocol Data

Once the verbal protocols have been collected, they can be used in a variety of methods. For example, verbal protocols may be a particularly valuable source of data during the early phases of an investigation of consumer behavior. The data can be used to search for regularities in behavior. In addition, a preliminary coding of the protocols may serve as the basis for the calculation of descriptive statistics relevant to theoretical issues. Svenson (Note 1), for example, had six subjects make hypothetical decisions to buy one of seven houses presented in great detail in booklets, one for each house. This study took place in a controlled laboratory environment. Information was obtained on the attributes being used to judge the houses. Information was also obtained on the evaluation of a particular house on a particular attribute in terms of a comparison with a criterion or in terms of a comparison with another alternative. Finally, Svenson was able to track possible changes in decision rules over time. The study of supermarket shopping behavior to be presented later represents an example of the use of verbal protocols to do exploratory consumer research in field settings.

Another very valuable use of verbal protocols is to confirm and extend the interpretations of data collected by other methods. In particular, verbal protocols have already been used successfully to support the interpretation of process data collected by the monitoring of information acquisition behavior (Payne, 1976). In addition, Russo and Doshier (Note 2) have used a "prompted protocols" for the same purpose. Prompted protocols are verbal reports given by the subject after the decision has been made but prompted by presenting the subject with a record of his behavior during the task.

Verbal protocols can also be used to test specific hypotheses about behavior in experimental settings. An example of this use of verbal protocols is provided by Montgomery (1976). He was interested in replicating Tversky's (1969) study on intransitive preference patterns. However, unlike Tversky's procedure, the subjects in Montgomery's study were asked to "think aloud" while making their choices. Statements were coded with the focus on explicit dimensional comparisons such as "fairly small differences" or "they do not differ so much." The coded protocols were used to test theoretical predictions concerning whether a lexicographic choice rule or an addition of utility differences procedure was employed by the subjects. Finally,

verbal protocols have been used by a number of researchers as a basis for computer models of consumer behavior (e.g. Bettman, 1970; Haines, 1974; Payne, 1976). A good discussion of the prospects and problems of such models may be found in Bettman (1974). A more extensive discussion of verbal protocols and other process tracing methods is provided in Payne, Braunstein, and Carroll (Note 3).

The next section of the paper will illustrate the use of verbal protocols, and other more traditional marketing tools (questionnaires, consumer purchase diaries), to study the behavior of consumers shopping in supermarkets.

Supermarket Shopping Behavior¹

Method

The subjects were a convenience sample of 19 housewives with children in the five to twelve year old age bracket. The subjects all lived in Chicago area suburbs. The firm sponsoring the study, a candy manufacturer, set the condition that the housewives have school-age children; previous marketing research indicated that consumers meeting this requirement were most likely to be heavy purchasers of candy. Shoppers were recruited by offering a \$30 payment to each individual who completed all the study requirements. Each shopper also received a small gift part way through the study.

Each shopper supplied verbal protocols during six "major" weekly shopping trips to the supermarket. The shoppers were accompanied by female graduate students acting as observers. At the beginning of each trip, the observers read a standard set of instructions to the subjects:

"We want you to think aloud while shopping. Say what you are doing and where you are going in the store. Whenever you see something as you are walking through the store, mention it. Talk about the products and brands that you are buying as well as those you notice but do not buy. For instance, say what observations you are making about brands, their location in the store, package size, price, ingredients, flavors, and so on. Remember, say anything that comes to your mind no matter how unimportant it seems to you."

When necessary, the observers also made use of a set of standardized prompts to remind the subjects to continuously think aloud:

1. "Remember, say anything that comes to your mind, no matter how unimportant it seems to you."
2. "Say what you are doing now."
3. "Remember talk about whatever you see."
4. "Talk about what observations you are making."
5. "Mention anything that you are thinking about."
6. "Be sure to say what you are doing now."

Great care was taken to minimize the amount of prompting and the amount of interaction between observer and subject.

Finally, in order to familiarize the subjects with the procedure of thinking aloud, they were asked to give verbal protocols while examining a small booklet containing full page magazine advertisements. This task

was completed at the subject's home prior to the first shopping trip.

A great deal of information was acquired in addition to the verbal protocol data. Demographic and shopping behavior data were obtained from a small questionnaire completed by the subjects when they were recruited. Consumer purchase diaries were maintained during the six-week period of in-store observation and during a two-week period either immediately preceding or following the observation period. While in the store, the observers recorded the following information about the shopper's behavior: (1) the path taken through the store; (2) any items taken from major point-of-purchase displays (free standing or end-of aisle displays); (3) the use of a shopping list (all shopping lists were collected by the observers); (4) the use of coupons; and (5) the shopper's nonverbal behavior when passing the candy department.

The methods used in our study extend the previous efforts to study shopping behavior using protocols along several dimensions (e.g., Bettman, 1970; King, 1969; Haines, 1974). For example, Bettman (1970), in perhaps the best known protocol study in marketing, used protocols obtained from only two shoppers. The protocols were used to develop a model of each subject in the form of a decision net or tree. Our study utilized a much larger sample of shoppers. In addition, protocols were obtained over a large number of shopping trips. Also, unlike the Bettman study, the subjects in the present study were not known personally by the researchers, and interactions were kept to a minimum during the shopping trip, e.g., use of only a structured set of prompts. We also did not attempt to build an idiosyncratic model of each subject. Finally, our use of a variety of data collection methods enabled us to cross validate our results. We strongly believe that a multi-method approach is essential to the study of consumer behavior processes.

Results

The final four verbal protocols for each shopper were treated as the basic data base. The first two shopping trips were considered to be practice trials.

The first step in the protocol analysis was to make a complete transcript of the verbal reports given by each shopper. The next step was to break the protocols up into single statements or phrases. According to Newell and Simon (1972), each phrase should correspond to a naive assessment of what constitutes a single task assertion or reference by the subject. Breaking up protocols in this way serves to clarify the sequential nature of the observations and to create units of analysis. As an example of this procedure, excerpts from one protocol are presented below. Complete transcripts can be obtained from the second author.

- D1: OK, alongside the window, we have Heritage House mayonnaise.
D2: and it is on sale this week.
D3: and it is only 79 cents;
D4: and I'm going to take one quart.
D5: Now I am going to buy tuna fish,
D6: that is Starkist tuna fish;
D7: and it is 49 cents a can;
D8: I am going to buy six cans;
D9: OK, 2, 4, 6 Starkist tuna fish, OK.
D10: Along the window they have the specials
D11: Welch grape juice
D12: Oh, they have the great big bottles.
D13: \$1.09.
D14: I did not know that they had the big ones.
. . .

¹The research reported in this section of the paper was conducted by Robert Blattberg, Harry Davis, and the two authors, at the University of Chicago.

D152: Now, there is the apple juice
 D153: They like that
 D154: Hawaiian Punch
 D155: it is \$2.47
 D156: usually they have the orange juice over here
 D157: tea bags
 D158: They have their own brand
 D159: \$1.39
 D160: I bought National tea bags
 D161: and they were pretty good
 D162: I kind of like them
 D163: so I am not about to switch
 .
 .
 D429: Let us look at some of this zucchini squash,
 D430: and then that is it.
 D431: That is not too bad.
 D432: Check over and see what we have on the list,
 D433: and see if they have red cabbage.
 D434: That is it on the list.
 D435: OK, that is about it for today.

Once the protocol has been broken up into small phrases, a major issue in protocol analysis is whether the verbalizations should be further encoded into formal categories. Newell and Simon (1972) argue that encoding the verbalizations can result in a substantial loss of information since language is already a device for encoding information. Consequently, they emphasize dealing with a protocol in the form of small phrases. Although treating protocols at this level of analysis can prove valuable in consumer research (e.g., Payne, 1976), a detailed and formal analysis of verbal data will probably require some form of encoding the verbalizations.

In the present study, each phrase in a protocol was coded in terms of a product category code and a process code.² There were 41 separate product category codes, generated from lists of product categories found in the supermarket trade journal *Progressive Grocer*. Because not all statements referred to a particular product category, three additional codes were used to reflect shopper movement statements, general comments about supermarkets, and miscellaneous statements.

The statements were also assigned one of 20 process codes grouped under five general headings: (1) statements of goals, needs, or strategies, e.g., "Do I need some butter"; (2) statements of simple awareness, such as item identification or item location, e.g., "There's the 2% milk"; (3) statements concerning information processing within product categories (levels of product attributes, absolute evaluations of product attributes or products, comparison of products), e.g., "This is 3 for \$99." "This is too sweet." Coke tastes better than Pepsi."; (4) product choice decisions, e.g., "OK, I'll buy the M&M's with peanuts."; and (5) miscellaneous statements.

The coding scheme used was based on two considerations. First, any coding strategy must reflect the nature of the task environment. In our case, coding the statements in terms of product categories emphasizes the organizing principles of all supermarket environments. Second, a scheme for coding must also reflect the theoretical interests and concerns of the researchers.

²The results to be presented are based on a partial analysis of our data base-35 protocols reflecting the behavior of 10 shoppers. The protocol analyses are based on approximately 20,000 coded statements.

For example, two important issues affecting the coding of statements were the amount of absolute evaluation versus comparative judgment and the amount of evaluation involving self and involving others. Absolute evaluations against internal or external standards and direct comparison of alternatives on their respective attributes has been identified as a crucial distinction in decision theory (Pitz, 1975; Payne and Braunstein, Note 4). The potential importance of viewing the shopper as a family purchasing agent has been stressed by Davis (1976). Consequently, our coding scheme distinguished between statement referring to the shopper's belief and those referring to the beliefs of others. Other aspects of the coding scheme, including the emphasis on shopper strategies, were derived from similar considerations. The amount of attention given to different product categories was measured by the number of times an attribute was mentioned with reference to the product category. Across all shoppers, the product categories with the largest number of references included: fresh meat, fresh fruits and vegetables, dairy products, paper products, canned fruits and vegetables, cookies and snacks. The categories with the fewest mentions included canned meats, pet foods and supplies, specialty foods, and candy, gum, and nuts. A ranking of product categories by the number of attribute references proved to be similar to the ranking of product categories by the percentage of shoppers purchasing in each category (see *Progressive Grocer*, January, 1964; October, 1975).

Table 1 presents a breakdown of the product attributes mentioned by the shoppers. Notice that the most frequently mentioned product attribute was price. This was true for all shoppers and for all but three product categories (specialty foods, breakfast cereals, and desserts). This result supports earlier studies that indicate price sensitivity among shoppers (e.g., Russo, Krieser, and Miyashita, 1975). However, the result conflicts with studies that have found shoppers to be poor estimators of product prices (see *Progressive Grocer*, 1974). One possible explanation is that shoppers do not store all price information in memory (where it can be retrieved when asked for prices in an interview before or after shopping). Instead, shoppers make use of the store environment (with prices displayed on every package) as form of external memory.

TABLE 1
 PRODUCT ATTRIBUTES MENTIONED DURING GROCERY SHOPPING

Product Attributes	Percentage of Mentions
Price (specific mention of price, item on sale, special, coupon)	45.7%
Size, Quantity	16.1
Form, Type	7.5
Brand	5.9
Ingredients	4.7
Taste, Flavor	4.7
Freshness, Appearance	3.2
Color	2.5
Package	2.0
Other	7.7
Number of Mentions of Product Attributes ¹	4,160

1. This analysis is based upon mentions of product attribute levels only; absolute evaluations and comparisons of product attributes were excluded.

This explanation is only speculative, but it does point up one of the possible advantages of in-store protocols as opposed to shopper interviews.

Table 2 presents a summary of the types of process statements. The results appeared to be reasonably stable across individual shoppers. Measured in terms of amount of verbal activity, shoppers made relatively little effort comparing brands within product categories while shopping (2.1% of all statements). One possible interpretation of this result is that while in the store, shoppers may decide whether or not to purchase in a particular product category (e.g., to buy rice for dinner), but once the decision is made, the brand choice is more or less routine. A related interpretation is that a substantial amount of shopper behavior in super-markets may involve processing at the product choice level in a shopper's goal hierarchy, and only a limited amount of processing may occur at the brand choice level.

The protocols also provided evidence supporting the concept that housewives seem to act as purchasing agents for their families. For example, Table 3 present excerpts from the protocols relating candy buying to other family members.

Additional information on shopper behavior was obtained through direct observation and purchase diaries. Table 4, for instance, presents the relationships between the use of a shopping list and the number of items and amount purchased. The data presented in Table 4 are based on the entire sample of 19 shoppers. Notice that when lists were used, only approximately 41% of the items purchased were found on the list. The percent of items on the list to total items bought per trip ranged

TABLE 3

EXAMPLES OF SHOPPER COMMENTS RELATING CANDY BUYING TO OTHER FAMILY MEMBERS

"It's very difficult to buy candy at this time of year that satisfies my husband's sugar tooth, because he likes chocolates and they damage and then he cannot hold them. They melt. He loves M&M's."

"Everybody likes these caramel creams. And what does my husband like? He eats one candy bar--Butterfingers. These are awful."

"I do not think my husband will chew the sugarless stuff. He likes Juicy Fruit which I cannot stand; but I will buy it for him."

"Barnum's Animals, Chuckles, Jujubees. This is my husband's favorite kind of candy; it pulls fillings out of teeth, but it's really good while going down--you know, jelly. I think I'll buy him some animals. He'll be trilled by that, I know."

(Mother shopping with child)
 Mother: "Do you like the peanuts?"
 Child: "I like the plain."
 Mother: "The plain ones. All right, we will get the plain M&M's."

1. Trips with incomplete data were excluded from these analyses.
2. All shoppers were included in this analysis.
3. Shoppers who purchased only with or without lists were excluded from this analysis.

from 22% to 76% across shoppers.

The extent of buying from end-of-aisle and free standing displays was also determined by combining data from direct observation and the record of purchases. It was found, for example, that taking all shoppers together, 14% of all purchases were from displays. Looking at individual shoppers, the proportion of items purchased from displays ranged from 1% to 25%. However, these results should be interpreted with caution. The results may reflect differences among shoppers in terms of strategies, or could be due to differences among the stores' use of point-of-purchase materials.

Summary

The results presented here illustrate how verbal protocols, in conjunction with other, more traditional marketing research tools, provided information about consumer decision behavior at a level of detail difficult to achieve otherwise. Data was obtained on the goals and attributes used by supermarket shoppers, e.g., price awareness; the choice processes used by shoppers, e.g.,

amount of brand comparison; and the effect of in-store and social influences on shopping behavior. The collection of such data, along with other forms of high density, sequential data seems essential if we are going to develop and test complex and dynamic models of consumer behavior.

With regard to other process tracing techniques, there are differences of opinion as to whether such methods as eye movement recording or explicit information search procedures, should be preferred over verbal protocols as a method of collecting process data. Russo and Rosen (1975) argue that eye-movement records are better because "They are unobtrusive, detailed, and difficult to misrepresent." These claims may be true, although it is not clear how unobtrusive eye-movement recording has been given the apparatus used. Simon (1976), on the other hand, has argued that "verbal protocols provide a rich source of data at densities comparable to the densities of eye-movement records, and containing far more information per data than the latter" (p.261).

Jacoby (1976) has argued even more strongly for the use

of information search techniques as opposed to verbal protocol procedures. He apparently feels that information search data are "behavioral" whereas verbal protocol data are not to be trusted. Jacoby does not seem to make any distinction between verbal protocols and other types of verbal data, such as responses to post-decision questionnaires and interviews. However, as was noted earlier, there are important distinctions between verbal protocol data and post-decision verbal reports. These distinctions make verbal protocols a much more valid source of process information.

One problem with the information acquisition methods is that they focus exclusively on the subject's use of objective, external information. The method does not easily allow for insights into an individual's use of information stored in internal memory. This problem relates to Simon's (1976) statement that verbal protocols provide more information about cognitive processes than eye-movement records.

Another problem is that information acquisition methods provide little or no indication of when and if the information being acquired is actually being processed. Payne and Braunstein (Note 4), for example, found one subject who (according to a monitoring of the subject's acquisition of information) appeared to be consistently searching all available information in an interdimensional fashion. The search appeared to be independent of all number of alternative gambles presented. Such a pattern of information use suggested that some form of an additive decision rule was being employed by the subject (see Payne, 1976). However, examination of the protocol showed that some of the acquired information was ignored by the subject and that the amount of information (number of attributes or dimensions) considered per alternative varied across alternatives; this pattern suggested a conjunctive type of model. Excerpts from the protocol made it clear that the subject had adopted the practice of obtaining all the available information before proceeding with the decision process. The ability of verbal protocols to detect such activity represents one of the greatest advantages of protocol over eye-movement and explicit information acquisition procedures.

Finally, information acquisition studies usually require the decision task to be more structured. This may present problems as consumer researchers attempt to do more "real-world" research.

Obviously, the preferred research strategy would be to employ more than one process tracing technique. Examples of such a multimethod approach to research can be found in Payne and Braunstein (Note 4) and Russo and Doshier (Note 2). Where a multimethod approach is impossible, the researcher will have to choose among process tracing methods on the basis of theoretical concerns, the availability of apparatus, and the relative difficulty in analyzing data collected by each method. The researcher faced with this choice can find encouragement in the results of efforts to compare methods. Newell and Simon (1972), for example, present evidence of a high degree of convergence in the interpretations about problem solving based on eye-movement data and on verbal protocols.

Finally, while we have argued the values of verbal protocols, it is clear that there are definite costs associated with the use of such a process tracing method. Protocols for example, provide researchers with a large amount of detailed data, which at present cannot be simply run through a computer program for analysis. While procedures for examining protocol data are currently being developed, it is clear that an investigator choosing to do a protocol study will probably have to settle for an intensive investigation of a

relatively small number of subjects. However, as illustrated by the efforts to investigate contingent processing in decision making (Payne, 1976; Payne & Braunstein, Note 4), it does appear that process tracing techniques can lead to generalities about behavior, in spite of the limited number of subjects run in any particular experiment.

Another problem with using verbal protocols is that standard summary statistics for such data are not well developed. Consequently, a researcher using such methods is often forced to present the results of his study in great detail, e.g., parts of the protocols themselves. Haines (1974), in fact, advocates such a procedure. Finally, it is obvious that verbal protocols represent an obtrusive measure of behavior. We have examined the obtrusiveness of the verbal protocol procedure as part of two studies of decision making (Carroll & Payne, 1977; Payne & Braunstein, Note 4). Our results seem to indicate that the verbal protocol procedure may slow down the decision process slightly but does not change it fundamentally. A similar effect for verbal protocols has been suggested by other researchers (e.g., Dansereau and Gregg, 1966; Newell and Simon, 1972). However, much more research is needed to examine directly the effects of various process tracing data collection methods on the behavior exhibited by subjects.

In summary then, verbal protocols are a valuable source of data for consumer research. However, it does not appear that by themselves they will "Save The World."

THE USE OF THE ACTIVE PROFILE EVALUATION PARADIGM IN
STUDYING CONSUMER JUDGMENT PROCESSES

Peter Wright, Stanford University
Peter Rip (student), Stanford University

A number of methods have recently been developed in the study of consumer information processing. In this paper we review how the Active Profile Evaluation paradigm has been used as one method of inquiry. We will also attempt to outline alternative applications of the paradigm in the study of consumers' judgment processes.

The paradigm requires the decision maker (DM) to rate or rank order several real or hypothetical alternatives. The profiles are generally composed of few (2-6) cues, with product dimensions generally referring to tangible characteristics. The analysis then proceeds to relate variations in a consumer's preferences to variations in the product characteristics. A variety of estimation procedures are available; all yielding an index of goodness-or poorness-of-fit and estimates of the relative value the DM assigned to the various attribute levels. Within this paradigm, researchers have asked a number of questions. The most popular issue has been the comparison of relative fits of various mathematical representations of evaluative strategies. The criteria of fit have generally been the multiple correlation coefficients, stress values, and cross-validation coefficients. Since this is an individual-level method of analysis, one generally examines these statistics using cross-sectional designs. One such approach would be to ask whether systematic individual differences, situational, or psychological factors (e.g. risk, distraction) lead to better fits for certain non-linear integration processes. Examples of this type of analysis are papers by Einhorn (1971) and Wright (1974; Scott and Wright, 1976).

The general linear model (OLS, ANOVA) has been the predominant technology associated with this paradigm (Slovic and Lichtenstein, 1971). Recent studies in marketing have also used non-metric estimation methods (e.g. linear programming [Parker and Srinivasan, 1976; Pekelman and Sen, 1974] and conjoint measurement [Green and Wind, 1973]). One consequence of these technologies has been the remarkable robustness of linear additive models of judgment, naive theories notwithstanding. Much of the early research focused upon the detection of non-linearities in judgment processes (Einhorn, 1971; Slovic, 1969; Slovic, Fleissner, and Bauman, 1971). The apparent robustness of the arithmetically simple, but cognitively complex, linear additive models now seems to be more an artifact of the model, rather than any real congruence with mental processes (Birnbaum, 1973; Einhorn and Hogarth, 1974; Wainer, 1975).

The search for appropriate statistical representations of choice processes naturally invites comparisons of alternative models of the same behavior. A number of formal approximations of alternative choice strategies have been developed (e.g. Einhorn [1971]). Typically, the approach has been to estimate the parameters of a variety of different models and select the one with the lowest mean squared error or stress as the best representation. This criterion of selection has been severely criticized (Birnbaum, 1973) because it artificially favors certain model forms.

Aside from the mere inspection of multiple correlations or cross validation coefficients of alternative models, two related validation methodologies have developed in the search for the "appropriate" paramorphic representation (Hoffman, 1960). Neither approach has been applied

extensively in the consumer behavior literature, for reasons which will be discussed later. One method is based upon the axiomatic analysis of choice rules (Krantz and Tversky, 1971; Luce and Tukey, 1964). This method reduces a choice rule to a set of unique axioms, which can then be tested by inspection of the data. The analysis is diagnostic, rather than statistical, searching for alternative models which best account for the empirical results. The principal limitation of this method of assessment is the lack of an error theory (Krantz and Tversky, 1971) which allows us to distinguish minor perturbations in the data from systematic deviations. An alternative, but related, method of validation is Anderson's (1974) functional measurement technology. The details of the method are available from a variety of sources (Anderson, 1974; Slovic and Lichtenstein, 1971). The method, essentially, achieves a monotonic rescaling of the dependent variable such that the postulated model can usually be tested in an ANOVA framework. Although Anderson and colleagues have applied the technology across a number of tasks, there have been few applications of functional measurement in the consumer behavior literature. Exceptions are the work of Bettman, Capon, and Lutz (1974; 1975) and Troutman and Shanteau (1976).

Aside from the question of model comparisons, the weight and utility estimates derived from the procedure can be used as indirect measures of those factors which drive behavior. In a more familiar sense, we can either ask consumers for their attitudes directly or supplement their self-reports with indirect or derived estimates of their attitudes. These indirect methods of assessment may often be more reliable than more obtrusive techniques. Application of the active profile evaluation paradigm in these situations has been less common, but is potentially more powerful. Explicitly, if one's research pertains to certain aspects of consumers' product evaluation strategies, the weights and utilities are directly relevant. Using estimated weights or utilities as dependent variables, rather than global fits, it becomes less critical for these weights to be derived from a model which is a "true" description of the process. The research emphasis shifts from absolute fit to one of between- or within-subject differences in weights or utilities. Applied in this way, the active profile evaluation paradigm is simply a measurement technique for tapping cognitive events. Our concern for the reliability and validity of the measures obtained should parallel the concern we show over these issues with respect to other techniques.

One of the most interesting issues concerns a person's self-insight with respect to his or her own judgment processes. Evidence from a variety of sources (Cook and Stewart, 1975; Nisbett and Wilson, 1977; Scott and Wright, 1976; Slovic, Fleissner, and Bauman, 1972) suggests that subjects tend to report their behavior was influenced by more than the small subset actually observed. In cases of disagreements between derived parameters and subjective reports, one looks for systematic patterns in the deviations. The more thorough one's tests of reliability and validity of model-fitting analysis, the more confident one feels in attributing systematic differences to reporting biases. Observed discrepancies between self-reports and derived parameters have inspired further analyses of the source of the

reporting bias and the meaning of "relative importance" to naive judges (Cook and Stewart, 1975; Scott and Wright, 1976).

Until now we have discussed self-insight with respect to relative weights among dimensions. However, we may use estimated utilities within a dimension to assess how well consumers can recall preference orderings along that dimension. Interrogating consumers about relative preferences as just stated, rather than introspective reconstruction of cognitive processes, may prove to be a very fruitful area of research. This allows us to directly examine the extent of various cutoff-types of strategies in consumer choice. For example, we might expect that someone with accurate self-insight about his or her use of absolute cutoffs would demonstrate certain non-linearities within that dimension.

Often the research question may concern the effects of specific treatments upon generic aspects of the product evaluation strategy. Examples would be its complexity or degree of unidimensionality, or the presence of certain risk preferences or aversions. The first question may be addressed by comparing the relative weights that consumers gave to their two most important dimensions (Wright and Weitz, 1977), or the variance across the set of weights. The second question may be addressed by comparing gaps between the utilities of specific levels of a dimension. For example, one recent study found that women showed much larger decreases in utilities as the chance of negative outcomes increased modestly. This effect was particularly strong for those consumers for whom the outcome seemed imminent relative to when it seemed more distant.

A related question of interest to consumer researchers is how DMs account for others' preferences when making their own choices. Clearly, self-insight and awareness of others' utility functions are relevant to this point.

The actor-observer distinction (Jones and Nisbett, 1971; Ross, 1977) could serve as a useful model in studying how we assess others' utilities. The study of how we judge and integrate others' preferences is one area of basic consumer research which may be potentially fruitful.

A question related to the general problem of assessing others' utility functions is the degree to which group judgments reflect preferences of the individual members. One approach to this question is to examine the correspondence between the individual members' utilities and those of the group outcome as derived from a group rating or ranking of hypothetical alternatives. While this method does not offer direct evidence concerning group decision making processes, it does offer a means of examining members' impact in terms of measures of net effect, rather than process-oriented criteria such as the number of influence attempts. Indeed, one of the major advantages of the active evaluation paradigm is its ability to complement process-oriented measures (e.g. protocols, eye movements) with rigorous behavioral measures of outcomes.

A final highly promising application of the active profile evaluation paradigm is in assessing the effects of alternative persuasive messages or other types of information displays upon consumers' evaluation strategies. If alternative messages and information displays impact upon such things as cue weights, relative or absolute attention, cutoff usage, attribute utilities, complexity of choice strategy, and accuracy of interpersonal assessment of utilities, the active evaluation of profiles promises to be one useful way of tracking these effects.

While the active profile evaluation paradigm is quite flexible and a potentially attractive measurement tech-

nique, one limitation seems noteworthy. The active evaluation paradigm requires multiple judgments in order to derive reliable parameter estimates. Often the number of judgments can be reduced by the use of fractional designs. However, ten to thirty judgments may still be necessary for reliable parameterization. Therefore, there may be a strong task effect; biasing subjects toward simpler rules and candidate-wise processing. So the evidence produced may not generalize too well beyond situations in which people make a number of judgments in a limited period of time. A researcher can control the time span over which the succession of judgments is made, thereby replicating a setting in which rapid or highly dispersed judgments are made. Perhaps our ingenuity and flexible use of this task factor will allow us to minimize the potential for bias introduced by this essential task factor.

In conclusion, the versatility of the active profile evaluation paradigm should not be ignored. We continue to recommend that a hypothesis worth testing is worth testing in several ways, and the outputs from this paradigm should be viewed from this perspective. Furthermore, the paradigm provides important confirmatory behavioral evidence in a task which is fully compatible with other consumer choice technologies.

CHRONOMETRIC ANALYSIS: AN INTRODUCTION AND AN APPLICATION TO
LOW INVOLVEMENT PERCEPTION OF ADVERTISEMENTS

Meryl P. Gardner (student), Carnegie-Mellon University
Andrew A. Mitchell, Carnegie-Mellon University
J. Edward Russo, University of Chicago

Abstract

The methodology involved in using response times to examine internal information processing is briefly reviewed and the application of this approach to consumer research is discussed. A study is described that uses response times to examine the differential effects of high and low involvement learning of advertising messages. Low involvement learning is hypothesized to take place under either attention limited or strategy limited conditions. The experiment examined the latter condition where consumers fully attend to the advertisement but not for the purpose of evaluating the advertised good. The results of the experiment confirm several predicted effects of this type of low involvement processing, including the formation of more positive attitudes toward the advertised brand.

Introduction

All consumer decisions rely, to some extent, on information stored in memory. Recent research on consumer decision making, however, has deemphasized the role of memory in consumer decision processes by concentrating attention on external information acquisition. Since acquisition responses, such as reaching or looking, are conveniently observable, they offer a clear methodological advantage. In contrast, retrieval of information from memory is covert.

It seems clear, however, that if we are to understand consumer decision processes the important role of memory and internal processing cannot be excluded from experimental investigation. Currently, a consensus seems to be forming that the time is appropriate for consumer research to direct its attention at the internal processes of information encoding and storage and to their effect on consumer decision making (Bettman, 1978; Chestnut and Jacoby, 1977; Johnson and Russo, 1977; Olson, 1978).

Available Methodologies

The investigation of internal processes is hindered by the lack of associated overt behavior. There are, however, two observations that can always be made on a cognitive process: the output of that process and the time taken to complete it. Both of these measures provide a data base for methodologies that can successfully investigate internal processes. The focal point of this paper is on chronometric analysis or the use of response times to examine internal processes; however, it might be helpful to first discuss methodologies based on output. To use output effectively, the experimental environment has to be designed so that the observed response can discriminate among possible processes. This is called input-output analysis, or, in its most refined form, the axiomatic method (Chase, 1977).

The output of a process can be elaborated by two process tracing techniques. The more common requires subjects to generate a verbal report of their own cognitive processes. Technically, these verbal protocols are the output of a second process, that of self-commentary. Although often very informative, they are difficult to analyze formally and are susceptible to distortion when based on memory

rather than emitted concurrently with the primary task. Furthermore, verbal protocols are almost useless for brief or highly automatized cognitive processes of which subjects are not consciously aware (Nesbitt and Wilson, 1977). Unfortunately, much consumer behavior, such as encoding information from advertisements, may be of this nature.

A second elaboration of simple output analysis is the recording of intermediate responses, such as information acquisition behavior. This is still output analysis, except now the output of subprocesses is analyzed alongside that of the primary process. Recent consumer research has made excellent use of this technique. Through its application we have learned that people often ignore large amounts of product information, they adapt to the presentation mode or format of the information and they are flexible in their selection of decision strategies, seldom using a single, "pure" strategy. This progress has been achieved, however, in laboratory settings characterized by external sources of product information, and, when investigating known alternatives, has failed to take into account previously stored information (Bettman, 1978).

Apart from these two process tracing elaborations, the input-output framework includes a wide variety of specific experimental paradigms for the investigation of memory. Tulving and Bower (1974) provide a list of ten such techniques commonly used in cognitive psychology. These include: feature probing, recall intrusions, retrieval cueing, and clustering in recall. Although we shall now turn out attention to chronometric analysis, the power and diversity of input-output analyses should not be ignored.

Chronometric Analysis

As mentioned previously, the purpose of chronometric analysis is to use response times to examine internal information processes. In this context, response times (RT's) are generally defined as the amount of time between the presentation of a stimulus to an individual and his or her response to that stimulus.

Chronometric analysis has been used extensively by cognitive psychologists to examine a wide range of mental processes. It has been used, for instance, to examine the underlying mental processes involved in verifying that a presented stimulus belongs to a previously memorized set (Chase and Clark, 1972; Clark and Chase, 1972) and the quantification of visual stimuli (Klahr and Williams, 1976).

The fundamental principle of chronometric analysis is that response time measures the amount of processing that has taken place. In order to do this we generally have to assume that the processes are executed in series rather than in parallel. For many applications this principle alone is sufficient. Subjects, for instance, may be asked to respond to the same stimulus under different conditions that imply different response times. The observed RT's are then used to test the theory from which the predictions were derived.

Before we discuss general procedures for using chronometric analysis to examine internal processes, it will be helpful to present a specific example of its use from the cognitive psychological literature. Collins and Quillian (1969) used response times to test Quillian's (1969) model of semantic memory. According to the model, semantic memory can be represented as a hierarchical network with each node representing an object or concept. An example of such a hypothetical semantic network¹ for cola and lemon lime soft drinks is presented in Figure 1. Moving

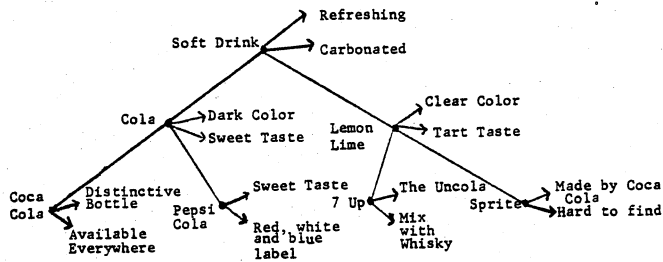

FIGURE 1. HYPOTHETICAL THREE LEVEL HIERARCHY FOR COLA AND LEMON LIME SOFT DRINK

to a higher level in the network signals a superset relation. For example, cola is the superset of Pepsi Cola, and soft drink is the superset of cola.

The power of this conceptualization is both the efficiency of information storage, since information is stored at its highest level of generality and the ability to infer or verify novel facts. For example, an individual does not have to store both "Coca Cola has a dark color" and "Pepsi Cola has a dark color"; this information is stored with the concept cola. Also, the sentence "Pepsi Cola has a dark color" can be verified even though that particular association has never been encountered.

According to the model, the verification process requires a search through the nodes of the semantic network. For instance, verifying "Coca Cola has a stimulating taste" would require activating the links from Coca Cola to cola to soft drink where the property "has a stimulating taste" can be accessed.

To test the model, RT's were recorded as subjects verified statements that involved searching different levels of the hierarchy. In general, the results supported the model.² The more hierarchies that needed to be searched to respond to a question, the longer the response time. (Other models of memory have since been shown to be compatible with the results; see Chase, 1977³). The response times also provided estimates of the time needed to traverse between nodes (about 75 msec) and to retrieve a property at a node (about 225 msec). The former can be measured by subtracting the times to verify sentences

¹In Collins and Quillian's experiment, the structure of semantic memory for animals was examined by using the subsets of birds and fish.

²The data for positive responses fit the model well, however, this was not true for negative responses. It was hypothesized that different strategies may be involved in falsifying sentences.

³For instance, distance in semantic network is confounded with past associative frequency and, therefore, with associative strength.

like "Sprite is lemon lime" from "Sprite is a soft drink" or "Sprite is made by Coca Cola" from "Sprite has a clear color." Each pair of sentences involves the same processing except for an additional level change in the second sentence.

The Subtractive Method

The Collins and Quillian experiment illustrates the use of the subtractive method which was first proposed by Donders (1868). Logically the method is quite simple. If a number of mental processes occur serially, then by eliminating one or more of the processes in a particular experimental condition, one may obtain a measure of the time required for the remaining processes. In the Collins and Quillian experiment, the serial operations are an original retrieval of a concept from memory and then a sequential search through the different hierarchies. The occurrence of this relationship in an actual experiment provides evidence supporting the hypothesized model.

The validity of the subtractive method relies on an assumption that might be called the Principle of Process Deletion. It is assumed that the process of interest can be deleted from some sequence of processes without affecting any of the others. That is, the deleted process does not interact with any other process. (Technically, the durations among processes must not interact.) This assumption is critical to the validity of the subtractive method but, unfortunately, is not always testable.

From the above discussion, it should be clear that the subtractive method requires an adequate theory of the process that is to be examined. In order to construct a task that deletes only the specific process of interest, one should know the sequence of cognitive activities that occurs between stimulus and response. At the least, one must know enough to be certain that the Principle of Process Deletion is applicable, but usually this knowledge is only part of a theory of the complete process.

The Additive Factor Method

The additive factor method, proposed by Sternberg (1969), is an elaboration of the subtractive method. Its principal concern is to provide procedures for developing a conceptual model of the cognitive processes that intervene between stimulus presentation and the subjects' response. Whereas the subtraction method requires a well-developed theory in order to interpret the resulting reaction times, the additive factor method is designed to aid in the development of a theory of the intervening processes.

The basic logic underlying this method is that each reaction time interval contains a series of independent stages. Each stage of the process transforms the information received from the previous stage and outputs it to the next stage. It is assumed that the duration of each stage is independent of the stages that precede it. The implications of this conceptualization are as follows. First, the total reaction time of a particular process is the sum of the stage durations. Second, independent effects on total reaction time will be produced whenever experimental manipulations (independent variables) affect different stages. Finally, if the effects of two experimental manipulations interact in a statistical sense then they must affect the same stage. Thus, in using the additive factor method, a multifactor experiment is applied to a particular information processing task. Each pair of factors that have an additive effect on reaction time affect different stages of the process, and each pair that interact affect the same stage. Consequently, in order to obtain a precise analysis of the stages for definitional purposes, more than a few factors must be manipulated.

To illustrate the additive factor method, we rely on the experiments of Sternberg (1969) which investigated short term character recognition. In these experiments a subject was required to memorize a set of stimuli and then, upon presentation of a stimulus, to respond positively or negatively depending on whether it was contained in the previously memorized set. The factors manipulated in these experiments included: pictorial clarity of the presented stimulus, size of the previously memorized set, whether a positive or negative response was required, and the relative frequency of either a positive or negative response. The results of these experiments indicated that all four factors had a significant effect on reaction time and that all six pairwise interactions were either insignificant or there was a compelling a priori reason for not expecting a statistically significant interaction. Consequently, Sternberg (1969) hypothesized that the task involved four independent stages, each associated with one of the factors tested: encoding, comparison, response choice and response execution. Note that four stages are the most that could be discovered in a four factor design and that there could possibly be more stages to the process that could not be identified in this experiment.

Methodological Problems

As with any technique, chronometric analysis has accompanying methodological problems. The primary problem is the natural trade-off between speed and accuracy. Subjects can usually perform faster if they sacrifice accuracy or more accurately if they sacrifice speed. This relation is captured by the speed-accuracy operating characteristic (Pew, 1969). An idealized version of this function, adapted from Pachella (1974), is shown in Figure 2.

FIGURE 2. IDEALIZED SPEED-ACCURACY OPERATING CHARACTERISTIC AFTER PEW (1969)

According to the definition of reaction time, subjects should be responding at point A. However, they generally operate below this point. Most of the problems associated with the speed-accuracy trade-off can be avoided if subjects perform at the same accuracy level under all experimental conditions. Then the relative values of the observed RT's will reflect the effect of the independent variables and not the effect of a different accuracy strategy. When accuracy fails to remain constant across conditions, there is a danger that incorrect inferences will be drawn from the RT data. (For an example, see Pachella, 1974). A number of procedures have been proposed for adjusting reaction times if different accuracy levels occur in an experiment. A critique of these procedures may be found in Pachella (1974).

The second problem to be discussed concerns the interpretation of response times. Whenever detailed processes are manifested only in behavior as aggregate as response time, the theoretical conclusions must rely heavily on the theoretical input. In spite of the power of the ad-

ditive factors method, it still requires reasonable hypotheses about potential stages of the process in order to design an appropriate multifactor experiment.

Prior to Sternberg's introduction of the additive factors method, the subtractive method had fallen in disfavor. In discussing this particular period, Chase (1977) states, "In retrospect, it appears that the lack of success with the subtractive technique was due primarily to the absence of good cognitive theory." For consumer researchers interested in relatively complex tasks, this means that RT's are not the proverbial free lunch. Even the most sophisticated chronometric analysis can only refine theory, not create it.

Response Time and Consumer Behavior

There are a number of different areas in consumer behavior where the use of reaction times would seem to be useful. One area is the structure of product knowledge (i.e., the organization of memory for product information). A number of questions are of interest here. What is the structure linking brands and attributes within a product class? Is it hierarchical as pictured in Figure 1, or organized in accord with the more recent models of semantic memory (e.g., Anderson and Bower, 1973, or Norman and Rumelhart, 1975)? Does brand name play a central role linking all brand associations, as some researchers have argued? What is the relative efficacy of brand-based versus attribute-based memory organizations? When the structure of product knowledge is identified, will it be invariant across individuals and product categories? These are only some of the more obvious questions that need to be answered about product knowledge, a major understudied area of consumer research.

The use of chronometric analysis to explore the structure of product knowledge has recently been demonstrated by Johnson and Russo (1977). The duration of a cued retrieval task identified the distance in the memory structure between the cue and the target item. This method was used to show that memory structure was largely determined by the input organization of the product information. Interestingly, some reorganization of the structure did occur, and it appeared to favor storage by attribute.

Just as important as the structure of product knowledge is the content of that knowledge. In a study of multiple decision making on a single information set, Green, Mitchell and Staelin (1977) found that subjects do not examine all the available information and more importantly, they are able to retrieve only a small portion of the examined information in memory. Examining what information is stored, in what form and how it enters memory are natural problems for response time techniques.

The importance of the content issue can be demonstrated by noting that either verbal report techniques or self administered scales have traditionally been used in most applied and theoretical research for identifying the contents of semantic memory. Of interest is how much of this reported information is based on stored information and how much on inference. While the retrieval of stored information is apt to be similar in the laboratory and in a real purchase situation, the inference processes may be very different in these two contexts.

A third use of reaction times is for examining the development of cognitive structures. Familiarity with the product class and experience with a brand have been shown to be important determinants of both purchase behavior and evaluation processes. For example, Dover and Olson (1977) have presented evidence that the predictability of the Fishbein model changes as experience with a brand changes. Psychological theory suggests that learning about a particular concept both strengthens and

adds components to a cognitive structure until it becomes unitized, i.e., may be considered a single chunk of information (Hayes-Roth, 1977). When this occurs, retrieval of information from the cognitive structure will be much quicker than at earlier stages.

In a pretest for one of our experiments (Edell and Mitchell, 1977) one group of subjects was exposed to product information. A second group received this information and, in addition, was allowed to use sample products. The resulting cognitive structure of the second group enabled the retrieval of the identical information to be completed, on the average, a full second faster than for the first group.

The previous illustrations have suggested the use of response times to measure the structure, content, or development of cognitive structures for storing product knowledge. Many of the questions raised can be answered with the simplest use of total RT's, without partitioning the process into stages or subprocesses. Others, such as determining the subprocesses involved in information acquisition, will require the use of the subtractive or additive factors methods. Although there is considerable opportunity for fruitful application of these various RT techniques to consumer research, we conclude this section with a few caveats to overenthusiasm.

Many areas of consumer behavior do not yet have process-oriented theories with the strength to support chronometric experimentation. If one cannot start without a reasonable idea of the processes being examined, no methodology, chronometric analysis included, is capable of single-handedly generating truth. Second, using response times to identify the information retrieved from memory versus that based on inferences may prove very difficult. This is especially true if retrieval times exhibit large variances both between and within individuals, as they usually do. Third, unlike artificial laboratory environments, many questions appropriate to consumer situations do not have correct answers. This will cause difficulties in adjusting RT's for the effects of a speed-accuracy trade-off. Finally, note that chronometric analysis is a sophisticated methodology developed by experimental psychologists over a period of many years. Strong behavioral and experimental expertise is required of researchers who want to benefit fully from the application of this technology to consumer behavior.

An Examination of Low Involvement Effects

Low involvement learning of advertising information was first hypothesized by Krugman (1965) over a decade ago. Since that time the concept has generated considerable speculation (e.g. Ray, 1973), but almost no empirical research. Perhaps one reason for the dearth of empirical research is that we do not have a precise definition of low involvement learning in terms of cognitive processes. One of the goals of this study is to provide such a definition.

High Involvement Learning

We might begin the task of defining low involvement by first considering what occurs in high involvement learning. Here we hypothesize that interest in the product category is high and the consumer is actively processing the information in the advertisement to reach an overall evaluation of the advertised brand. For example, individuals intending to purchase stereo components may actively seek and read advertisements to evaluate alternative components or vendors. In this situation the consumer has a goal, evaluation of alternative components, which determines the processing strategy that is used during exposure to an advertisement. Under these condi-

tions, we would expect the consumer to critically evaluate the information about the brand from the advertisement by generating thoughts or cognitive responses (Wright, 1973, Greenwald, 1968).

Low Involvement Learning

Alternatively, no evaluative processing may take place during exposure to an advertisement. This may occur, for instance, when an individual becomes involved in the photograph of a print advertisement for a brand in a product category that he or she does not intend purchasing. Alternatively, this may also occur when an external stimulus diverts attention from the processing of information contained in the advertisement. Since in both of these situations little evaluative processing is taking place, we would not consider them examples of high involvement learning.

Based on these examples, let us distinguish between two causes of low involvement processing of advertising messages: attention limitations and strategy limitations. Processing is attention limited when the advertisement does not receive enough attention for it to be fully perceived or evaluated. Following Kahneman (1973) or Norman and Bobrow (1976), attention is considered to be a limited cognitive resource. In other words, the system for processing information at any given point in time has limited capacity. Consequently, insufficient attention can be caused by a deliberate diversion of attention to other processes. For instance, an ongoing conversation with another person may divert whatever attention the individual was devoting to a radio advertisement. This type of low involvement learning has been termed distraction and has been studied by psychologists (Festinger and Maccoby, 1964) and within a marketing context (Bither, 1972). Theoretically, the diversion of attention to other processes limits the attention devoted to the processing of information from the advertisement and, consequently, reduces the number of thoughts or cognitive responses that might be generated. The usual research result under this paradigm is that more positive attitudes are formed with distraction than without. Notice that the attention limitation may be caused by either the individual or the environment.

Low involvement learning can also occur in situations of full attention, if that attention is not devoted to an evaluative processing of the advertising message. Recall the earlier example of attention devoted to the photograph in a print advertisement rather than to brand related information. We call this strategy-limited low involvement because the person processes the advertisement with other than an evaluative strategy. Under these conditions few, if any, cognitive responses about brand information from the advertisement would be generated during exposure to the advertisement with little or no resulting effect on the contents of semantic memory for the brand. However, since the individual was devoting full attention to the advertisement, a trace of the advertisement would be stored in episodic memory (Tulving, 1972). At some later point, information from the advertisement might be retrieved from episodic memory and transferred to semantic memory. However, during this transfer process, we hypothesize that the information would not be as critically evaluated as it would be if it had been received directly from the environment under conditions of high involvement. Consequently, we would expect differences in the resulting cognitive structures after exposure to the same advertisement under the two conditions. More specifically, we would expect more positive attitudes to be formed under conditions of strategy limited processing as opposed to high involvement processing.

This phenomena of strategy limited low involvement may be especially prevalent in the broadcast media where

effort is required to avoid exposure to an advertisement. In situations where the viewer has little interest in the brand being advertised, he or she may resort to nonevaluative processing instead of exposure avoidance.

Several further points should be noted. First, both attention-limited and strategy-limited low involvement can occur simultaneously. The same advertisement can experience low involvement for both reasons. Second, in neither low involvement situation is it claimed that no evaluative processing occurs. Instead, partial evaluative processing can, and probably does, occur under both attention-limited or strategy limited conditions. This partial processing, combined with repeated exposure, can lead to the learning of the advertising message. Third, the low and high involvement conditions described previously should be viewed as end points on a continuum. One example of a point along this continuum might be the case where an individual processes information from an advertisement to learn about an alternative, but he or she does not choose to make an overall evaluation of the brand at this point. Fourth, the analysis of low involvement learning presented above is constructed within an information processing framework. The emphasis is on the cognitive processes that are active during the perception of an advertisement. The subject state or even the intentions of the individual are relevant only in as much as they affect those processes.

Since attention-limited low involvement learning has been studied previously, we direct our efforts toward strategy limited low involvement learning under the condition of full attention.

Research Purpose

The purpose of this study is threefold. First, we wanted to demonstrate the nature of processing under strategy limited low involvement conditions and contrast it to processing under high involvement conditions. Second, we wanted to examine the differential effects on the resulting cognitive structures of individuals exposed to the same advertisements under these two conditions. Finally, we wanted to demonstrate the usefulness of chronometric analysis in examining the processing that takes place during exposure to advertisements.

Consequently, we wanted to design an experiment where the manipulation would be the creation of the two different involvement conditions during exposure to a number of advertisements. The difference in processes under the two conditions would be demonstrated by chronometric analysis. Subjects would be asked to verify statements which would require different mental processes and, therefore, different response times, under the two conditions. Finally, measures would be taken of the resulting cognitive structures of the brands featured in the advertisements.

The experiment should be viewed as an exploratory study whose purpose was to provide insights into the effects of low involvement processing of advertising information and the general cognitive processes involved in the learning of information from advertising.

Method

Rationale

High involvement was produced in the experiment by instructing subjects to examine the advertisements as though they were planning a purchase of the product class of the brand in the advertisement. To enforce this evaluation task, subjects were required to think aloud while making their evaluations and if they did not reach an

overall evaluation of the brand, they were prompted to do so.

The low involvement task involved evaluating the advertisements as to their ability to attract and hold attention. Since subjects would generally be unfamiliar with this task, a number of criteria were given to them which they were to use in making their evaluations. These criteria were the amount of otomotopia, assonance, alliteration, rhyme, hyperbole in the copy and the number of times the words "you" and "your" appeared. Subjects were also required to think aloud while making their evaluations and again, if they did not reach an overall evaluation of the advertisement, they were prompted to do so.

Statements were developed whose verification should require different cognitive mental processes under each experimental manipulation. Since little is known about these processes our model was necessarily simple. The high involvement group was expected to form both brand and attribute evaluations during exposure to the advertisements, therefore, the only cognitive processes required in verifying these statements should be the direct retrieval of information from semantic memory. For the low involvement group, verification of similar statements should require both retrieval of the information contained in the advertisement from episodic memory and then additional processing of this information to form attribute and brand evaluations. Therefore, the response times to these statements should be longer for the low involvement group than the high involvement group.

Similarly, the low involvement group should form evaluations with respect to the different "attention" criteria and an overall evaluation of the advertisements' ability to attract and hold attention. Verification of these types of statements should require only the direct retrieval of this information from semantic memory. The high involvement group, however, will need to retrieve the trace of the advertisement from episodic memory and then evaluate the advertisement according to the stated criteria in order to verify these statements. Therefore, the response times for the high involvement group should be longer than those for the low involvement group on these statements. An example of each type of statement is given in Table 1.

TABLE 1

EXAMPLES OF STATEMENTS

Brand Evaluation

New Car received an overall rating in the top 50% for all cars.

Attention Evaluation

The ad for New Car scores well on attention getting ability.

Attribute Evaluation

New Car is rated in the top 50% of all cars for ease of repair.
New Car is rate in the most expensive 50% of all cars.

Attention Criteria

The ad for New Car contains few rhymes.
The ad for New Car uses words like "you" and "your".

Design

An after only design was used with the main manipulation being the two different levels of involvement. Two different dependent variables were examined. The first was the response time to the four different types of statements: brand evaluations, attribute evaluations, attention evaluations and attention criteria evaluations. Advertisements for four different brands from four different product categories were used. For each brand, one brand evaluation, one attention evaluation, two attribute evaluation and two attention criteria evaluation statements were used.

The second dependent variable was the attitude toward each brand. The mean score of three bipolar evaluative scales (good-bad, dislike very much-like very much, poor quality-high quality) was used for this measure. These evaluations were obtained from a questionnaire administered after the response time statements.

Stimuli

The product categories selected for the advertisements were automobiles, pens, tires and shoes since these types of products would be familiar to our subjects. The copy for each advertisement was designed to provide factual information about the brand so that an overall evaluation of the brand along two different attributes, such as "riding comfort" for the automobile, could be made by subjects. The copy was then given to an artist who made an ink sketch of a picture to go with the advertisement. Each advertisement contained a picture, headline below the picture and then copy below the headline. The advertisements were not of professional quality. It was obvious to the subjects that they were constructed by the experimenters.

Subjects

The subjects were 30 individuals of both sexes recruited from the campus community. The sample included students, secretaries and staff members. The payment of subjects was based on the number of correct responses to a subset of response time statements. This subset includes attribute evaluations and attention criteria evaluations. Subjects received 10¢ for each correct response and lost 10¢ for each incorrect response. Any subject who earned less than \$1.00, based on the number of correct and incorrect responses, was given a dollar.

Apparatus

Response times were measured on a tachistoscope. The questions were placed at one end of the apparatus. Subjects looked into the tachistoscope at the other end, but could not see the questions until they pressed the starter pedal. This simultaneously exposed the question and started the timer. The subject answered the question by pressing either a "true" or "false" button which stopped the timer.

Procedure

Subjects were alternately assigned to low and high involvement conditions to achieve randomization and were run one at a time. At the beginning of the experiment subjects were given instructions depending on their assigned experimental condition and then given two advertisements to evaluate so they would become familiar with their respective tasks. Next they were shown the four advertisements one at a time and asked to think aloud as they did their evaluations. These verbal responses were recorded on a tape recorder.

Subjects were then directed to the tachistoscope and given instructions as to its use. They were then given ten sample statements, completely removed from the context of the experiment, to allow them to become familiar

with the operation of the machine. Prior to the experimental questions, subjects were informed that they may receive some questions that they might not be prepared to answer but that they could do so if they thought back to the advertisements. They were also told that factual statements in the advertisement were true, that they should attempt to answer all questions with equal accuracy, and were informed of the payment schedule. Finally, subjects in the high involvement task were given the criteria for evaluating each advertisement on its ability to attract and hold attention.

The statements were asked in the same order for all subjects. The order was: brand evaluation statements, attention evaluation statements, attribute evaluation statements, and attention criteria statements. Within each statement type, the order of the products was also the same: car, pen, tire and shoe.

After answering the questions on the tachistoscope, the subjects were given a questionnaire to complete and after this they were debriefed and paid. The entire procedure took approximately an hour for each subject.

Data Analysis

Response time data are almost always skewed upward (Pachella, 1974). In this experiment, the average response time over all subjects and conditions was 4.45 seconds, yet some of the observations were as large as 23 seconds. In these instances, processes other than direct retrieval or inference were being executed.

In analyzing response times with these characteristics, two approaches are commonly employed (Pachella, 1974). Either medians are substituted for means or all observations above some cutoff value are dropped. This initial analysis of the data took the second approach. All observations that were twice as long as the average were eliminated. The resulting means were also compared to the median of all the observations for a particular cell.

When two questions were used for a particular question type, these two observations were averaged to produce a single observation for a subject. If one of the response times was greater than the cutoff value, then the response time for the other question was used for that observation.

Results

Response Times

The main prediction of the experiment is the faster verification of brand evaluation statements by the high involvement group. Similarly, the low involvement group should exhibit faster verification of attention evaluation statements. The mean response times for these two types of statements confirm both predictions. These data are plotted in Figure 3. A one tailed test of the means of the brand evaluation statements (3.54 vs. 4.61) was significant ($p < 0.001$) as was the same test on the attention evaluations (4.32 vs. 3.80; $p < 0.05$).

The mean response times for attribute evaluation and attention criteria evaluations are plotted in Figure 4. As predicted, the high involvement group verified attribute evaluation statements faster (3.53 vs. 4.00) and the low involvement group verified attention criteria statements faster (5.46 vs. 4.61). A one tailed test on the means of these two statement types was significant for both the attribute evaluation statements ($p < 0.05$) and attention criteria statements ($p < 0.005$). Notice also that, in general, it took longer for both groups to verify attention criteria statements than attribute evaluation statements.

FIGURE 3. PLOT OF RESPONSE TIMES FOR BRAND AND ATTENTION EVALUATION STATEMENTS BY INVOLVEMENT LEVELS

FIGURE 4. PLOT OF ATTRIBUTE AND ATTENTION CRITERIA EVALUATION STATEMENTS BY INVOLVEMENT LEVELS

Medians

The median scores for each group by statement type is given in Table 2. All of the predicted effects, except for attention evaluations, are confirmed. An examination of the data indicated that two subjects in the low involvement group were largely responsible for this result. Their response times to attention evaluation statements were consistently above 8 seconds which caused the median of this group to be almost equal to the median response of the high involvement group on this type of statement.

TABLE 2
MEDIAN BY GROUP AND STATEMENT TYPE

Group	Statement Type			
	Brand Evaluation	Attention Evaluation	Attribute Evaluation	Attention Criteria
High Involvement	3.32	4.06	3.37	5.57
Low Involvement	4.38	4.16	3.74	4.77

In general, the mean response times, after eliminating observations greater than 9 seconds, are larger than the medians. This indicates that in these cases the data is still skewed.

Correct Responses

As mentioned previously, the attribute evaluation and the attention criteria evaluation statements were structured so there was a correct response. We hypothesize that the high involvement group should be more accurate on attribute evaluation statements and on attention criteria evaluation statements, the low involvement group should be more accurate. This prediction held for the attribute evaluation statements, where the high involvement group verified a 77% of the statements correctly, while the low involvement group verified 63% correctly. This difference is significant for a one tailed test ($p < 0.05$). The high involvement group performed slightly better than the low involvement group on the attention criteria statements (55% vs. 52%), however, this difference is not significant ($p < .25$).

Attitude Toward the Brand

A 2 x 4 ANOVA on each subject's overall attitude toward the brand (Table 3) resulted in both a main effect due to group ($p < 0.01$) and product ($p < 0.001$). These main

TABLE 3
ANOVA: ATTITUDE TOWARD THE BRAND

Source	MS	d.f.	F
Between Subjects			
Group Effect	10.016	1	10.487 ^b
Subjects with Groups	0.955	28	
Within Subjects			
Product Effect	4.071	3	7.306 ^a
Product Group Interaction	0.839	3	1.5059
Product Subjects within Group Interaction	0.557	84	

^a $p < 0.001$

^b $p < 0.01$

effects indicate a systematic difference in attitudes between groups and products. The group-brand interaction was not significant. A plot of the mean attitude scores for each brand and group is presented in Figure 5. It should be noted that the attitude toward each brand is more positive in all cases for the low involvement group.

SUMMARY AND DISCUSSION

In this paper we have discussed the use of chronometric analysis to examine internal information processing. Different approaches for using the technique were presented, along with methodological problems and finally suggestions of areas in consumer behavior where the technique might be applied.

^aLarger values indicate a more positive attitude

FIGURE 5. PLOT OF ATTITUDES TOWARD THE BRAND BY GROUP AND PRODUCT

An experiment examining the effects of high and low involvement learning of advertising information which utilized response time measures was described. Two different types of low involvement learning were hypothesized. The first, attention limited, occurs when only partial attention is directed at advertisements and has been examined previously as distraction effects. The second, strategy limited, occurs when individuals devote full attention to an advertisement, but do not process the information contained in the advertisement to reach overall evaluations.

In this study, strategy limited low involvement learning under the condition of full attention was examined. Response times were used to examine the retrieval of different types of information from memory under the two conditions. The pattern of the response times between groups for different statement types indicated that the high and low involvement groups processed information from the advertisements differently. Furthermore, the data indicated that more positive attitudes toward the brands were formed under low involvement conditions.

Problems

The preliminary results from the experiment illustrate many of the problems in using chronometric analysis in general and to examine consumer behavior specifically. First, the distribution of response times for each statement type within groups was highly skewed. Generally, observations that are considerably greater than average indicate that the subject, in that particular instance, was executing a very different process. These occurrences must be taken into account in the data analysis. In our initial analysis, response times greater than twice the overall average response time were eliminated. Second, there was some indication that the two groups may have been operating on different parts of the speed-accuracy operating characteristic. The low involvement group had slightly lower accuracy on the attention criteria statement than the high involvement group although it had been hypothesized that they should have had greater accuracy. This may be an indication that the response times for this group had a downward bias. Finally, the results

indicated that a model of the process that is more sophisticated than the one initially postulated may be required. For instance, more time was required to retrieve attention criteria information than attention criteria information. Our simple model did not provide an explanation of these differences.

In summary, the experiment indicated that low involvement learning of advertising can occur and that in our experiment more positive attitudes were formed with low involvement learning than with high involvement learning. We are now in the process of doing additional data analysis to understand why more positive attitudes were formed under low involvement conditions and also examining the amount of learning of information under each condition.

Abstract

Motivation-need theories are reviewed, their implications to consumer behavior investigated, and the various findings and concepts integrated in formulating a model of generic choice prediction.

product attributes. Absence of necessary attributes gives rise to dissatisfaction, while the presence of motivating attributes leads to satisfaction.

Instincts and Needs

In the mainstream of Darwinian evolutionary theory, certain behavioral tendencies are innately built into organisms for survival of the individual and thus the species. William James (1890) and William McDougall (1923) made lists of instincts that were seen as main-springs of all kinds of behaviors, simple and complex. Later, Murray (1937) made another classification of human needs. Murray, however, distinguished a directional aspect and an arousal component that actually kicks the behavior off and that can be motivated in a number of ways. Needs, in Murray's concepts, are hypothetical constructs directing behavior toward certain goals, or end states. Classifications of needs, as provided by McDougall or Murray look similar to classifications of elements in chemistry, but lack their strictly defined structure and usefulness. A structural principle is needed to explain the dynamic interactions of needs and their fulfillments.

Maslow's Need Hierarchy

Abraham Maslow (1965) postulates that needs are hierarchically structured and that needs low in the hierarchy must be fulfilled before need higher in the hierarchy become salient. Interrelationships between needs are specified, which are missing in McDougall's and Murray's systems. According to Maslow, the physiological needs (e.g., hunger, thirst) come first, followed by security needs, social needs (affiliation), self-esteem needs (recognition), and finally self-actualization needs. Recently, the need to know and to understand, and aesthetic needs are added to the list (Maslow, 1970). The need to know and to understand is comparable to Berlyne's (1963) epistemic behavior.

Maslow's basic needs (Maslow, 1943, 1965, 1970) are thought to be structured in such a way that the satisfaction or gratification of the lower-order needs leads to the activation of the next higher-order need in the hierarchy. This is the gratification/activation principle. The other principle is the deprivation/domination principle, which states that the most deficient need is the most important need. A distinction is sometimes made between deficiency and growth needs. Needs for belongingness, love, and self-actualization are referred to as growth needs; the others are deficiency needs. To achieve growth needs, deficiency needs must first be satisfied. This may be compared with Herzberg's (1966) hygienic and motivating factors in his job satisfaction theory. A deficiency in the hygienic factors creates dissatisfaction, while fulfillment of these factors does not create satisfaction. The motivating factors, when fulfilled, give rise to job satisfaction. Job satisfaction, and probably also consumer satisfaction, is not measurable on a simple bipolar scale but consists of two more or less independent (sets of) factors. In consumer research, we may distinguish between necessary product attributes (hygienic factors) and motivating

Evaluation of Maslow's Need Hierarchy

Despite its vagueness and lack of adequate empirical support (Wahba and Bridwell, 1976), Maslow's need hierarchy has influenced the work of numerous psychologists (Argyris, 1964; Clark, 1960; Dichter, 1964; Leavitt, 1964; McGregor, 1960; Schein, 1965). Nonetheless, the findings remain largely controversial; and an evaluation of interdisciplinary approaches is rare (Jacoby, 1976). A number of factors seem to have favored the appeal of Maslow's need hierarchy, while the lack of foresight among researchers and the absence of standardized measurement techniques seem to have forestalled the comprehensive evaluation of the interdisciplinary approaches. 1. Maslow's approach is a theory of motivation, in that it links basic needs-motives to general behavior (Wahba and Bridwell, 1976). In other words, the basic needs/motives are linked to behavior through a theory of motivation which asserts that (i) deprivation is followed by gratification; (ii) less potent needs emerge upon the gratification of the more preponderant ones (Maslow, 1970); (iii) and it is a dynamic process where deprivation is hypothesized to lead to domination, which leads to gratification that culminates in the activation of the next higher order need in the echelon. 2. At times, the findings have been used to support two apparently contradictory hypotheses. For instance, Maslow (1965) postulated that (i) gratification of the self-actualization need results in an increase of its importance rather than a decrease, and also that (ii) a long-time deprivation of a need may create a fixation for that need. Maslow noted the exception to his model; that, it is possible for higher-order needs to emerge not after gratification of the next-lower need, but after long-time deprivation (Maslow, 1970). The state of affairs remains that Maslow's need hierarchy, and his propositions regarding gratification and activation, especially in the self-actualization stage, remain controversial. His need hierarchy is by no means definitive, and is rather out of focus in comparison with the role of learning, perception, values, and expectations in human behavior (Atkinson, 1964).

Alderfer (1972) points out that satisfaction with regard to some environmental and job characteristics are studied rather than satisfaction with the postulated needs. Maslow initially postulated that high satisfaction or dissatisfaction is given high ranked importance (Maslow, 1965). Contrary to what is postulated by Maslow, high job satisfaction rather than deprivation is correlated with importance (Dachler and Hulin, 1969). In another study, again, contrary to what Maslow hypothesized, Mobley and Locke (1970) concluded that extreme satisfaction and dissatisfaction depend on the importance attached to them, and not importance determining satisfaction and dissatisfaction.

Some support has been found for Maslow's (1965) deficiency and growth needs in studies that compared executives and workers in an organization. In these studies higher-order (growth, actualizing) needs are judged to be more important for top executives than for underprivileged workers (Davis, 1946; Pellegrin and Coates, 1957). In a deprived environment, lower-order needs

(existence hygienic) needs seem to be more important than higher order need, (Cofer and Appley, 1964; Porter, 1961, 1962; Porter and Mitchell, 1967). By implication, the rating of importance of job satisfaction seems to be positively related to the level of the job one holds (Porter, 1961; Porter and Mitchell, 1967) or "that the deprivation domination principle may only be operative in the case of the deprivation of the lower-order needs, especially physiological needs" (Wahba & Bridwell, 1976, p. 231).

Notwithstanding the above conclusions, the concept of deprivation/domination seems to have little or no effect on the behavior of consumers in relatively affluent societies for a number of reasons. (1) The daily purchases are mostly over and above what is (basically) needed. (2) Until the time that the law of diminishing returns sets in or depleting raw material resources make "abundant" consumption difficult, there is a "need" to buy and possess more. Instead, consumption is influenced by relative deprivation compared with "relevant other consumers". This relative deprivation may trigger the dominance of the desire "to keep up" with the reference group.

Satisfaction/Dissatisfaction

Consumer satisfaction/dissatisfaction studies will benefit from the two-factor need theories (Maslow, 1965; Alderfer, 1969; Herzberg, 1966). Brands possess two types of attributes. The first type of attributes (inhibitors) give rise to dissatisfaction, if their level is below a certain threshold. A car that is insufficiently safe causes dissatisfaction, while no satisfaction is derived from a car that is sufficiently safe. The second type of attributes (facilitators) give rise to satisfaction, if their level is above a certain threshold. Similar to the deprivation/domination principle, the presence of inhibitors causes dissatisfaction and (extending the above principle) this dissatisfaction cannot be compensated for by facilitators. If no inhibitors are present, a "zero point" has been reached. Consumer satisfaction can only be obtained through the absence of inhibitors and the presence of facilitators.

The distinction between inhibitors and facilitators has its analogy in consumer decision making. In terms of decision rules, the first type of attributes (inhibitors) elicit the conjunctive decision rule to eliminate brands with inhibiting (below threshold) values on certain attributes. The second type of attributes (facilitators) elicit the disjunctive decision rule to select brands with facilitating (above threshold) values on other attributes. The conjunctive rule must occur before the disjunctive rule.

Jacoby (1976) emphasizes the applicability of Herzberg's (1966) two-factor model for the study of consumer satisfaction, which may be compared to a simple choice heuristic: the sequence of conjunctive and disjunctive information processing (Van Raaij, 1977, p. 23-26). Some problems exist, however, in applying Herzberg's (1966) two-factor model in consumer satisfaction research:

1. In the decision process the consumer will avoid brands that give rise to dissatisfaction through the application of the conjunctive decision rule. Dissatisfaction may only occur after an incorrect application of the conjunctive rule, or after using incomplete or deceptive information.

2. As Jacoby (1976) points out, Herzberg's propositions as well as the findings cited before are involved with the determinants of satisfaction/dissatisfaction and not with performance. Therefore, they cannot be directly extended to a purchase situation that involves a combination of dichotomies involving purchase behavior-satisfaction and purchase behavior-dissatisfaction. As a solution, he proposes another behavior-satisfaction dimension orthogonal to the facilitator-inhibitor di-

mension (Jacoby, 1971).

Motivation Models

Cognitive motivation models fall into three broad categories: equity, need achievement and expectancy-value models (see Table 1). The commonality of the models is that the units of framework we present are of cognitive, subjective nature, and that they include hypothetical constructs as perceived equity, need achievement, expectation, and values. A similar, but shorter, review of the three categories is given in Van Raaij (1976).

Equity

The concept of equity may be explicitly stated as the even exchange of values such that what is received is presumed to be equal to what is given (Adams, 1965). Equity operates within a range, with a lower and upper limit. Inputs ("what is given") are defined as "what a person perceives as his contributions to the exchange for which he expects a just return" (Walster and Walster, 1975). Apparently, equity theory may be applied to social relations such as amnagement-worker and seller-buyer. Further, the concept of power seems to be related to perceived and subjective equity.

It is our hypothesis that the ranges of equity (upper and lower limits) may well be measured by the expectancy-value type of model (Table 1) for two reasons: (1) The expectancy component of the model is general, comprehensive and brand specific. (2) The expectancy component handles expectations about equity as compared with "relevant others". We return later to the discussion of how consumer behavior is motivated by perceived inequity or a disparity between the desired and actual state. The application of the equity concept of consumer behavior may be restricted to some aspects of consumption.

TABLE 1
Motivation Models

Type	Formulae	Explanation
1. Equity-expectancy		
a. job performance: (Vroom, 1964)	$MF = E \times V$	MF = Motivational force E = Expectancy force of achieving desired outcome V = Value of desired outcome
b. attitude:	$A_o = PI \times VI$	A = Attitude PI = Perceived Instrumentality VI = Value importance
2. Need-achievement:	$T_s = M_s \times P_s \times I_s$ $T_f = M_f \times P_f \times I_f$ $I_f + P_s = 0$ and $P_s + P_f = 1$ and $P_s + I_s = 1$ $T_a = T_s - T_f$ $T_a = (M_s - M_f) \{P_s - P_s^2\}$	T_s = Strength of motivation to achieve success T_f = Strength of motivation to avoid failure M_s = Motive or need to achieve success M_f = Motive or need to avoid failure I_f = Incentive value of failure I_s = Incentive value of success P_f = Probability of failure P_s = Probability of success

Such equity-based motivational forces include sensitivity of consumers toward primarily price, time and effort expended (e.g., Gabor and Granger, 1966). However, it has to be pointed out that (1) it is not prior known how equity is created and what its upper and lower limits are; (2) promotional activities make the equity relation relative and situation-affected, depending on whether the purchase has been prompted by a deal or not, for instance; (3) consumers tend to "satisfice" (March and Simon, 1958), and do not necessarily maximize as implied in the equity concept (e.g., Pritchard, 1969).

To summarize, equity is useful in two ways for consumer research. First, the inequity of the seller-buyer relation may give rise to consumer dissatisfaction and the motivation to restore equity. Armstrong (1976) provides some examples of the restoration of equity between consumers and marketers. As with Herzberg's (1966) two-factor model, an equitable relation as perceived by the consumer prevents the elicitation of dissatisfaction. On the other hand, an inequitable relation is a necessary but not a sufficient prerequisite for consumer satisfaction. Second, the equity relations holds for the consumer with regard to "relevant others" (reference groups). Here, an inequitable relation motivates the consumer to restore equity, that means he is motivated to bring his consumption level and pattern into agreement with that of his reference group. Generally, this results in an increase in consumption expenditures, as aspirations and expectations become higher (e.g., Duessenberry's 1949) "relative income hypothesis" and Katona, Strumpel and Zahn's (1971) "rising aspirations and affluence").

Need Achievement

The concept of need achievement (McClelland, 1961) is basically another variation of the expectancy-value approach. Need achievement resembles Maslow's (1970) self-actualization motive in a number of ways. The main difference, however, is that it includes the probability of attaining a goal and a probability of failure. The need achievement model (Table 1) attributes the strength of motivation to the cognitive expectation that the action will result in the consequence. Stated somewhat differently, the tendency to engage in an activity is determined by the desired goal of the action. Therefore, the outcome or consequence has attraction or value to the individual. Assuming that $I_f = -P = 1$ (a particular outcome is either a success or a failure). As indicated in Table 1, the summation of T_s and T_f provides the tendency or motive to achieve (T_a), which may be derived from the given algebraic relationship: $T_a = (M_s - M_f) / (P_s - P_f)$.

The need achievement concept is only applicable in cases where the consumer perceives some risk of failure. Two ways exist to increase the tendency to achieve (T_a): (1) Increase the "approach" tendency (T_s) by making the product more attractive, and (2) decrease the "avoidance" tendency (T_f) by reducing perceived risk (see Roselius (1971) for possible risk relievers). Again, a congruence with Herzberg's two-factor model can be observed. The avoidance tendency (T_f) may be related to some unsatisfactory product attributes (inhibitors) and the approach tendency (T_s) may be related to other, satisfactory product attributes (facilitators). The only difference is that in the approach-avoidance paradigm unsatisfactory attributes can be compensated by satisfactory product attributes. As Schewe (1973) points out, "The greatest problem appears to be determining a valid and reliable measure of the need achievement construct" (Schewe, 1973, p. 33). In addition, achievement needs are not operating in all purchase situations. P and I may have low levels and, hence, result in low T_s levels of the strength of the motive to achieve success (T_a). He concludes that further research is necessary to find its true potential as a determinant of consumer behavior (Schewe, 1973).

Finally, contrary to the postulate of need achievement, motives are not stable behavioral dispositions, though they may well be partly learned. Also, it must be emphasized that it is not necessary for motives in general to operate after they are aroused by the presence of the incentives or situational cues that have been associated with the incentive (see Campbell and Pritchard, 1976, pp. 112-14).

Expectancy-Value Models

The basis for expectancy models has been made by Tolman (1932) and Lewin (1938). It seems to be influenced more by Lewin's field theory in that it involves the perceptual analysis of (1) alternatives with their (2) desirabilities and (3) expectancies, and their (4) outcomes in the immediate psychological field.

Many psychological theories come under the label of expectancy-value models: subjective expected utility theory (Edwards, 1954), social learning theory (Rotter, 1954), motivation theory (Atkinson, 1964), and attitude theories (e.g., Rosenberg, 1956; Fishbein, 1967). An overview of these theories can be found in Van Raaij (1977).

Expectancy theory states that the desire or motive to engage in a certain behavior is a composite of the expected outcome of that behavior and the value or evaluation of that behavior. As can be seen from Table 1 the motivational force to engage in a particular behavior, as applied in organizational psychology, is a function of the four factors stated above (Vroom, 1964; Graen, 1969; Porter and Lawler, 1968; Campbell, Dunnette, Lawler and Weick, 1970). However, it needs to be pointed out that the expectancy concept is not without questions. We will try to find answers to these questions before we apply this concept to consumer motivation.

First, the extension of the concept of "evoked set" (Howard and Sheth, 1969) seems to provide an answer to the question of how many alternatives, as well as type of alternatives are considered by the individual. Second, the desirability or attractiveness of the alternatives is a function of the probability that the alternative possesses a certain attribute times the evaluation of that attribute on a bipolar favorable-unfavorable scale. Third, Jacoby (1976) emphasizes not to overlook that the desired outcomes of a behavior are influenced by "motivational inputs". A distinction is made between input and output. "Outputs or outcomes refer to the primary functional aspects of the alternatives in the product set; they are the basic purpose for buying and using the product. Inputs, on the other hand, are those motivational forces other than perceived functional consequences which influence the selection of one specific behavioral alternative over the other available alternatives" (Jacoby, 1976, p. 1049).

If the functional goal of the purchase of a car is its service and economy, say, as opposed to status or a combination of all these, then these consequences constitute the desired outcomes. The inputs such as advertising, availability of deals, past satisfaction with the product, referred to as "antecedents" (Jacoby, 1976), may induce the consideration of one brand over another. Jacoby suggests the partitioning of the evaluation component into input (or antecedent) and output (or consequent) "values". Unfortunately, this is only at the brand level, and even at that level, it fails to resolve a number of questions raised earlier. Although Jacoby's revision make the traditional models more comprehensive and richer in their construct composition, some drawbacks have to be mentioned: (1) It fails to answer how and why an individual becomes motivated to consider certain outcomes or consequences. (2) It ignores the interdependency between product and brand, that is, the desire to consider a product class and then to engage

in brand(s) selection. (3) It fails to note that some repetitive buying behavior is influenced by simple S-R relationships, or may even be stochastic, making motivational models too elaborate or irrelevant for this kind of buying behavior.

Our interest in motivational models of consumer behavior is mainly at the product class level (generic choice) but has also implications for the brand level (specific choice).

Motivational Model for Product Choice

We think that motivational models are especially useful for the generic choice (among product classes) and less useful for the specific choice (within product classes). For the latter case, multi-attribute attitude and preference models may hold better predictions for brand choice within the product class. In most cases, the generic choice is more important and critical for the consumer; however, this seems to be a neglected area of research in marketing. We think that the generic choice, whether to buy a car or to go on a vacation, for example, has more relevance for general economic policy, consumer education, and also for marketing mix decisions. Between the generic and specific choice, a "modal choice" or method choice can be distinguished in many cases (see, for instance, Sheth (1975) for travel mode selection).

Figure 1 gives the sequence of the three choice levels as they occur in consumer decision making regarding travel. The product choice is the first to be made. Sub-

FIGURE 1
Sequence of Choices in Consumer Decision Making

- A. generic choice (travel vs. other product classes)
- B. modal choice (airline vs. train)
- C. specific choice (American vs. United)

sequently, a selection of a modal or method within the product class is made. Then, within the mode, the consumer selects a specific brand.

Sheth (1975) distinguishes five utility needs. These utility needs can be seen as the basic needs that products satisfy. In the generic choice process, consumers compare the product classes on their ability to satisfy the basic needs. We may also conceive these utility needs as the basic dimensions of motivation. In all cases, consumers want to reach certain goal states and the products are instrumental in reaching the goals.

The five motivational dimensions are (Sheth, 1975): (1) functional motives, (2) aesthetic-emotional motives, (3) social motives, (4) situational motives, and (5) curiosity motives. 1. Functional motives are related to the technical functions the product performs. The combination of product attributes forms the total functional utility of a product. 2. Aesthetic-emotional motives are the style, design, luxury, and comfort of a product (class). These motives are not only important for the specific (brand) choice but also for the generic (product) choice. The product class is evaluated in terms of the fundamental values of the consumer in the emotive areas of fear, social concern, respect for quality of life, appreciation of fine arts, religion, and other emotional feelings. Thus, it may be contended that individuals tend to select those product classes that match with their life styles and enable them to express their fundamental values. 3. Social motives are related to the impact that consumption makes on relevant others. Status, prestige, and esteem may be derived from the possession and usage of products and their con-

spicuous features. Some products are selected for their conspicuousness only ("conversation pieces"), sometimes in combination with aesthetic motives. 4. Situational motives are not motives in the sense of long-term desires to reach a certain goal. The selection of a product may be triggered by situational determinants such as availability, price discount, and/or accessibility. These situational factors apply usually for a specific brand or type. The brand choice is usually made in these cases without a careful evaluation of the product class(es). 5. Curiosity motives are motives that are supposed to prompt trials of new and/or innovative products. The consumer may try a new product; however, his repeat-purchase may be independent of such trials.

Choice Modal Prediction

It has to be emphasized that the motivational model suggested here is mainly applicable to consumers' product choices, involving large financial outlays or high perceived social and/or physical risk. Repetitive brand or product choice triggered by depletion of stock is not relevantly described and predicted by our motivational model. Further, note that within each of the five motivational dimensions subclasses exist for different product classes. For example, the generic choice between a refrigerator and a TV set involves different functional utilities-cooling food versus entertainment/information, respectively. In the generic choice process, the consumer essentially compares products on a different set of dimensions for each product, while in the specific choice process the same set of dimensions apply for all brands within the product class. The consumer necessarily, unlike in the specific choice situation, has to "compute" an overall utility for each product class to see whether it satisfies a number of motives, and then compare these overall utilities to make a final choice. To depict these relationships, we suggest a straightforward multi-attribute model. In this model (eq. 1), overall preference or total utility a product class satisfies and the evaluation of these motives may be written as,

$$U_j = \sum_{i=1}^m M_{ij} \times V_i \dots\dots (1)$$

U_j is the utility of product class j that satisfies m motives (M_{ij}), and V_i is the evaluation of the m motives on a favorable-unfavorable scale. M_{ij} can be thought of as a vector of probabilities that the product class j satisfies a specific motive i . These probabilities are strictly zero or above zero, and therefore, only positive. This composite measure, U_j , is expected to cover the five dimensions outlined above. Thus the behavior or behavioral intention (BI) of the consumer equals the maximum of U_j ($j=1, \dots, m$) if m product classes are considered.

$$B = BI = \max U_j \quad (j=1, \dots, m) \dots\dots (2)$$

Usually, the number of product classes is smaller than the number of brands in the specific choice situation.

Individual consumers differ not only in their evaluation of motivational dimensions (V_i), but also in the saliency of these dimensions over time. Recent gratification of a motivational dimension may lead to a decrease in the evaluation of that motivational dimension. This is especially true for the functional, social, and curiosity motives. Lack of gratification of a motivational dimension increases the evaluation of that motive (the deprivation/dominance principle).

Basically, motives are "means-end beliefs" (Tolman, 1932). That is, there is cognitive association between a specific product class or the buying of a certain product from a set of product classes, and the expectation that the product contributes to the attainment of a goal or the satisfaction of a motivational dimen-

sion. This expectation is thought to be a subjective probability. Parenthetically, the strength of motives or motivational dimensions is largely determined by cultural and life history factors. Further, motives become salient if a disparity exists between a desired goal state and the actual state on a motivational dimension. A desired state is triggered in the comparison of one's own position and the position of "relevant others" on the various functional as well as non-functional utility dimension(s). Equity theory (Adams, 1965) predicts that differences in the input/output ratio bring about a change in the desired goal state. Need-achievement theory (McClelland, 1961) attributes the strength of motivation to the cognitive expectation that the action will result in the consequence. The origin of motivation is external in equity theory (reference groups) and internal in need-achievement theory. We assume that an intermediate disparity between desired and actual state of the individual has the strongest effect on motivation. For a small disparity an assimilation effect is thought to occur; the disparity is rationalized away. For a large disparity, a contrast effect is more likely; the disparity is too great to be bridged by the acquisition of a product. The desired goal state is perceived as unattainable in this case. This curvilinear relationship between motive strength and disparity may be effectively compared with Berlyne's (1963) exploratory behavior theory and the level of arousal potential.

Operationalization

The elicitation of the motivational dimensions can be done in two subsequent pilot surveys constituting depth interviews and other non-attributive methods. In the depth interview method no particular forms and orders of motives should be elicited with the help of probing questions, incomplete sentences and the Kelly grid method. Such elicited motives constitute a listing of the relevant needs or motives applicable to a specific situation. In non-attributive method the researcher has to start with a listing of these possible motives and request the consumer to indicate the ones he considers salient.

Summary

Motivation-need theories are reviewed, their implications to consumer behavior investigated, and the various findings and concepts integrated in formulating a model of choice prediction.

In our opinion, motivational models are highly relevant for the generic choice process, while multi-attribute attitude models are relevant for the specific choice process. A motivational model for the generic choice is proposed, with the notion that consumer behavior in its various ramifications (i.e., from the consumer, economist, social marketer, etc., perspectives) can be better understood from the analysis of generic choices.

INFORMATION ABOUT CONSUMER PROBLEMS BY THE POLICY-DELPHI PROCEDURE.
A NEW METHOD FOR EVALUATING THE MARKETING SYSTEM.

Solveig Wikstrom, Stockholm University

Abstract

The basic premise of this paper is that the marketing system does not perform adequately as seen from a consumer's perspective. For various different reasons the sellers' offerings do not sufficiently match the consumers' needs and wants. The performance of the socio-economic system to which the marketing system belong depends on adequate feedback. Existing information mechanisms are inadequate. In this paper a new method is presented for gathering information about the consumer situation for use as feedback. By this method a panel of informed persons assess the consumer situation in several rounds according to the so called Delphi procedure. By this method the gathering of subjective and objective information is made through one approach. Experience reported in this paper indicates that further development of the method should be carried out.

Introduction

In Sweden as in most industrialized countries intense activities are going on in the consumer policy area to strengthen the consumer's position on the market. Examples of important policy actions in Sweden in the 70's are:

1971: The Consumer Ombudsman, the market Court Act, the Marketing Practices Act, the Act Prohibiting Improper Contract Terms, the Door-to-Door Sales Act.

1972: The Food Office, the Food Act.

1973: The National Board for Consumer Policy, the Act on Products Hazardous to Man and Environment.

1974: The Consumer Sales Act.

1975: Decision about expanding the local consumer advisor activities.

1976: The New Marketing Practices Act.

There are more activities under consideration as a result of recent government commissions.

If we take these new laws and norms to be well motivated, they can be seen as indicators of deficiencies in the marketing system. Consumers as a whole or categories of consumers seem to have problems which consumer policy activities are supposed to counteract. What are the effects of these activities for the performance of the marketing system? What are the consequences for the consumers?

As a matter of fact there are no answers to such fundamental questions about the consumers' situation as:

- How often do consumers meet problems in their planning of purchases, buying and consumption of goods and services?
- What has been the trend over time?
- How serious are these problems?
- Are There product and service areas which have more problems than average?
- How much of the problems are the consumers themselves aware of?

In reality very little effort has been made to get this kind of feedback. To some extent this may be due to the lack of workable information mechanisms.

This paper presents some of the work carried out last year developing and implementing a new method for evaluating some aspects of the marketing system from

a consumer's perspective (Wikstrom, Eliasson 1976) This was done by having a panel of informed people assess the extent to which consumers meet problems and what implications these problems have for the consumers. The assessments were carried out in several rounds following the so called Delphi method.

In this case the Delphi assessment of the consumer situation was used as a method for evaluating what has been done up to date to improve the marketing system. I particularly want to emphasize that this new approach by no means fills the information gap pointed at above. It however does reveal new aspects of the problem not obtainable by existing methods and the experience gained indicates that further development of the method should be carried out. As a frame of reference for the presentation of the new approach a short overview is given of methods used at present.

Information generated by present methods

From the literature discussing criteria variables for evaluating the marketing system from a consumer perspective the following matrix can be arranged (Renoux, 1973, Lingoos, Pfaff, 1972, Olander, 1976, Andreasen, 1975)

FIGURE 1

Figure 1.

The information encompasses		
The databasis are ...	The micro marketing system	The macro marketing system
<u>Subjective</u>	- consumer complaints - consumer satisfaction/dissatisfaction surveys	Studies of consumer attitudes to the business policy in advertising, product development, product safety etc.
<u>Objective</u>	Studies of - number and location of retail outlets, shopping distances - trends in life span, quality, prices and repair costs of goods - the occurrence of unsafe and unhealthy products - consumer shopping pattern	Studies of - innovation capacity of the business - restraints in competition - advertising volume - brand differentiation etc.

Subjective data basis means statements based on individual consumers' evaluations of their situation and the state of their environment. Objective data basis implies that data used are not directly dependent on the consumers' evaluations of the situation. Information about the micro marketing system includes aspects

such as individual products and firms, shopping possibilities, the buyer situation in the outlets, the consumption and repair of products etc. The macro marketing system covers the total system. The evaluation concerns its functions from a wholistic view.

The advantage of information based on subjective indicators is that these reveal what the consumers themselves perceive as their problems and as deficiencies in their marketing environment. These types of indicators can not, however, be used as a decision basis either by public policy regulators or by business planners without analysis and evaluation. One has to clarify what, if any, are the alternatives available within the present technology and the resulting costs to consumers. The consumer should be informed as to whether or not there are alternatives. There are serious "consumer problems" which can not be dealt with within the marketing system. In this case the government must step in and provide some solution outside the marketing system, e.g., in public transportation, in housing, or in education.

The main weaknesses of the subjective indicators are their dependence on consumer aspiration levels and their inability to generate information about those problems which the consumers may not be conscious of.

Evaluations based on objective indicators, on the contrary, have the advantage of recognizing problems which the consumers are unaware of. Trends in this kind of data can also be used as indicators for future problems.

There are however validity problems in using objective indicators. You really do not know how close a relationship there is between the indicators and the state you want to measure. Besides that you do not know if the set of indicators used is sufficient for measuring a certain consumer state.

The conclusion is that either subjective or objective indicators separately are sufficient as information instruments. Both types of indicators are needed, which implies that the information gathering becomes extensive and costly. Besides that there are still unfilled gaps.

The new method of evaluating the consumer situation by using assessments by a panel of "experts" combines the subjective and objective approach. By treating the gathering of subjective and objective information through one approach we are able to put them on a relative or comparative basis in terms of what we believe is now an efficient process for producing relevant information. First the panels' professional background implies good insights into what is called objective indicators. Second these people are also well informed and knowledgeable consumers themselves. Therefore, they should have qualifications to integrate subjective and objective aspects in their assessments.

The panel assessment in the actual method study has been directed towards micro aspects, but in a systematic way so that the marketing system in large has been covered. This way micro and macro aspects have been integrated.

Referring to the matrix in Figure 1, the position of the Delphi assessment is between subjective and objective and between micro and macro and thus integrating these aspects.

Definition of the Consumer Problem Concept

In Russell Ackoffs terms (1962) the concept problem implies a tension between what a person should achieve and in fact does achieve, i.e., a deficiency in goal fulfilment. What a person should achieve has however

to be kept within what is technologically possible and attainable. With the restriction to what is attainable the utopias are out of question. This definition is illustrated in Figure 2.

FIGURE 2 Consumer problem as a deviation between the achieved state (a) and the desirable and attainable state (g_n).

Defining consumer problems in this manner presupposes knowledge about consumers' achieved states, knowledge about attainable states and values about what is desirable. Differences in these components lead to differing views about how widespread and urgent the consumer problems are.

When defining consumer problems it is possible to distinguish between a number of concepts related to this problem concept in the way indicated in Figure 3.

- (1) Problems from consumer complaints. Spontaneous dissatisfaction measured by number of consumer complaints.
 - (2) Problems from surveys. All problems which the consumers are aware of and admit. This concept is used in surveys of consumer satisfaction/dissatisfaction.
 - (3) Unconscious problems as well. Relevant subsets of problem areas (1) and (2) as well as some specific problems not admitted or perceived by the consumers. We know that in some situations the consumer denies his problems. He rationalizes his poor decisions in order to reach internal harmony, acknowledging information which supports his decision and avoiding stimuli which are in conflict with it. These mechanisms are explained by the theory of dissonance (see e.g. Festinger, 1964). The consumer would not admit these kind of problems.
- Then there are problems which the consumer is unaware of for another reason. He lacks information about his possibilities to attain better states. Better alternatives already exist, but the consumer does not know about them.
- (4) Problems caused by lack of dynamics. Better Alternatives are attainable with present technology including better organization of the marketing systems. Because of lack of dynamics these alternatives are not realized.
 - (5) Problems from deliberate behavior. Certain kinds of consumer behavior give rise to a state which, according to established norms, is poor. An inadequate diet and consumption of alcohol and drugs are illustrative examples. Buying groceries very frequently is another kind of behavior which consumer policy planners regard as a problem. The consumers themselves however behave as they are used to. According to their own present values their state apparently is better than the other state which the planners consider highly preferable.

Figure 3 The consumer problem concept and subconcepts

In Figure 3 the consumer concept is seen as a vector. The subconcepts - the numbers refer to the explanatory text above - are arranged along the vector after degree of verbalization, consciousness etc.

It is to be noticed that all consumer dissatisfaction can not be regarded as consumer problems. If there are no better alternatives attainable, the consumer dissatisfaction does not indicate consumer problems, according to the definition used. This is illustrated in Figure 3. Parts of the subconcept (1) in (2) are located outside the consumer problem vector. Seen from an individual consumer perspective the type (4) problems are not consumer problems either. The better state is not desirable for the consumer.

It is also to be noticed that we do not know the relations between the subconcepts. The size of these vectors in Figure 3 are arbitrary.

All the above problem areas have been discussed in the literature; however, the distinction between the problem types is hardly ever made explicit. When policy actions are considered these distinctions should be noticed.

Our exercise was aimed at clarifying problems of type (3) and (4). Using a panel with knowledge about consumer behavior as well as present and potential supply gives an opportunity to take into account those problems which individual consumers are unaware of or are unwilling to admit.

In the operationalization we tried to exclude (4) thus measuring the amount of consumer problems perceived by fully informed but not necessarily rational consumers in a narrow sense. The working hypothesis was that people strive at using their economic and other resources in such a way that they get as good a life as possible. In this goal seeking behavior conflicts arise. In balancing these conflicts people sometimes consciously choose a poor alternative in fulfilling a certain sub-goal. In a narrow perspective the decision seems irrational, from a wider perspective quite rational.

Design and Implementation of the Panel Assessment

The panel composition

In selecting the panel members two qualities were important. First, the members should have good knowledge about consumer behavior and about present and potential supply, i.e., about data earlier described as objective indicators. The knowledge areas aimed at were identified from the members' employment or professional position. Second, as has been emphasized above, values hold an important role in defining consumer problems. Considering this, efforts were made to include members

viewing the consumers' situations from different perspectives and representing different value structures. As a consequence the panel was composed of the following categories.

- (1) Local consumer advisors (LA)
- (2) Representatives of public authorities (PA)
- (3) Representatives of the business sector (BR)

The guidelines for the panel size was about 30 participants, which is considered sufficient for a Delphi-procedure. The final panel consisted of 9 from the (LA) category and 10 each from both others.

Method for Data Collection

Data were generated by a survey in different rounds by means of the so called Delphi method. With this method the participants give their answers individually on written questionnaires. The individual answers remain anonymous. The answers of the panel are reported back to the panel in statistical form as median and quartile answers. Questions and remarks are also fed back to the panel, together with explanations and clarifications from the panel director. On the basis of such information the participants reassess their previous statements in new rounds.

The Delphi inquiry utilizes well-informed people's subjective judgements. The method was originally developed as a forecasting tool. It has however been used more and more to generate approximations and judgements about other situations where "hard data" are difficult to obtain. The method has been used for instance to define different opinions of important social issues (see eg. Jolson, 1975, and Dahl, 1974), as a basis for decision making in marketing (Jolson and Rossow, 1971) and as a general tool in evaluation research. For more details about the method, see eg. Linstone, Turoff (1975) or Wikstrom (1973).

The Questioning

The panel assessment concerned two different aspects:

- a) how frequent and how serious are consumer problems in planning of purchases, buying and consumption of goods and services.
- b) what desirable and feasible policy actions are to be taken to counteract these problems.

The latter aspect was included not only to give a wide spectrum of ideas about possible action, but to highlight what ideas there are about causes to these problems.

The panel was provided with some information about the general idea behind this assessment and a presentation of the outline of the study. This was done by the conceptual model in Figure 4.

FIGURE 4

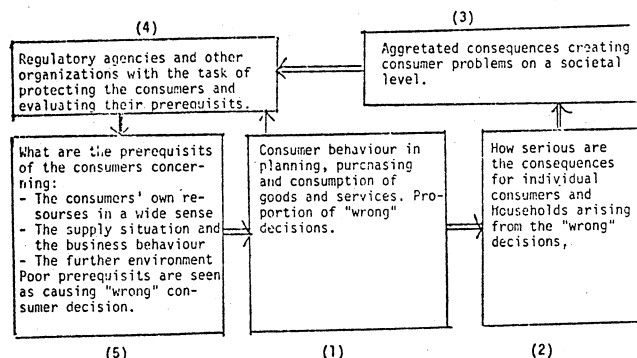

Figure 4

The first part of the assessment considered (1) and (2) in Figure 4. In this the panel was asked to use available data about (5). The outcome of this assessment gives (3). In the second part, (4) and (5) are dealt with. The panel was asked to suggest possible and feasible actions to counteract the stated problems. The panel was exhorted to seek information and ask questions if anything seemed confusing.

The Operationalization of the Consumer Problem Concept

Consumer problems were seen as situations in the planning, buying and consumption process, where consumers unwittingly make "incorrect" decisions, i.e., behave in a way which affects their budget or need satisfaction negatively. In order for an action to be defined as a wrong decision, it should have clearly noticeable negative effects. "Unwittingly" means that the consumer would not have behaved in that way if he had foreseen the consequences and if there had been other alternatives at hand.

The frequency of problems was measured as the average number of wrong decisions the consumer makes per 100 decisions. How serious the wrong decisions were was measured according to a 3 point ordinal scale.

As a second part of the study the panel suggested steps to be taken to counteract the problems they had established. In the second round the panel evaluated all measures suggested.

To get a systematic view of the consumer situation the panel was asked to assess the amount of problems in the following situations. For durable goods and more expensive services such as cars, private homes, boats, dishwashers, television sets and package vacation tours, the question was how often consumers make "incorrect" decisions on an average when they:

1. plan and consider and ultimately decide to buy a certain product or service.
2. choose product class, size, price level, and retail outlet.
3. carry out the buying: choose how to pay, agree to purchase conditions, make complaints etc.
4. use the product or service.
5. buy repair services.

For convenience goods the incorrect decisions concern:

6. the shopping pattern including frequency of shopping choice of retail outlets, time, transportation etc.
7. the choice of brand, package, size, price level, etc.

These steps in the buying process are based on ideas from Gredals typology (Gredal, 1971).

The panel was also to mention and assess consumer categories and product areas with particularly high frequency of wrong decisions.

The Delphi process

The written questioning consisting of two rounds was carried out in spring 1976. The panel answered each questionnaire within 3 weeks. After the first round some questions had to be rewritten and new instructions given. Misunderstandings of the concept and the assessment procedure had appeared.

After a working report had been finished and sent to the panel members a telephone round was carried out in early 1977. The subject was the panel's experience of the assessment process and the opinions about the final results.

Some Results

The Amount and Seriousness of Consumer Problems

The assessment of the frequency of problems for the average consumer is shown in the profile below.

FIGURE 5

The assessment of the percentage of total number of wrong decisions made by the average consumer in planning purchases, buying and consumption of goods and services.

According to the median assessment there are problems for the consumers in 15-35 percent of the decisions in the different steps in the buying and consumption process.

The frequency of problems is one dimension, the seriousness of the problems is another.

In analyzing the panel assessments a total score was used for the negative economic and need satisfaction consequences. As mentioned before the consequences were measured according to a 3 point scale. The most serious consequences were given 3 points, the next group 2 points and the least serious 1 point. As shown by Figure 6, the first two aspects, planning in a wide sense, has the highest scores for negative consequences. As a whole negative economic effects are bigger than the need satisfaction effects. For the choice of convenience goods the opposite holds good.

FIGURE 6

Importance scores for the negative economic and need satisfaction consequences of consumer's wrong decisions.

The diagram shows that the (LA) representatives tend to consider the consumer situation to be more problematic than the other categories. The differences are, however, not as clear as I had expected.

For two reasons I had anticipated that the (BR) category would have given the most positive view of the consumer situation. First, business people regard consumers as a powerful group. The consumers "vote" by buying or not buying. From the business people's view they are not very easy to convince. Second, for tactical reasons this category could be expected to be optimistic. A problematic consumer situation calls for more regulations, which are mostly directed against the business.

As the diagram shows, there are no clear differences between the (BR) and (PA) categories. The assessments by these categories by no means reflect the differing views between the same categories in the public debate. After having analyzed the assessments and discussed the results with the panel in the telephone round the small differences between the categories can be explained. In the assessment process individual values and personal experience of buying have had a much stronger impact than group values and professional experience. In other parts of the assessment, concerning possible policy actions to be taken to counteract the stated problems, there was much more explicit groups differences.

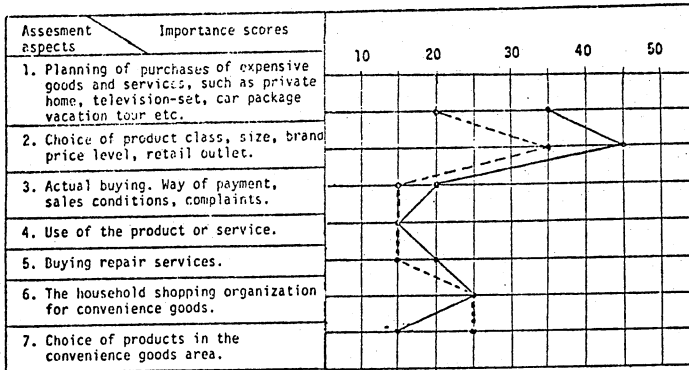

Suggested policy actions

The panel as a whole suggested about 60 policy actions of very different character. About half of them were business oriented, one third were market oriented and the rest were consumer oriented. The panel evaluated these actions remarkably positively according to desirability and feasibility.

In order to give an idea of what kind of actions the panel suggested, some examples are quoted. All the three panel categories rated these actions as definitely feasible and desirable. There is also a set of more radical actions suggested, about which there were disagreements.

- Actions to improve the consumers' planning of purchases:
- Improved education of young people and adults in consumer issues, particularly in budgeting.
 - Increased consumer information in present and new forms.
 - Extensive use of the television for consumer information.
 - Expanding the local consumer advisor and consumer information activities.
 - Increased product information based on product tests from the National Board for Consumer Policies.
- Actions to improve the buying decisions:
- Compulsory use of simple contract forms.
 - Compulsory information about actual interest in all installment buying.
 - Develop standard forms for consumer complaints.
- Actions to improve the use of products:
- Claim for instructions easy to understand for normal use and when troubles occur.
 - More consideration to an easy use in product design and product development.
 - Seller responsibility for complete and correct information about product use.
- Actions to improve the household shopping organization:
- Prevent the closing down of retail outlets in rural areas.
 - Increased consumer influence in local retail planning.
 - Prohibit further hypermarkets.
- Actions to improve the choice of products in the convenience goods area.
- Compulsory price comparison.

Economic —————
Need satisfaction - - - - -

x) As mentioned before the consequences were measured according to a 3 point scale. The most serious consequences were given 3 points, the next group 2 points and the least serious 1 point.

An important part of this study was to inquire into the differences in values and views between the three subgroups of the panel. These differences are shown in Figure 7.

FIGURE 7

The assessment of the percentage of total number of wrong decisions according to the median assessment of the three subpanels.

————— Local consumer advisers (LA)
- - - - - Representatives of the public authorities (PA)
..... Representatives of the business sector (BR)

- Educate the consumers to read the declarations of content.
- Standard packs.

The business representatives however opposed some actions directed towards their own sector, such as:

- Increased consumer insight into and influence on the product development.
- Reducing advertising volume.
- Brand differentiation prohibited.
- Product variety reduced in certain areas.
- Reduced "bargain" prices.

The professional background of the panel members seemed to have a stronger impact in the assessment of possible policy actions than in their stating the amount of consumer problems.

Analysis and Conclusions

What do these panel assessments measure and how valid are the results? Compared with the subjective and objective indicators discussed in an introductory passage the panel assessment aims at measuring the total consumer problem concept. This measurement procedure covers the problems which the consumers are aware of as well as those they do not know about.

The subjective and objective indicators illustrated in Figure 1 are fairly accurate measures. They are, however, partial and we do not know how valid they are as measurements of the total consumer problem situation. This issue was discussed in connection with the different subconcept in Figure 3.

Validity includes, however, good reliability. In a panel assessment we know very little about the measurement procedure, about what model the individual members use and about what data they feed into the model when they do their assessments. We know however that their assessments are some sort of syntheses of a very complex reality. In a Delphi procedure using panel assessment as the data source, the reliability problem is a validity problem on the individual level. Do the individual members process the data they are supposed to (see Figure 4) and do they generate good information? We just do not know. With these questions one enters another theory of science. Keywords such as dialectical and phenomenological indicate what kind of theory is referred to. According to this theory the reality is too complex to apply any concrete validity criteria. One criterion suggested is to what extent the actors involved accept the results and the interpretations. This subject is however very difficult and more thinking is needed.

The quality of the information gathered was also discussed with the panel. Their reaction was that the assessments could be used as rough measures. I would say that the outcome in this case should be expressed by the interquartile rather than by the median figures (see Figure 5). This means that you can not from the figures say if the proportion of "wrong" decisions is 15 or 35%, you can however see that some steps are more problematic than others.

Another vital question is how the stated problem situation should be interpreted. Do the figures indicate a satisfactory consumer situation or not? According to the panel the consumer situation is unacceptable. Policy actions should be taken. The panel has suggested a long list of possible actions, most of them directed toward suppliers. You can also see from the results to what extent different panel members agree on the suggested actions.

The policy Delphi procedure is not only a possible information and evaluation instrument but is also a tool

for generating ideas about how the stated problems should be cured.

In our study the Delphi assessment was used to gather information about the effects of the policy actions taken up to now on the consumer situation and to evaluate that situation. The results indicate that there are considerable problems. For this kind of statement there is no need for very accurate measurements. The results also show comparisons between different areas. For this kind of assessment there is a need for a somewhat higher accuracy. I think that the method is valid for this kind of assessment too. One has however to take into consideration that if a special aspect has been openly debated recently this may effect the results considerably.

In comparing of situations at two different points in time a rather high accuracy in the measurements is needed. The same holds true if the aim is to compare the situation between different countries. At present I would be hesitant to use the method for this kind of comparisons. More knowledge, experience and thinking are needed.

Finally when judging the value and the possibilities of this method one should keep in mind that this study was a test of the method. It is possible to improve the results considerably by a better design of the assessment procedure.

You should also, when judging the value of this method, ask how good results you could get for the same money using another method. In this aspect I think the panel assessment is quite competitive.

THE PERCEPTION OF FOREIGN PRODUCTS IN FRANCE

Gary Baumgartner, Maitre de Conférences
Alain Jolibert, Maitre Assistant

Abstract

Despite numerous articles which have been published, there seems to have been no real advancement in the development of theories which might explain why consumers view foreign products differently than they do domestic products. This paper reports a study of French perception of foreign products using the theory of perceived risk as criteria for the choice of products to be studied.

Studies of Foreign Product Perception

To date the published research in the field of foreign product perception can be classified into two types: research which essentially eliminates the product from consideration, and research on the perception of apparently randomly chosen specific foreign products and their images.

The first type can be classified as national product stereotype research. The theory has been that attitudes specific to a country emerge when products from that country are perceived. However, these studies are based on either abstract notions such as "Italian Products", or else on products with such low profiles that the consumers naturally only perceive the national origins of the product. For example, Schooler (1965) in studying the Central American Common Market found that evaluations of beige fabric and fruit juice varied according to the country of origin; these evaluations were related to preconceptions regarding attitudes toward the people of that country. Reiersen (1966, 1967) in studies involving American consumers evaluating "Italian Products" and "Japanese Products" found that foreign product quality tended to be stereotyped and that the communication medium used to promote the particular foreign product influenced the stereotyped image. Nagashima (1970) found that when Japanese and American consumers evaluated the notion of "all products" made in a particular country, attitudes varied according to the opinion of the country of origin. Anderson and Cunningham (1972) in using the general classification of "foreign products" found significant differences in the socio-demographic and psychological characteristics of those consumers who were favorably disposed toward foreign products and those who were not.

Whereas these types of studies permit a certain generalization of their results, such generalizations tend to be inappropriate or misleading when applied to specific products. In fact, this is the rationale adopted for the second type of research which involves very specific products such as toys, autos, cameras, etc. Unfortunately, the fact that such products are chosen in the absence of a theoretical framework eliminates the possibility of generalizing the results. A good example of this type of study is presented by Etzel and Walker (1974) who present evidence to show that the general use of national product stereotype can be very misleading. However, the alternative they offer is to restudy each individual product.

Perceived Risk and the Perception of Foreign Products

One theory in consumer behavior which seems particularly appropriate to the study of foreign product perception

is the theory of perceived risk. Perceived risk related to purchase depends upon two determinants (Cox, 1967). First is the degree of uncertainty concerning the suitability of the product. Second is the importance which the consumer affects to the possible adverse consequences of the purchase. Both of these determinants could be intimately linked to foreign products. In addition to the uncertainty linked to the product proper, there is an additional uncertainty due to the origin of the product. As to the possible adverse consequences of the purchase, Jacoby and Kaplan (1972) have operationally defined and studied 5 different varieties of perceived risk, each linked to some form of adverse consequence of the purchase. These five components of perceived risk are financial risk, performance risk, physical risk, psychological risk, and social risk. It would seem that the consumer's stereotype of the product's foreign origin could in fact influence his appreciation of the particular risk involved in the purchase of the product. For example, it would seem that the purchase of life insurance from a company based in a country which is actually experiencing economic difficulties would increase the risk perception involved in the purchase.

The working hypothesis for the study was that perceived risk is a significant component in the judging of foreign products. It was thus expected that:

- foreign products with different types of risk components would be judged differently,
- foreign products would be judged differently than domestic products involving the same risk.
- the perception of the risk component of the product is conditioned by the national origin of the product.

Method

A questionnaire was developed to obtain a measure of consumer interest for each of 16 products varying according to 4 different types of risk and with 4 different national origins. The data were analysed by analysis of variance (ANOVA) techniques.

The Product Classes

Four product classes were chosen to represent one or several specific components of perceived risk:

- playing cards (absence of perceived risk)
- life insurance (financial and performance risk)
- cough syrup (physical risk)
- winter coat (social and psychological risk)

We started with the list of products published by Jacoby and Kaplan (1972) from which we retained certain products and eliminated or substituted others. Certain ones were eliminated on the basis of too strong a domination of the French market by a particular country. For instance, color television was eliminated because German made televisions are quite popular in France whereas English made televisions are unknown as such. Vitamins and aspirins were eliminated as physical risk products on the grounds that the French consumption pattern of

vitamins and aspirins and consequently their perception of these products are very different from that of Americans. Cough syrup is a product which in the French context closely approximates the American perception of vitamins and aspirins. Products were chosen to be appropriate for both sexes.

The National Origins

In addition to French, which was included as a control and as a basis of comparison, the foreign origins retained for study were American, English, and German. These were chosen according to the criteria of equivalence and relevance. The study was limited to the comparison of countries considered to be equal, respected trading partners of France. Countries with low prestige profiles due either to low economic development or to an unfavorable foreign product stereotype were eliminated. This was done on the basis that an overall prejudicial image could dominate so strongly that the perception of the differential product risk, might be affected.

Questionnaire

A seven point scale was constructed with scale values ranging from "extremely interesting" (1) to "not at all interesting" (7). The respondents were placed in a purchasing situation and asked to evaluate each one of 16 products (4x4) presented in random order. Sociodemographic as well as political data were collected but were not analyzed in this study.

Subjects

120 French consumers were interviewed of whom 108 complete questionnaires were retained for analysis. Characteristics of the sample indicate a slight predominance of female (57%) over male respondents. A slight bias of educational level was present with 39% of the respondents had attended at least one year of undergraduate study.

Data Analysis

Given the nature of the data, a fixed-effects 4 x 4 repeated measures randomized block factorial design was selected as the most appropriate analytical technique (Kirk, 1968). This design is justified since each of the 108 subjects was exposed to all levels of the two factors (4 nationalities x 4 product risk classes). Because of this, each subject is technically considered a block; this means that there are 1728 (4 x 4 x 108) cells in the design and no subject x factor interaction is possible.

Analysis and Results

The model for a repeated-measures analysis is appropriate if the variance-covariance matrices are equal and if the pooled variance-covariance matrix is symmetrical (Kirk, 1968). The homogeneity of variance was tested using Hartley's F_{max} test. At a risk of $p < .05$, F_{max} was not significant and thus the assumption of homogeneity of variances within cells can be assumed.

The ANOVA results are presented in Table 1. All main effects as well as the interaction effects are significant ($p < .05$).

TABLE 1

Analysis of Variance for Perceived Interest

SOURCE	df	MS	F
Subjects	107	6.52	
Nationality (N)	3	163.76	109.60 *
Products (P)	3	27.47	18.38 *
NxP	9	5.11	3.42 *
Error	1605	1.49	

* $p < .05$

The study of each effect as well as the interactions were analyzed by a multiple comparison of the means. Dundan's Multiple-Range test, which is a more stringent test procedure than the t test, was used. The significant results are summarized below.

1. French consumers prefer French products to foreign products.
2. All products were judged equal with the exception of the winter-coat which was judged more interesting than the others.
3. Figure 1 presents the interaction between nationality and product. The most preferred combination was the French winter coat, and German playing cards the least preferred combination. A notable exception to the French perception of foreign products is that the English winter coat is not judged as unfavorably as other foreign products. However, the French winter coat was still preferred.

FIGURE 1

Discussion

The results indicate that the French consumer has a very strong preference for domestic products. This is not surprising in light of the values inherent in the French culture, notably individualism and nationalism (Dubois, 1972). This means that the manufacturers of foreign products should not in general stress their origin in brand image strategy.

Perhaps the most interesting results of the study is the extremely good showing of the English winter coat. This is all the more surprising because French winter coats have an excellent reputation, even outside of France. Since the winter coat assumedly implies an inherent social and psychological risk, we advance the hypothesis that foreign products in France are more likely to be purchased if they fall into that category. Indeed this could explain why certain foreign products are popular in France.

The English winter coat might have been appreciated by the French consumers because the English presently enjoy a favorable national stereotype in terms of fashion. From these observations, we advance the second hypothesis that for the French consumer, favorable national stereotypes are ineffectual unless they are related to products with a certain degree of social and/or psychological risk. The implications of this hypothesis for foreign manufacturers would be the following. If a product enjoys a favorable national stereotype in France, the product's publicity could perhaps best be oriented towards an emphasis on the social-psychological risks of the product class. This seems to be the area where foreign products compete most effectively with French domestic products.

Naturally, the results of this study must be tempered in the light of the relatively small sample size as well as the characteristics of the sample. Nevertheless, the results indicate that the theory of risk perception provides an interesting insight on the judgment of foreign products. More important perhaps is that specific objective criteria founded on a theoretical framework were for choosing the products used in this study. Because of this, generalization of the results become possible. In our case, we limited these generalizations to the formulation of hypotheses because of the study's restricted nature and its small sample size. Nevertheless, we hope that our study will act as a stimulus in the area of foreign product perception. Indeed, much remains to be done in the way of practical research as well as theoretical development before foreign product perception is understood.

EXPOSURE TO CULTURAL ACTIVITIES
AND OPINION LEADERSHIP

E. Langeard, University of California, Berkeley
M. Crousillat, Université d'Aix-Marseille
R. Weisz, Université d'Aix-Marseille

Abstract

Consumer services have recently been subjected to systematic research at both conceptual and empirical levels (4,8). This paper focuses on a service activity which objects very much to the use of marketing terminology and concepts and even more so when it is located in the European environment. However, cultural activities and, among them, performing arts have serious attendance problems and difficult communication channels with both their actual and potential audience. Several studies have already been made of attendants' behavior, taking into account usual socio-demographic characteristics (5,6,9).

The objective of this paper is to study the phenomenon related to interpersonal communication within groups of consumers more or less exposed to cultural activities. The first part is devoted to an analysis of the communication process which is precominant for cultural or artistic services. The second part presents the research methodology and the set of hypotheses, and the statistical findings of the survey made the third part. Finally managerial implications that might be drawn from the survey are given.

Interpersonal Communication
And Attendance Of Cultural Services

The decrease of attendance has been a major concern for the last ten or fifteen years in many countries. Several surveys of live theaters' and movies theaters' attendance have been made. From them it is known that in 1974 63% of the total French population have been at least once a year at a movie theater and 69% of the U.S. population of 12 major cities (12, 14). Also in 1974, 22% of the total French population have seen at least one amateur or professional theater play and 31% of the U.S. population of 12 major cities (12, 14). The data do not provide us with information only on attendance levels but also give us clues about why attendance levels are so low. Take the example of theater attendance. Pricing is not a major issue, at least in France where tickets from subsidized theaters are not much more expensive than movie theater tickets. Theater attendance is a highly socialized process. Willingness to go to theaters is related to education level and social status. Translating willingness to go into actual attendance requires the support of a group providing key-information, companionship, and a discussion platform. When people who do not go anymore to theaters are asked why, the reason they give most often is they have been cut off from the group with whom they attended or their new companions do not like to go to theaters. Sixty percent of the population which is not exposed to theater performance give as a main explanation the lack of guides, of "persons who know" among relatives and friends (12). Interpersonal communication has a strong influence on theater attendance and the lack of funds for mass communication which generally prevails increases even more this influence. Mass communication media are more widely used in other performing arts such as film. Reading as a cultural activity is more and more under the pressure of huge advertising campaigns. In both cases, word of mouth has still devastating or

highly positive influence. Therefore, it is necessary to have a better understanding of the consumer search and communication process in the area of cultural services.

From prior research, a conceptual framework has been built which can be applied to many different types of service situations (3). Facing services, consumers have a problem of confidence. It's difficult to test or try services without the occurrence of an excessive cost. Without experience of the service and because its image is unclear, consumers do not know if it fits their needs or not. Finally, the performance and the quality of many services vary unexpectedly. These three remarks apply to cultural services. Potential customers try to sustain their confidence through an active search process of information from those who know, those who have experience the services. It creates optimal conditions for the existence of personal influence.

Methodology and Hypotheses

The self-designated method has been chosen for this survey, with the use of three questions based on Katz and Lazarsfeld (7) and Rogers and Cartano (11) researches. Identifying opinion-leaders by self-report has been validated (2,10,13) although some accuracy is sacrificed for economy and expediency (1).

In a large city of the south of France, three consumers' groups have been investigated in relation with the most important Repertoire Theater Company performing in the city on a permanent basis.

The first consumer group is made of subscribers to yearly programmed events. They agree in advance to attend a minimum number of shows at specific dates. They are given a fifty percent discount on ticket prices.

The second consumer group is made of non-subscribers, paying full price for a show they chose to attend.

The third consumer group is made of a sample of the general population, with quotas based on the repartition of the subscribers' group among occupational categories.

The questionnaire has been sent by mail to the subscribers. A stratified sample of 1,200 people has been used out of 6,000 subscribers. 529 answered the questionnaire which gives a 45% response rate. The questionnaire has been administered by interviews to 202 non-subscribers when attending a show. The sampling method introduces a bias and the probability was high to get a bigger share of "heavy-users" among non-subscribers. The general population sample has been interviewed at home. 205 persons answered the questionnaire, half male, half female. In the two other samples females represent 60% of the total, and the males 40% only.

Theater is generally considered as the most accessible of the performing arts outside of the mass media (compared with opera, ballet, symphony). It was decided to compare exposure to theater with other kinds of cultural activities. We selected one which is directly

related to mass communication: films in movie theaters, another one which does not require to go out and attend to a specific performance, which is book reading.

The questionnaire has been designed in such a way that provides information about universal leaders versus specialized leaders for theaters, films, and readings, and the overlaps between them. The relationship between the intensity of exposure to a specific cultural activity and the amount of information received and diffused by the people has also been investigated as well as the communication process being used. A set of hypotheses has been formulated in accordance with the primary objectives of the research.

On one hand the research had to verify if characteristics generally associated with opinion leadership would show up when studying cultural opinion leaders (H₅, H₆, H₇); on the other hand it had to explore any relationship between opinion leadership propensity and the willingness to subscribe and to commit oneself to a whole program of cultural events (H₂). Besides these two phenomena a third one was added which is the relationship between the extent of overall cultural activities someone has in the three domains (theater, films, reading) and his categorization as an opinion leader and as a theater subscriber (H₁ and H₃). Last it was expected that opinion leadership overlap would be verified between the three categories of cultural activities (H₄). Therefore the set of hypotheses is the following:

- H₁ Subscribers are not only attending more theater performances than non-subscribers; they are also seeing more films and reading more books.
- H₂ Subscribers have a greater propensity to be opinion leaders.
- H₃ Cultural opinion leaders are more exposed to cultural events or more committed to cultural activities than non-leaders.
- H₄ Opinion leadership overlaps exist between the three sub-categories of cultural activities taken into account in the research survey.
- H₅ Opinion leaders look more for information in the mass media than non-opinion leaders.
- H₆ The influence of personal sources of information is stronger on non-opinion leaders than leaders.
- H₇ Cultural opinion leaders are disseminating more cultural information than non-opinion leaders.

Findings

All hypotheses have been confirmed totally or partially except the one dealing with opinion leadership overlap and the one expecting theatre subscribers to be "heavy users" of performing arts. One of the unexpected findings is the lack of openness of the subscribers' group. This has important marketing implications. This study has demonstrated once more, and after many other researches with similar results, that it did not exist a significant relationship between opinion leadership and socio-demographic variables such as age, sex, occupation, family status or income.

1. Subscribers have a "middle of the road" pattern of performing arts consumption. They are less likely heavy book readers than non-subscribers or the general population.

Table 1 presents selected data for both extremes of non-consumption and heavy-consumption. Chi-square tests have been computed for each consumer group and each type of consumption taken by pairs. All differences are statistically significant (probability .001) except the one about book reading between the non-subscribers'

sample and the sample of general population (χ^2 test value 2.13, d.f. 5).

The sample of general population is heavily loaded with a high percentage of people who do not go out. The same sample has the highest percentage of people who read more than three books a month. Let's remember that this sample is not representative of the total population. It has been built with the same socio-demographic characteristics of the two other samples. For instance, among other traits, the level of education is similar and strongly skewed toward secondary and university education. The level of cultural interest is not the main difference between this sample and the two others. The gap between them is related to time budget, how people allocate their leisure time, are they in favor of going out or do they choose to stay home. More explanation of time budget is needed to get a better understanding of cultural consumption patterns. The two groups of subscribers and non-subscribers differ with regards to their homogeneity. The subscribers' group is very homogenous. Very few people in this group do not go to movies or do not read. At the same time, their theatre attendance does not reach the level of non-subscribers. One explanation might be that a majority of subscribers have their cultural needs fully satisfied with the theatre company performances for which they have subscribed. On the contrary among the very heterogeneous non-subscribers' sample, we have an uncommitted group with a pattern of high cultural consumption and strong desire of preserving their freedom of choice. As it can be expected we have in the same sample another group whom level of involvement with performing arts is very low. Nin percent of the non-subscribers' sample declared that their theater attendance was exceptional and due to unusual events.

TABLE 1

(% of each sample)	Subscribers	Non Subscribers	General Population
Do not go to movie-theatre	11.2	22.3	39.5
Do not go to theatre	0.6	9.4	46.3
Do not read books	5.5	10.4	11.2
Go to movie-theatre more than four times per month	7.4	10.9	5.9
Go to theatre more than ten times per year	9.5	12.4	2.9
Read more than three books per month	21.4	25.6	29.8

2. Subscribers have a greater propensity to be cultural opinion leaders than the general population; however, when their opinion leadership is compared with those of non-subscribers no significant statistical differences have been found.

Percentage differences shown in Table 2 are statistically significant between the general population and the subscribers' samples (χ^2 with probability .0001) or the non-subscribers' group (χ^2 with probability .05). It is

possible that the lack of statistical difference between subscribers and non-subscribers is due to a bias when administering the questionnaires - by mail for subscribers, by interviews within the theatre for non-subscribers. Whatsoever, the second hypothesis - H_2 - is not fully verified.

TABLE 2

(% of each sample)	Subscribers	Non Subscribers	General Population
Leaders	29.1	23.5	15.1
Non-leaders	70.9	76.5	84.9

Twenty-nine percent of the subscribers, twenty-three percent of the non-subscribers and fifteen percent of the general population viewed themselves as exercising some cultural influence on relatives and friends. Based on three distinctive cultural areas such as theatre, films and books, we look at these percentages as a measure of general opinion leadership and influence within the multi-faceted domain of culture.

TABLE 3

Own Advice Recently Asked About:	Subscribers		General Population
	Subscribers	Non Subscribers	General Population
A film	69%	56.9%	55.1%
A theatre play	60.5%	32.8%	17.6%
A book	58.2%	62.4%	60%

As it can be seen in Table 3, subscribers looked at themselves as opinion leaders about films and plays, much more than non-subscribers or the general population. Advices about books infer a similar pattern of influence when the three groups are compared.

- Cultural opinion leaders are more exposed to cultural events or more committed to cultural activities than non-leaders. This hypothesis - H_3 - is fully confirmed. Chi-square tests have been used on all differences (shown on Table 4) between leaders and non-leaders are statistically significant.

TABLE 4

% of each sample	Table 4					
	Subscribers		Non Subscribers		General Population	
	L	NL	L	NL	L	NL
Go to movie-theatres more than twice a month	39.6	30.7	57.4	35.3	41.9	21.3
Go to theatres more than five times per year.	38.3	27.5	31.9	14.4	16.2	4.6
Read more than two books per month.	55.8	38.7	68.1	43.2	81.6	43.1

- Opinion leadership overlaps exist between the three sub-categories of cultural activities taken into account in the research survey. However, this overlap varies greatly among the three groups that have been surveyed.

In Table 5 and for each three samples, the differences between observed dual leadership and estimated dual leadership have been displayed. When their differences are statistically significant, opinion leadership overlap is verified. For the subscribers' group overlap exists in all cases. Overlap is verified only in two cases with the non-subscribers' group. As for the general population sample, not only opinion leadership overlap does not exist, but in one case, movie-theatre leaders and theatre leaders, the observed dual leadership is smaller than the estimated dual leadership. Based on these three samples it seems that opinion leadership overlap is related to the cultural consumption pattern of each group. In the case where the interests of the group is strongly focused on one activity, opinion leadership overlap is unlikely. Once more it brings the question of the existence of universal opinion leaders. This study shows some evidence of the contrary. Opinion leadership overlap is verified when a group of people look at various activities as parts of a common domain. If for another group these same activities have very little in common, the overlap is not going to be verified.

- Opinion leaders look more for information in the mass media than non-opinion leaders and the influence of personal sources of information is stronger on non-opinion leaders than leaders.

Both hypotheses H_5 and H_6 are verified. This is a confirmation in the cultural and artistic domain of opinion leaders characteristics which have been well tested elsewhere.

Table 6 clearly shows the differentiation between opinion leaders and non-opinion leaders on what sources influence them most. A usual scenario would be that of an opinion leader reading in magazines the analysis of a film by one or several critics and as an intermediate expert he would transmit and influence other people looking for advice.

- Cultural opinion leaders are disseminating more cultural information than non-opinion leaders.

This hypothesis H_7 has also been verified. From previous research done by many authors on interpersonal communication and diffusion of information, we had to expect such an active behavior of cultural opinion leaders. This behavior has been approached through two questions: last time you go to the theatre, how many people have been told by you of your project? and did you try to decide people to come with you? On Table 7 all significant statistical differences between leaders and non-leaders of subscribers' and non-subscribers' samples have been reported.

- Subscribers appear to live in a closed world. Very few people like to go to the theatre alone. Going out to the theatre is a highly socialized experience. Ninety-three percent of subscribers and ninety-six percent of non-subscribers do not usually go alone to the theatre. However, these two groups of subscribers and non-subscribers rarely met. During their last theatre attendance, only six percent of all subscribers were joined by non-subscribers, and only ten percent of all non-subscribers were joined by subscribers. Finally the subscribers network of personal relations seems more

restricted and smaller than the one of non-subscribers. Sixty-four percent of subscribers told five persons or less about their intention to go to the theatre instead of only fifty-five percent of all non-subscribers.

Managerial Implications For The Performing Arts Organizations

Most services have to be fully experienced before consumers can really decide if their expectations are met. Of all consumer services, performing arts are the least standardized and the most influenced by situational variables. Rather than searching and processing complex information on their own, many consumers look for personal help. This explains the importance and the intensity of interpersonal communication which takes place in the cultural and artistic domain.

This situation has to be well understood by any art manager in charge of the design and the implementation of a communication policy. He has to recognize group influence which may very successfully counterbalance the influence of mass communication. Looking for the identification of opinion leaders and some way of communicating with them, is another good reason leading to the implementation of subscription policy, aside of the obvious need for loyalty and fidelity. Information from and to the subscribers is easy to get. This direct two-way of communication should be used more systematically, more creatively and more selectively. A panel of self-designated opinion leaders should be selected in order that no more than 25% of the subscribers data bank would be actively used. Not only should the season program be mailed for once, but systematic reminders of coming events should be done by mail or by phone. Creativity should be applied to both the style and the content of communication.

This communication policy with selected subscribers should be handled by art managers with a clear understanding of its limitations. One of them being the lack of openness of the subscribers' group. Opinion leaders belonging to this group are not likely to spread a cultural influence to a large number of people. It is also unlikely that they will have a natural tendency to recruit new subscribers. So the marketing plan of performing arts organizations has to recognize the existence of a de facto segmentation of subscribers and non-subscribers. The marketing mix should be adjusted to each group and specific actions should be taken for communicating with opinion leaders belonging to the non-subscribers' is very eclectic and their loyalty very difficult to obtain. However, a two sided, very informative communication should be well received by them and develop a quality image of the organization.

IMAGERY-ELICITING STRATEGIES:
REVIEW AND IMPLICATIONS OF RESEARCH

Kathy A. Lutz, University of Southern California
Richard J. Lutz, University of California, Los Angeles

Abstract

Recent research in cognitive psychology has focused on the use of illustration and imagery as facilitators of learning in a variety of situations. Results of this research are reviewed, with a key distinction being drawn between imagery-eliciting strategies and mental imagery. Speculations regarding the use of imagery in advertising are made in several important decision areas: advertising design and creativity, media selection and scheduling, measuring advertising effectiveness, and advertising regulation and public policy.

Introduction

The field of advertising has a long tradition of borrowing explanations for advertising effects from psychology. Among the more prominent and fruitful constructs which have been used are those associated with various learning theories, ranging from classic contiguity principles to the more currently fashionable cognitive information processing approach. A major trend in recent research in cognitive psychology has been the study of imagery and its effects on human learning and memory. This rich research tradition has remained relatively obscure to consumer researchers, although it would appear to have major implications for the study of advertising effectiveness. The purpose of the present paper, therefore, is to provide a brief review of the research on imagery in psychology, followed by a discussion of possible implications for advertising decision-making.

Review of Research on Imagery

Research on imagery has become increasingly popular recently, perhaps because the demonstrated effect of imagery is quite dramatic. Folklore suggests that a picture is worth a thousand words, yet it has been the task of empirical research to discover the full meaning and implications of this truism. In general, the literature on imagery indicates that presentations which elicit imagery are better remembered and more positively evaluated than presentations which do not. In this section, three strategies for eliciting imagery will be defined and their relationship to one another discussed. After reviewing research on each of the strategies, this section concludes with a summary and discussion of research findings.

Definition of Imagery

Imagery is defined as a mental event involving visualization of a concept or relationship. Despite its recent "re-discovery" by psychologists, mental imagery is still a rather poorly understood construct. One conception of mental imagery is physiologically based, wherein picture viewing and reported mental visualizations correspond to increased right hemisphere activity in the brain, while reading and verbal behavior correspond to a higher activation of the left hemisphere (Calloway & Harris, 1974; Galin and Ornstein, 1972; Morgan, McDonald, and MacDonald, 1971). These findings are based on studies with normal adults, but studies with brain-damaged or "split-brain" patients provide more dramatic evidence that the two sides of the brain differ. Nebes (1974) reviewed this research and con-

cluded that the two sides of the brain are not necessarily specialized for storing different types of stimuli but rather process information in different ways. The left hemisphere processes information analytically and propositionally, while the right hemisphere involves holistic or parallel processing.

The implication of brain research is that mental imagery may be better understood in terms of parallel processing than picture processing per se. The parallel processing notion is compatible with the convincing arguments and evidence that memory is propositional with one common storage format (Anderson and Bower, 1973; Norman and Rumelhart, 1976; Palmer, 1975; Pylyshin, 1973). In other words, there may be no storage distinction between visual and verbal memory, but rather the information stored as propositions or schemata could be processed in different ways. Picture processing would not, however, result in a stored representation that is identical to that resulting from processing an equivalent verbal stimulus. The differences in storage representation are caused by differences in processing rather than by different and separate storage systems. This is a difficult concept and the reader is referred to Palmer (1975) for a discussion of how mental images may be represented in a common, propositional storage system. The point is that imagery processes can affect learning and memory even though images are stored in the same type of knowledge structure that accommodates verbal information.

These speculations about the nature of mental imagery do not explain how or why mental imagery aids memory. However, the definition of mental imagery offered here emphasizes that mental imagery is a way to process information. This working definition of mental imagery is useful in interpreting and applying research results, as well as for making speculations regarding theoretical explanations of imagery processes and effects. Unfortunately, an adequate theory of imagery and visual information processing does not yet exist, despite some recent progress (Paivio, 1971; Palmer, 1975; Yuille & Catchpole, 1977).

Imagery-Eliciting Strategies

Mental imagery is generally thought to be elicited by one of the following three types of strategies, or external treatment variables: 1) pictorial stimuli such as pictures, graphs, etc.; 2) concrete verbal stimuli; and 3) imagery instructions or direct inducements. Each of these strategies will be defined and described in turn.

Most researchers accept the common dictionary definition of a picture, using their intuition to identify pictorial material. Here, pictorial material (also referred to as a picture or an illustration) is defined as any two-dimensional representation in which the stimulus array contains at least one element that is not alphabetic, numeric, or arithmetic. According to this definition, an equation or arithmetic problem would not be a picture while a word containing a "picture-letter" would be considered pictorial. One well-known example of an illustration involving a "picture-letter" is the logo for Ford Motor Company in which a light bulb replaces the 'o' in "Ford." Illustrations should also be conceptually related in some way to the topic of the communication. The effectiveness of the picture may depend on how the picture relates to the verbal information; this will be

treated later in the paper. However, pictures which are completely unrelated to the topic of the message will not be treated in this paper as they are assumed to be of no desirable consequence. For example, the use of sexy models in ads, when the model has no relationship to the product whatsoever, does not facilitate memory and may even promote negative attitudes toward the product and company (Marketing News, 1977; Steadman, 1969). On the other hand, seemingly unrelated pictures could conceivably set a mood that promotes desirable affective outcomes. For purposes of delimitation, only pictures that are conceptually relevant to the message content will be treated in this paper.

The second type of imagery strategy--concrete verbal stimuli--is perhaps the most well-defined operationally. "Imagery values" for hundreds of words have been established by having readers rate the ease with which a word arouses sensory images. These ratings are available for nouns (Paivio, Yuille, and Madigan, 1968), for verbs (Lippman, 1974), and for words commonly used by children (van der Veur, 1975). Imagery ratings are independent of other word attributes such as word frequency and associative meaningfulness, so that this variable can be studied independently of the factors that affect recall.

The two types of strategies discussed so far are examples of external stimuli that presumably affect learning and memory indirectly by eliciting internal or mental imagery. Giving instructions to the recipient to form mental pictures is a more direct way to elicit this type of mental processing. Imagery instructions refer to a statement to the learner that directs him or her to form a mental picture of the concept to be learned.

The common thread running through all three strategies or experimental treatments is the assumption that they elicit, to some degree, mental imagery, which is in turn believed to enhance memory and learning. The research findings with respect to the effects of each of the strategies on learning are now summarized.

Research on pictures. Research in this area includes studies that test the effects of

- 1) supplanting (i.e., replacing) verbal information with pictures or
- 2) supplementing (i.e., repeating) verbal information with pictures.

The findings are grouped by type of material learned in the studies including single items, paired associates, and connected discourse (i.e., sentences or stories).

Paivio (1971) reviewed studies that compared memory for pictures to memory for words. The findings indicated that pictures are remembered better than either concrete words or abstract words. Memory for visual information greatly surpasses word memory according to several more recent studies (Frdelyi and Becker, 1974; Haber, 1970; Nelson and Brooks, 1973; Paivio and Csapo, 1973). The superiority of memory for pictures has been demonstrated using advertising stimuli in an earlier study (Shepard, 1967), which showed that pictures used in magazine advertisements are easily recognized again. Comparing memory for pictures to word memory, as many of these studies did, may be inappropriate, however. The verbal equivalent of a picture is probably not a single word but rather a story or description. Since memory for words in context is better than for an unconnected word list, picture memory may not surpass verbal memory if the two types of information are equated for meaning. Another factor that may contribute to the superiority of visual memory is schematic similarity among the pictures to be remembered (Nelson, Reed and Walling, 1976). In that study, pictures that were graphically similar, were not better remembered than words. This finding suggests that other variables

should be controlled when testing the pictorial superiority effect.

Paivio (1971) also discussed studies that tested the effect of presenting a picture along with its verbal counterpart on word learning. Words were recalled better when the subject saw its accompanying picture; again, similar results have been obtained using advertising stimuli. Students recalled more company names when they had seen a pictorial depiction of the name (Lutz and Lutz, 1977). In that study, actual company names and pictures were taken from the Yellow Pages of a phone directory. Not all companies have the kind of names that lend themselves to pictorial depiction, so stimuli used in the study varied in terms of the degree of correspondence between the company name and its graphic depiction. Some pictures in the study were direct translations of the name, such as the picture for O'Bear Abrasive Saw Company which showed a bear holding a large letter "o". Other verbal-visual correspondences were not as direct. A cactus cowboy depicted Western Glass Company and Weiss Auctioneers used an owl to symbolize their name. It could be that pictures which are equivalent to their verbal counterparts facilitate memory for the company name better than pictures with a lower degree of correspondence. Perhaps future research on how verbal and visual information may be equated on the dimensions of meaning and amount of information will aid research efforts on this issue.

There are many studies on paired associated learning which indicate that a supplementary picture helps the viewer associate the two words to be learned. Learners shown a picture relating two items in a paired-associate learning task typically have significantly higher retention scores than those not presented with a picture and told only to learn the association through repetition (Davidson, 1964; Kerst and Levin, 1973; Lippman and Shanahan, 1973; Reese, 1965). One necessary condition for the facilitative effect is the interactive nature of the picture. An interactive picture integrates the two items in some mutual or reciprocal action. When the picture is not interactive and the items are depicted or imagined side by side, paired associate learning is not necessarily facilitated (Bernbach and Stalonas, 1973; Bower, 1972; Neisser and Kerr, 1973).

Interactive pictures facilitate memory for ads according to a study mentioned earlier, which used company-product pairs and their accompanying pictures from ads in the Yellow Pages of a telephone directory (Lutz and Lutz, 1977). The group receiving the interactive imagery treatment remembered significantly more company names than the non-interactive imagery group. Also, while the interactive imagery group remembered more brand names than its control group who saw only the company-product names with no accompanying pictures, the non-interactive imagery group did not differ significantly from its control group.

The interactive imagery group in the Lutz and Lutz (1977) study received two types of pictures, including picture-interaction items and letter accentuation pictures. In the latter type, some letter or letters in the brand name are made to look like the product or one of its characteristics. The logo for Mullin Lumber Company, in which the letters of "Mullin" are drawn as wood grain boards, is an example of letter accentuation. Picture-interaction items unite a depiction of the brand and of the product or service in one picture. An example is the logo for Jack's Camera Shop which shows a playing card jack holding a movie camera to his eye. Students remembered picture interaction items better than letter accentuation pictures, which was also the finding in an earlier study (Lippman and Shanahan, 1973).

One dimension of an interactive picture that has not yet been investigated is the "dynamism" or animation of the

interaction. Interactive pictures may be either dynamic or static, with dynamic interactions probably being the more memorable type. Television ads provide examples of dynamic interactive pictures in which the interaction is animated. Research on attention and reinforcement indicates that a visual stimulus change in the environment elicits attention to that action by the viewer (Kish, 1966). So the viewer's attention can be drawn to the important information by animating the interaction.

Presenting pictures along with stories and other forms of connected discourse is also facilitative. As mentioned before, pictures can accompany verbal material by supplanting or replacing part of it and by supplementing the verbal information. Although findings are not conclusive, some studies indicate that learning and attitude are positively enhanced when pictures replace some of the verbal information (Booher, 1975; Rigney and Lutz, 1976). When pictures completely replace the verbal text, however, comprehension may not be facilitated. Children who received a story in the form of a series of pictures remembered no more than students who read the printed text (Levin, 1973). Levin speculated that the pictorial treatment would have been more beneficial with some accompanying verbal labels. Another explanation of Levin's result is that his verbal comprehension test may have failed to test the kind of knowledge acquired by the pictorial treatment.

Most investigations in the literature on illustration have tested the effect of supplementing verbal material with pictures and have assessed outcomes with verbal posttests. In an earlier review, Samuels (1970) concluded that "pictures, when used as adjuncts to the printed text, do not facilitate comprehension." However, several recent studies indicate that supplemental pictures facilitate learning under some circumstances at a variety of age levels. Recent findings indicate that children learn more from a prose passage when it is accompanied by pictures (Bender and Levin, 1976; Lesgold, Levin, Shimron and Guttman, 1975; Rohwer and Harris, 1975; Rohwer and Matz, 1975). Illustrations also aid children's memory for more difficult material that contains new concepts (De Rose, 1976). Seeing pictures apparently helps adults and high school students learn new concepts (Dwyer, 1972; Holliday, 1975). In Dwyer's study, pictures aided performance on graphic or drawing tests but not on verbal learning measures, indicating that pictures may result in non-verbal outcomes.

One recent study, however, found no facilitative effect for supplementary illustrations with adult populations. College students who read a passage about revolutions did not benefit from supplemental drawings, but mental imagery instructions did facilitate their performance (Rasco, Tennyson, and Boutwell, 1975). A second study yielded a similar outcome with high school seniors. Perhaps, when the visual information and verbal information are redundant and the verbal information is easily understood, illustration may not be beneficial for adult learners.

Research on pictures also indicates that learning is improved when students are asked to draw their own illustrations. Subject-generated pictures facilitated paired-associate and word learning (Bull and Wittrock, 1973; Wittrock and Goldberg, 1975), story comprehension (Lesgold, Levin, Shimron, and Guttman, 1975, Snowman and Cunningham, 1975), and recall of new concepts (Dansereau et al., 1975; Rasco, Tennyson, and Boutwell, 1975).

Although many ads are presented in a story format with accompanying pictures, no studies have empirically tested the differential effects of supplementing or supplanting the story line with pictures.

Research on concrete verbal stimuli. Research findings on the imagery value of verbal stimuli generally indicate that concreteness facilitates memory for words, paired-associates, and connected discourse. Studies will again be grouped around these three stimulus categories.

Paivio (1969) reviewed the effects of concreteness or imagery value on word recall. He cited a series of experiments that varied imagery value and word meaningfulness independently (or partialled out meaningfulness, and found that word recall was positively related to the level of word concreteness. More recent studies have confirmed the finding that words high in imagery value are remembered better than words of low imagery value when other factors affecting recall such as meaningfulness and frequency are held constant (Craig, 1973; Elliott, 1973; Griffith and Johnson, 1973; Paivio and Csapo, 1973; Wortman and Sparling, 1974).

No published studies have yet investigated the effects of word concreteness on recall of brand or company names. According to the research evidence, names that are concrete and picturable should be more memorable than abstract words, proper names, or abbreviated names.

Concreteness also affects paired-associate learning. When words are to be associated, memory for the pair can be affected by concrete connective words. Several studies varied the kind of connective words used to relate word pairs and found that verbs were more effective in facilitating memory for the pair than conjunctions or prepositions (Reese, 1965; Rohwer, Lynch, Levin and Suzuki, 1967). Although imagery values for the connecting words were not compared, it seems quite likely that the verbs had much higher imagery values than the conjunctions and prepositions used in those experiments. Other results suggest that embedding the word pair in the context of a sentence aids memory for the pair (Davidson, 1964; Levin, Davidson, Wolff and Citron, 1973; Lippman and Shanahan, 1973; Milgram, 1967). The sentences related the word pairs with action verbs, which probably made the association of the pair more concrete and picturable.

The use of concrete connectives in advertising messages has not yet been investigated. The research evidence suggests that messages which use concrete words to connect company name and product claims should make the messages more memorable. Assuming that action verbs are more concrete than linking verbs (although this has yet to be established empirically), the more effective ad will tell what the product does (its usage benefits) rather than what the product is (its attributes).

Connected discourse such as sentences prose passages, and stories, is better remembered if it contains concrete words rather than words of low imagery value (Anderson, 1974; Johnson, Bransford, Wyberg, and Cleary, 1972; Montague & Carter, 1973; Yuille and Paivio, 1969). However, words used in advertising stories and vignettes have not been systematically varied to test the thesis that concrete words would make the brand name and product claims more memorable.

Research on imagery instructions. The results of numerous studies on mental imagery instructions are reviewed and discussed by Paivio (1971) and will be only briefly summarized here. Giving learners imagery instructions facilitates paired-associate and word learning and the effects are much like those reported in the previous section on pictures. The interactive feature of the resultant image remains a necessary condition for maximum effectiveness. Learners told to mentally imagine two objects in interaction remember more word pairs than learners told to mentally picture the objects side by side or on opposite sides of a room.

One advantage of interactive imagery, as opposed to experimenter-supplied interaction pictures, is that the interaction can be idiosyncratic and bizarre, which has been recommended by ancient as well as modern day mnemonists (Lorayne & Lucas, 1974). The claim that bizarre images facilitate memory was not supported, however, by a recent empirical study (Nappe & Wollen, 1973). In fact, students in that study took longer to form bizarre mental images than "common" images. Although bizarreness does not appear to be facilitative, the related attribute of uniqueness or distinctiveness may be an effective attribute of facilitative mental images. A recent study varied the level of schematic and conceptual similarity of pictures and found that visual recall was no better than word recall under conditions of high schematic similarity (Nelson, et al., 1976). These results suggested that pictures or mental images which are too common may be confused with other visual information and may not be remembered.

Although there are no studies on the effects of imagery instructions on associating brand names with product claims in advertising, one particular ad provides an example of how to induce a common yet distinctive image. A Johnston's Yogurt ad directs the listener to "look for the sunny yellow cups" which probably elicits a mental image that is easy to form and yet is distinctive from other, similar products (unless other yogurt manufacturers use yellow containers as well).

Recent findings indicate that imagery instructions also facilitate memory for connected discourse. Children remember more after reading a passage when they receive imagery instructions, especially if the instructions are preceded by training in the use of this strategy (Kulhavy and Swenson, 1975; Lesgold, McCormick and Golinkoff, 1975; Pressley, 1976). Children may not benefit from imagery instructions, however, if the material to be learned is new or difficult (De Rose, 1976).

The pattern of effects is similar for adults. Imagery instructions facilitate memory for easy material such as sentences and narratives (Anderson, 1971; Anderson and Hiddi, 1971; Rasco et al., 1975). Imagery instructions per se appeared to have no effect on memory in one study, but closer analysis reveals that mental imagery did facilitate learning (Anderson and Kulhavy, 1972). Students in that study who reported that they learned the text passage by using "mental pictures" remembered more than students who reported not using mental imagery. The findings of this study are important because, while the nominal treatment of imagery instructions may fail to elicit mental imagery, reported use of mental imagery does correspond to increased recall. Another study showed no overall benefit from imagery instructions during a limited time period (Lesgold, Curtis, De Good, Golinkoff, McCormick and Shimron, 1974). However, adults who received the imagery instructions remembered more from the first half of the passage than did control subjects, suggesting that the imagery strategy required more time but was beneficial. The authors noted that imagery should not be considered a useful strategy if it produces no learning gains per unit time.

Directing adults to use mental imagery while learning new concepts may not facilitate learning, according to recent findings (Rigney & Lutz, 1976). The failure of mental imagery instructions to aid new concept learning in both adults and children is plausible because it would not be expected that people are capable of forming mental images of concepts with which they are not yet familiar.

One problem with trying to induce the learner to use mental imagery while reading is that the act of reading tends to interfere with imagery production, because both activities presumably involve some visual information processing. Findings by Levin and Divine-Hawkins (1974)

indicated that imagery instructions were more facilitative when children listened to a passage rather than read it. Brooks (1967) also found that mental imagery was more readily elicited during listening than reading by adults. Most of the studies on imagery instructions told the subject to visualize while reading, so the results of those studies may have been even stronger if the subjects had listened to, rather than read, the verbal information.

Telling an advertising audience to form mental imagery while hearing or reading an advertising message has not been empirically tested, but the literature on this treatment suggests that it could facilitate memory for the ad. Imagery instructions may be especially effective with auditory media such as TV and radio, which would allow listeners to form idiosyncratic mental images while listening to the message.

Discussion and Summary

Outcome measures. The effects of imagery strategies must be viewed relative to the way learning outcomes are assessed. Tests of comprehension are most often only verbal, meaning that only verbal outcomes of presentation mode are assessed. Several studies tested the effects of pictorial treatments with graphic retention measures, which tapped knowledge not assessed by the verbal posttests (Dwyer, 1972; Lutz and Rigney, 1977).

Recent evidence on left and right hemispheric processes of the brain suggests that the left brain often dominates in processing and retrieving verbal or propositional information while the right hemisphere processes and retrieves information holistically. Levy, Trevarthen, and Sperry (1972) presented a dramatic demonstration of this difference when they showed split-brain patients a chimerical picture such as a face of which each half is actually from a different face. Using tachistoscopic methods, each half of the picture is sent to a different hemisphere and because of the nature of the patients' surgery, the hemispheres cannot communicate as in the normal brain. Results indicate that when the patient is asked to point to the face that he saw (i.e., recognize it), he points to the face corresponding to the half sent to the right hemisphere with no realization that the presented stimulus was composed of two different faces. When the patient is asked to verbally describe the features of the face that was shown (i.e., recall it), however, the face corresponding to the half projected to the left hemisphere is retrieved and described. This is convincing evidence that the left hemisphere is analytical and propositional while the right is holistic. But, more important to the point of assessing outcomes of treatments, this study demonstrates that the retrieval task may determine the nature of the information retrieved. Although this evidence comes from patients with altered brain function, normal individuals may display recall and recognition differences to some degree.

In assessing advertising effects, asking consumers to recall and state ad claims is probably a left hemisphere task. In contrast, a recognition test requiring the consumer to identify illustrations used in an ad may elicit more right hemisphere processing. The nature or type of information retrieved using these two approaches may differ. One recent study suggests that graphic assessment techniques reveal information stored in memory that is not necessarily retrieved by verbal measures (Rossiter, 1976).

Most of the outcomes assessed by the studies reviewed in this section dealt primarily with cognitive rather than affective outcomes of imagery-eliciting strategies. A few of the studies assessed the effects of imagery on attitude and found that imagery-eliciting strategies seem to promote positive attitudes in addition to

facilitating learning. Samuels (1970) concluded in his earlier review on imagery effects that although pictures may not always affect cognitive outcomes, they do seem to facilitate favorable affective outcomes. More research is needed to clearly establish the effects of imagery on attitude.

Imagery-eliciting strategies may also affect decision making processes. Some evidence suggests that people weight concrete examples more heavily than abstract information when making judgments or decisions (Nisbett, et al., 1976). Thus outcomes other than learning alone should be considered when determining the effects of imagery-eliciting strategies.

Summary of facilitative conditions. Although findings are mixed, the literature on imagery generally indicates that pictures, concrete words, and mental imagery instructions facilitate memory and may enhance attitude as well. Individual differences in prior knowledge may influence the size of the imagery effect. Pictures may not help a reader who already knows a lot about a topic. For example, adults in the Rasco et al. study (1975) did not benefit from seeing pictures. These readers did benefit, however, by forming their own mental images while reading. The opposite pattern of results was found in a study with children who were learning material intended to be difficult or instructional. The children remembered more when adjunct pictures accompanied the text than when they were given mental imagery instructions (De Rose, 1976).

These seemingly conflicting results may be explained by an interaction hypothesis that mental imagery is facilitative under conditions of prior familiarity while pictures are more beneficial when the learner has less prior knowledge. There are several plausible arguments favoring this hypothesis. People should not be capable of forming mental images of concepts that they have not yet acquired, so a mental imagery strategy would be rather ineffective for new concept learning. Pictures, on the other hand, do aid learning of difficult material but may not make any difference when an adult reads prose text that is easy to comprehend.

Another way to look at the differential effectiveness of these strategies is that learners may benefit more from their own strategies than imposed strategies, under certain conditions. Bobrow and Bower (1969) demonstrated that subject-generated verbal mediators were superior to experimenter-provided verbal mediators in a paired-associate learning task. Since that study, other researchers have turned attention to the potential value of instructing or training learners to apply their own learning strategies. Picture drawing and mental imagery generation are examples of learner-generated strategies that appear to facilitate learning when the learner is capable of performing these tasks.

Other variables that may affect the strength of the imagery effect include characteristics of the picture such as figural interaction and dynamism and the relationship between the verbal and visual information in a message. Pictures must be related to but not always repetitive of passage content to be facilitative. Adults who are good readers may not benefit from viewing a supplementary picture when they read simple narratives or familiar material. When the illustration presents additional information, however, picture viewing results in more effective and efficient learning. Children or learners with little prior knowledge seem to benefit from illustrations whether they supplement or supplant some of the verbal information. Hence, the learner's prior knowledge may interact with the relationship of verbal and visual information.

A consideration of the principles and effects of imagery is relevant to a number of important decision variables in the advertising mix. While little empirical research on imagery and advertising has been undertaken to date, the perspective provided by the imagery literature can, nevertheless, be useful in structuring advertising decision-making along lines consistent with imagery principles.

The following discussion of advertising implications is not intended to be exhaustive and conclusive, but rather speculative and limited to the areas showing the most obvious potential benefits of adopting an imagery perspective. The areas to be considered include the use of imagery in 1) advertising design and creativity, 2) media selection and scheduling, 3) measuring advertising effectiveness, and 4) advertising regulation and public policy.

Advertising Design and Creativity

Imagery has its most obvious implications in the area of advertising design. For instance, the use of pictures in ads is hardly a new idea to advertisers, who have relied on illustrations for years in the quest for more interesting and persuasive advertising campaigns. However, the principles of imagery suggest a richer perspective on the problem of using pictures to communicate.

Some illustrations are more effective than others. For instance, the use of interactive imagery, wherein a brand name is pictorially portrayed in relation to a product concept, should result in increased association of the brand and its attributes or benefits as demonstrated by Lutz and Lutz (1977). In contrast, a non-interactive image portraying either the brand or its benefits (or perhaps both, but not in a single, integrative picture) may result in retention of the pictorially presented stimulus, but not the critical relationship between the brand and its benefits. Krugman (1978) has argued for the use of "memorable" illustrations as an aid to effective advertising. The concept of interactive imagery suggests that it is not enough that the illustration be memorable but that it must also depict the relationship between the brand and its proffered benefits. A Los Angeles exterminator named Arrow Pest Control uses as its logo an insect pierced by an arrow. Remembering the illustration also means remembering the brand name (Arrow) and its product offering (bug killing). A cursory examination of much contemporary advertising suggests that many advertisers conjure up dramatic illustrations which do little to communicate the brand-benefit linkage.

From an imagery perspective, then, appropriate illustrations can vividly portray information - i.e., the concepts that the advertiser wishes to communicate. When pictures do not communicate relevant information, they should not be expected to enhance advertising effectiveness, except perhaps indirectly, as under the distraction hypothesis (Bither, 1972; Wright, 1973). One important issue in treating illustrations as information presentations is whether they should serve as supplements to, or as substitutions, for, verbal presentations of the same information. While the former use would imply some redundancy in the commercial message, this redundancy may constitute a type of repetition within the ad, which is presumably a desirable feature. Additionally, the use of pictures in lieu of verbal copy claims may be hazardous, in that audience interpretations of pictures may be more varied than comprehension of verbal claims. A picture may indeed be worth 1000 words, but it may not be the same 1000 words for all members of the audience. The use of concurrent verbal stimuli may help to homogenize response to the illustration while preserving the increased vividness gained by use of the picture.

Thus far, the use of imagery in advertising design has focused on external imagery in the form of pictures and illustrations. Pictures are assumed to be facilitative because they elicit internal or mental imagery. Mental imagery may be induced through means other than the presentation of pictures, however. The use of concrete terms, verbal descriptions of pictures, and imagery instructions are other ways to elicit mental imagery in the mind of the potential consumer.

An interesting consideration in the use of nonpictorial spurs to mental imagery is the possibility that there are two operators at work in the process. One operator is the ability of the consumer to come up with an appropriate image without being shown one by the advertiser. It would seem likely that this ability is not equally present in all audience members and that some will be "lost" at this step. The second operator conceivably at work is the idiosyncratic nature of the images that are created. The power of the human imagination is vast and may supercede any advertiser-provided stimulus in being personally relevant or vivid to the consumer. Thus, for those consumers who do form mental images, the resultant images may be much more powerful than those stimulated by an illustration.

One may question whether consumers are sufficiently involved with commercial advertising to actually devote time and effort to forming a mental image. A similar criticism applies to the cognitive response model of communications effects (Wright, 1973) to which an ingenious, if risky, counterploy by an advertiser might be to instruct the consumer to "think about it" (i.e., generate cognitive responses) (Ray, 1977). A similar solution to the mental imagery problem may involve telling the consumer to "imagine yourself" in a particular situation or performing a certain behavior.

Media Selection and Scheduling

Viewing the communications task from an imagery perspective immediately suggests that certain media vehicles are more suited to certain kinds of imagery uses. The various media have different strengths and weaknesses which can be taken into consideration in planning a campaign relying on imagery principles. One basic distinction which has been made is that between the broadcast media (TV, radio) and print media (magazines, newspapers). The former are presumably more "intrusive" but characterized by less audience involvement than the latter (Krugman 1965), a source of concern to many advertisers. Consideration of imagery principles may help advertisers to overcome or perhaps even benefit from low involvement on the part of consumers.

Television. This medium is especially suited to the use of dynamic interactive imagery, thus making full use of the power of illustrations in affecting learning, attitudes, and behavior. The use of action in the commercial can focus the viewer's attention on the critical interaction between the brand and the product or service and make it much more memorable. An example of this type of imagery is the ad for Hunt's tomato sauce in which thick tomato sauce is shown being poured into the "u" in Hunt's. This is an example of a letter accentuation image, which is useful for brand names that cannot be depicted pictorially. An example of dynamic imagery that may not direct attention to the brand-benefit association is the ad for AMC that shows a number of interesting pictures appearing next to a moving, flashing line. The line holds the viewer's attention very well, but the viewer may fail to notice what brand was advertised. Thus, the ad may not direct the viewer's attention to the critical information.

Another imagery technique made possible by the capability of TV is modeling. Viewers can be shown the actual use of a product, thus portraying the behavior desired of

the audience, as well as communicating beliefs and cognitions about the product.

As noted previously, viewers are often described as having "low involvement" when viewing TV ads. Viewing pictures as opposed to words seems to require much less involvement or cognitive processing for perception and comprehension. As suggested by Krugman (1978), right hemispheric processing may be at work. This can work to the advertiser's advantage, since it takes less effort to attend to and comprehend a picture than is required to understand an equivalent amount of information presented verbally. Thus the use of pictures and models to create interactive, highly memorable images is especially important in TV advertising since this is generally considered to be a low involvement medium.

Radio. While the use of imagery in radio advertising has certain limitations inherent to the medium (i.e., low involvement and inability to present information pictorial), creative inducements to use mental imagery could make radio ads as effective if not more effective than media which present external imagery. The literature on mental imagery indicates that subject-generated imagery may be superior to picture viewing for adult learners. Lorayne and Lucas (1974) in their popular The Memory Book, claim that bizarre, unique, individualized mental images are the most effective. Instructions to use individual mental imagery may result in not only improved memory for the message, but also increased involvement by the listener.

There are several ways to induce imagery on radio. One is to use concrete language to describe a picture, hopefully inducing the listener to form a mental image. The description should ideally be of an interactive image. Perhaps the most effective approach would be to coordinate radio descriptions with dynamic interactive pictures that are presented in TV ads. A description of the image may elicit memory for the already viewed dynamic image so that the listener "sees" the picture again in the "mind's eye".

Another way to elicit imagery is to give imagery instructions to the listener either directly or implicitly, telling the listener to picture themselves in a situation. An example of imagery instructions in a radio commercial is the Delta Airlines ad that directs listeners to "raise your hand, look at your watch, and repeat after me: Delta is ready when you are." The listeners mentally picture themselves looking at their watches and thinking about Delta Airlines' attribute of being on time.

Print. Magazines and newspapers are assumed to enjoy higher involvement on the part of their readers so ads in these media can safely devote more of the communications task to verbal information. The relationship between the verbal and visual information presented in print media may be different than in media with lower audience involvement. Pictures can supplement the main points made verbally.

Also a particular advantage in the print media as a result of higher reader involvement is the possibility of providing mental imagery instructions with somewhat more assurance that some portion of the audience will actually attempt to form mental images. Another related possibility would be to leave space in the ad for readers to draw a picture of themselves using the product. A modified picture-generation task such as "connect the dots" may be successful. Even the covert response of thinking about drawing the picture may help to crystallize an image in the consumer's mind.

Outdoor. Outdoor advertising or billboards are mentioned here only briefly as a medium which can benefit greatly from the use of imagery principles. Severely restricted in space and exposure time, a billboard will be most

effective by arousing some sort of mental imagery in the consumer, either through the use of illustrations or brief imagery instructions. It is also noted in passing that certain types of mechanical billboards may take advantage of dynamic interactive imagery, although this would be the exception rather than the rule.

Media mix. In selecting the media mix for a complete advertising campaign, integrated use of imagery-eliciting strategies in the various media should be one of the objectives. For instance, the more involving print media might use concrete language and imagery instructions, with the broadcast media serving the role of eliciting a reconstruction of those images. As another example, television advertising might utilize dynamic interactive pictures, with static portrayals of the same picture appearing in print form. The basic notion is to use each media vehicle to its own particular advantage, perhaps shifting the mix to match the type of imagery appeal being used. A campaign emphasizing dynamic interactive imagery may use more TV initially, followed by a shift into more print media and radio spots.

Media scheduling. One of the primary advantages offered by the use of imagery-eliciting strategies in advertising is the improved efficiency of communication. Presumably the same advertising effects can be achieved with fewer exposures to imagery-eliciting ads than their non-image counterparts. Germane to this point, Tversky and Kahneman (1973) discuss the so-called availability hypothesis: "any incident that makes the occurrence of an event easy to imagine or recall is likely to enhance its perceived frequency". This hypothesis has obvious implications for the problem of ad wearout. If an image-eliciting ad is easier to recall, consumers are likely to believe that they have seen the ad more often. Thus, the ad may have a shorter "life cycle" before becoming an annoyance to consumers, unless the ad is scheduled less frequently to counteract this effect. Less frequent scheduling of the ad means improved cost effectiveness.

Measuring Advertising Effectiveness

Hierarchy-of-effects. Perhaps one of the most controversial issues in advertising evaluation revolves around the notion of the "hierarchy-of-effects" (e.g., Lavidge and Steiner, 1961). Critics have assailed the hierarchy as inaccurate in its portrayal of response to low involvement advertising (e.g., Krugman, 1965), and others have suggested that as many as three different forms of hierarchy may exist (Ray, 1977). Imagery may be an important determinant of the power of a hierarchy-of-effects approach to modeling communications effects.

In its simplest form, the hierarchy consists of three steps: 1) cognition, or beliefs about the brand, 2) affect, which represents attitude toward, or evaluation of, the brand, and 3) conation, representing behavior with respect to the brand. For "high involvement" products, the steps are believed to occur in the order listed above, while in the "low involvement" case, Steps 2 and 3 are thought to be reversed (Ray, 1977). If this reversal is in effect, then traditional forms of advertising pretesting which rely on brand attitude as a surrogate for subsequent market behavior may be quite useless. Consumers are viewed as being in a very passive role, learning "without involvement" (Krugman, 1965) and not forming any true evaluation of the brand until after initial purchase.

The use of effective imagery strategies in advertising may act to 1) lift the low involvement situation to a higher level of involvement, 2) promote non-verbal cognitions and 3) elicit attitudes toward that brand, thus making the cognition-affect-conation hierarchy a viable one for assessing advertising effects. Pictorial treatments are associated with more positive attitude

toward the message, according to several studies reviewed earlier. Nisbett, et al. (1976) cite several studies showing that concrete information is much more influential in human judgmental processes than is more abstract information. It is not unreasonable to expect that the very presentation of concrete information in an ad may stimulate the sorts of judgmental processes upon which the hierarchy-of-effects model rests.

Recall vs. recognition. A related issue in advertising evaluation is the appropriate measure of consumer learning outcomes. Krugman (1965, 1978) has argued for the use of recognition rather than the more traditional verbal recall. The importance of using visual in addition to verbal assessment techniques after picture viewing has been recognized recently in consumer research. Rossiter (1976) reasoned that product information perceived and retrieved visually may differ considerably from attribute information retrieved verbally. Children at several age levels in his study appeared to have much information about cereals available when drawing a picture of the product that did not coincide with verbal recall. More importantly, this visual information also influenced their preferences to some extent.

The use of imagery in advertising may engage the brain more fully in the response to the ad. Both the left and right hemispheres probably become more activated in processing a combination of verbal and pictorial information. Ad testing technology must keep pace by using procedures adequate for assessing the effects of the image-related portion of the ad.

Advertising Regulation and Public Policy

Recent consumer-oriented public policy has heavily emphasized the need for advertising to serve an informational function for the consumer. The essential thrusts of affirmative disclosure, nutrient labeling, and advertising substantiation all rest on the notion of the consumer as an information processor. Unfortunately, most of the focus has tended to be on verbally presented information, rather than on visually presented information, despite the fact that the FTC is concerned about "implied" product claims.

As noted by Eighmy (1978), much of the work being done presently in public policy relies on the use of copy testing, which has as its main focus verbal copy claims, and to a lesser extent the implications of a visual context. Yet good imagery in advertising may be much more powerful than any verbal claim, in part due to the former's concreteness (Nisbett, et al., 1976). Thus, public policy directed at advertising should immediately shift greater attention to the imagery in advertising in order to more adequately perform its job of protecting/informing consumers. The prevailing view of the consumer as an information processor must be broadened to encompass not only left hemispheric verbal processing, but also the more subtle yet perhaps more powerful right hemispheric processing of visual imagery.

Conclusion

This paper has attempted to summarize briefly the research on illustration and imagery which has appeared primarily in the psychology literature. Implications of these findings for research on, and the practice of, advertising would seem to be rather far-ranging. A number of potential issues have been raised for the application of imagery principles to advertising decisions. Further research is needed to determine which areas of advertising can benefit most from an imagery perspective, and how communications in general can be improved through the use of imagery.

VISUAL IMAGING ABILITY AS A MEDIATOR OF ADVERTISING RESPONSE¹

John R. Rossiter, University of Pennsylvania
Larry Percy, Gardner Advertising Company

Abstract

This study examines the role of visual imaging ability as a mediating variable in consumer response to advertising. A model is proposed in which visual imaging ability is hypothesized to mediate the effects of both visual and verbal stimulus content in advertising through a process which we term visual reinforcement. Data are provided in support of the model and in support of the visual reinforcement hypothesis. Visual imaging ability appears to be a powerful and hitherto overlooked mediating variable in consumer information processing.

Introduction

Advertising, in all media except radio, relies heavily on visual as well as verbal information to present the advertised product. Research on consumer response to advertising, however, has focused almost exclusively on verbal information processing; witness the plethora of advertising response studies in which verbalized beliefs, attitudes, recalled message points and so forth represent the main informational constructs. Most importantly, visual information processing has not been represented in any models of advertising response with the exception of one model developed for children by Rossiter (1976). The present study proposes a more elaborate model which examines the nature of visual information processing as it applies to advertising.

Researchers have not been blind to the importance of visual information per se. Studies of consumer spatial behavior in retail location research (for a review see Reynolds and Wells, 1977), of packaging, and of the effects of illustration size in print advertising (for a review see Hendon, 1973) are at least partially concerned with consumer response to visual information. However, these studies have employed S-R designs of an input-output type in which the nature of visual information processing has not been assessed.

The concept of information processing implies that something theoretically necessary if not directly accessible is going on inside the organism which operates on the incoming information and consequently affects the output response. Variables which tap these organismic processes constitute valid O-variables in the basic S-O-R paradigm assumed by most information processing theorists and are to be distinguished from individual difference variables such as those of the demographic, psychographic or past product usage variety which may be correlated with output responses but which have not yet been shown to affect information processing in any causative or even specifiable manner.

¹The authors are indebted to the creative staff at Gardner Advertising Company for preparing the stimuli used in the study; to the research staff at Gardner for collecting the data; and to Frank Hayson of the Wharton School for computer assistance. Professors James Bettman, Kathy Lutz and Richard Lutz of UCLA provided valuable comments on the manuscript.

O-variables which mediate verbal information include intelligence, anxiety, and sex (Hovland and Janis, 1959; McGuire, 1969). O-variables which mediate visual information are beginning to be identified in the cognitive psychology literature. An extensive review can be found in Richardson (1969).

Most of the research on individual differences in visual information processing has been concerned with the mediating effects of these O-variables on verbal learning (item recall and recognition) and motor learning (performance improvement after visualized practice). However, Richardson speculates that visually oriented O-variables may also mediate the learning of affective (attitudinal) responses. But no one has yet demonstrated visual mediation of affective learning empirically nor developed a theoretical model that would predict it. This joint theoretical and empirical endeavor is highly relevant to advertising and provides the basis for present study.

The O-variable examined in this study is visual imaging ability. Visual imaging ability may be colloquially defined as the individual tendency to "think in pictures" (Richardson, 1969). Although everyone experiences pictorial imagery at some time or other, individuals vary widely in the extent to which they employ visual imagery as a habitual mode of thinking and simultaneously in the extent to which visual imagery occurs easily and spontaneously as a covert response to external stimuli (Paivio, 1969; Richardson, 1969).

The Model

The theoretical model on which the present study is based is shown in Figure 1. The model holds a crucial implication for individual differences in visual imaging ability. It predicts that visual imaging ability will mediate the processing of both visual and verbal stimuli. The hypothesized processes are explained below for verbal stimuli and then visual stimuli.

Verbal Stimuli

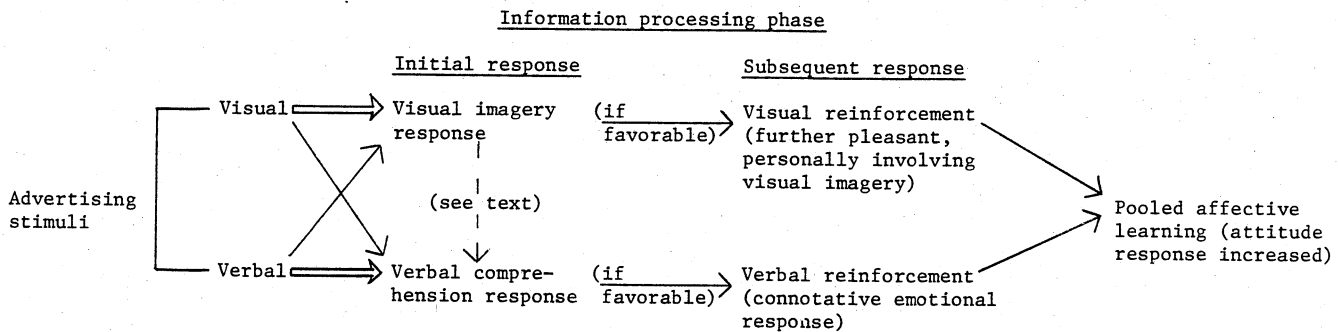

The initial and primary reaction to a verbal stimulus consists of a verbal comprehension response; that is, the verbal stimulus (word, sentence, or larger textual unit) is decoded and understood.

However, it has also been shown that verbal stimuli may simultaneously evoke visual imagery responses. Indeed, the imagery value of a verbal stimulus has consistently been shown to have a more powerful influence on verbal learning than verbal comprehension factors such as the meaningfulness of the stimulus (Paivio, 1969; 1971; Hulse, Deese and Egeth, 1975). Verbal stimuli having the highest imagery value are generally those of a more concrete nature. Concrete verbal stimuli are those which have clear, "real world" referents as opposed to vague, abstract referents. It is easier for most people, for example, to experience visual imagery in response to the word BEER than to the word BEAUTY.

The initial covert information processing response to

Figure 1

ADVERTISING RESPONSE MODEL FOR THE PRESENT STUDY¹

¹Note: The response linkages have been shown merely in graphical form. Functional relationships would follow a multistage mediational ($r_m \rightarrow s_m$) process which, for clarity, is not shown here.

verbal stimuli therefore has two hypothesized components as shown in Figure 1: a verbal comprehension response and, frequently though not always, a visual imagery response.

It is the subsequent responses, however, that are of most theoretical interest in the processing of persuasive information. The present model posits that if the verbally comprehended stimulus is recognized as a favorable one (e.g., the word GOOD vs. the word BAD) verbal reinforcement will occur; and that, likewise, if the visual imagery response to the verbal stimulus is a favorable one (e.g., a pleasant, perhaps personally involving mental picture) visual reinforcement will occur.

The verbal reinforcement phenomenon has solid empirical support. A long history of evidence beginning with a classic experiment by Staats and Staats (1957) has demonstrated that favorably evaluated words can function as verbal reinforcers. By associating objects or other words (e.g., the name of a product) with these verbal reinforcers attitudinal responses toward the object or word can be increased. Advertisers, of course, have always known this implicitly, hence their predilection for highly favorable words such as NEW or FREE in copy.

The visual reinforcement phenomenon in the processing of verbal stimuli has yet to be demonstrated. It has been shown by Paivio (1971) that the verbal learning superiority of high imagery value words occurs regardless of their connotative value; that is, "good" words are learned just as well as "bad" words providing their visual imagery values are equivalent. This at first would seem to indicate that verbal reinforcement is not involved in verbal learning but that some type of visual reinforcement, mediated through the word's evoked image, may be. However, "learning" in verbal learning and imagery studies has invariably been defined in terms of recognition or recall. This can be contrasted with the type of affective learning involved in the Staats-type experiments (and in the present study) where the dependent variable is an attitudinal or evaluative response. No one has yet investigated whether the visual imagery value of verbal stimuli relates to affective learning; that is, Paivio's finding that imagery independently increases recognition and recall can not be taken as evidence that imagery could also increase attitude because the latter type of dependent variable has not been employed in imagery studies.

Demonstration of visual reinforcement of attitudes through the use of verbal stimuli would be extremely significant for advertisers. In contrast with verbal learning researchers who try to select connotatively neutral verbal stimuli, advertisers deliberately select affectively loaded verbal stimuli to describe products. If these affectively loaded stimuli not only produce verbal reinforcement (of the GOOD type) but also visual reinforcement (of the pleasant, personally involving mental picture type) then such stimuli may constitute extra reinforcement for affectively learned responses such as attitude.

Visual Stimuli

If verbal stimuli can elicit visual imagery responses then visual stimuli should almost certainly do so. The model in Figure 1 assumes that the initial and primary reaction to a visual stimulus is some type of visual or iconic (picture-like) encoding which we have called a visual imagery response. However, as shown by the smaller arrow in the figure, a verbal reaction may also occur. Let us examine the visual reaction first.

A well known experiment by Shepard (1967) suggests that visual imagery always occurs in response to visual stimuli. Shepard's experiment is interesting because, although it was conducted in the context of experimental psychology, the stimuli employed happened to be magazine advertisements. Subjects in the experiment studied 612 illustrated magazine advertisements at their leisure. They were given a recognition test on 68 pairs of ads in which the pairs consisted of one ad from the originally studied set plus a new ad of the same type as the rest. The task was to identify which of each pair had been in the original set. On an immediate recognition test, subjects were 98.5% accurate. On a delayed test one week later subjects were still 90% accurate. Performance did not fall to the chance level (50%) until four months afterward. This normal but amazing recognition feat implies that people store visual images of every visual stimulus they pay attention to. The alternative, non-imagery explanation, that the subjects in Shepard's experiment generated verbal responses to the 612 advertisements which later aided them in the recognition test, is hardly convincing because this would imply that the subjects could accurately recall a list of 612 words in one trial, which simply cannot be done. Visual imagery therefore seems to be an inevitable

response to attended-to visual stimuli.

People may also generate verbal responses to visual stimuli just as they may generate visual responses to verbal stimuli. However, our model suggests, and the evidence on cognition indicates, that intramodal responses (i.e., an initial imagery response to visual stimuli and an initial verbal comprehension response to verbal stimuli) are the typical and dominant ones even though cross-modal responses may also occur. Dominant intramodal responses are illustrated by the larger arrows in Figure 1.

With visual stimuli, as with verbal stimuli, it is the subsequent responses that are in dispute. One school of thought acknowledges that the initial response to a visual stimulus may be a visual imagery response but that the subsequent responses are verbal. That is, the person mentally "describes" or interprets the visual stimulus in verbal terms. The verbal response then provides the basis for further effects such as recall or recognition. The best known theory in this verbal coding school is the "verbal loop hypothesis" (Glanzer and Clark, 1969). We have already argued that verbal labeling of this type would have difficulty accounting for visual recognition findings such as those of Shepard (1967). However, verbal labeling would appear to be a possibility with fewer visual stimuli than in Shepard's experiment. The verbal labeling viewpoint remains popular (Pylyshin, 1973) and stands as an alternative to the subsequent response interpretation in the present model.

The present model proposes that subsequent responses to visual stimuli may not pass through any "verbal loop" at all. It is hypothesized that the initial imagery response can serve as an internal stimulus which triggers further visual imagery. If this imagery is favorable, visual reinforcement will occur.²

The Nature of Attitudes

Several comments are necessary concerning the nature of the ultimate response in affective learning. In the present case this is an attitude (see Figure 1). Up until this ultimate response our model is quite clearly a modality specific "dual trace" model of the type advocated by Paivio (1971). Our model hypothesizes that both visual and verbal stimuli can produce verbal and visual "traces" in the form of covert stimuli and responses during information processing. However, we do not maintain that the ultimate effect, i.e., an attitude, is modality specific. Following Anderson and Bower (1974) and to some extent Pylyshin (1973) we regard the ultimate retained effect as being abstract and conceptual in nature. In retaining a response such as an attitude there is no requirement that the person also

²This view should be carefully distinguished from the imagery coding theory advanced by Bugelski (1970; 1977). Bugelski's imagery coding theory is the diametric opposite of the verbal coding theories of Glanzer and Clark and Pylyshin in that it holds that all coding is imaginal. However, Bugelski is not referring to a picture-like visual image when he uses the term "image" whereas we, in contrast, are. In this sense our view of imagery follows that of Richardson (1969) who defines visual imagery as a consciously experienced, quasi-perceptual event. We differ from Richardson, however, in that our model hypothesizes that visual imagery may also have reinforcing properties. In particular, subsequent visual imagery responses made to the initial iconic image are capable of assuming reinforcing qualities, hence our concept of visual reinforcement.

retain the original verbal or visual learning experience in toto. Just as it is possible for people to undergo an attitude change without recalling the original verbal content of the persuasive message (Greenwald, 1968; Calder, Insko and Yandell, 1974) it is similarly possible to undergo a visually mediated attitude change without recalling the original visual imagery that produced it.

Although attitudes themselves are not modality specific, attitudes learned under verbal and visual reinforcement conditions should be retrievable via appropriate cues in either modality: external stimuli similar to those under which the original learning occurred. Consequently, the product attitude response may be elicited by a visual cue, as when the product is seen again in another advertisement or in a store, or by a verbal cue, as when the product name is heard or the name read while filling out an attitude questionnaire.

Finally, the conceptualization of attitude as an automatic, involuntary, elicited response implies that visual (and verbal) reinforcement in our model operates via a classical conditioning process. All that is necessary is the contiguous association of a brand or product stimulus with a visual stimulus. The occurrence of subjectively pleasant visual imagery within the individual beyond the initial iconic encoding response then becomes a sufficient condition for visual reinforcement to occur via classical conditioning. The classical conditioning possibilities of visual imagery were first recognized by Leuba (1940) who referred to images as "conditioned sensations." This view was later elaborated by Mowrer (1960). Since 1960, with attention turning from behaviorism to the newer cognitive theories, psychologists have not addressed the potential classical (UCS) reinforcing value of visual imagery. Instead, behavioristic research on imagery has tended to follow the paradigm developed by Wolpe (1958) which focuses on the operant reinforcing value of visual imagery of a voluntary type (Cautela, 1977). Our concern, however, is with "involuntary" visual imagery and thus the classical conditioning paradigm is appropriate.

Visual Imaging Ability and Visual Reinforcement

Our model requires us to demonstrate that a visually mediated type of reinforcement occurs independently of the "standard" verbally mediated reinforcement. Verbal coding theorists could argue that all reinforcement is verbal, due in the case of visual stimuli to verbal labeling (see dashed line in Figure 1).

Examination of individual differences in visual imaging ability provides a test of the competing hypotheses. Individuals who are high in terms of visual imaging ability should be more likely to generate visual imagery to any stimulus with visual or verbal content and therefore to show greater affective learning in general because of the dual reinforcement idea. But isolation of visual and verbal content provides a more crucial test. If visualizers (this convenient shorthand will be used hereafter) show greater affective learning only in response to verbal stimuli it could be argued that they are simply generating more initial visual imagery responses to words which are then labeled and translated into verbal reinforcement. However, if it could be demonstrated that visualizers also show greater affective learning in response to visual stimuli then a clear-cut case for the validity of visual reinforcement would emerge. This is because the initial imagery response to visual stimuli is common to all individuals (cf. the Shepard experiment). Increased reinforcing effects among high visualizers would therefore make it almost impossible to avoid the conclusion that these individuals are deriving extra visual reinforcement (further spontaneously generated pleasant visual imagery) from

the same initial image because any verbal reinforcement from this image would be constant. An extreme counter-argument, that this further imagery is nonreinforcing per se but is verbally labeled and then reinforcing, seems unlikely. In any event, such an argument would not vitiate the reinforcing potentiality of visual information processing in its own right.

The Study

The test of the visual reinforcement hypothesis (and of the advertising response model in general) was devised by exposing consumers to two new brands of beer via separate print advertisements. The brand names were fictional and were equated beforehand to ensure that names per se had no effect on attitude. One brand was presented via visually oriented (strong visual) advertising: a large picture of the product with small verbal copy underneath. The other brand was presented via verbally oriented (weak visual) advertising: large verbal copy with a small picture of the product underneath. A "no picture" control condition was rejected as being atypical of beer advertisements.

Experimental conditions were further arranged so that half the consumers, in a rotated 2x2 design, received advertisements in which the verbal copy was highly concrete in nature (superlative and explicit product claims) and half received advertisements in which the verbal copy was highly abstract in nature (superlative but vague product claims).

Consumers were asked to rate their attitude toward the brand after each exposure as a measure of affective learning produced by the advertisements. Beer was selected as the product category because previous research (e.g., Allison and Uhl, 1964; Woodside, 1972) has shown that brand attitude engendered by advertising is a very good precursor of purchase behavior. Too often a haphazard selection of dependent variables such as beliefs, attitudes, or recall is made. As argued by Rossiter and Percy (in preparation) the dependent "advertising effect" variable should always be dictated by an a priori advertising response model applicable to the particular product category, consumer segment, and brand choice situation. The latter consideration (see also Wright, 1976) makes recall, for example, an unsuitable dependent variable for the beer category except, perhaps, in restaurant ordering situations where no verbal or visual cues are present. For most applications concerning beer advertising, attitude is the appropriate dependent variable.

The central issue in this study was not just whether affective learning would differ by stimulus condition but whether it would also differ predictably across individuals. A measure was therefore taken of visual imaging ability as a predictor variable. For comparison purposes, a nonvisual predictor variable, intelligence, was also included and sex differences were assessed. The main theoretical predictions, however, were: (1) visualizers would show greater affective learning than other consumers because of the greater likelihood of spontaneous occurrence of visual reinforcement from both the verbal and the visual stimulus content in advertising; (2) that this individual difference should be accentuated when the visual stimulus content of advertising favors visual imagery formation, i.e., contains strong visual emphasis; and similarly (3) when the verbal stimulus content of advertising also favors visual imagery formation, i.e., contains concrete copy. Each of these effects would provide evidence in support of the visual reinforcement component of the model.

Method

Subjects. Participants in this study were 88 adults (44 men and 44 women) recruited from a typical Mid-western suburban shopping center. All respondents were beer drinkers and an additional attempt was made to ensure a range of ages in the sample in case favored beer product attributes should vary as a function of age.

Materials and design. Four print advertisements representing the possible 2x2 combinations of visual versus verbal emphasis and concrete versus abstract copy were constructed professionally by the staff of a major national advertising agency. Visually oriented advertisements consisted of (a) a brand name at the top of the page, (b) a large picture of a mug of beer bearing the brand label and (c) concrete or abstract copy beneath. Verbally oriented advertisements consisted of (a) a brand name at the top of the page, (b) concrete or abstract copy as the main body of the advertisement and (c) a small picture of a mug of beer bearing the brand label beneath. Brand names (to serve later as the product cue) were in very large type of identical size for the visually and verbally oriented advertisements. Pictures and copy were also identical between versions except that the visually oriented advertisements used a 3:1 picture to copy size ratio whereas the verbally oriented advertisements reversed this ratio. Print size was adjusted slightly between concrete and abstract versions so that the total space allocated to copy was constant within visually and verbally oriented advertisements respectively.

The design of the study required each respondent to be exposed to both the visually oriented and verbally oriented advertising stimuli and to the concrete and abstract copy in order that visual imaging ability could be applied as a predictor on a within-subject basis. This meant that each respondent could see a visually oriented advertisement and a verbally oriented advertisement but, obviously, the brand names and copy content would have to differ.

The copy manipulation was taken care of by the concrete-abstract manipulation: each respondent simply saw the visually oriented advertisement with either concrete or abstract copy then the verbally oriented version with the complementary type of copy; this, and also the order of exposure for visually versus verbally oriented advertisements was rotated across respondents in a balanced design.

The brand name factor required the selection of two different brand names so that two different advertisement types could be rated by each respondent. To make the learning task as realistic as possible it was decided to use realistic brand names rather than abstract symbolic designations such as X or Y. The two brands of beer were introduced as new Bavarian imports (see copy below). Accordingly it was thought that Germanic sounding words would be appropriate as brand names without having immediately meaningful denotation to most consumers. The purpose would then be to select two Germanic sounding words whose connotative or affective associations were as equal and as neutral as possible so that the names alone would not influence product attitude. Nine two-syllable nouns were selected from a German dictionary. These were arranged in two randomly ordered lists. A separate pretest sample of 60 consumers (30 men and 30 women) drawn from the same population as those in the main study were then asked to rate each word on a scale of 1 to 7 in terms of how they "like [7] or dislike [1] each name as a brand name for beer." This task was explained by a short scenario which claimed that a Bavarian beer company was considering several brand names for a new import entry to the U.S. market. Two names, BAUER and LAUFER, were selected on the basis

of this pretest as being most equal and closest to the neutral affective rating position. Mean affective ratings for each of the two names were identical (3.8 for men and 3.7 for women) as were their standard deviations (2.0 and 2.1 respectively). By a coin toss, the name BAUER was used in the visually oriented advertisements and LAUFER in the verbally oriented advertisements.

The visual stimuli selected for inclusion in the advertisements consisted of identical pictures of a "foaming mug of beer." The stimuli varied only in size, location, and brand name, as described earlier. The purpose of this selection was to ensure a fairly unitary stimulus (as far as intuitive judgment is concerned since, unlike verbal stimuli, there is no standard taxonomy for visual stimuli) so that the attentional focus, which is presumably the basis of the initial imagery response, would be singular or wholistic for all respondents. Theoretical complications would arise if the visual stimulus were multidimensional. A picture of people drinking beer or a beer bottle in an environmental setting might provoke differential attention to various substimuli within the visual display. This possibility was virtually removed with the "mug shot" which at the same time represented a visual stimulus that would not be atypical of a beer advertisement. The verbal stimuli in the advertisements consisted of either concrete or abstract copy. Three beer product attributes were selected for inclusion in the copy: overall quality, taste, and price. These three attributes have been found in proprietary research to be the main determinants of beer brand attitudes. The limitation to three attributes ensured that verbal processing to generate an attitude could easily take place. The use of five or more attributes might exceed short-term memory capacity (7 ± 2) and result in differential attribute focus across respondents.

The concrete copy was designed to be superlative and explicit, of the "factual documentation" type. The text for the concrete copy was:

BAVARIA'S NUMBER 1 SELLING BEER FOR
THE LAST 10 YEARS

WINNER OF 5 OUT OF 5 TASTE TESTS IN
THE U.S. AGAINST ALL MAJOR AMERICAN
BEERS AND LEADING IMPORTS

AFFORDABLY PRICED AT \$1.79 PER
SIX-PACK OF 12 OZ. BOTTLES

The \$1.79 price was determined from the pretest by asking respondents to estimate what "affordably priced" would mean for the new Bavarian import and then computing the mean estimate.

The abstract copy was designed to present the same copy points in superlative but vague form of the more "emotional" type. The text for the abstract copy was:

BAVARIA'S FINEST BEER

GREAT TASTE

AFFORDABLY PRICED

The concrete copy is longer than the abstract copy. This is necessitated by the inclusion of sufficient information to provide an explicit referent for each attribute claim.

Procedure. Consumers participating in the study first answered some preliminary screening questions and then answered the 15-item Visualizer-Verbalizer Questionnaire (VVQ) developed by Richardson (1977) as a measure of visual imaging ability. The VVQ has been shown to have

very high convergent and discriminant validity with other measures of visual imagery, including both other self-report and also physiologically based measures of right- and left-brain processing. Test-retest reliabilities to the order of .90 have been obtained for the VVQ although its internal consistency reliability has not been established (see White, Sheehan and Ashton, 1977). The range for this test is 0 to 15. The VVQ is scored so that high scores designate individuals whose characteristic mode of thinking is exclusively visual; low scores designate individuals whose characteristic mode of thinking is exclusively verbal; with dual visual and verbal types tending toward the middle of the score distribution. This scoring method was ideal for present purposes in that visual imagery as a predictor is unconfounded by dual types of processing.

Each respondent was then shown the first advertisement which was either visually or verbally oriented and contained either concrete or abstract copy, depending on the predetermined experimental condition. After the respondent had finished looking at the advertisement, he or she was asked, "As best you can judge, based on this advertisement, how would you rate this brand?" Respondents were handed a card on which the name BAUER BEER or LAUFER BEER, respectively, was printed followed by four, 7-point bipolar rating scales. The rating scales--good-bad, inferior-superior, unpleasant-pleasant, and interesting-boring, with the end-adjectives in this order--were selected from Osgood, Suci and Tannenbaum (1957) and Fishbein and Ajzen (1975) for their high loadings on the semantic evaluation factor. The scales were scored on a 7-point -3 to +3 system with the sum (range: -12 to +12) constituting the overall affective measure of brand attitude, the dependent variable in the study. This type of multi-item index has been shown elsewhere (Fishbein & Ajzen, 1975) to be a highly valid and reliable measure of attitude. The process was then repeated with the second advertisement assigned to each respondent's experimental condition.

Finally, each respondent completed a 3-minute, timed, Number Series test. The Number Series test (Lumsden, 1959) is a highly reliable and unidimensional measure of general intelligence which correlates highly with standard I.Q. measures. The score range is 0 to 22 in terms of number correct. Its focus on numerical rather than verbal or visual stimuli makes it eminently suitable as an alternative predictor variable in the present study.

Results

The four advertisements employed in the study revealed strong stimulus effects on brand attitude ratings (Figure 2). This conclusion is warranted when it is realized that, in the pretest, the brand names alone elicited neutral attitudes. Visually oriented advertisements were more effective in inducing positive brand attitudes than verbally oriented advertisements ($p < .01$) and concrete copy was similarly more effective than abstract copy ($p < .05$). The presence of significant interaction is also evident from Figure 2, with visual emphasis and concrete copy combining to elicit the strongest attitudes. This result would be predicted by the visual reinforcement hypothesis and these overall results lend strong support to our dual reinforcement advertising model.

However, our main concern in this paper is to assess the validity of the visual reinforcement component of the model. This requires an examination of individual differences in affective learning. Accordingly, brand attitude scores were regressed against the three individual difference predictor variables, visual imaging ability (VVQ), intelligence (Number Series) and sex, plus copy type (concrete versus abstract). The correla-

Figure 2

BRAND ATTITUDE RATINGS BY STIMULUS CONDITION

tions between the predictor variables did not differ significantly from zero ($p > .05$) which eliminates the problem of multicollinearity. The results are shown in Table 1. There are three dependent variables to be considered. The first is total attitude, computed as the sum of visually and verbally induced attitudes, which provides a test of the hypothesis that visualizers will reveal greater affective learning from advertising in general. Copy type was not employed as a predictor variable for total attitude as this variable is automatically summed into the total attitude score. The second two dependent variables represent brand attitudes induced by visually and verbally oriented advertisements respectively, recalling that each respondent rated one brand under each condition.

Looking first at the total attitude results it is seen that the only significant predictor is visual imaging ability ($F = 5.32$, $p < .05$; shown to be stable in randomly split samples). Neither sex nor intelligence revealed significant mediational effects. The regression coefficient for visual imaging ability indicated that visualizers showed the greatest degree of affective learning. This finding supports the first hypothesis of the study. The bivariate correlation between visual imaging ability and total attitude was $r = .26$ ($p < .05$) which indicates that individual differences in visual imaging ability accounted for about 7% of the variance in attitude scores on an overall basis.

Looking next at the predictors of brand attitude induced by visually oriented advertising it is seen that copy type is a significant predictor ($F = 11.83$, $p < .01$; stable in randomly split samples) as is visual imaging ability ($F = 8.58$, $p < .01$; stable in randomly split samples). The sign of regression coefficient for copy type indicated that the former result was due to the previously mentioned interaction favoring visually oriented advertising with concrete copy. The sign of

TABLE 1

REGRESSIONS OF BRAND ATTITUDE RATINGS
WITH PREDICTOR VARIABLES¹

Predictor variable	Brand attitude rating		
	Total	Visual	Verbal
Copy type		11.83**	
Visual imaging ability	5.32*	8.58**	
Intelligence			
Sex			
R	.28*	.48**	.19
R ²	.08	.23	.03

* $p < .05$ (1-tailed test) ** $p < .01$ (1-tailed test)

the regression coefficient for visual imaging ability indicated that, as predicted, visualizers showed significantly greater affective learning under visually oriented presentation conditions than other individuals. The bivariate correlation in this case is $r = .49$ ($p < .01$) which indicates that individual differences in visual imaging ability accounted for about 25% of the variance in visually induced attitude scores. This finding supports the second hypothesis of the study.

However, in view of the apparent interaction between visually oriented advertising and the concrete versus abstract copy dimension a further analysis was conducted by running separate regressions for the 44 respondents who received the visually oriented advertising with concrete copy and the other 44 respondents who received the visually oriented advertising with abstract copy. These results are shown in Table 2. Interestingly, the relationship between visual imaging ability and brand attitudes induced by visually oriented advertising appears to hold only for the combination of visually oriented advertising with abstract copy ($F = 12.49$, $p < .01$; stable in randomly split samples). The only significant predictor of brand attitude induced by visually oriented advertising with concrete copy is sex ($F = 7.31$, $p < .05$). However, this F value was not stable in a randomly split sample test and should be regarded with caution. Nevertheless, the regression coefficient for the sex variable indicated that women showed significantly greater affective learning from the visual-concrete combination than did men. Implications of these results for the visual reinforcement hypothesis are addressed in the discussion.

Returning to Table 1 and looking finally at the predictors of brand attitude induced by verbally oriented advertising it is seen that none of the predictors had significant univariate F-values. The absence of a significant effect for copy type indicates that visual reinforcement is not differentially triggered in visualizers by concrete copy alone. This finding counts against the third hypothesis of the study.

Discussion

The overall results produced impressive evidence in favor of the dual reinforcement model of advertising effects. That is, across all individuals, the use of a visually oriented layout and concrete verbal copy--the two factors hypothesized to maximize visual reinforcement--generated the strongest affective learning both separately and, more powerfully, in combination.

However, the main purpose of this study was not to test the model so much as to test the validity of the visual reinforcement component of the model. The validity tests required that individuals who possess high visual imaging ability show differentially greater affective learning (1) under all stimulus conditions and especially (2) under conditions of visually oriented advertising and (3) concrete copy content. The results supported the first two of these tests but not the third. Exclusive visualizers were superior to other individuals in terms of total affective learning and in terms of affective learning induced by visually oriented advertising. But visualizers did not show any superiority to other individuals in terms of affective learning induced by concrete advertising copy.

One post hoc interpretation of this latter result is that visualizers become so preoccupied with the visual elements of advertising that they pay less attention to the copy. This may be accentuated when the copy is longer--as it was in the concrete case. The finding that visualizers showed greater affective learning with the shorter, abstract copy under the strong visual stimulus condition (Table 2) would support this "distraction" hypothesis.

The emergence of a possible sex difference in Table 2 also merits discussion.³ The sex difference occurred only in response to the strong visual stimulus-concrete

³The sex difference is described as "possible" because, as noted, the associated F-value was not stable in a split sample test.

verbal copy combination. Visual imagery is thought to be an activity which occurs, like other spatial processing, in the right brain hemisphere. Verbal comprehension, and other verbal reasoning activities, are thought to occur in the left brain hemisphere. Physiologists have found that women tend to be bilateral information processors whereas men tend to be unilateral processors (see White, Sheehan and Ashton, 1977). If so, there may be a multiplicative effect of visually and verbally induced imagery among women which leads to a stronger apparent preference for the visual-concrete combination. Women may be less "distracted" from longer advertising copy by visual stimuli in advertising because they are more able to process both types of information. This possibility has interesting implications for advertising directed to female audiences.

Also of interest was the failure of differences in intelligence to play a mediational role in the processing of persuasive information. Intelligence differences should be inversely related to persuasion when reception is constant (McGuire, 1969). However, this result has most commonly been obtained with more complex verbal messages than those employed here.

Methodological Considerations

One methodological consideration that is central to the conclusions drawn from this study concerns the possibility that the relationship between visual imaging ability and affective learning (positive attitude inducement) may be due to a "yea-saying" response bias. That is, individuals who checked the "yes" responses on the VVQ test may also have favored the positive extremes of the attitude scales used to measure affective learning.

The "yea-saying" possibility can be confidently ruled out. As noted in the Method section, the VVQ test is scored such that "yea-sayers" would fall into the middle of the total score distribution. A person answering "yes" to most or all items would emerge as a mixed imager, not a visualizer. Moreover, the VVQ test permits only dichotomous (yes-no) responses so that a tendency toward extreme responses is also precluded. The relationship between visual imaging ability and affective learning therefore remains unaffected by the measurement methods employed in the study.

A second consideration concerns the definition of "concrete" versus "abstract" verbal copy. The copy used in the concrete condition was certainly more specific and factually oriented than the copy used in the abstract condition. The idea here was to provide a singular and explicit referent for each attribute claim in the concrete copy. This is in line with the definition of concrete words as having single and explicit referents rather than multiple and often vague referents characteristic of abstract words (e.g., BEER versus BEAUTY).

However, the concrete copy required more words--regardless of the individual words' concrete versus abstract status--than the abstract copy. Our attempt to develop concrete versus abstract text was thus confounded by text length.

Nevertheless, the differential effects of the two types of text, not so much for visualizers but for the sample as a whole, remain valid. The fact that visualizers were not affected as predicted by the imagery-producing concrete text suggests that the methodology may have been in error but not necessarily the theory. In practical terms, advertisers might still see the results as generally favoring longer, factually oriented copy over shorter but vaguer superlatives.

Further Applications

The identification of individual differences in visual imaging ability may itself have limited application to advertising unless such individuals can be easily located. To be of practical use, visual imaging ability would have to be shown to be correlated with standard media demographic variables or to be prevalent in the target segment for a given brand.

Individual differences in visual imaging ability have, however, made it possible to validate the existence of the process which we term visual reinforcement--a far more general phenomenon.

The concept of visual reinforcement has provocative implications for advertising. Visual reinforcement resulting from visual imagery may explain the superior learning produced by television commercials even when television commercials and print advertisements are apparently "equated" for visual and verbal content (Grass and Wallace, 1974). The multiple visual stimuli provided in a television commercial video should produce multiple initial imagery responses and thus increase the amount of visual reinforcement experienced by the viewer.

The present study focused on positive visual reinforcement. However, our model would predict that visual imagery can have negatively reinforcing and also punishing consequences for the affective learning of brand attitudes. Advertisements for pain relievers, for example, frequently employ the negative reinforcement principle. Negative verbal reinforcement from the copy or audio may be enhanced by negative visual reinforcement from the visual elements of the picture or video. Similarly, public service announcements entailing health warnings often employ the punishment principle. These too may be enhanced by visual imagery.

Visual reinforcement therefore has many unrecognized applications in advertising and probably in other areas of marketing communication as well. Indeed, any visual or verbal stimulus which reaches the consumer may produce visual reinforcement. The present model, although tested in an advertising context, should encourage examination of visual reinforcement in other marketing communication situations.

Finally, and not to be overlooked, is that visual imaging ability represents the first visually oriented individual difference variable to be identified in consumer research. Perhaps this will speed the development of better theories of visual information processing as an obviously relevant but surprisingly neglected aspect of consumer behavior.

COGNITIVE RESPONSE, IMAGERY, AND SCRIPTS:
WHAT IS THE COGNITIVE BASIS OF ATTITUDE?

Bobby J. Calder, Northwestern University

Abstract

It is argued that cognitive response theory must be extended to take into account memory structure and probably visual imagery coding as well. Moreover, the notion of scripts suggests a qualitatively different view of cognitive response.

Introduction

It has become increasingly clear that to understand how attitudes are related to consumer behavior we must first understand better how attitudes themselves arise. The classical definition of attitudes as relatively enduring predispositions to respond has outlived its usefulness. Attitudes are often, perhaps usually, not enduring. They derive from what the individual is thinking about at a point in time (see, for example, Salancik, 1974, 1976; Salancik and Conway, 1975). An individual may express quite different attitudes toward the same object or behavior at different times. Not only this, equally positive expressions of attitude may be differentially related to behavior depending on the nature of their underlying thoughts (Regan and Fazio, 1977).

The purpose of this paper is to lay out what I believe are the emerging issues in understanding the cognitive basis of attitude. More questions will be raised than answered. The goal is to provide a sense of direction rather than a complete theory.

Research on the Fishbein attitude-belief model has provided a strong impetus, particularly in consumer research, to investigating the cognitive basis of attitude. The contribution of this research has been to demonstrate convincingly that attitudes are not based on a simple list of beliefs, where the beliefs are "objective" in the sense that different individuals process pretty much the same beliefs (cf. Calder, 1975). The Fishbein model is an improvement over the classic assumption originating with Hovland that attitudes are based on the rote learning of completely external (message) information. But it appears necessary to go beyond the Fishbein model to allow for an even more complex and subjective basis of attitude. It should be noted that, from this perspective, attempts merely to shore up the model by adding other variables are ill-advised.

Currently the most promising direction for research is cognitive response theory. As Lutz and Swasy (1977) have shown, cognitive response theory is essentially compatible with and a step beyond the Fishbein model. A review of cognitive response studies is provided by Wright (in press). The focus here will be on the status of the theory and how it might profitably be extended. It is argued that the theory must be elaborated to take into account the structure of human information processing. A subsequent section attempts to look beyond the present concept of cognitive response. It may be necessary to allow for alternative memory codes, such as imagery, as well as structure.

Extending Cognitive Response Theory:
Memory Structure

The new idea of cognitive response theory is that beliefs, or the thought underlying attitudes, cannot be treated as "objective." The beliefs which are pro-

cessed to yield an attitude are not just those originating in external communications; nor can they be in any sense standardized across people. Beliefs must be treated as any thought which might come to mind in a situation. The new idea of cognitive response is simply the old idea of cognitive mediation updated to a view of the person as an active information processor. Cognitive mediation is held to be better reflected in the idiosyncratic thoughts listed by a person as coming to mind after a message than by measures of message recall or standard lists of beliefs.

The cognitive response variable has stimulated research because it predicts interesting effects. For instance, Brock and his colleagues (cf. Petty, Wells, and Brock, 1977; Petty, 1977) have demonstrated that distraction can increase persuasion by inhibiting the negative thoughts which would otherwise arise with a counter-attitudinal message and that distraction can decrease persuasion by inhibiting the favorable thoughts which would otherwise accompany an attitudinally consistent message. Another illustrative effect is source credibility. In a series of studies, Sternthal (cf. Dholakia and Sternthal, in press) finds that a low credibility source produces more attitude change than a high credibility source when a person's initial attitude is already favorable. The low credibility source stimulates positive thoughts.

While such effects are intriguing, notice that there is no theoretical explanation involved beyond that of cognitive mediation. A variable's effect on persuasion is explained by whether it inhibits or stimulates cognitive response and whether positive or negative thoughts are a priori more likely. Whether positive or negative thoughts are more likely can be inferred somewhat loosely from the person's initial attitude or from the nature of the message (see Figure 1). Cognitive response is thus a mediator variable expected to proceed attitude change.

No doubt the notion of cognitive response mediation will suggest additional interesting effects. It is my opinion, however, that we must also begin to examine the nature of cognitive mediation as well as the fact of it.

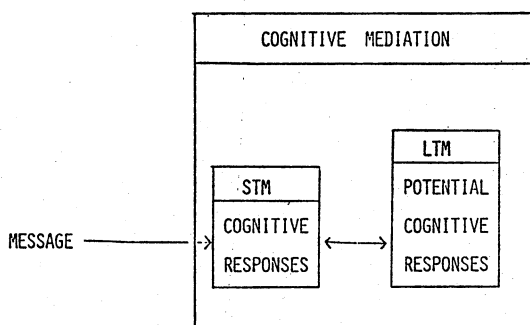

FIGURE 1
EFFECTS OF A COMMUNICATION VARIABLE ON PERSUASION

		MOST LIKELY THOUGHTS	
		POSITIVE	NEGATIVE
THOUGHTS	INHIBITS	DECREASES PERSUASION	INCREASES PERSUASION
	STIMULATES	INCREASES PERSUASION	DECREASES PERSUASION

My research has been concerned with how the structure of cognitive mediation affects persuasion. The most striking aspect of this structure is limitation. Evidence from cognitive psychology indicates that mediation is realized structurally by a limited capacity short-term memory store and a long-term memory store. The consensus model is that short-term memory holds information which is actively being processed. Long-term memory is a larger store of most, if not all, of the information that a person has ever processed. To be processed further, the information in long-term memory must be retrieved and transferred to short-term memory. The basis for this retrieval is the content of short-term memory of any point.

In terms of cognitive response theory, this model implies that information from a message, along with other incoming information, is initially represented in short-term memory as cognitive responses. These cognitive responses in turn trigger retrieval from long-term memory and the registration in short-term memory of further cognitive responses (see Figure 2). Note that any information in long-term memory is a potential cognitive response depending on what is triggered by short-term memory. But, since short-term memory is limited in its capacity, only so many cognitive responses can be represented.

FIGURE 2
THE STRUCTURE OF COGNITIVE MEDIATION

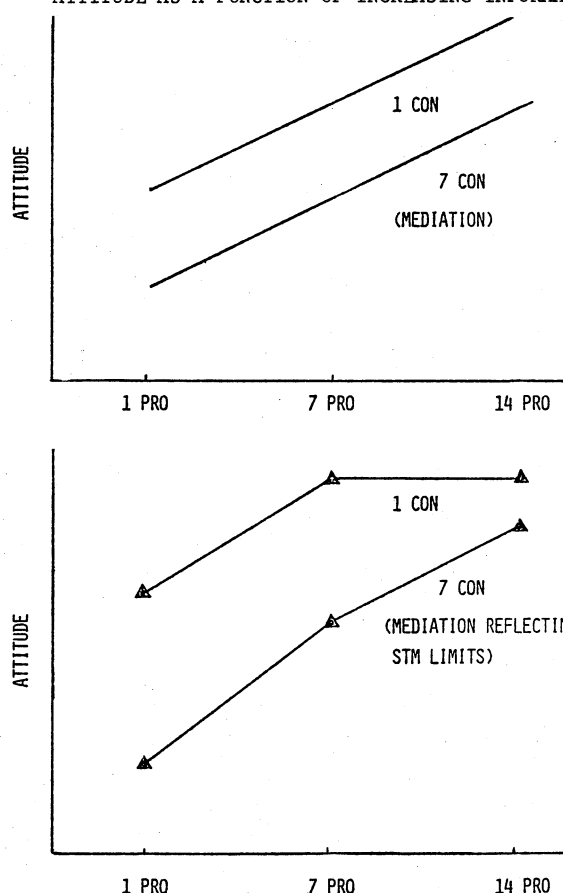

This leads to a prediction: When a message involves unfamiliar material and there is little time for rehearsal, cognitive responses to that message will be limited by the capacity of short-term memory. If the capacity of short-term memory is exceeded, additional cognitive responses cannot be represented, and thereby cannot affect attitude.

I have tested this prediction in a series of experiments which vary the amount of information in a message. Let me describe the first of these experiments. A two-sided message was used in which the pro side consisted of either one, seven, or fourteen distinct arguments and the con side of either one or seven arguments. The arguments were testimony in a jury trial. They were equated in style and content and were counterbalanced in the experimental design. After reading the message, subjects went through a thought listing procedure and indicated their overall attitude.

Without considering cognitive structure, one would expect that the number of pro cognitive responses would increase with the pro arguments and the number of con cognitive responses would increase with the number of con arguments. Attitude would thus be a linear function of the number of arguments (see Figure 3). If the number of cognitive responses is constrained by short-term memory, however, a different pattern would be expected. Beyond some point, increasing the number of arguments on one side of the message should not affect persuasion.

FIGURE 3
ATTITUDE AS A FUNCTION OF INCREASING INFORMATION

In a limited capacity short-term memory, cognitive responses favorable to the pro side must in general be represented at the expense of potential cognitive responses favorable to the con side. So the number of pro cognitive responses will increase with the number of pro arguments only to the extent that the number of con cognitive responses can be reduced. At the point where the con cognitive responses cannot be further reduced, or none are left, then further pro cognitive responses cannot be represented, and more pro arguments will have no impact.

The results of this experiment indicated that persuasion did level off with increasing number of pro arguments (see Figure 3). With one con argument, increasing the pro arguments from one to seven yielded more persuasion. The thought listing data showed that the additional pro arguments were represented at the expense of con cognitive responses. Increasing the pro arguments from seven to fourteen, however, yielded no further persuasion. The number of pro and con cognitive responses remained the same as with seven pro arguments, additional pro cognitive responses were not represented.

With seven con arguments, increasing the prosecution arguments to fourteen also yielded persuasion (see Figure 3). Changes in the number of pro arguments were reflected in changes in the number of pro cognitive responses at the expense of con cognitive responses. The reverse occurred when the number of pro arguments was decreased to one. Con cognitive responses were represented at the expense of pro cognitive responses. I believe this data demonstrates rather clearly the importance of structure to cognitive response theory.

To illustrate further the importance of structure, I would like to describe one other theoretical implication.

The more extensively information is rehearsed in short-term memory, the more likely it is to enter long-term memory. When a message is received, cognitive responses to the initial part should be rehearsed longer and therefore enter long-term memory. Cognitive responses to subsequent parts should be less likely to enter long-term memory. Now if attitudes are formed just after a message is received, two classes of cognitive responses are most likely to be represented in short-term memory. Cognitive responses from the end of the message are more likely because they should still be in short-term memory. And cognitive responses from the initial part of the message are more likely because they can be retrieved from long-term memory. Cognitive responses arising from the middle of the message should be relatively less available. This provides a more dynamic view of cognitive response. Not all cognitive responses are likely to mediate persuasion.

This implication was tested in a study conducted with Jerry Salancik. Subjects were asked to go through a long questionnaire checking religious behaviors which applied to them. Their attitudes toward religion were measured either before or after doing this. The idea was that responding to the questionnaire constituted a type of self-perception message. The effect of this message was indicated by a higher correlation between engaging in religious behaviors and expressing a religious attitude when the behavioral items were measured before rather than after attitudes. Reviewing one's behavior affected the attitude reported.

Several studies have shown this effect. What interested us was viewing the behavioral items as a message which would elicit cognitive responses. This message could be partitioned into parts by simply dividing the list of items into quarters. For each quarter we then computed a separate index of the number of religious behaviors checked. While we did not directly assess cognitive responses, we reasoned that they should reflect the items checked on each part of the list -- so that the four indices would reflect first quarter cognitive responses, second quarter cognitive responses, and so on.

The four indices were correlated for before and after subjects with attitudes. The results are shown in Figure 4. There were no significant differences in the correlations for subjects who gave their attitudes before their behaviors. But after subjects displayed a marked serial position effect. The indices for the first quarter and the last quarter correlated most with attitudes. We conclude that more cognitive responses stimulated by the beginning and the end of the message than by the middle must have been represented in short-term memory. Since the behavior items were randomized, we can think of no other explanation besides the memorial effect.

Important methodological issues are also raised by this structural view of cognitive response theory. One is that the thought listing procedures used in cognitive response studies themselves depend on memory. Thought listing cannot be treated as automatically dumping the short-term memory contents which yield attitude.

If other activities occur after a message and before thought listing, thought listing procedures must necessarily tap long-term memory. The original contents of short-term memory will be erased by the other activities. Moreover, cognitive responses which are represented in short-term memory after a message and which do affect attitude will nonetheless be unavailable for thought listing if they have not been rehearsed enough to be placed in long-term memory. And retrieval of the thoughts which are available will be biased by the cues present at the time of thought listing. As Nisbett and Wilson (1977) have contended for other kinds of reports

on mental processes, subjects may not be able to report very well on what has affected their attitudes, and there may be good reasons why they cannot.

FIGURE 4
SERIAL POSITIONS CURVES

Extending Cognitive Response Theory: Imagery?

In a 1975 paper on the cognitive basis of Fishbein and other multi-attribute models, I pointed out that, in addition to ignoring memory structure, these models also implicitly assume that beliefs are based on linguistic verbal codes. Memory codes refer to the format in which information is stored. While it might seem that an issue as basic as memory codes should be left to the cognitive psychologist, there is a growing realization that an understanding of the cognitive basis of attitudes may require consideration of alternative memory codes as well as memory structure.

The most interesting possibility is that attitudes are based on visual imagery coding as well as verbal coding. Visual imagery is not simply pictures, or even mental pictures, though the term "quasi-pictorial" has descriptive value. It must be remembered that visual images are not objective or external, as are pictures. Imagery is a mental format for representing pictorial information. This format is thought to be the same whether it comes from visual sensation (i.e., seeing something) or from long-term memory (Hebb, 1968). Pictures are the referents of images.

If images are not mental pictures, what are they? Therein lies a controversy in cognitive psychology. Some theorists (c.g., Anderson and Bower, 1973; Clark and Chase, 1972; Polyshyn, 1973) argue against viewing visual imagery as an alternative code. The most influential argument is that of Polyshyn. He claims that all information is represented in a propositional format. Propositions are abstract logical relationships. Images and even verbal statements are surface manifestations of underlying propositions, which are themselves unavailable to consciousness. Any model of behavior must be based on propositional codes. According to this argument, visual imagery would be accorded no role in attitude theory. The experience of imagery is "epiphenomenal," that is, a mental by-product. Kosslyn and Pomerantz (1977), however, have provided a convinc-

ing rebuttal to this argument. They contend that, even if propositional coding does underlie both imagery and verbal statements, the latter have emergent properties which propositions lack. Although imagery may be constructed from propositions, the properties of visual imagery are necessary in accounting for behavior. Moreover, they doubt the necessity of even postulating underlying propositions. Contrary to Polysn, only a set of transformational rules, not a common propositional code, is necessary. These rules would specify how imagery is mapped into verbal coding.

At this point, the construct of visual imagery does seem useful in explaining many empirical findings (cf. Kosslyn and Pomerantz, 1977). A dual code (imagery and verbal coding) appears more reasonable than a propositional one. But, as this controversy points up, though the construct of imagery coding has some integrity, it is very fuzzy. Even so, it seems to me that we should begin to amend cognitive response theory to allow for imagery as well as verbal coding.

Dual-code cognitive response theory will remain pre-theoretical, however, until we can move beyond a quasi-pictorial definition of imagery. Postulating the existence of imagery coding is in itself no help in understanding attitudes. Fortunately, a recent theoretical notion called "scripts," which is attracting wide attention in social psychology, may be helpful in further developing a dual-code cognitive response theory.

Cognitive Responses as Scripts

Abelson (1976, p. 41) proposes that attitude toward an object is an "ensemble of scripts concerning that object." A script is the expectation of a sequence of events learned from direct or vicarious experience. Scripts are composed of vignettes which are the individual events, or frames, of the sequence. Vignettes generally have both a visual imagery and verbal component. Abelson uses the shorthand of "picture plus caption" to describe them. Vignettes are linked together in a coherent and causal chain to yield a script. Continuing the metaphor, the script is a cartoon strip where the separate panels combine to tell a story.

Scripts may be more or less concrete. At the most concrete level are episodic scripts. They reflect single experiences. The features of multiple experiences may be synthesized into categorical scripts. Still higher levels in which scripts are reduced completely to abstract features with no episodic character are also possible.

As an illustration, consider my experience in shopping at Marshall Field on a Saturday. What I have stored is a categorical script consisting of four vignettes: I-need-something, and the subsequent it-takes-forever-to-find-a-parking-place, followed by pushing-through-wall-to-wall-people, and finally not-being-able-to-find-a-sales-clerk. Each caption being accompanied by a suitable picture. Abelson's proposal is that it is this script, as well as any others which might come to mind, which determines the attitude I express toward the Marshall Field store. Processing this script would tend to yield a negative attitude.

The script proposal is certainly in need of further theoretical specification. I believe it suggests, however, an interesting way of relating imagery to attitudes. A product might conceivably conjure up any number of images. The script notion provides a rationale for specifying which images will be important -- those that fit together coherently to represent relevant experiences.

More generally, it seems to me that it may be useful to view cognitive responses as scripts. The usual concept

of cognitive response may be far too abstract. Cognitive responses are taken to be general thoughts about good or bad features where these thoughts are removed from any context. As scripts, cognitive responses would be firmly anchored in the stored experience of the individual. This is, of course, consistent with the major premise of cognitive response theory which is that persuasion in fundamentally self-persuasion and is, as contended by Tybout, Sternthal, and Calder (in press), initiated by self-perception.

To make the distinction between the usual view of cognitive response and script cognitive response clearer, consider an example. Suppose a woman sees a commercial for a new brand of shampoo. The usual view is that her attitude is based on thoughts about the features of the product plus any other general ideas that come to mind such as that most new cosmetic products are not very different. The script view is that her attitude is based on concrete event sequences. One cognitive response might be the categorical script ads-for-new-shampoo-products-have-caught-my-eye-before, followed by I-am-always-disappointed-when-I-try-them. Another might be the episodic script maybe-this-shampoo-would-make-my-hair-shinier, followed by my-husband-admiring-my-hair. The script view is more intensely autobiographical and far more concrete. Features and ideas do not exist in isolation but in causal chains of expectations.

The concrete character of scripts cannot be overemphasized. Nisbett, Borgida, Crandall, and Reed (1976) relate scripts to people's preference for specific information. Their example is a man deciding between a Volvo or a Saab. He might encounter all kinds of information. He might read an article in Consumer Reports based on a large sample indicating that Volvo has a better record. Or he might hear about someone's brother-in-law's who has had experience with a Volvo: "A Volvo! You've got to be kidding. My brother-in-law had a Volvo. First, that fancy fuel injection computer thing went out. 250 bucks. Next he started having trouble with the rear end. Had to replace it. Then the transmission and the clutch. Finally sold it in three years for junk." (1975, p. 129). The brother-in-law-information seems more persuasive, and there is research to support that people are biased toward such specific information. This would be expected if attitudes are based on script cognitive responses.

Conclusion

Two directions for extending cognitive response theory have been proposed. Cognitive response theory must take into account memory structure and probably visual imagery coding. Beyond this, the notion of scripts also calls attention to the need to view cognitive responses as ordered, contextual, and autobiographical. Scripts are a qualitatively different kind of memory. Given these complexities, it is not surprising that progress has been slow, and will continue to be slow, in understanding the cognitive basis of attitude.

PARTICIPATION IN ORGANIZATIONAL BUYING:
SOME CONCEPTUAL AND METHODOLOGICAL PROBLEMS

Kjell Grønhaug, Norwegian School of Economics and Business Administration

Abstract

This paper focuses on problems related to participation in organizational buying decisions. Examination of previous research reveals that the most basic questions are not answered, partly due to conceptual ambiguities and methodological weaknesses.

Introduction

The present point of departure is that organizational buying may be regarded as a subset of organizational decision making.¹ An important, if not the important, element in every organization is people, that is, "organizations are social units. . ." (Etzioni, 1964, p. 3).

The frequently posed questions like who make(s) the decisions and how to reach the influentials, indicate that problems related to participation in organizational buying are important.

Based on well known, almost "classic" studies (Buckner, 1967; Harding, 1966; Walsh, 1961) leading textbooks claim that "many" people are involved in the buying decision. The widely accepted term "buying center", further indicates that not all the members of the organization need to be involved in the buying decision. Empirical research has demonstrated great variations with regard to participation both within and across organizations. However, the main impression seems to be that the number of unresolved questions still are numerous. (Zaltman, Bonoma, 1977).

Problems, Interested Parties, and Purposes

Problems

In order to proceed, let us try to pose the most basic questions. Review of the literature (Webster, Wind, 1972; Sheth, 1976) reveals that important questions are: (1) who participates, and (2) with what degree of influence? Due to the contingency perspective in organizational research (Thompson, 1967) the following question also ought to be added: (3) under what conditions?

Parties Interested

Insight related to participation in organizational buying all probably be of interest to several parties, such as:
--the buyer (in order to improve the buying system etc.)
--the marketer (in order to design effective marketing program and improve the marketing information system).
--authorities (as basis for regulations)
--researchers (as basis for further and hopefully more relevant research).
--educational institutions (as basis for educational programs).

¹Organizational buying is adopted as the appropriate term both because it is broader and more fruitful compared with terms like "industry", "bank" and so forth, and because of accumulated research on organizations assumed relevant in the context of buying. Organizational decision making has been an important research areas for decades. (March, Simon, 1958; Thompson, 1967; March, Olsen, 1976)

This list of interest groups is in no way meant to be complete, but will probably be sufficient to demonstrate variations in interests and scope.

Purposes

The various interest groups may have different purposes in mind when occupied with questions related to participation in organizational buying. Here we may make a distinction between descriptive - explanatory - predictive and prescriptive purposes. When relating the various purposes to the interest groups, we get the following matrix:

FIGURE 1

Interest Groups and Purposes

Purpose:	Interest Groups		
	Buyer	Marketer	Others
1. Descriptive			
2. Explanatory			
3. Predictive			
4. Prescriptive			

In Figure 1, some interest groups have been collapsed into "others". Obviously there will be some inter-relationships between the various purposes, such as description is made in order to explain and predict, prediction is made in order to take prescriptive actions and so forth.

From a normative point of view the buyer ought to undertake descriptive research based on relevant theories in order to take prescriptive actions. The predominant purpose for the marketer ought to be predictions as basis for prescriptive actions as it ought to be for authorities and educational institutions.

However, when making a confrontation with research conducted the following picture emerges:

--In spite of the vast amount of research related to organizational buying surprisingly few studies have focused on participation.

--Furthermore, most studies seem to have a marketing perspective in mind. The descriptive aspects, however, are predominant.

--The buyer's interests mainly taken care of in the purchasing literature on the other hand, seem to be dominated by a normative approach with almost no emphasis on the descriptive aspect.

--The all-over impression is that the various pieces of research are scattered with few (if any?) attempts to further generalizations and theory-building. (Sheth, 1976; Webster, Wind, 1972; Bonoma, Zaltman, 1977)

Some years ago Sheth (1972) made a distinction between four phases when assessing the research related to buying behavior with regard to the present theme, however, the research conducted has to be classified in the first

two phases, i.e. the "empirical - inductive" and probably the first part of the "formative phase" respectively.

Paradigm and Research

In order to pursue problems related to critique and explanations of the present state, and, hopefully, indicate future guidelines, let us point at:

FIGURE 2

The figure is to be interpreted as follows: Given specific problems in mind, existing "models" or "paradigms" will exert influence on the research. The broken feedback-line indicates that "paradigm"/"model" may change. However, as maintained by Kuhn (1962) and demonstrated in recent research on organizational decision-making by March and Olsen (1976), existing "models" and "paradigms" often prove to be very stable and unaffected by feed-back.

In the following we will discuss problems related to "paradigm/model" and research, respectively.

The process - paradigm

These seem to be an almost complete agreement that purchase ought to be studied in a process perspective. (Engel, 1973) However, as will be demonstrated in the following, such a perspective is not without ambiguities.

For one thing, a process has to start. Almost no attention has been given to the underlying "mechanism". In consumer buying it is often assumed that an instability such as a "felt need" or "problem recognition" represents the starting point, i.e. human needs activated by internal and external stimuli. In organizational buying this "mechanism" may prove more problematic. Where the purchase is closely related to the output such as raw materials, the "need perception" or "problem recognition" will probably be unproblematic. But when there are only loose ties between the organizational output and the potential purchase, this need in no way to be the case.

This may lead us to one often overlooked point, namely, that organizational buying, as a subset of organizational decision making, involved both cognitive and social processes. (Vroom, Yetton, 1973) Most studies have concentrated on only one aspect, mainly the cognitive, and have neglected the interaction between cognition and participation.

This perspective may furthermore be related to the starting point or "the problem recognition". In most studies on organizational buying, the assumption (also reflected in the research designs) seems to be that there exists an unambiguous stimulus situation. However, the contrary may be the case, which may require both internal and external participation. (Cyert, et. al., 1956; Hakansson, et. al., 1977)

This neglect is probably related to the almost unconscious intraorganizational perspective for most studies, which also is reflected in a commonly used definition of buying center as "... members of the organization." (Webster, Wind, 1972, p. 77) By applying an interorganizational perspective, members not included in the focal organization may participate in the purchase (Guillet de

Monthoux, 1975; Hakansson, et. al. 1977)

The buying process is often perceived as a set of stages. (McMillian, 1973) However, two problems still seem overlooked:

- (1) There may be interactions between the various stages, which also may have implications for participation and outcome,
- (2) A purchase usually involves several decisions, where the sequence between the various decisions may vary, and thus participation and outcomes need in no way to be predetermined.

In organizational buying there seems to be a firm belief in "long-lasting-relationships." (Hill, Alexander, Cross, 1975) Such Perspective, however, intuitively has an impact both on the process per se and on participation. Obviously a purchase at time t may influence a purchase at time t+1. In a study both reduction in number of decisions and participants were observed over time. (Grønhaug, 1971) This coincides with the proposition that "... cost reducing tendencies generally will function to deepen and stabilize social relations. . . ." (Emerson, 1962, p. 35)

Most (all?) studies related to organizational buying are based on the assumption that buying has to be regarded as purposeful behavior. The same observation with regard to consumer buying has been made by Sheth (1972). However, for some years, there has been some focus on artifactual decision-making, particularly as related to situations involving ambiguity and characterized by problematic preferences, unclear technology, and fluid participation. (Cohen, et. al. 1971) From the discussion above, such a perspective may also prove useful in the context of organizational buying. From the discussion so far it follows that the dominating process-paradigm involves ambiguities and has implications for participation in organizational buying only partly dealt with in previous research. Even more surprising is the picture of man emerging implicitly from the discussion above. In consumer buying the model of an active problem solver seems to be common. The neglected participant seems passive almost without influence on the buying process and outcome, just contrary to what is predominant in management thinking. (Vroom, 1976)

Part time participants

Our discussion so far has only focused on our first question, i.e. who participate(s) which naturally is related to the next two questions, degree of influence and modifying conditions.

A common observation is that people outside the purchasing department (Buckner, 1967; Grønhaug, 1977; Harding, 1966; Spekman, 1977; Walsh, 1961) may also participate in the organizational buying decision. This, however, implies that for many participants buying represents only a part-time activity, and thus the time devoted to this activity will partly depend on the total load of activities.

Degree of Influence

In spite of the importance of questions related to degree of influence, surprisingly few studies have dealt with this in the context of organizational buying. The interorganizational distribution literature, which of course includes organizational buying activities, represents an exception. (Grønhaug, 1976) When reviewing the literature, one finds the buyer described by a multitude of characteristics such as by socio-economics, attitudes, motives and personality traits. The impact of such variables on participation in organizational buying has hardly been discussed at all. However, when

reexamining the findings, variables related to insight (such as education and experience) are found positively related to degree of influence. Furthermore, insight may be viewed as one dimension of capability or a source of power. Other dimensions probably positively related to degree of influence are: political access, control over information and group support. (Pettigrew, 1973)

Conditions

With reference for the contingency perspective in organizational research, the modifying question "under which conditions" was raised. In the context of participation in organizational buying, this perspective has hardly been examined at all. This, however, does not mean that such an approach is irrelevant. From previous research it is evident that the product per se may influence participation. (Buckner, 1967; Spekman 1977; Grønhaug, 1975) The impact of individual capabilities was discussed above. Furthermore, factors related to the organization and environment have been demonstrated to affect participation. (Grønhaug, 1976, 1977; Spekman, 1977)

Research

In spite of the predominant emphasis on the buying process, very few studies, if any, really have been designed to map the processes. The interactions between process and participation have also been neglected. This somewhat limited perspective on process has naturally influenced the designs of the research conducted.

The samples studied, in terms of both underlying frames and sizes, may cause some interpretational problems. First the samples/populations studied are often restricted to one industry/area. Furthermore, many studies, in particular the more "serious" ones, are often found to be based on small samples. This does not mean that this research is inappropriate. However, at least the following seems important to consider. If certain variables are assumed to exert influence, they have at least to be present in the study. Furthermore, when going back to Figure 1, the use of research findings will often include generalizations:

FIGURE 3

Directions of Generalizations

		Organization	
		Same	New
Product	Same	1	2
	New	3	4

Different directions of generalizations from research concluded are indicated in Figure 3. Intuitively it is easier to generalize with regard to a future, purchase for the same product within the same organization than it is with regard to new products in new organizations. The degree of variation between organizations is important in this context. Frequently made generalizations based on observations from big organizations in one specific industry need not to be valid in all industries. (Buckner, 1967; Harding, 1966; Walsh, 1961) In a similar way variations across purchases may affect to what degree specific findings may be generalized, as in the Copeland's (1924) pioneering classification of

markets. Both the unit of observation and analysis will obviously influence the research. Neither isolated studies of professional buyers, such as previous studies related to "emotional" factors in buying, or the main emphasis on process seem to be adequate in order to answer the questions raised at the outset of this paper. Both information about the various actors and information related to the processes and constraints seem relevant in this context.

Research related to participation in organizational buying will of course raise measurement problems which are in no way trivial but which will be overlooked here. (March, 1955)

Concluding Comments

At the outset of this paper we pointed to three basic questions related to participation in organizational buying. These questions are in no way satisfactorily answered. In spite of this, the questions related to participation are important with relevance for both buying and selling organizations, as well as to authorities, educational institutions and so forth. How to proceed? There definitely is more than one road to Rome, and probably there does not exist one best way. However, to the present author, the following ought to be done:

- Make explicit the underlying models and paradigms in order to improve the feedback from conducted research (see Figure 2)
- Reanalyze the process-perspective in order to use it properly as basis for research, and
- Reorient thinking to include the participation-perspective.
- As noted in previous "state-of-the-art" reviews much research has been conducted. However, there definitely is a need to integrate including results from other disciplines, to advance theory construction and help the generalizations of present findings. (Sheth, 1973)
- When reviewing the literature a multitude of used concepts emerges. It is almost like new concepts are created for every problem. A better strategy would probably be to reduce the number of concepts to a few basic ones, use these intensively and concentrate our energy on the relevant questions.
- From this follows that choice of concepts and the borrowing from other disciplines should be done in a more systematic way.
- Attempts should also be done in order to reduce the time-lag between what is going on in the mother disciplines and what is borrowed.
- The various interest groups and purposes in Figure 1 may prove helpful when trying to list the research questions. Attention should also be given to when questions related to participation are relevant. The marketer's interest is related to the choices of the buyers. However, in some cases the actor has no choice, as in authority innovation - decisions, and thus questions related to participation from the marketer's side, if monopolist, are almost irrelevant. (Rogers, Shoemaker, 1971, p. 300-315) In a similar way, if there exists some type of agreement that this product--shall always be bought from. . . " then a narrow analysis of the buying center within the buyer organization will probably not prove to be very helpful for the marketer. Future research should aim at advancing our pool of relevant knowledge, and should include examination of underlying paradigms and reanalysis of previous results before adding one more empirical study.

RESEARCH APPROACHES TO MULTI-PARTICIPANT DECISION PROCESSES

David T. Wilson, The Pennsylvania State University

Abstract

The study of organizational buying behavior has generated a number of concepts and models relevant to multi-person decision making. The purpose of this paper is to present some of these concepts and relate them to multi-person buying decision behavior in family decision making. A second purpose is to discuss some research approaches to multi-person buying decision making which may be relevant to the study of both organizational and family buying decisions.

Basic Concepts

The Buying Center

The concept of a buying center has been defined as "those members of the organization who interact during the decision process" (Webster and Wind, 1972, p. 77). Although the concept is intellectually appealing, most researchers have not operationalized it in their studies. This lack of use likely comes from the difficulty encountered in identifying the legitimate members of the buying center and measuring their individual influence in the decision process. Several distinct roles in the buying center have been identified: users, influencers, buyers, deciders and gatekeepers (Wind and Webster, 1972, p. 77). Although these roles are conceptually clear it is very difficult to sort out who is playing what role at a particular point in time as an individual's role may change during the decision process. Wind (1977) has neatly summarized the potential of the concept and the problem inherent in applying the concept of a buying center. He suggests that

"The relevance of the buying center concept is not limited to organizational buying, one could easily apply it to the study of consumer behavior. In this context, it is not the housewife--the traditional purchasing agent for the family--nor the entire family that should be the relevant unit of analysis. It is the family buying center which is relevant." (Wind, 1977)

Davis (1976, p. 248) points out that in most studies of family decision making "family" is usually just husband and wife and not children, relatives or friends. The concept of a family buying center would include all of the relevant influences on a purchase. Organizational buying studies should be useful to researchers studying decision making within the household as both groups of researchers must solve similar measurement problems. The cross-fertilization of ideas and approaches would benefit all.

Davis (1976) touches on many of the same research issues that Wind (1977) does. For example, the degree of influence, role versus people, number of respondents and organization of the center are issues relevant to both research areas. A reader of both papers (Davis, 1976; Wind, 1977) will be impressed by the similarities of the research problems. The concept of a multi-person buying center is useful to both groups.

The Buy-Grid

The organizational buying process can be categorized into three classes of buying situations. In each of these situations the decision process can be described by an eight-staged model (Robinson, Farris, Wind, 1967) which

is described in figure 1.

The new task situation is analogous to the extensive problem-solving situation of Howard and Sheth (1969). It is the most complex of the three buying situations and involves the largest number of decision makers and buying influences. On the other end of the scale the rebuy situation relates to automatic purchase behavior (Howard and Sheth, 1969) in which a purchase "habit" has been established. In the middle is the modified rebuy situation which occurs when the product or service purchase in a normal rebuy situation is perceived to be no longer meeting the "buyer's" needs. Product faults or competitive market forces may produce this change in the buyer's need perception.

Figure 1
The Buy-Grid Model

BUY PHASES	BUY CLASSES		
	New Task	Modified Rebuy	Straight Rebuy
1. Anticipation or Recognition of a Problem (need) and a General Solution			
2. Determination of Characteristics and Quantity of Needed Item			
3. Description of Characteristics and Quantity of Need Item			
4. Search for Qualification of Potential Sources			
5. Acquisition and Analysis of Proposals			
6. Evaluation of Proposals and Selection of Supplier(s)			
7. Selection of an Order Routine			
8. Performance Feedback and Evaluation			

The eight-stage step decision process is more suitable for organizations which document their purchasing by writing specifications than for family units who operate in a more free form environment.

Some researchers studying family decisions have used a three-phase model; problem recognition, internal and external search, and final decision (Davis and Rigaux, 1974) while others have used a four-stage model; identification of unmet needs in the form of plans, choosing the best course of action, action in the form of purchase, post-purchase evaluation (Hill, 1965). Another family decision research approach has been to examine particular aspects of a major decision (Munsinger, Weber, and Hansen, 1975) without categorizing the aspects in one of the above models.

It can be seen that organizational buying and family

buying models of the decision process have many points of similarity. Both groups of researchers are seeking to define a decision process involving multiple influences over time. A major difference is that in many instances the organizational buying process is better documented due to corporate or government regulations. Nevertheless, there are many areas where common research problems may benefit from the insights gained by one group or the others.

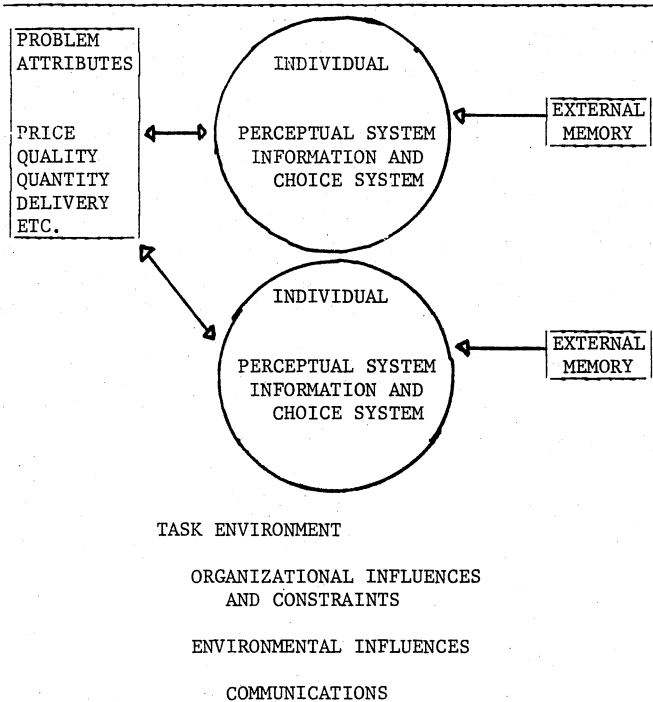

Although the buy-grid has a number of faults it does provide guidance for conceptualizing and organizing research.

A Decision Process Model

It is possible to combine the buy-grid and buying center concepts to develop a simple decision process model of the organizational buying process.

The basic structure of the model is detailed in Figure 2. The individual decision maker is the core of the model. Figure 2 depicts two individuals representing the concept of the buying center. The actual size of the buying center is a function of the buying task and the organization; in other words, its size is situation specific.

Figure 2
Structural Elements of the Decision Process Model

The term "decision process" is used as shorthand for the process that includes information-acquisition, processing activities, choice processes, and development of goals and other criteria used in choosing among alternatives (Webster and Wind, 1972: 2).

Each individual has an information processing system, the input to which is filtered through a perceptual system (Sheth, 1972, 1973). The external memory represents the notion that an organization buyer's information processing system is likely to be supported by some form of external memory ranging from a hand calculator to an on-line package of analytical programs.

The other important element in this basic structure is the conceptualization of the buying problem as a set of attributes representing the product and the vendor

(Weigand, 1966: 82; Robinson, Faris, and Wind, 1967: 40; Lehmann and O'Shaughnessy, 1974: 36). This is not a new concept, but it is an important one for this model. Attributes such as design of product, cost of application, performance life, engineering help (Weigand, 1966: 82) along with the traditional attributes of price, quality, and delivery make up the set of product-vendor attributes. This attribute set may be perceived differently by each member of the buying center in accordance with the individual's goals. Lehmann and O'Shaughnessy (1974) suggest that the importance of individual attributes varies as a function of the buying situation.

The task environment in which the individual operates likely shapes the importance of the individual attributes in total product-vendor bundle. In Figure 2, the task environment represents both environmental influences and organizational influences and constraints. Webster and Wind (1972: 40) characterize the external environment as a source of information which is input into the individual's decision process. A great deal of this information is the persuasive communications of marketers.

To review, the basic elements of the model are an individual in a task environment attempting to make a choice from a number of sets of product vendor attribute sets. This model is the most parsimonious representation of a complex process. It can be operationalized to describe simple (rebuy) or complex (new task) buying behavior.

Operationalizing The Model

It is contended that the task environment is the specifier of the operationalization of the model. The type of buying task, rebuy, modified rebuy, or new task, and the structural properties of the corporate organization greatly influence the relationship of the individuals one to another within the buying center. In addition, Newell and Simon (1972: 788) suggest that the task environment determines, to a large extent, the behavior of the individual. Their definition (1972: 55) of task environment, "refers to an environment coupled with a goal, problem or task." They note the distinction between the demands of a task environment and the psychology of the subject. This model accepts this distinction without further amplification.

Given a task environment, the four relational concepts: quasi-resolution of conflict, uncertainty avoidance, problematic search, and organizational learning (Cyert and March, 1963; Robinson, Faris, and Wind, 1967) suggest the forms that the model will assume as the buying task moves from a rebuy situation to a new task situation.

The Simple Case

In a straight rebuy situation the buyer has a clear understanding of the importance of the attributes in the situation and the possession of each attribute by each product-vendor set. A decision rule, the exact nature of which is not the concern of this paper, is applied, and a choice of vendor is made. This rebuy process can be relatively easily converted to a closed loop automatic purchasing process in which the buyer need only participate under the rule of management by expectations (Wilson and Mathews, 1971: 52) and only take over the control of the decision-making system when an abnormality exists.

It should be noted that a rebuy situation develops as the result of a new task situation. The four relational concepts have resulted in a stable rebuying situation as uncertainty has been reduced to acceptable levels and the coalition in the buying center has been satisfied.

A More Complex Case

The new task situation represents the other end of the

scale. There are many product-vendor attribute sets to be evaluated. Uncertainty is high as to the actual possession of attributes by the individual product-vendor combination. As the complexity of the task increases, a larger buying center may be created to represent groups with conflicting goals and interests.

The model can be conceived as operating in the following manner. First, responsibility for individual attributes within the bundle of product-vendor attributes is assigned to individuals within the buying center utilizing the rules of the quasi-resolution of conflict proposition. Organizational learning may be operative in that past experience may influence the current allocation of attributes to the individuals. Also, the assignment of responsibility would likely reflect the nature of the task, the skills of the individual, and other organizational variables.

A complex task situation confronts the individuals in the buying center with a likely information overload. It is suggested that the buying center seeks to reduce the complexity of the task by the easiest means possible. Problemistic search of some sort following to the principle of "information processing parsimony" (Haines, 1972) is required to reduce the number of product-vendor sets under consideration. The actual methods that buying centers use have not been addressed in the organizational buying behavior literature. Nevertheless, some speculations can be made based on studies of consumer and choice information processing behavior.

A similar decision process model could be developed for the multi-person family decision situation. Organizational variables would be replaced by variables such as stage in the family life-cycle and intergenerational influences.

The next section of the paper examines some research approaches that may be useful in the multi-person decision process.

Methodological Approaches

The complexity of multi-person decision processes in organizational and consumer buying is well documented (Davis, 1976; Wind, 1976) and has tended to retard research. Most organizational buying studies have collected data only from purchasing agents while family buying studies usually include only the husband and wife.

There is a need to develop a flexible methodology that will cut across many of the variables such as corporate size and structure. Wind (1976) has suggested that joint measurement may be one technique to quantify the effect of a relevant other person's preference on a decision maker. The amount of data that must be collected to deal with a large buying center may limit this approach but it does have promise for some decision situations.

Another approach is based upon the work in multi-attribute attitude theories. Organizational buying problems (and family buying problems) can be disaggregated into sub-problem and decision responsibility assigned to different individuals in the buying center. One way to evaluate the influence of members of a buying center may be through a version of an extended Fishbein model.

Individual members of the center would be questioned to ascertain their evaluation of the attributes salient to them. In addition, the evaluations of relevant others in the buying center, as well as their motivation to be influenced by these relevant others, would be measured. One problem will be in the individual combining to make an overall choice. It is likely that insights into this problem will come from work on noncompensatory models.

Most everyone can think of the numerous problems inherent in this approach. Nevertheless, it does offer the beginning of a method to collect and assess the influence of relevant others. There is developing a body of theory to guide researchers in developing their research approach. Hansen (1976) presents an excellent summary of these choice models.

There is a need for field work to test the viability of the above approach. For example, one way would be to analyze a number of buying situations to determine:

- (1) the individuals involved in the buying process
- (2) the attributes tacitly specified
- (3) the time-frame from initiation of project to the final choice of a supplier
- (4) an insight into decision rules for choice.

The second stage would involve individual and group interviews with members of the buying group to:

- (1) determine their views on attributes used in choice
- (2) determine the rules for the disaggregation of problems into sub-problems
- (3) determine their views on the choice processes
- (4) select several buying problems that have broad commonalities

The final stage would be the development of instrumentation to measure in field experiment:

- (1) attribute importance or saliency
- (2) attribute possession by alternative suppliers
- (3) disaggregation of the attribute set
- (4) choice rules for selecting of a supplier.

Such a study may begin to develop a methodology and instrument base founded on solid theory that would be useful for both organizational and consumer family buying studies.

Both organizational and consumer family buying involves a multi-person decision process which has many similar facets. There is much to be gained by an exchange of ideas and results by the two research streams.

OBSERVATIONS OF BUYER AND SELLER TRANSACTIONS¹

Arch G. Woodside, University of South Carolina
James L. Taylor, Texas A & M University

Abstract

Wilson and Bambic's (1977) model of a multi-stage sequence of buyer-seller interactions is supported in a field observation study of forty buying centers meeting with one of three selling centers for life and health insurance. Interactions of meetings of the buying and selling centers were tape recorded. Retrospective analyses were performed separately on both buyer and selling center participants of three groups, i.e., the tape recordings of the meetings between the centers were played to the participants in separate later meetings and their verbalized thoughts and strategies were tape recorded of their prior conversations. The results support the general hypothesis that decision net models replicating mental processes in buyer-seller transactions can be developed.

Processes of Buyer-Seller Interactions

Capon, Holbrook, and Hulbert (1977) and Wilson and Bambic (1977) provide reviews of part of the buyer-seller transactions literature and these authors reach similar conclusions: most studies have been research of one stage of a multi-stage interaction process, more research is needed to identify and measure the multi-stage interaction process of buying selling behaviors, and the use of field observations of buyer-seller transactions is healthy and necessary to advance the knowledge of consumer behavior. Few field observations studies are available which include measurements of all stages of buyer-seller interactions. The research on buyers and retail-appliance salespersons reported by Willett and Pennington (1966), Pennington (1968), and Olshavsky (1973) is likely to be the most well-known literature of field research which includes measures on multi-stages in the interaction processes. This evidence does indicate that buyer-seller interactions are likely to follow an orderly process and that the successful retail-appliance salesperson is able to influence various aspects of the buyer's behavior, including the importance of product attributes, number of alternatives considered, and amount of search for information.

Additional evidence is available to support the hypotheses that a few patterns or types of buyer-seller interaction processes are likely to exist and that such patterns are likely to vary by situational variables, e.g., importance of the purchase economically or psychologically, size of the firm or family acting as the buying center. While this literature is reviewed elsewhere (Taylor, 1977; Woodside, Taylor, Pritchett, and Morgenroth, 1977), several hypotheses and findings should be noted here. Cyert, Simon, and Trow (1956) hypothesized that replicating the decision process to purchase computer equipment in a firm which they observed for several months would be possible by describing each of the activities in the process taken one step at a time (if the rules that determined when action would switch from one program step to another were specified, and if the program steps were

described in enough detail). Cyert, et al. (1956) illustrate multiple tasks performed by many persons in the buying center observed in their study and they report two common processes: communication and problem solving processes. The communication processes observed indicated the presence of gatekeepers who act as information filters to secure a large influence over the decisions reached by the decider in the buying center. Also, the search for alternative suppliers and products terminated when a satisfactory solution was discovered even though the field of possibilities had not been exhausted. "Hence, we have reason to suppose that changes in the search process or its outcome will actually have major effects on the final decision" (Cyert, et al., 1956, p. 247). For an industrial buying center purchasing computer equipment, this research suggests that search processes and information gathering processes constitute significant parts of decision making and must be incorporated in a theory of decisions if such a theory is to be adequate.

Wilson and Bambic (1977) and Bambic (1977) develop and partially test the adequacy of a five stage decision process to describe buyer-seller interactions in industrial marketing situations. Their dyadic process model is concerned basically with the development of long-term buyer-seller relationships rather than "one-shot" selling situations. The model begins with an initial meeting between the buyer and seller and moves through a number of stages which presumably take place over time and a number of meetings of the dyad:

1. Source legitimization - the buyer establishes whether the salesperson is a representative of a qualified source of supply
2. Problem identification and information exchange - the salesperson identified problem and seeks information from the buyer
3. Attribute delineation - buyer-seller determine product attribute sets which may solve problems
4. Attribute value negotiation - negotiation of the attribute set and the exchange rate for each
5. Relationship maintenance - the dyad members maintain and build upon their business relationships; perhaps the relationship becomes personal.

The duration of the stages overlap each other as a number of activities may be carried on simultaneously among buyer-seller interactions. However, the requirements of the basic stages must be met in order to move to the advanced stages (steps 4 and 5) of the model (Wilson and Bambic, 1977).

Additional research evidence is reported here in an attempt to support the general hypotheses that a few models of buyer-seller interactions can be developed to describe the stages in the decision processes.

¹Financial support of the Division of Research, College of Business Administration, University of South Carolina, and agreement to participate of company officials in a national life insurance firm (anonymous in this study) which made this research possible are appreciated.

Field Observations of Buyer-Seller Interactions for Life Insurance

Buyer-seller interactions in the field of life insurance was selected for analysis because of previous survey and laboratory research in this field (Evans, 1963; Gadel,

1964; Busch and Wilson, 1976), the large financial investment for life insurance by the buyer, and the multiple meetings and generally complex nature of the interactions. The general purpose of the research is to build upon prior life insurance research of buyer-seller interactions, and the work of Cyert, et al. (1956), Olshavsky (1976), and others (Woodside and Fleck, 1977; Bettman, 1974; Tucker, 1967) who advocate the need to know the decision process of each member involved with the buying center with respect to the task at hand.

The research approach is an application of inductive model building instead of the more widely used deductive method of theory construction of buyer-seller interactions. Olshavsky (1976), Newell and Simon (1972), and Cyert, et al. (1956) advocate an inductive approach as an initial step to theory development through the development of descriptions and programs of decision processes. This inductive approach begins with observing buyer-seller interactions and attempts to construct anatomies of decision processes, while the deductive approach begins with insight and attempts to test conceptualizations to behavior later observed. Sheth's (1976) model of buyer-seller interaction is an example of the deductive approach to theory construction. The work by Tucker (1967) is an early example of the inductive approach.

Method

The national, regional, and local headquarters of an insurance company agreed to participate in an observation study of selling and buying centers in Columbia, South Carolina. Forty prospective life and health insurance buying centers agreed to cooperate and permit tape recordings of the meetings with members of the selling centers (two buying centers contacted refused to have the meetings tape recorded). In 17 (43%) buying centers, two persons met with the salesperson (s) during the encounter; while in 23 (57%) encounters only one person met with the salesperson (s). Thus, a total of 57 buyers actually met with salespersons. Ten buying centers met with the salesperson two separate times, while 30 buying centers met with the salesperson one time each.

Buying centers were selected for the study on the basis of convenience by the three salespersons in the regular course of their selling duties. The buying centers participating appeared to the local sales manager and researchers to be representative of the type of client normally sought by the participating salespersons. Twenty-two (55%) of the buying centers were contacted initially by the salesperson via telephone, six (15%) by direct mail, and twelve (30%) by "cold call." A "cold call" refers to a salesperson's unannounced visit to a prospect's place of business or home.

The three salespersons selling experience ranged from 1 to 5 years with the cooperating company and their ages from 28-34. None of the salespersons sold insurance for any other firm. Two salespersons were white males and one was a black male. All had at least some college training ranging from a degree in insurance at a local technical school to a Masters in Business Administration.

Data Collection Procedure

Two types of data were collected. First, encounters between salespersons and prospects were tape recorded, and second, postpurchase in-depth interviews were conducted with members of three selling and buying centers. The selection of centers from in-depth interviews was done randomly among the 40 buying centers.

The in-depth interviews following the meetings of the buying-selling centers permitted a "retrospective analysis" (Olshavsky, 1976) of persons in each center, i.e., the tape recording was played back to the buying and

selling centers separately and the participants were requested to comment on the meanings and strategies behind their own statements in the interactions.

The conversations between salespersons and buyers were recorded by the researchers while accompanying the salespersons when calls were made on potential clients. In 32 (80%) of the initial meetings the buyer(s) did not know that a researcher would be accompanying the salesperson before arrival. This was a result of the difficulty in synchronizing work schedules. Additionally, the salespersons believed that permission to record the transaction was better obtained when the buyer(s) could meet and evaluate the researcher in person.

The participating buying centers were told by the researchers that the researchers were interested in determining if people who meet for the first time or who have known each other for a short time communicate differently than persons who have known each other for a long while.

All three buying centers contacted for the retrospective analysis agreed to meet with the researchers for separate interviews. Members of these three buying centers were first asked a series of open-ended questions, e.g., "When did you first come into contact with (the salesperson)?" "What were your feelings when the salesperson first contacted you?" Answers to these open-ended questions were tape recorded. Then, small segments of the original transaction was played back to the buying center members. Individuals were questioned as to their thoughts, feelings, goals, and strategies after listening to each of these tape segments of their previous conversation with the salesperson. Buying center members were also informed to stop the recording at any point that they desired to make a comment.

Buying center members who were not present when the salesperson-prospect encounter took place (e.g., neighbors, friends, family), were identified by asking subjects what other persons they had discussed their purchase decision with. These buying center members were then contacted and interviewed by the researchers. Two such persons were interviewed by telephone.

Salespersons involved in the chosen interactions were interviewed in a similar manner. The salespersons were first asked (1) how they became aware of the prospect(s), (2) how they contacted the prospect(s), and (3) what their initial goals and strategies were when making first contact. Then, the original transaction was played back after instructing the salesperson to stop the recording at any point to comment on goals, strategies, thoughts and feelings. The recorder was stopped after playing small segments to probe for these mental processes.

Analysis

Protocol analysis and correlational analysis were utilized to analyze the data. Verbal and graphic process models were developed for three buying centers and for three selling centers using protocol analysis.

Protocol analysis for the purpose of this study includes the modification suggested by Olshavsky (1976). Generally, a protocol is a transcript of the verbalized thoughts and actions of a subject when the subject has been instructed to think or problem solve aloud (Alexis, Haines and Simon, 1968). A protocol in this study is a transcript of verbalized thoughts and actions obtained by asking subjects to relive their mental processes through recorded conversations. In either approach, the transcript is a record of the subject's thought processes while engaged in making a decision.

The theory of human thinking and problem solving from which protocol analysis sprang postulates that the human operates as an information processing system (Newell,

Shaw and Simon, 1958). The theory posits that there exists: (1) a memory, (2) search and selection procedures, and (3) a set of rules or criteria which guide the decision making process.

The tasks in the protocol analysis were to reveal the individual's mental processes through in-depth interview and to reproduce the process in the form of a graphical decision net. Similar applications of the technique to marketing problems have been reported (Cyert and March, 1963; Morgenroth, 1964; Howard and Morgenroth, 1968; Woodside and Fleck, 1977).

Decision processes are described in terms of inputs, information processing decision rules and outputs (Howard, Hulber, and Farley, 1975). The models in this study are represented graphically as a set of decision nodes with arcs (lines connecting pairs of nodes). Each decision node represents a test on a particular decision cue (such as, should I meet with this salesperson?) and the arcs represent the processing sequence taken (yes or no), depending on the values of the cues.

Generalizations and hypotheses about buyer-seller behavior in insurance exchanges were inferred from the decision models. The findings of the protocol analysis are not meant to be conclusive, but may provide a platform to the development of theory and future research. These decision models of buyers and sellers interacting, along with similar models, may serve as valuable data points from which more universal generalizations about consumer and salesperson decision-making in naturalistic environments can be made.

The findings which follow refer only to the interactions and decision processes of the buying and selling centers included in the retrospective analysis.

Process Model Showing Buyer-Seller Interaction Effects for Buying and Selling Centers A

Buying center A consisted of one prospect, Kathy Berryman, and two other persons who participated in this prospect's decision-making process. Only Kathy Berryman interacted with the salesperson representative from the selling center. Selling center A consisted of the salesperson Jed Sutton, and the agency manager, Stan Trotter. Only Jed Sutton interacted with the buyer. Stan Trotter's influence on the transaction was indirect through the advice provided Jed as to the need of being flexible in the sales encounter. This advice was offered at a sales meeting one week prior to Jed's meeting with Kathy.

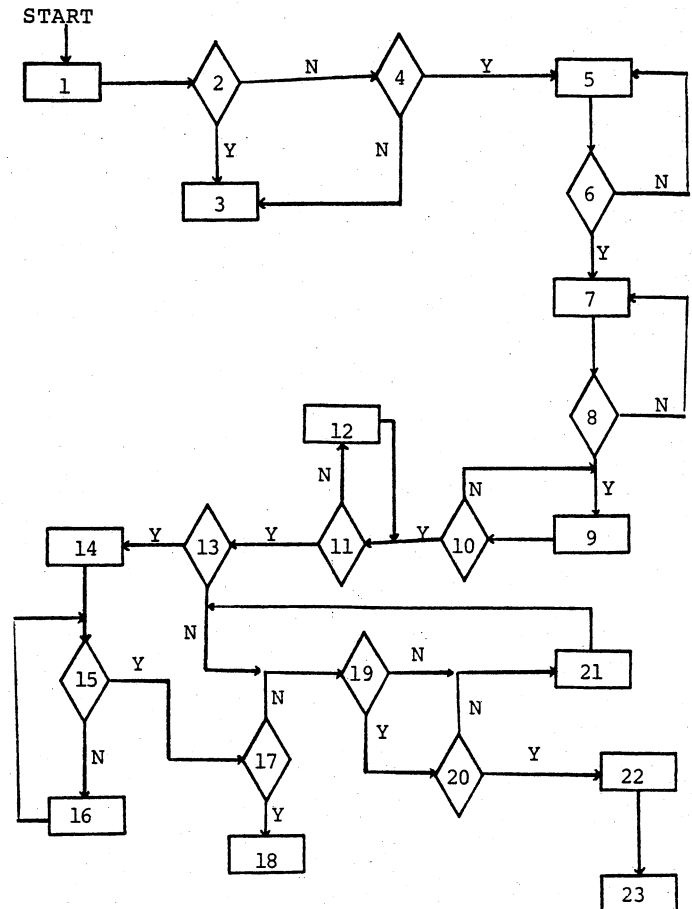

Two separate one-hour in-depth interviews were conducted with both the salesperson and the buyer. Both interviews with Kathy Berryman were conducted in her home; one interview with Jed Sutton was in his home and another in his business office. The two members of the buying center who did not meet with the salesperson were contacted and interviewed by telephone. Conversations with these latter buying center members lasted approximately 10-15 minutes.

Verbal and graphical process models for both Jed Sutton and Kathy Berryman were developed from the retrospective analyses. The models first were developed from the interview data and then presented to the salesperson and buyer for possible revision. Both parties indicated necessary revisions and then, that the models accurately represented the content of their mental activity during the sales encounter.

The verbal process models for the salesperson and buyer are included in Table 1. The words expressed in the verbal models are generally those of the participants. Some editing was required, however, for purposes of brevity and clarity. The graphical models of salesperson and buyer are shown in Figures 1 and 2 respectively.

1. Review prospect's present coverage.
2. Does prospect's present mortgage policy meet her needs?
3. Do not try to make a sale with this prospect.
4. Will prospect meet with me?
5. Establish rapport with prospect by emphasizing similarities between us and by references to familiar others.
6. Have I established sufficient rapport with prospect?
7. Discuss reasons prospect does not need mortgage insurance (such as prospect's age and marital status).
8. Have I convinced prospect that she does not need mortgage insurance?
9. Establish a need for whole life coverage by discussing cash value and paid-up features.
10. Have I established a need for converting the mortgage policy to whole life coverage?
11. Is prospect convinced that a whole life policy will supplement other policies presently held?
12. Discuss endowment features of present policies.
13. Does prospect seem to be more interested in disability income protection?
14. Revise goal to sell disability income policy.
15. Does prospect understand what social security benefits she would receive if disabled?

16. Explain social security benefits.
17. Is prospect still interested in disability income protection after learning of social security benefits?
18. Attempt to close sale on a disability income policy.
19. Have I established a need for converting to at least \$6,000 in whole life coverage?
20. Will prospect convert to whole life if payments do not exceed \$20.
21. Reiterate merits of converting to whole life.
22. Close sale of whole life policy by completing application and getting a check from prospect.
23. Make attempt to develop a long term relationship as customer and agent.

The Salesperson

Jed Sutton is a 30-year-old white male who is married and has a two-year-old son. Jed has been a salesperson with the cooperating company for one year.

Jed graduated from the University of South Carolina with a bachelor of science degree in electrical engineering and economics. After graduation, he served four and a half years in the U.S. Navy as a submarine officer. The rank of Navy Lieutenant was obtained while on active duty. Jed is still a member of the Navy Reserve.

After completing military service, Jed returned to the University of South Carolina and earned a master's degree in business administration (MBA). He then worked for Proctor and Gamble as a production manager for two years. Jed left Proctor and Gamble to go to work as a salesperson for the cooperating company. He also serves as an ACE consultant for the Small Business Administration.

The Buyer

Kathy Berryman is an unmarried white female who is 50 years old. She works as a nurse for the American Red Cross and attends the University of South Carolina on a part-time basis. She is working toward a master's degree in public health service at the University. Kathy owns her own home which is valued at approximately \$46,000.

Preexchange Activity

Kathy Berryman had previously purchased a mortgage protection (term insurance) policy from the cooperating company. The salesperson who had sold her the policy had left the company and Jed Sutton had been assigned to handle her case. Jed had reviewed her coverage and

TABLE 1

Verbal Process Model for Buying and Selling Centers A

Salesperson's Decision Process

Prospect's Decision Process

Prior to Meeting

I review the prospect's coverage and find that she has a \$30,000 term insurance policy. Her policy builds no cash value over time. She does not need \$30,000 worth of protection because she is 50 years old, has no dependents and has two other endowment policies. My goal is to convert the term policy to a \$10,000 whole life policy. My strategy is to show the prospect that she is spending \$20 a month when she has no one to protect, therefore she should do something for herself.

The salesperson calls to inform me that he has been assigned by his company to review my coverage. The agent who sold me my old policy has left the company. The salesperson recommends we get together and talk about my present coverage. I wonder whether my present coverage should be reviewed. A long time has passed since I last looked at my coverage. I may need to revise my policies. I consent to meet with the salesperson.

First Meeting

0-5 Minutes

I arrive at Kathy's home as scheduled. My first goal is to build rapport with the prospect. My strategy for doing this calls for talking about things of interest to Kathy. We talk about Columbia and the local university. I discover a common ground between us. Kathy knows and likes a professor that I once worked for. I make several references to this fact.

The salesperson arrives as scheduled. My first goal is to find out more about him. I ask how long he has lived in Columbia. I find that he graduated from the local university where I attend as a part-time student. I ask if he has ever met a particular professor that I know and like. I am surprised to discover that the salesperson once worked for this professor.

5-7 Minutes

I ask the prospect if anyone is dependent on her. My strategy is to establish that no one would suffer an economic loss at her death. Kathy needs only sufficient insurance to cover burial expense, since the value of her home far exceeds the remaining mortgage. Her house could be sold to pay off the mortgage. Thus, \$30,000 worth of term insurance is too much.

Jed asks if anyone is dependent on me. I admit that no one is. I wonder why he brought this point up. He probably wonders why I have insurance with no one to protect. I remember that my mortgage company recommended, but did not require, that I purchase a mortgage protection policy when I bought the house.

7-10 Minutes

I review the prospect's present policy with her. I show how the value of her present policy has decreased to \$26,400 and how the value will continue to decrease to \$8,400 by age 65. Her payments remain the same. My strategy is to establish a need for revising her coverage.

The salesperson tells me how the value of my policy is decreasing while my payments remain the same. He draws a graph to show this. My goal here is to comprehend what this means. I want more information.

10-15 Minutes

My strategy is to establish an economic motive for converting to a \$10,000 whole life policy. I explain the accumulation of cash value and the net costs (premiums minus cash value) associated with the whole life policy. I try to show that, at age 65, Kathy would have some accumulated cash value and would have the option of (1) continuing the policy, (2) taking a paid-up policy, or (3) taking the cash value.

I am getting a lot of information. I understand the cash value part but am not sure I comprehend the different options completely. I explain that I purchased my present policy to cover part of my mortgage. I ask the salesperson to explain the options again.

15-18 Minutes

Kathy is confused on the options. I attempt to clarify what choice she can make at age 65. I emphasize the flexibility she would have with the whole life policy.

I am beginning to understand the different options I would have with a whole life policy. I wonder whether my other insurance policies should be taken into account. I ask Jed about this.

19-21 Minutes

Oh, oh! I knew this was coming. I know she has two policies but am not sure of the face amounts or types. I must be flexible here. I ask about the face amounts and when they endow. The face amounts are \$2,000 and \$3,000 and both endow at age 65. I am in luck. Since both endow at age 65, her coverage stops at that time. My strategy now is to show her that in order to have coverage extending beyond age 65 she should convert to

Jed tells me he assumed I had other coverage. He asks about the face values and when they endow. I tell him from memory because I am not sure where they are. I ask if it might not be a good idea to look at these two policies before deciding.

the whole life policy recommended.

21-24 Minutes

I attempt to educate Kathy on endowment policies. I see no advantage of having to look up the policies since I know what they are designed for -- retirement.

Jed tells me endowment policies are usually designed for retirement, thus he is sure my policies endow at age 65. Since I am not sure where the policies are, I will drop the matter of looking at them.

24-27 Minutes

I inform Kathy that the whole life policy would take up protection where the others leave off. My strategy is to get back on track (i.e., talking about the whole life policy).

I was not aware that my protection ends at age 65. But I do have protection until that time.

28-32 Minutes

Kathy has some coverage until age 65. Thus, I revise my goal. I try to convert to some amount less than \$10,000. I suggest she convert to whatever amount would keep her payments the same as now (approximately \$20).

Jed tells me I can convert to an amount less than \$10,000 and keep my payments the same. If I change the policy, this is what I would probably do. But, I'm not ready to decide yet. I want to think about it for a while.

32-33 Minutes

I solicit a commitment from Kathy by asking which way she wants to go -- \$10,000 or a lesser amount.

I don't know what I want to do. I want more time. I know the value of my house is greater than \$26,400. The reason I bought the policy in the first place was to pay off most of the mortgage. I ask Jed if the policy would not still do this even though my house has increased in value. I think I am asking this to get more time to think.

33-35 Minutes

Kathy's not ready to commit herself. She digresses to talking about her mortgage. I want to get her back on track. I point out that, since the value of her house exceeds the mortgage, the house could be sold to pay off the mortgage. My strategy is to establish that the mortgage policy is not needed since no one depends on her.

I am beginning to believe that I should not have bought a mortgage protection policy in the first place. I wonder why my old agent sold it to me. I guess he sold it to me simply because that is what I asked for.

35-37 Minutes

I try again to close. I ask whether she would prefer to go with the \$10,000 conversion or with the \$20 a month. I recommend the \$10,000 conversion.

I'm being asked what I want to do. I want some time to think about this. I tell Jed I want to think about it and talk it over with a friend of mine before deciding.

37-40 Minutes

Two close attempts have failed. She appears to be leaning toward conversion but uncertain what to do. I try again to get a commitment by showing how easy it is to convert. I stress administrative factors of converting that make it desirable to act now. My strategy is to establish that by acting now she will be able to keep her payment date the same. But, to do this I must send her new application in soon.

Jed tells me that I need to get the application in as soon as possible to keep my payment date on the 10th. This is not important to me. I just want time to think all this through before deciding. If I do not need so much mortgage protection, maybe I should investigate something like disability income protection. I ask Jed about this

40-43 Minutes

Oh, boy! Kathy has shifted to disability income. This may be a potential sale, but for now I want to keep discussion on the whole life alternative. I mention the "waiver of premium" option on the whole life policy. This pays policy premiums if the insured becomes disabled. My strategy is to get back on track.

Jed tells me about a "waiver of premium" option. This isn't exactly what I had in mind but it sounds like a good idea. I still want more time to think about all this, however. I change the subject by asking Jed where his home is.

43-45 Minutes

It's obvious Kathy is not going to purchase tonight. My strategy at this point is to ensure that I get another appointment with her.

Jed asks when we can get together again. We discuss several dates and set up a time. I ensure that I will have enough time to talk to several friends before we meet again.
(Remainder of first and second meetings are not described here.)

45-50 Minutes

Before leaving, my strategy is to reiterate all my main selling points because I know that I will be competing with some unknown third party. I accomplish this.

Jed summarizes the merits of converting. I think of these things after Jed leaves. I'm trying to assure myself that the change is necessary and a wise move.

50-52 Minutes

We engage in a few minutes of "small talk" and I leave.

We talk about school for a few minutes and Jed leaves.

Between the First and Second Meetings

Things are out of my hands now. If the "friend" advises Kathy not to convert, my strategy will be to get both Kathy and her friend together so my side of the story can be heard. I hope this does not become necessary.

I call my brother-in-law in Greenville. I ask him what he thinks I should do. He advises me to look into a disability income policy. He thinks that it would be better for me to have some income protection in case I became disabled. He adds that he does not believe that any agent would fail to advise me properly but that I should ask about the disability plan to be sure I had considered all alternatives. I call another friend. He is not much help. He just tells me that the agent would probably not mislead me. I want him to tell me whether I would be making a wise move by converting but he avoids being explicit about this. I decide to pursue information on disability income protection. This is my goal for the second meeting.

Second Meeting

0-4 Minutes

Kathy arrives at my office. She asks about disability income protection. I change my goal to one of selling her a disability income policy. My strategy is to educate Kathy on disability income protection. I explain the 39, 60, 90 and 120 day elimination period plans.

I arrive as scheduled at Jed's office. I tell Jed about talking to my brother-in-law. I ask if my policy can be converted to a disability income policy. Jed says no. But, he explains the different elimination period plans. The smaller the elimination period the more expensive the plan. I think of this as being much like deductible automobile insurance.

4-9 Minutes

I explain how Kathy would receive \$450 a month after 90 days with the 90-day elimination plan. I mention she would get less per month for a partial disability. I attempt to show that this plan would augment social security benefits. I find Kathy is unaware of the social security benefits.

Jed provides information on a specific plan. He mentions social security benefits. I have to work 12 more years for social security. No??? Jed says I would have disability benefits coming after one year. I seek more information on this.

9-15 Minutes

I compute that Kathy would receive \$422 per month after one year if she became disabled. I tell her this. I then simply let her talk for awhile to determine what she thinks of this.

I'm surprised to find out what benefits I could receive through social security. I'm not sure that I need disability income in light of this. Converting to a whole life policy may be a better idea. I ask Jed what's involved in converting my term policy.

15-20 Minutes

We are back to conversion of the term policy to a whole life policy. How did this happen? Kathy appears to have had a change of heart concerning disability insurance. I tell her what needs to be done. My goal changes to getting her to convert to whole life. My strategy calls for just being flexible.

I have decided to convert my present policy to whole life but only to such an amount that my monthly premiums remain the same as now. I decide this after considering the social security benefits.

20-26 Minutes

I reiterate the merits of converting. I believe we are at a compromise point in which she will buy, but I need to find out what amount she desires. I try to probe for the amount she wants by talking about the options at age 65.

Jed tells me more about the options that I would have at age 65. I remark that I would use the options for purposes of retirement when I reached age 65. I am waiting for the chance to find out what amount of coverage I can get without paying more in monthly premiums.

26-30 Minutes

I know the sale is made when she said she would use her options for retirement purposes. But, I still don't know what amount. I believe about \$6,000 is needed. I decide on this as a goal. Kathy mentions disability income

I try to explain to Jed why I thought it was important to look at the disability income protection. I do this primarily because he has worked so hard at explaining both plans to me.

decided that the policy she was carrying was not appropriate to her needs. Jed called to set up an appointment in order to discuss changing her insurance coverage. Kathy had never met Jed before this time.

The Process Model

The verbal and graphical process models shown in Table 1 and Figure 1 reflect the prior knowledge of the buyer possessed by the salesperson. He had reviewed the buyer's insurance coverage and believed he had uncovered an unrecognized need. Thus, the salesperson had formulated a well-defined goal to convert the buyer's mortgage policy into a \$10,000 whole life policy. Kathy, on the other hand, had no prior knowledge of the salesperson and had no well defined goals or strategies. Vague goals of "finding out more about the salesperson" and "seeking information" were cited to the researcher.

Jed's strategy for accomplishing his goal was also explicit. His strategy required that he first get an appointment with the buyer; then establish rapport with his potential client; then show the buyer that the present policy carried was not needed; and finally convince the buyer that a whole policy would better meet her insurance needs. References to familiar others were relied on to establish rapport. Thus, for the salesperson, decision nodes 4, 6, 8 and 10 in Figure 1 were critical points in attempting to achieve his original goal.

Kathy attempted to accomplish her goal of learning about the salesperson during the first five minutes of the sales encounter. Questions directed to the salesperson for this purpose centered on (1) the salesperson's place of residence, (2) his place of education, and (3) persons known to both parties. This initial evaluation of the salesperson is reflected in decision node 3 in Figure 2. Such evaluations are consistent with social exchange theory.

The models in Figures 1 and 2 reflect the impact that actions by one party had on the other person's decision network. For example, a decision path compatible with the salesperson's original goal and strategy would have been: 1→2→4→5→6→7→8→9→10→22. The buyer, however, raised questions that required the salesperson to revise his original goal and strategy. Specifically, Kathy wanted to know (1) if the whole life policy would be compatible with other endowment policies (Figure 2, node 12), and (2) whether she should consider purchasing a disability income policy (Figure 2, node 13). The salesperson also reported detecting nonverbal cues as to Kathy's price expectations. This feedback represented a new array of cues to be faced by the salesperson, with the result that Jed's actual decision path was: 1→2→4→5→6→7→8→9→10→11→13→14→15→16→17→19→20→22. That is, the salesperson had to be flexible in changing his sales approach to include the selling of a disability income policy or a lesser valued whole life policy. Professional advice provided by Stan Trotter, the agency manager, to be flexible in the sales encounter was applicable with this buyer.

The salesperson, on the other hand, apparently exerted influence on what the buyer evaluated in her decision process. The salesperson initiated evaluations of whether the mortgage insurance was needed and whether a whole life policy should be considered as an alternative. The salesperson provided information on cash value and paid-up insurance features of the whole life policy that became part of the buyer's decision net. Finally, the buyer's purchase decision was made immediately following information on social security benefits that was provided by the salesperson (Table 1). Thus, decision nodes 5, 7, 9, 11, and 18 in the buyer's decision network may be attributed to the salesperson's influence.

Extensive problem solving behavior seems to characterize Kathy's decision process for insurance. She did not have

a well-formed set of choice criteria and had low familiarity and high search needs when considering an insurance purchase. She admitted to being confused with information provided by Jed on policy options. High search needs led Kathy to seek information from her brother-in-law and a friend. Both of these persons were contacted by the researcher, but no additional insight into their influence was gained. The brother-in-law did not advise against the whole life plan, but recommended that she explore the merits of a disability income policy first. The friend that Kathy contacted thought that she was worried that the insurance agent might be trying to sell her something unnecessary. He provided assurance that she need not worry. The basis on which this assurance was given was the reputation of the cooperating company.

In Kathy's decision net, nodes 18 and 20 were important turning points. As soon as Kathy discovered that she would be able to receive social security benefits if disabled, the purchase decision was made contingent upon her being able to keep monthly premiums below \$20. The salesperson did not detect her willingness to purchase and continued the sales presentation for approximately 15 minutes before attempting to close. Jed accurately perceived Kathy's concern for the price, however, and modified his own expectations to reflect this. Kathy admitted to the researcher that she did not want to tell the salesperson that she wanted to limit her premium to \$20 or less. Thus, she continued interaction without informing Jed of her purchase decision. This behavior suggests that the sale may have been lost if not for the correct reading of nonverbal cues and the willingness to be flexible by the salesperson. The reasons for Kathy's willingness to reveal her concern for the premium costs to the researcher and not to the salesperson were not determined.

Attempts by Jed at the end of the sales encounter to develop the long term relationship between customer and agent suggest that developmental selling may characterize the life and health insurance selling process. Jed's efforts were compatible with similar observations by the researcher of other salespersons.

Buyer-Seller Compatibility

Kathy was asked several questions concerning characteristics of the salesperson and the sales approach used in the retrospective analysis. Kathy described Jed as a person much like herself in respect to personality and values. When asked if he was similar in terms of social class and economic status, Kathy stated that she had not considered these factors. Kathy based her evaluations of Jed on information solicited as to where he lived and where he had gone to school.

Jed was considered by Kathy to be knowledgeable about insurance and a person to be trusted. His sales presentation was described as being unstructured and nonpressuring. Kathy particularly liked the concern she believed Jed expressed for her personally. She summarized her evaluation of Jed this way:

I do not think he was really out to sell the policy. I might have misinterpreted it, but he made me feel that the policy itself was for my betterment.

Process Models for Buying and Selling Centers B and C

Decision process models for two additional buying centers and two additional selling centers were constructed following one to two hours of retrospective analysis with each center. These models are not described here because of the complexity of the models and space requirements. Buyer center B consisted of two buyers,

Charles and Pam Trout. Unlike the case of Kathy Berryman, the Trouts met with the salesperson only one time and decided to purchase. Selling center B consisted of one salesperson. Excerpts of the interaction between the centers are reported elsewhere (Woodside, et al., 1977).

Selling center C consisted of two salespersons. Two buyers, Seaborn and Barbara Sellers, made up the buying center. A single sales encounter between these two centers took place in the Sellers home, the buying center consulted no outside sources before making a decision to purchase. Details of the process models for centers. B and C may be found elsewhere (Taylor, 1977).

The process models for centers B and C generally support the pattern of communication and problem solving described for center A. The results provide additional support to the Wilson and Bambic (1977) model of a multiple stage sequence of decision process in buyer-seller interactions. Wilson's model was formulated from the tenets of Homan's (1961) social exchange theory. Thus, the finding that the selling process proceeded through stages as posited by Wilson supports the view of life insurance buying-selling as social exchange. This is also supported by the observation that salespersons and buyers spent a relatively large amount of time engaged in social commentary that was unrelated to the product per se. Salespersons typically spent a relatively large part of the sales encounter in attempts to develop rapport and to establish a continuing relationship with the buyer. Similarly, buyers spent much effort attempting to learn more about the salesperson. In the retrospective analyses, the buyers emphasized the importance of salesperson characteristics on their willingness to purchase from a particular salesperson. One salesperson, on the other hand, informed the researchers that he did not try to sell to professional people because he never felt comfortable with professionals. To this salesperson, the social costs of interacting with businessmen, lawyers and other professionals apparently outweighed potential rewards of making a sale. Thus, the study findings reflect the importance of compatibility between buyer and seller such that the rewards of exchange are high relative to the social costs of exchange. Compatibility between buyer and seller was suggested by Sheth (1976) in his conceptualization of a successful buyer-seller interaction. Thus, the study also provides some support to Sheth's deductive model.

Implications

The feasibility of using recorded conversations in which participants know that they are being recorded was demonstrated in the study. Conversations with buyers following the sales encounter indicated that the researcher and recorder's presence was usually forgotten after a few minutes. Future research of this type, however, should attempt to supplement the audio recordings with video recordings. By doing so, measures of nonverbal communication behavior can be devised and results correlated with the buyer's verbal communication behavior. Results so obtained might lead to a richer understanding of the content of interaction between buyers and sellers.

This study conducted would be classed by Holbrook and O'Shaughnessy (1976) as interaction synchronization research; that is, the focus was on communications variables and a two-way perspective was taken. This is an improvement over past personal selling research that either focused on static characteristics of the buyer or seller or adopted a one-way perspective. Nevertheless, important independent variables in the study were not under the researcher's control. Future research of this type should attempt to manipulate the frequencies of using the bargaining and selling variables in order to ascertain the impact of their use on purchase. Sales-

persons might, for example, be provided with questionnaires that involve high and low levels of question usage. The different treatments (high versus low levels of asking questions) could be assigned to different customers in an attempt to evaluate their influence on sales success. Similar manipulations could be used for the other independent variables in the study.

A large number of salespersons and prospects should be used in future studies of this type. By using a larger number of buyers, more sophisticated statistical analyses can be conducted. Multiple regression could be used, for example, to determine the relative influences of the selling variables on purchase. Additionally, interaction effects between the independent variables could be studied. By using a larger number of salespersons, individual differences between salespersons can be examined; thus, leading to a greater confidence in generalizing study results.

NARROWING THE CONCEPTUAL-EMPIRICAL GAP IN ORGANIZATIONAL BUYING BEHAVIOR

Robert E. Spekman, University of Maryland
Bobby J. Calder, Northwestern University

Abstract

Marketing theorists depict the organizational buying process as comprised of several organizational members, each participating, to a greater or lesser extent, in the purchasing decision. At the same time, however, there is a noticeable lack of empirical research directed at the collective level of analysis with the goal of capturing the interpersonal dynamics of the procurement process. This paper attempts to narrow the gap between conceptualizing the process of joint decision-making and empirically investigating aspects of the collectivity responsible for purchasing related decisions. Specifically, a macro-sociological and a structural role approach are discussed as two feasible methodologies.

Introduction

In an attempt to develop an historical perspective to the study of organizational buying behavior from the aggregated, or collective, level of analysis an early study by Strauss (1962) will serve as a point of departure. Strauss, capturing the bureaucratic infighting between purchasing and other functional areas, portrayed organizational procurement as a political process in which each participant attempts to influence the purchasing decision. Interestingly, however, a great deal of the subsequent research (e.g., Leavitt, 1967; Lehmann and O'Shaughnessy, 1974; Wilson, 1971; Wind, 1970) focused solely on a key organizational member, such as the purchasing agent, and examined the extent to which various factors affected this individual's decision to select a particular vendor. While the managerial implications gleaned from an investigation of individual preferences and differences may further the development of micro-segmentation strategies (Wind and Cardozo, 1974), it is probably safe to conclude that an individual level of analysis is not very useful in capturing the dynamic interactions among those organizational members who share in the procurement process.

Beginning with descriptive studies by Robinson, Faris and Wind (1967), other researchers (Feldman and Cardozo, 1966; Grønhaug, 1976; Patchen, 1974; Sheth, 1973; Weigand, 1968) have built upon Strauss' representation of organizational buying as a joint decision making process. Webster and Wind (1972), in their influential analysis of organizational buying behavior, developed the concept of the buying center and thereby attempted to raise the level of analysis to include that collectivity responsible for purchasing related decisions. Embodying Strauss' conceptualization of the buying process, the buying center notion focuses on those formal and informal relationships which develop between the purchasing agent and those other organizational actors with whom he interacts during the purchasing process. It should be noted that unlike a formal structural subunit (i.e., the purchasing department or the marketing department), the buying center is a more nebulous construct, reaching across functional boundaries, whose composition can only be determined through empirical investigation.

In light of the realities of organizational decision-making (see, Cyert and March, 1963), a collective level of analysis would seem to more accurately reflect the dynamic interactions which depict the organizational

procurement process. Why, then, is there a paucity of empirical research focusing on a collective level of analysis? An explanation appears to lie in the lack of an appropriate methodology. The purpose of this paper is to narrow the gap between conceptualizing the process of joint decision-making and empirically analyzing aspects of the collectivity referred to as the buying center. To achieve this goal we will explicate two methods for conducting research which reveal information about how the activities of many individuals come together to affect purchasing decisions. One approach emerges from macro-sociology and is concerned with structural properties of the buying center. The second approach evolves from role theory and emphasizes the role structure of those individuals composing the buying center.

Structural Properties of the Buying Center

Background

Structural properties of the buying center are obtained by analyzing data about the relations of each buying center member to some or all of its members (Lazarsfeld and Menzel, 1969). With the advent of open systems thinking (Kast and Rosenzweig, 1972), some organizational theorists (Burns and Stalker, 1959; Duncan, 1972; Galbraith, 1973; Hall, 1963; Lawrence and Lorsch, 1967) began to view the organization (as well as its subunits) as dynamic, responsive entities in continual, and necessary, interaction with its environment. In short, the organization became an information processing entity and its structural configuration defined its ability to gather and process information. Breaking from the Weberian tradition, these contingency researchers posited that some structural configurations are more adept than others for dealing with the varied environmental factors with which the organization must contend. Moreover, a basic premise of this stream of research is that of all the environmental factors with which a firm (or one of its subunits, for that matter) must contend the most pervasive and all encompassing is environmental uncertainty. By adapting its structural configuration to match the level of uncertainty in its environment, a firm (or a subunit) can facilitate the gathering and processing of information crucial to its decision-making process.¹

Dimensions of Structure

Following a contingency related paradigm, the buying center is conceived of as a "decision unit" whose members are charged with making purchasing related decisions (Spekman, 1977a). In this fashion, the buying center exists as a communication network which does not necessarily derive its structural configuration from the formal organizational per se; but rather from the regularized patterning of behavior and communication flows which typify the industrial procurement process. In a very real sense, the buying center's structural configuration also serves to define its decision-making

¹It should be noted that while uncertainty has been portrayed as an independent variable here, other researchers have relied on technology (Mohr, 1971; Woodward, 1965), size (Child, 1972) and other environmental factors as antecedents to the structural dependent variables.

potential. Extant contingency research (Duncan, 1972; Hall, 1963) has, for the most part, concentrated on four dimensions of structure: 1) centralization--the degree to which authority and responsibility rests with a particular organization member; 2) rules and procedures--the extent to which activity in an organization is formally defined; 3) division of labor--the degree to which tasks are differentiated; and 4) participation in decision making--the extent to which organizational members are involved in decision-making. From an analysis of these structural measures one is able to generate a profile of the interactions which take place in the buying center during the decision process.

As stated earlier, some structural configurations are more conducive to information gathering and processing than other forms. Specifically, a highly bureaucratized structure restricts the flow of information to rigidly established channels of communication and is best suited for decision-making when 1) time is of the essence; 2) the decision is routine in nature; and 3) environmental demands are clear and uncomplicated (Katz and Kahn, 1966). Clearly, it can be seen that a highly bureaucratized structure--with its high degree of centralization, strict rules and procedures, clearly defined and distinct division of labor, and low levels of participation in decision-making--places severe limitations on the amounts of information available to the decision unit (i.e., the buying center).

As the decision-making requirements become more complex--perhaps as a result of greater environmental uncertainty--empirical evidence (Duncan, 1972; Lawrence and Lorsch, 1967) would suggest that a less bureaucratized structure would improve the information gathering and processing capabilities of the decision unit. For instance, a lower level of centralization would promote decision-making at the point of information gathering rather than restricting the flow of information to a more rigidly defined communication path. Further, the content of purchasing-related communication would consist of greater information passage and less instructions.

Similarly, a less rigid division of labor enables the decision unit to remain flexible enough to allow for a constant redefinition of tasks which may be necessitated by the demands of a highly complex, non-routine decision-making situation. Through increased lateral communication and a more flexible design, the buying center members can more quickly and more easily respond to changing demands and contingencies. Furthermore, flexible rules and procedures enhance effectual processing of novel and non-routine information by permitting greater individual discretion. Such structural adaptation can lead to innovative behavior on the part of the buying center members and, thus, allow them to adapt to contingencies and information requirements which may not have been foreseen when the rules and procedures were initially developed.

The last structural dimension concerns the degree of participation in decision-making. Greater participation is an outgrowth of the adaptation associated with the previous structural dimensions. It logically should follow that as the buying center members are faced with more difficult decisions greater dependency should be placed on informal, lateral channels of communication. This increased participation in decision-making should improve the decision-making potential of the buying center members by enlarging the information base available to them as well as by providing opportunities for more sources of information feedback (Argyris, 1973).

From the dimensions of structure outlined above one can then position a buying center along a bureaucratic/non-bureaucratic continuum. A particular buying center

profile would presumably connote a particular communication network, concentration of authority, workflow and so on among the buying center members. These, and other, organizational factors have been shown to impact upon aspects of the buying process (Grønhaug, 1976; Webster and Wind, 1972). While superior to Webster and Wind's descriptive, functional role approach, a possible flaw in these structural measures, as presently operationalized, is that these constructs may not accurately reflect the informal interactions among the buying center members. For example, it is possible to infer that a less bureaucratized, more flexible buying center profile represents a more democratic, participative decision-making atmosphere with a high degree of shared purchasing responsibilities and a de-emphasis on impersonal behavior. Yet, such organizational level analyses do not readily permit the researcher to examine the precise nature of the various sociometric linkages which emerge during the procurement process.

It should also be mentioned that the aggregation procedure itself tends to mask any individual level behavior since the buying center profile reflects an average of the individual responses. Moreover, recent findings suggest that there is a relatively low degree of consensus among the various buying center members with respect to their perceptions of the buying center structure (Spekman, 1977b). Despite the inflated error variance associated with each buying center score resulting from the above instability (Cook and Campbell, 1976), the macro-sociological approach does furnish insights pertinent to the decision-making potential of the buying center members. Specifically, it has been shown that the various structural dimensions have important implications for the decision unit's ability to gather and process information. Nonetheless, what may be more relevant to the researcher is a methodology which focuses on an aggregated, or collective, level of analysis and, as importantly, also facilitates the examination of the individual as he interacts as a member of the particular collectivity under examination.

Structural Role Analysis

Role theory provides a conceptual framework for linking an individual to a collectivity and, as Hickson (1966) suggests, it is a useful vehicle for bridging the organizational and individual level of analysis. Hall (1976) states that role theory is a helpful device for understanding the interplay among persons, interpersonal and organizational factors as they impinge upon the behavior of organizational members. Structural role analysis, a subset of role theory, concerns itself primarily with the structure of role relationship. In comparison to the macro-sociological approach, structural role analysis is a more micro-level orientation in that it calls for an intensive analysis of the individual decision unit or organization.

Elements of Role Structure

Basic to the concept of role structure is that any collectivity is linked by various tasks which must be accomplished. The particular workflow which emerges establishes specific relationships among the members of the collectivity. In the context of the buying center, for instance, there are generalized decision stages--ranging from identification of a buying need to performance feedback and evaluation--which must be performed during the procurement process. While the exact nature and sequence of the decision states (i.e., BUY-PHASES) may vary depending upon the type of purchase (i.e., straight rebuy, modified rebuy or novel purchase) there is usually a clearly established workflow which can be discerned.

A second element, the concept of positions, links a particular person to a task element. If, for example, one of the decision stages in the procurement process is the setting of specifications, we may find that the individual performing this task is called a design engineer--regardless of who the individual is, the job is always done by a design engineer. The notion of positions is quite consistent with the impersonal, Weberian notion of organization. In this manner, the set of linkages illustrated by the various positions within the buying center serves to 1) establish the formal relationships among buying center members and 2) represent the functional role (i.e., design engineer, buyer, etc.) assigned to a particular task. Simply, the concept of position defines one's position on an organizational chart and specifies the nature of one's formal interactions with other members of the organization or organizational subunit (in this case, the buying center).

Since the formal structure does not, in many cases, depict all the interactions within an organization, a third set of relationships emerges. The third set of elements concerns persons who are individuals initially interrelated by their assignment to a particular position and who, over time, can develop informal relationships which need not be specified by the formal hierarchy of the organization. It can be seen that this set of persons serves to complete the communications network (Oeser and Harary, 1962 and 1964) not fully accounted for by the more formal delineation of positions or tasks.

Digraphs, roughly defined as patterns of relationships among pairs of abstract elements (Harary, Norman and Cartwright, 1965), are used to illustrate and describe how any set of tasks, positions, and persons are conceived to be logically interrelated. While Figure 1 maps out a completed structural role system, it is possible to isolate a series of graphs where a P-graph depicts the formal relationships among buying center members, a T-graph outlines the sequence of purchasing related tasks, and an H-graph delineates the informal relationships among the buying center members. From Figure 1 one can discern 1) a sequence of buying activity (beginning with t_1 and ending with t_3); 2) a superior-subordinate relationship between a buyer (p_2) and a purchasing manager (p_1); and 3) an informal relationship between individuals acting as a buyer (h_1) and a design engineer (h_2) both of whom share the task of setting a particular product's specification (t_2). While no doubt a simplified structural role relationship, one can easily envision quite an elaborate set of digraphs encompassing many individuals, occupying several organizational positions, and engaging in a detailed sequence of procurement activities.

Figure 1

A Simplified Digraph Depicting a Structural Role System in a Buying Center

From a highly schematic form of digraph one is able to more deeply delve into the interpersonal dynamics of the buying center. Not only can one more easily discern the sequence of purchasing related events and the various positions sharing these activities, a researcher is able to trace informal power relationships and other sociometric linkages which cannot be examined directly from a more macro-perspective. A structural role approach offers a basis for aggregating across organizations while still preserving an individual, micro-level perspective.

It should be noted that the use of structural role analysis in an organizational buying context is presently not well developed (Calder, 1976) and, therefore, it is not our intention to propose it as a panacea for existing methodological weaknesses. Rather, our purpose has been to portray structural role analysis as a useful conceptual framework for capturing the micro-level relationships which lie at the core of the buying center construct. Utilizing a structural role perspective, we have, in fact, just finished collecting data pertinent to the decision-making properties of organizational buying centers. Yet, we sought to capture the actual micro-level relationships among buying center members through a multidimensional scaling technique. The point to be made is that structural role analysis is not a method in and of itself; it merely provides a guide by which to conduct collective level analyses.

Conclusions and Implications

The issue of whether the individual or the collectivity is the proper level of analysis for conducting inquiry into organizational buying behavior is one with which future researchers must come to grips. While it is quite acceptable to empirically deal at both levels, it is felt that for much of the information germane to the joint decision-making properties of the collectivity responsible for purchasing related decisions (i.e., the buying center) the aggregated level of analysis is appropriate. For the present, the major stumbling block appears to be the lack of a suitable methodology.

The objective of this paper has been to stress the need for narrowing the gap between the conceptualization of organizational buying as a joint decision-making process and the method by which a researcher can empirically investigate that process. While still in the exploratory stages both the macro-sociological approach and the structural role approach appear to be viable methods for capturing aspects of the joint decision-making behavior of the buying center members. Moreover, both approaches permit the researcher to examine relationships among variables both endogenous and exogenous to the system thereby surmounting many of the pitfalls of investigating the individual members of the buying center as isolated entities.

The macro-sociological approach, however, primarily allows the researcher to infer particular interpersonal relationships from the structural configuration of the collectivity under scrutiny while the structural role approach can result in a more revealing picture of the interpersonal dynamics of the buying process. That is, much more verbal information can be gleaned from a graphic representation of the various structural role elements than is available from a macro-sociological investigation. It may be possible, for example, to infer from a rather flexible structural configuration that a purchasing agent is involved in several stages of the purchasing decision as a result of the more participative style of decision-making. Yet, a structural role analysis of the same buying center may disclose that this same purchasing agent influences particular decision stages (perhaps, the setting of

specifications) through his informal, social relationships with a particular design engineer. Since competitive suppliers may only meet with the purchasing agent such information has important implications for the future conduct of their marketing efforts. Clearly, one can envision the strategy implications which can be distilled from a thorough analysis of organizational buying behavior from the collective level of analysis. We have presented two feasible directions for empirically examining aspects of organizational buying behavior from the collective level of analysis.

ON THE INTERFACE BETWEEN ORGANIZATIONAL AND
CONSUMER BUYING BEHAVIOR

Yoram Wind, University of Pennsylvania

Abstract

The relevance of organizational buying behavior concepts and methods to the study of consumer behavior is examined. The paper suggests a number of implications for the study of consumer behavior and calls for the legitimization of the study of organizational buying behavior within the boundaries of the consumer behavior discipline.

Introduction

The basic premise of this paper is that our concepts of and approaches to the study of consumer behavior can benefit from a close examination of the organizational buying behavior literature.¹ Many of the consumer behavior models recognize the social context and multiperson nature of most purchase and consumption behavior. Yet, to date, these models and most of the consumer behavior concepts and studies have focused on the individual as the unit of analysis.

The lopsided emphasis on the individual and the tendency to ignore the multiperson issue can be attributed to three major reasons:

1. Conceptual difficulties involving the development of multiperson variables (as distinct from individual variables) and hypotheses.
2. Methodological difficulties involving the analysis of multiperson data.
3. Operational difficulties involving added time and monetary costs for collection and analysis of multiperson data.

Organizational buying behavior, on the other hand, did not have the luxury of focusing on the individual. Even the early conceptual and empirical organizational buying behavior studies recognized the fact that meaningful studies cannot focus only on the purchasing agent but rather should be concerned also with other organizational members (e.g., users) involved with the purchase and usage of the given products or services.

In this respect then, the usually neglected area of organizational buying behavior could conceivably provide concepts and methods relevant to the study of multiperson consumer behavior. The objective of this paper is to briefly outline some of these possible contributions and suggest that advances in our understanding of consumer behavior can be gained not only from research on consumer behavior but also indirectly from research on organizational buying behavior.

Conceptual Contributions

The conceptual contributions of organizational buying behavior to the study of consumer behavior include the concepts of:

¹The converse (i.e., the contribution of consumer behavior models, concepts, and findings to the study of organizational buying behavior) is also true. Yet, given the orientation of this audience, the paper focuses on the contributions of the organizational buying behavior area to the study of consumer behavior.

- . the buying center
- . decision stages and roles in the buying center
- . group choice models
- . buying situations
- . a building block modeling approach
- . buying center tasks and objectives
- . consumers' organizational climate and structure
- . consumers' organizational technology
- . consumers' organizational (vs. individual) variables

The Buying Center

Consumer products and services are purchased not only by individuals, but quite frequently by a number of individuals (not all of whom are members of the same household) or by an individual who buys for the consumption of someone else. Even when a person buys a product or service for his or her own consumption, a number of aspects of the purchase decision are often influenced by some relevant others. In all of these cases a sole focus on the individual could be quite misleading.

Recognizing the multiperson nature of most consumer behavior, greater emphasis has been placed in recent years on the study of the family and, in particular, the husband-wife dyad. Yet, the husband-wife dyad is not always the relevant unit of analysis (consider, for example, purchases involving products for children and the cases in which consumers are not living within the boundaries of the traditional family). It would be much more desirable, therefore, to accept the concept of the buying center, which was developed in the context of organizational buying behavior (Wind, 1967). The concept calls for the identification, in each purchase situation, of the relevant individuals involved in the buying decision process (whether they are members of the same household or not) and using them (the members of the buying center) as the relevant unit of analysis.

Conceptually, the buying center is the appropriate unit of analysis in consumer behavior. Yet, implementing the concept requires the resolution of a number of conceptual and methodological issues (Wind, 1977). A number of these issues are currently studied in the context of organizational buying behavior, and could provide better insight into consumer behavior.

Decision Stages and Roles in the Buying Center

Consumer behavior involves a large number of decisions² ranging from the identification of a need, through various stages of generation and evaluation of alternatives,

²A large number of models have been proposed in both the consumer and organizational behavior literature to describe the various buying decisions and their sequence. Since there does not seem to be any consensus as to the "true" sequence of purchase decisions, the readers may select the model of their choice replacing the rows in Exhibit 1 with the decision stages of their own model.

to the selection of a product, specific features of a given brand, and time and place of purchase. Since these decisions are typically made by a number of members in the buying center, it is useful to construct a matrix of decision stages by roles as illustrated in Exhibit 1 (which is an adaptation of a matrix developed in an industrial buying study). The specific decision stages and roles would most likely change across buying situations. The same individual could occupy a number of roles (e.g., buyer and user), and a number of individuals could occupy the same role (e.g., there may be a number of users).

EXHIBIT 1
Decision Stages by Roles³

DECISION STAGES	ROLES ⁴				
	Buyer	User	Influ- encer	De- cider	Gate- keeper
Identification of needs					
Establish specifications					
Search for alternatives					
Establish contact					
Set purchase and usage criteria					
Evaluate alternative buying actions					
Determine budget availability					
Evaluate specific alternatives					
Negotiate with suppliers					
Buy					
Use					
Conduct post-purchase evaluation					

Developing the relevant decision stages-by-roles matrix and establishing common patterns across various buying situations would help our understanding of consumer behavior and place the work on the individual consumer's decision processes in the proper perspective.

Furthermore, in many of these decision stages the person occupying a given role engages in a negotiative process with suppliers and other external personnel. In these cases the unit of analysis can be changed to the group of boundary persons (e.g., buyer and salesman).

Choice Models

The consumer behavior literature has been predominantly occupied with individual choice models. Yet, many consumer behavior situations involve a group choice⁵ which cannot be explained adequately by individual choice models.

The organizational buying behavior literature and its supporting disciplines (e.g., organizational behavior

³For alternate formulation of decision stages-by-roles matrix see, for example, Webster and Wind (1972).

⁴Roles can also be defined as husband, wife, children, friends, etc.

⁵The other case of individual choice subject to the influence of relevant others (Wind, 1976) can be viewed as being somewhat between the two extremes of the "pure" individual choice and the group choice situation.

and political science) have offered a number of group choice models. These models cover both formal "voting" type choice models and informal interaction type models. The formal group choice models vary with respect to the specific decision rules employed (e.g., simple majority), the way these rules are determined, and the weight given each group member. The informal interaction choice models vary with respect to the processes of interaction, influence, persuasion, bargaining, and conflict resolution procedures employed.⁶

Buying Situations

One of the early empirical organizational buying behavior studies (Robinson and Faris, 1967) distinguished between three major buying situations—the new task, modified rebuy, and straight rebuy situations. These situations vary with respect to the decision process and information inputs they require as well as with respect to the number of new alternatives considered and uncertainty involved.

Understanding the buying situation is as critical in the study of consumer behavior as it is in the study of organizational buying behavior. Yet, with the notable exception of Howard's (1963 and 1977) classification of consumer behavior into a similar trichotomy of routines, limited and extensive problem solving, and the theoretical and empirical work of him and his colleagues, little explicit attention has been given in the consumer research area to the importance of buying situations in the explanation of consumer research.⁷

A Building Block Modeling Approach

Whereas most consumer behavior models have attempted to specify the exact network of buying decisions, their interrelationships and determinants (e.g., Howard and Sheth (1969)), the organizational buying behavior model proposed by Webster and Wind (1972) is based on a building block approach, i.e., the model focuses on the identification of the major sets (blocks) of variables that could affect the organizational buying decisions.⁸ Recognizing that no deterministic model can explain and predict accurately all organizational buying decisions, the model provides a framework for the identification of variables and specification of hypotheses (reflecting the current state of knowledge) on the relationship among the key variables. As such, it serves only as a guideline for the selection of variables for specific empirical studies on organizational buying behavior with no attempt to specify general cause and effect type relationships.

Given the disappointing results (in terms of predictive efficacy) of most of the detailed consumer behavior models, it might be useful to lower our level of expectations from these models and reformulate them as building block models of consumer behavior. Alternatively, one can even take the organizational buying behavior block

⁶For a detailed discussion of a number of these group choice models see, for example, Patanik (1971), Fishburn (1973), and Guetzkow and Collins (1964). A comparison of the predictive ability of a number of these models in the context of both an organizational and family choice setting is being conducted by Buss (1977).

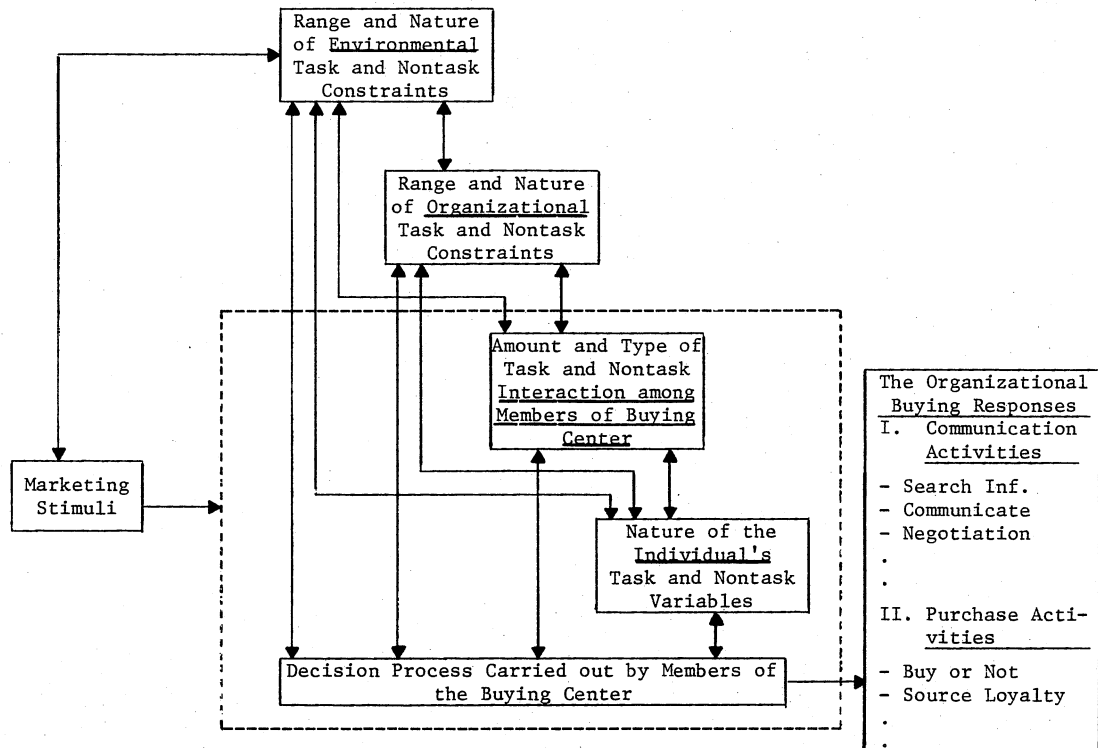

⁷Buying situations have also been approached from a different point of view by Belk (1975), who focused on the various dimensions of the consumer situational characteristics; namely, the physical and social surroundings, the temporal perspective, the task definition, and the antecedent states.

⁸For other modeling approaches to organizational buying behavior, see Sheth (1973), Hillier (1975), and Choffray and Lilien (1977).

model presented in Exhibit 2 (Webster and Wind, 1972) and use it in some modified form as a guideline for consumer behavior studies.

tural characteristics which have been ignored by the more conventional approaches to the study of consumer

EXHIBIT 2
An Organizational Buying Behavior Block Model

Buying Center Tasks and Objectives

The consumer behavior literature has given considerable attention to consumers' objectives as defined by their needs or benefits sought. Yet, little attention has been given to the identification of consumers' purchase related tasks, their relationship to the consumers' hierarchy of objectives, the ways consumers attempt to resolve conflicting objectives, and the evaluation of the purchase tasks (and functions).

It is in this context that the organizational buying behavior and procurement literature can be of help since one of their major concerns is with these issues (e.g., value analysis, economic order quantity procedures, etc.) and their impact on the buying process.

Consumers' Organizational⁹ Climate and Structure

The "organizational climate" literature distinguishes nine dimensions of organizational climate (Litwin and Stringer, 1968) which could also be used to describe the relevant consumer climate. These dimensions are: structure, responsibility, reward, risk, warmth, support, standards, conflict, and identity. The identification of these dimensions in the context of consumer behavior can add a rich new perspective to the more conventional consumer psychographic inventories.

Some of these dimensions are also related to the struc-

⁹The term consumers' organization is used to denote the group of people comprising the organization within which the consumers' purchase and consumption activities take place. The family, for example, can be considered such an organization.

behavior. Among the more relevant structural characteristics are:

The reward system. In the organizational buying context the behavior of individual buying center members was explained by their perceptions of the criteria used to distribute rewards (Wind, 1971). It seems, therefore, that in multiperson consumer buying centers the consumers' perceived rewards should be examined as one possible explanation (and predictor) of purchase behavior.

Division of responsibilities. The division of responsibilities within the consumer organization (the actual matrix of decisions by roles) and its stability (over time and situations) is one of the major factors which effect organizational buying behavior. It might be useful, therefore, to consider this variable (and its related concepts—the degree of decentralization and profit responsibilities of the buying function) in consumer studies as well.

Roles, role expectation, and role conflict. Organizational buying behavior and the sociological literature have suggested the importance of perceived roles, role expectations, and role conflicts in explaining the behavior of organizational members. The same concepts seem to be appropriate for the explanation of consumer purchase (and usage) behavior.

Authority structure. The buying authority and the extent of lateral vs. vertical involvement in the purchase process have long been recognized in organizational buying (for example, Strauss (1962)). These concepts have largely been ignored in consumer behavior despite the similarity between the authoritarian-democratic structure of the family and that of an organization. Simi-

larly, the purchase involvement of two parents (lateral relationship in egalitarian type family) differs from that of a parent and a child (vertical relationship).

Consumers' Organization Technology

It is well recognized in the organizational buying literature that technology has its impact both on the determination of which item to buy and on the nature of the buying process itself. It is reasonable to assume that technology is also a major factor in consumer behavior. Yet, it has been largely ignored in the study of consumer behavior.

In the consumer context, technology includes the house and equipment owned and used by the consumer, as well as the programs and procedures used to "manage" the household affairs in general and the buying function in particular.

The consumer's technology defines the technological constraints within which purchase and usage decisions and behavior take place. It is important to remember that the current house and equipment, as well as the technological orientation of the consumer, places significant constraints on the buying actions that can be considered. It might be useful, therefore, to examine consumer behavior conditional on the consumers' technological constraints.¹⁰ This is especially crucial for new products which either have to fit the consumers' current state of technology or change it (most likely at a high-er psychological and monetary cost).

Telephone and mail buying are examples of buying technology. Other technological developments should also be given attention. In particular, two-way cable TV and the recently introduced home computers which, at a price equivalent to a color TV set, have the potential of changing consumer buying technology, and affecting the buying decision process and outcomes.

Consumer Organizational (vs. Individual) Variables

The dependent variable in many consumer behavior studies has measured a response of the consumer organization (e.g., household purchase) and not of the individual decision maker. In contrast, the explanatory variables used in consumer behavior studies tend to be, with few exceptions (e.g., family income), individual in nature (e.g., education, sex, personality, attitudes, etc.).

Viewing the consumer as an organization suggests the addition of a new class of variables—namely, "organizational" type variables which measure the characteristics of the relevant consumer organization (apart from the characteristics of the individuals involved). The development of a set of consumer "organizational" measures requires a theoretical framework which encompasses the relevant dimensions of consumers' organizational behavior. In the absence of such a framework (which also does not exist for organizational buying situations) one may consider a number of variables¹¹ (and their possible consumer behavior descriptors) such as:

Domain consensus. (Levine and White, 1961)—the degree to which members of the consumer organization (e.g., household) agree on the goals, reference orientation, and tasks.

¹⁰This (technological) conditional analysis is similar in spirit to the one in which purchase and usage behavior is explained conditional on the consumers' existing inventory (assortment) or products (Wind, 1977c).

¹¹For a detailed discussion of organizational measures, see Price (1972).

Stability. (Caplow, 1964)—the length of time the consumer organization has been in its current structure (e.g., length of stay in a family life cycle stage, etc.).

Resource distribution. (Evan, 1966)—the amount and type of resources held by each member of the buying center compared with their needs.

Formalization. (Hage and Aiken, 1970)—the degree to which a consumer organization has rules and established guidelines for its purchase and consumption behavior.

Satisfaction. (Smith, Kendall, and Hulin, 1969)—the consumer's satisfaction with other members of the buying center (those occupying parallel roles to "co-workers" and "supervisors").

Efficiency. (Etzioni, 1964)—the amount of resources used by the consumer organization to achieve its intended purchase and consumption goals.

Intimacy. (Hemphill and Westie, 1950)—the degree to which members of the buying center are familiar with the preferences of the other members and know their probable reaction under widely different circumstances.

Participation. (Hemphill and Westie, 1950)—the degree to which members of the buying center apply time and effort to the purchase and consumption activities of the buying center.

In addition to the "new" consumer organizational type independent variables that the study of organizational buying behavior suggests for inclusion in consumer behavior models, there are a number of concepts suggested by the organizational buying behavior literature which should receive greater attention by consumer researchers. These concepts include:

The make, buy, or lease decision. Most consumer behavior studies focus on the buy decision ignoring the other two alternatives facing the consumer—leasing or making the product (or performing the service) by themselves.

The dyadic relationship between buyer and seller. Whereas most consumer studies focus on the consumer, a number of organizational buying studies have attempted to examine the nature of interactions between the buyer-seller, their negotiations, and bargaining processes. Given that in many consumer situations (e.g., in the retail environment) the consumer interacts directly with a seller, it might be useful to borrow from this area of the organizational buying behavior literature.

Multiple sourcing. Most organizations have policies against single source and attempt to maintain at any given time a number of alternative sources of supply. The consumer behavior literature has ignored this phenomenon and focused in many studies on the selection of a single brand or source. There is, however, some evidence to suggest that consumers do buy multiple brands from multiple sources. This was especially evident during the energy crisis when consumers tried to maintain "good customer relations" with more than a single gas station.

Methodological Contributions

Comparing the level of sophistication and innovativeness of consumer and organizational buying research suggests a clear dominance of consumer research.¹² Yet, despite

¹²For a discussion of some of the limitations of consumer research, see Jacoby (1976) and Wind (1977b).

the more advanced state of research on consumer behavior, there are a number of methodological contributions the organizational buying behavior literature can make to the advancement of consumer research. These contributions encompass areas which received considerably more attention in the study of organizational buying behavior and which could be applied to the study of consumer behavior. In particular these include:

- . greater emphasis on the analysis of purchase documents
- . reliance on protocol analysis
- . time and motion studies
- . input-output analysis
- . reliance on smaller samples

Greater emphasis on the Analysis of Purchase Documents

Examination of organizational buying research, and especially as conducted by industrial firms, suggests a much greater emphasis on secondary data analysis. Of particular interest is the utilization of purchase documents as the data for the analysis of various aspects of organizational buying behavior, such as source loyalty (Wind, 1970). Consumer researchers have relied heavily on panel purchase data (such as MRCA purchase diaries), with little attention, however, to the utilization of household purchase records, e.g., the analysis of bills paid, etc.

Reliance on Protocol Analysis

Protocol analysis—the analysis of transcripts of the verbalized thoughts and actions of a subject when the subject has been instructed to think or solve a problem aloud—has been employed in a number of problem solving situations. The early application of protocol analysis has been in the organizational buying behavior area with work of Clarkson (1963) on trust investment behavior and Wind (1968) on the decision process of purchasing agents. In both cases the protocol approach resulted in considerable insights into the subject's decision process. Consumer researchers should consider the use of this research approach in the study of consumer behavior.

Time and Motion Studies

Time and motion studies have been utilized (although infrequently) to study the work flow of the organizational purchasing function. This approach, whether conducted in the real world (by following consumers around on a shopping trip or during product consumption) or in a laboratory, could be applied to the study of consumer behavior and, in particular, to the study of product (and service) purchase and usage patterns.

Input-Output Analysis

The application of input-output analysis to the organizational buying function offers an interesting way of modeling the purchase function as a provider of inputs for the various users at various stages of the productive process (Watson and Smith, 1966). To date, to the best of this author's knowledge, this approach has not been applied in the study of consumer behavior. It does suggest, however, an approach which could provide intriguing insights into the role of consumer purchases in the maintenance of consumers' activities and standard of life.

Reliance on Smaller Samples

The relatively small number of organizational buyers (which characterize many industries), coupled with the high cost of conducting personal interviews with organizational buyers, have led to frequent reliance on relatively small samples. To achieve effective samples given these constraints, many organizational buying studies rely on careful telephone screening, followed by personal interviews with relatively small samples. Recent difficulties in obtaining consumers' cooperation and the increased cost of consumer interviewing suggest the desirability of following the example of organizational buying behavior studies. Certain advances in segmentation research—componential segmentation—are especially suited for such cases requiring relatively small samples. This approach was developed and first implemented in a number of organizational buying behavior studies (Green, Douglas, and Carmone, 1977). Yet, it is obviously appropriate for consumer segmentation efforts.

Concluding Remarks

The preceding discussion has highlighted some of the potential contributions the organizational buying behavior area can make to the study of consumer behavior. These and other contributions (which time and space constraints prevent me from discussing here) have a number of major implications to the study and teaching of consumer behavior. More specifically, they would suggest that:

1. Consumer researchers could benefit from a careful examination of the organizational buying behavior literature from which they can generate new variables, hypotheses, and even some methodological ideas.
2. The teaching of consumer behavior should not exclude the topic of organizational buying behavior. On the contrary, it seems that the study of organizational buying behavior should be viewed as an integral part of consumer behavior courses.
3. Innovative research on organizational buying behavior is a legitimate area of study for consumer researchers and hence should not be excluded (because of the subject matter) from either the Journal of Consumer Research or the sessions of the Association for Consumer Research.

Accepting my premise and conclusions we are still faced with the question of "how to best proceed toward improving our understanding of which aspects of organizational buying behavior can (and should) be applied to the study of consumer behavior?" Obviously, no prescriptions can, or even should, be given to researchers with respect to style, direction, and approach of their research. Yet, one possible route toward answering this question might be to list the "traditional" differences between organizational and consumer buying behavior and examine the extent to which each of these items can be utilized in the explanation of consumer behavior.

To illustrate this approach, let's consider the dimension of derived demand. The derived demand nature of organizational buying has often been presented as one of the major differences between organizational and consumer buying behavior. Yet, if one accepts the concepts of Becker (1965) and Lancaster (1966) consumer demand for goods can also be seen as a derived demand since goods are in this approach the inputs to the production of "commodities." Recreation, for example, can be considered a commodity which leads to a derived demand for sport equipment and time. Similarly, the demand for health can be viewed as a commodity with a

derived demand for medical care (Grossman, 1972).

These and other approaches should be further explored and experiments designed to test their suggestions concerning the application of organizational buying concepts to the study of consumer behavior. This transfer of organizational buying concepts and methods to the study of consumer behavior is, in my opinion, both feasible and valuable. It offers an exciting new challenge and a legitimate new area of study for consumer researchers.

A COMPARATIVE ANALYSIS
OF DETERMINANT ATTRIBUTES
IN RETAIL STORE SELECTION

Stephen J. Arnold, Queen's University
Sylvia Ma (Student), University of Toronto
Douglas J. Tigert, University of Toronto

Abstract

Results from twelve studies provided the opportunity to identify determinant attributes in retail store selection. Generalizations of the findings appeared possible in light of the variation among the studies in terms of retail environment, market differentiation, and national boundaries. Location and price appeared determinant in food stores selection while value for the money, assortment, and quality were determinant in the selection of fashion clothing stores. The results suggest implications for both super and box store strategies.

Introduction

Review studies such as that of Lindquist (1974-75) attest to the continued search for determinant attributes in the retail store selection process. Is price the major determinant or is it shopping convenience? Or is determinancy dependent upon some combination of other attributes such as assortment, service and quality?

The availability of results from twelve studies provided the opportunity to address these questions. A review of these results is first preceded by a discussion of the concept of determinancy. The results are further placed in context by a brief review of comparable studies. Additional questions are raised and discussed.

Attribute Determinance

The notion of attribute determinance was discussed by Myers and Alpert (1968) and Alpert (1971). In order for an attribute to be determinant in the choice process, or, in other words, predispose consumers to action, the attribute must exhibit two characteristics. First, the attribute must be regarded as important. By important, it is meant that the consumer is "extremely offended" (Myers and Alpert, 1968, citing Foote, 1961) by the attribute's absence. It also appears that "important" is related to the multi-attribute attitude notion (e.g. Fishbein, 1972) that the attribute is "highly evaluated" or that its presence provides the consumers "much satisfaction."

The second characteristic exhibited by a determinant attribute is that alternatives in the choice process are perceived as "differentiated" with respect to the presence of the important attribute. In the multiattribute attitude context, consumers state "different beliefs" or provide "different likelihoods" about the presence or absence of the attribute in each of the alternatives.

According to the preceding, determinant attributes would appear to be identifiable by either of two general approaches. Directly, they can be determined by relating the degree of presence of the attribute to the results of the choice process (Myers and Alpert's, 1968 "covariate analysis"). Less directly, they can be determined by identification of those attributes that consumers say are important, as well as identification of those attributes that consumers say differentiate the alternatives (Myers and Alpert's, 1968 "dual questioning"). Either approach, however, has limitations related to problems of causality and consumer vocalization of "real" motivations and

attitudes (Myers and Alpert, 1968). Following Alpert's (1971) conclusion that regression coefficient determination (covariate analysis) and direct dual questioning are the best methods, it is concluded here that combinations of both general approaches (direct and indirect) are necessary in the search for determinant attributes.

"Important" Attributes in Retail Store Selection

A review by Lindquist (1974-75) of 26 empirical and theoretical studies of retail store selection led him to observe that the following attributes were mentioned in at least 25% of the studies:

<u>Attribute</u>	<u>Scholarly Mentions</u>
Merchandise selection or assortment	42%
Merchandise quality	38
Merchandise pricing	38
Locational convenience	35
Merchandise styling, fashion	27
Service, General	27
Salesclerk service	27

While he provided a caveat, Lindquist suggested that this relative frequency of mention is a "valuable indicator" of the important attributes.

In a study not reviewed by Lindquist, Jolson and Spath (1973) found that price/value relationship, store specialization, quality of merchandise, salesclerk service, and location were the factors considered most important in the selection of eight stores at a local shopping center.

How valid it is to aggregate different retail environments (e.g. food, department, clothing, etc.) in order to identify important attributes is not clear. Presumably, each type of retail store exists to satisfy different consumer needs. Hence, the "evoked set" of attributes from which arise the "determinant" attributes would be different in each situation. Conversely, if all retail environments are characterized by the same evoked set, it would suggest that consumers would be indifferent in their pursuit of need satisfaction as to whether they went to a food, department or clothing store. Casual observation suggests that this indifference is not the case and it is thus concluded that each retail environment must be examined separately.

A separate analysis of department and grocery stores characterized a recent study by Hansen and Deutscher (forthcoming) of important attributes. In this investigation, it was found that the three top-ranked dimensions in grocery store selection were physical facilities (clean, easy to move through, easy to find items, fast checkout), store atmosphere (friendly store personnel), and merchandise (dependable products, high quality products, high value for the money, wide selection, fully stocked, numerous brands, well-known brands, low prices vs. competition, many specially-priced items).

In another recent study of men's clothing stores by James, Durand and Dreves (1976), it was found that price,

assortment and personnel were the attributes deemed most important by respondents.

"Determinant" Attributes in Retail Store Selection

While replication of the preceding studies in similar retail environments might identify consistently-rated "important" attributes, it is not clear that the same subset of attributes would be consistently identified as "determinant." To the extent that markets differ in the extent of differentiation on each of the important attributes, it would be expected that studies carried out in each market would also differ in their reports of determinant attributes. For example, a Toronto, Canada study of retail food stores (Arnold and Tigert, 1973-74) reported that Dominion Store increased its market share from 30% to 45% when it suddenly created a wide gap in the pricing structure by dropping its prices by about 12%. In other words, price appeared determinant among a large group of shoppers.

A year later, there was evidence that the key determinant attribute had changed. With the price war over, "best customer service" was found to be the variable most closely correlated with whether or not the respondent last shopped at Dominion. However, "lower price" still remained most highly correlated with Miracle Food Mart shopping behavior while "easiest to get to" characterized Loblaw's shoppers. That is, even in the same geographic market, determinancy appeared to change over time.

With changes even in the same market, it might be expected that determinant attributes would again be different when national boundaries are crossed and the search for determinant attributes is carried out in different cultures. Thus, Doyle and Fenwick (1974-75) found in a London, U.K. study of food stores that "most individuals preferred to move up the vertical or 'quality' dimension toward Sainsbury's and Marks and Spencer" (as opposed to the "greater variety" or "lower prices" dimensions in that study). Quality is a different determinant attribute than the determinant service, location, and price attributes found in the Toronto study.

It must be further noted that different measurement methodologies characterized the latter two studies. In the Arnold and Tigert (1973-74) study, respondents selected the store best on an attribute. That selection was then correlated against store last shopped. In the Doyle and Fenwick (1974-75) study, however, stores were both ranked by preference and rated on semantic differential scales. These data were then subjected to multi-dimensional scaling. Thus, different methodologies may also account for the different results in these two studies. It is consequently recognized that this factor may tend to confound the search for consistently rated important and determinant attributes.

In view of the preceding considerations, an analysis was made of results obtained in 12 different commercial studies. The usefulness of these studies arose from the fact that although there were differences in methodologies, national boundaries, and retail environments, there were enough replications of each condition to permit tentative conclusions about important and determinant attributes.

Research Methodology

Attribute importance and determinancy in retail store selection were investigated in twelve separate studies characterized by: i) three different countries (U.S., Canada, Netherlands); (ii) three different methodologies (open-ended questions, Likert type statements, forced-choice scales); (iii) three different interviewing techniques (telephone, in-home interview, in-home self-

administered questionnaires); and iv) two different retail environments (supermarkets, fashion). All studies were completed in 1976-77 and all involved random samples of between 1,000 and 3,000 female household heads drawn from Census Metropolitan Trading Areas. All studies involved a measurement of not only attribute importance but also attribute scores of retail outlets, shopping behaviour across outlets, and external validity data on actual prices, market share, performance/productivity, etc. One of the best comparative performance measures across stores and across markets is sales per square foot of gross leasable space (GLA) or sales per square foot of selling area, on either a weekly or annual basis. All ten studies reported here used that measurement, as well as others.

Retail Food

Seven of the twelve studies were surveys of retail food store patronage. In each of these seven studies, the attribute importance question was asked in an identical fashion using the open-ended question, "What is the single most important reason you shop at () for most of your food shopping?" Some 35 specifically recorded verbatim responses were post-coded into eight major components. Six of the seven studies were completed by telephone while the seventh utilized an in-home interview at the same time the telephone interview was being completed in the same market (i.e. the sixth study).

Clothing Fashions

Five separate measures were made of attribute importance in the selection of stores for women's fashions. Two of the studies involved the use of five point importance statements while the remaining three utilized an 11 point forced choice format. Unlike the supermarket studies, the fashion studies involved preselected store attributes that had been determined on the basis of a large number of focussed group interviews probing on the importance of various store characteristics. The derived list of 11 attributes included a number of economy/utility dimensions (price, value, location) as well as a number of fashion specific store characteristics. Three of these dimensions relate to how a store is positioned on the "fashion spectrum" from low (everyday, conservative wear) to high (latest, most fashionable women's wear). Respondents completed the questionnaires in their homes on a self-administered basis.

Results

Retail Food

Table 1 reports on the seven separate studies of supermarket shopping behavior. While the commercial nature of the data dictates disguise of each city's identity, it is nonetheless clear that location and price ranked either first or second in importance among the eight major attribute groupings.

With regards to determinancy, it was observed that in all seven studies, the chain with the highest market performance, as measured by sales per square foot of GLA, was also the market price leader, both in terms of consumer perceptions and in terms of an actual market basket measurement, or was within two percentage points of the price leader in the shopping basket measure. Price was thus concluded to be determinant.

There are several differences in the columns of Table 1 that relate primarily to differences in competitive activity and hence market differentiation but which reinforce the above conclusions about importance and determinancy.

COMPARATIVE ATTRIBUTE IMPORTANCE DATA FOR SUPERMARKETS: SHARE OF MENTIONS GOING TO EACH RESPONSE TO THE QUESTION..."ALL THINGS CONSIDERED, WHAT IS THE SINGLE MOST IMPORTANT REASON YOU SHOP AT (_____) FOR MOST OF YOUR FOOD SHOPPING"

REASONS GIVEN*	CITIES						
	NORTH AMERICA				NETHERLANDS		
	A	B	C	D	E	TEL	IN-HOME
1. Location/convenience/easy to get to.....	34%**	35%	36%	34%	27%	23%	22%
2. Prices/low price.....	14	18	16	13	40	33	37
3. Large variety/well stocked/assortment/everything you need.....	9	11	9	11	7	13	12
4. Meat quality/variety.....	11	6	8	7	5	0	0
5. Overall quality.....	9	3	5	5	1	6	5
6. Service/friendly/courteous/fast checkout.....	4	6	7	6	5	7	5
7. Specials/sales, coupons/stamps/weekly specials.....	7	5	6	7	3	2	1
8. Pleasant shopping environment.....	0	0	1	2	0	8	7
9. All others.....	<u>12</u>	<u>16</u>	<u>12</u>	<u>15</u>	<u>12</u>	<u>8</u>	<u>11</u>
TOTALS.....	100%	100%	100%	100%	100%	100%	100%
Sample Size (N).....	(1000)	(1000)	(1000)	(1000)	(1000)	(1000)	(1000)

* Question was asked in open-end form. Responses were recorded verbatim and later post-coded into the above categories.

** In U.S. city "A", 34 percent of the total sample said location/convenience was the most important reason why they chose the store where they do most of their food spending.

The first four cities (A, B, C, D) all show location/convenience to rank first by a wide margin with low price in second position but only slightly ahead of attributes like assortment, meat, quality and service. In these four markets, the price differential across the four leading chains in market share is less than four percentage points in the price basket. Thus, while there is limited but noticeable price differentiation, price clearly plays a lesser role as a determinant of patronage and the non-price variables play a more prominent role, particularly location.

In North American city "E" and in the two Netherlands studies, the low price attribute jumps into first place and by a wide margin over location. In these markets, the price leader is 12 to 15 percent below the next nearest competitor. Furthermore, the price leaders are also the market share leaders in these markets and have by far the highest performance records in sales per square foot. Clearly, the competitive structure of the market has forced price into the leading role as a determinant store attribute. In addition, but not shown in this report, low price is the single most important determinant of patronage for the market leaders in these markets. Finally, on store attributes like cleanliness, friendly personnel, etc., that received high ratings in the Hansen and Deutscher study, the leading chains in city "E" and the Netherlands cities have the lowest ratings in the market. They have traded away those

dimensions, as well as quality on such items as meat and produce, in favour of total market dominance on price and assortment. Their bottom line profitability indicates their strategy is working well.

In the two Netherlands cities, meat quality/variety received no mentions on the attribute importance question. That result should hardly be surprising given that upwards of 80 percent of all Dutch consumers buy their meat at a specialty butcher shop. Pleasant shopping environment, however, ranks fourth in the Netherlands while receiving almost no mentions in the North American studies.

Clothing Fashions

The results of the comparative investigation of important attributes in the selection of women's fashion clothing stores are found in Table 2. Value for the money, assortment/selection, and quality dominate the first three rank positions. Rank correlations above 0.99 for all 10 pairs of columns indicate that these results are highly consistent across the five studies.

Across national boundaries and assuming equivalent translation of the questions, it was found that there were significant differences in the mean score levels. For example, in the two forced choice scales in Canada in 1976 and 1977, "best value for the money" totally

TABLE 2

COMPARATIVE ATTRIBUTE IMPORTANCE DATA FOR WOMEN'S CLOTHING FASHIONS: MEAN AND RANK SCORES ON STORE CHARACTERISTICS FOR LIKERT SCALES AND FORCED CHOICE SCALES..."HOW IMPORTANT IS EACH SPECIFIC STORE CHARACTERISTIC TO YOU IN CHOOSING A STORE TO SHOP FOR WOMEN'S FASHIONS?"

STORE CHARACTERISTIC	5 POINT LIKERT SCALE				11 POINT FORCED CHOICE SCALE					
	NETHERLANDS (77)		CANADA (76)		NETHERLANDS (77)		CANADA			
	Mean	Rank	Mean	Rank	Mean	Rank	1976	1977	1976	1977
1. Gives best value for the money.....	4.5	1*	4.6**	1	3.9	2	2.5***	2.6	1	1
2. Has largest overall assortment/ selection.....	4.4	3	3.9	2	4.4	4	4.5	4.1	2	2
3. Has the highest quality women's fashions.....	4.5	2	3.8	3	3.2	1	4.9	5.5	3	4
4. Has the most knowledgeable, helpful salesclerks.....	4.2	4	3.6	4	4.1	3	5.3	6.1	4	6

9. Has the lowest prices.....	3.2	9	3.0	9	5.8	6	6.3	7.0	8	9
10. Has the best fashion advertising..	2.6	10	2.4	11	9.2	11	8.8	8.8	11	11
11. Has the most exciting merchandise display.....	2.6	11	2.9	10	9.0	10	7.8	7.4	10	10

* Rank scores involve examination of mean scores taken to third decimal place. For ease in reading, only first decimal is shown in the above table.

** Five point Likert scale ranges from "very important" (score of 5) to "not important at all" (score 1) with highest mean score ranking first.

*** Eleven point forced-choice scale ranges from "most important" (score 1) to "least important" (score 11) with the lowest mean score ranking first.

dominated the data with mean scores of 2.5 and 2.6 in the two years. The gap between this dimension in first place and the second ranked dimension, largest overall assortment, is enormous, about 20 standard errors. In the Netherlands, the top three store dimensions received almost identical mean scores on the importance scale and "highest quality" was in first place on the forced choice. In fact, highest quality ranked first or second in both Dutch studies.

An interesting trend was also observed in the two year period separating the two Canadian studies. "Best for current, up-to-date women's fashions" moved up from fifth to third position while "knowledgeable, helpful salesclerks" dropped from fourth to sixth position. While such a change could be attributed to sampling error, focussed group research suggested that salesclerk service was becoming universally poor across major fashion outlets with the result that the consumers perceived they would have to service themselves in the stores. Thus, importance of good in-store service was consequently declining as an important store attribute.

Discussion and Implications

What conclusions can be reached on the basis of these results and in the context of other studies devoted to the identification of important and determinant attributes? First, price/value for the money is an important attribute and will be determinant, it appears, with even small amounts of differentiation across competitors.

This finding, characterizing both the retail food and fashion clothing environments, clearly matches the results of Jolson and Spath (1973) and James *et al* (1976) and closely parallels those of Lindquist (1974-75) and Arnold and Tigert (1973-74). Only in the results of Hansen and Deutscher (forthcoming) does the effect of price appear absent. It is hypothesized that the latter result was obtained because there was little pricing differentiation in the Columbus, Ohio market at the time of their study and that respondents to the questionnaire were, in fact, identifying the determinant as opposed to the important attributes as suggested. Thus, overall, the economic model of the consumer is suggested as having strong validity in the retail store selection process.

Attributes either equally important or secondary to price appear to differ depending upon the environment. Among retail food stores, according to these studies, it is locational convenience. Among fashion clothing stores, however, it is assortment and quality.

In other words, there is considerable evidence that whenever there is noticeable dispersion across supermarket chains on the economy/utility dimensions (price, location), those store characteristics dominate the store choice process. Fashion shoppers, on the other hand are not as concerned about physical convenience. They search out value, quality, wide assortments, and up-to-date fashions. They appear to be willing to travel to whatever location is required to find what they want.

This second conclusion supports Arnold and Tigert (1973-74) in the retail food environment and James et al (1976), Lindquist (1974-75), and Jolson and Spath (1973) to the extent that their findings apply to fashion clothing stores. These two conclusions appear to hold implications for both retail food superstores and box stores. The supermarket chains that are now moving into the "superstore" game with 35-100,000 square foot outlets are implicitly trading on the assortment attribute which was not concluded to be as important as price and location. Thus, in order to be successful, superstores will at least have to match the competition on price. But the very nature of the large capital investment in physical plant, however, implies fewer stores and therefore less convenience. Their only apparent option in order to satisfy the important convenience attribute would be, as some have done, to add specialty bakeries, delicatessens, floral shop and general merchandise departments, which would then provide one-stop shopping for the consumer and thereby justify the greater distance they would have to travel on average. Superstores would then be perceived as satisfying the convenience criterion.

At the other end of the spectrum are the box stores such as Aldi in Iowa which are attempting to take a share of the market on the basis of only limited assortments of basic groceries (400 stock keeping units). Furthermore, prices are at least ten percent below the next nearest competitor.

While the box store strategy has worked well in Germany, the evidence is not yet available for North America. However, the results of this study appear to support the strategy. Pricing well below the competition automatically makes the important price attribute also determinant. In addition, low capital investment per outlet should also make them more amenable to greater numbers of units and hence more likely to satisfy the convenience attribute.

If the future brings a showdown between the superstore and the box store, the superstore may win. It is conceivable that over time, the cost advantages that accrue to the box store will be wiped out due to advances in technology. For example, no price stamping of merchandise in the box store could be countered by optical scanning of label codes. Thus, if price differentiation is erased and consumers perceive the fewer superstores just as convenient, the superstores will then completely dominate on assortment, the other important and consequently determinant attribute in retail food store selection.

A PRAGMATIC APPROACH FOR RETAIL FASHION MONITORING

Lawrence J. Ring, University of Virginia

Abstract

The need to monitor market changes, competitive activities, and individual company performance is a challenge to all retailers. And, in the fashion retailing business, it is especially important because of frequently changing consumer tastes and interests and the attendant shifts in merchandise styles and merchandising methods. This paper outlines a method for fashion market monitoring which tracks both consumer interests and store patronage and can be used to better understand store performance.

Introduction

Within the past decade, the fashion arena has become a popular topic of contemporary consumer research. Over the same period, the proliferation of new styles and fashions has pushed the industry to new sales heights here and abroad. Recent figures indicate that U.S. and Canadian consumers purchase well over 25 billion dollars worth of clothing and accessories annually from a diverse array of retail outlets.

In this mass market, recent studies (King, Tigert, and Ring, 1975, and Sproles and King, 1973) reveal that a large proportion of the population is interested in fashion participation and continuously monitors current fashion trends. In addition, mass fashions are simultaneously available to the fashion consumer in nearly all price ranges.

Mass communications and the rapid production of fashions have increased the rate of fashion diffusion throughout the population. We are now witnessing the accumulation of sizable and frequently updated wardrobes by almost all segments of the population.

Along with this development of mass manufacturing strategies, the proliferation of mass media information and influence, and the increased levels of disposable income has come a general explosion of new retailing and merchandising concepts which have strong implications for the individual firm's merchandising strategy and attendant "retail image."

In any particular fashion retail marketplace, the consumer is faced with a choice among a varied group of fashion outlets each developing and maintaining its own "fashion" profile. The ability of each of those competing retailers, and particularly among those large chains competing for the mass market, to meet consumer needs and at the same time monitor competitive changes in the marketplace is dependent upon the individual firm's ability to efficiently gather and synthesize information about the changing marketplace.

This paper describes a methodology for providing a complete diagnosis of the structure of an individual fashion market including patterns of buying behavior and determinants of patronage for major competing chains.

Fashion Involvement

Historically contemporary fashion research has focused on the fashion innovator and the fashion opinion leader

as prime sales targets and key links to the volume fashion market. A variety¹ of methodological studies designed to define, isolate, and profile these segments have dominated fashion research since the basic concept was first introduced by King (1963).

In general, fashion segmentation has been based on the division of consumers into relatively homogeneous segments based on demographic, psychological, and sociological measures, media exposure characteristics, and specific measures of fashion involvement and consciousness.

Contemporary fashion theory research has tended to focus on the fashion process and its interacting behavioral system. Researchers have been increasingly interested in the dynamics of fashion adoption and diffusion. The specific situations of fashion innovativeness, fashion opinion leadership, and the broad concept of the fashion change agent provide an expanding base of literature in the fashion arena.

In fashion apparel thought, the fashion change agent has been seen as more than simply an innovator or opinion leader as traditionally defined. Sproles and King (1973) have argued that while innovativeness and opinion leadership in fashion are theoretically distinct concepts, that the differentiation may not be either pragmatically necessary nor even a requirement for segmentation purposes. The time compression of contemporary fashion diffusion confounds the strict identification of innovators and opinion leaders and major or mass market adoption is accelerated instead by a broadly identified change agent segment of the population (Sproles and King, 1973).

From the retailer's point of view in the mass market, the problem is to determine the levels of fashion involvement of the population and ascertain the size and needs of each "level of fashion involvement" segment.

Fashion Involvement Measures

Over the last fifteen years, the author and others have conducted a number of research investigations of fashion involvement in the United States and Canada. The accumulated data base now contains measurements of fashion interest at different points in time in different geographic regions and among both male and female populations. As a result, a comparative data base spanning fifteen years has now been established.

In the case of one measure, data has been collected from over twenty independent populations using essentially identical methods of sample selection and exactly identical and, therefore, comparable measurements of fashion interest. That measure is general fashion interest (also sometimes referred to as fashion awareness). In

¹A representative list of fashion segmentation studies would include King (1963), Grindereing (1967), Pasnak and Ayers (1969), King and Summers (1970), Reynolds and Darden (1973), Sproles and King (1973), Baumgarten (1975), Tigert, Ring, and King (1975), and Painter and Grianzin (1976).

each of the investigations mentioned above, the following question was asked of all respondents:

"Which ONE of these statements best describes your reactions to changing fashions in men's (women's) clothes? Even though there may be no statement listed which exactly describes how you feel, make the best choice you can from the answers listed."

I read the fashion news regularly and try to keep my wardrobe up to date with the fashion trends . . . 1

I keep up to date on all the fashion changes, although I don't always attempt to dress according to these changes 2

I check to see what is currently fashionable only when I need to buy some new clothes 3

I don't pay much attention to fashion trends unless a major change takes place 4

I am not at all interested in fashion trends. . . 5

Comparative results using this measure have been reported elsewhere and provide a baseline for future comparison and tracking of fashion interest (see King, Tigert, and Ring, 1975, and Ring, 1977). Therefore, this particular question provides an excellent measure of fashion interest across any particular population.

Attitudes Toward Stores/Determinants of Patronage

The relationship between consumer attitudes and retail sales has long been a popular topic for examination by retail researchers -- and particularly with regard to department stores (Berry, 1969, Lazer and Wyckham, 1969, and Weale, 1971, for example.)

A number of techniques have been utilized by marketers in researching retail image. The semantic differential (Arons, 1961, Anderson and Scott, 1970, and Kelly and Stephenson, 1967) and the open-ended questionnaire (Berry, 1969), have been two of the more popular techniques employed.

As discussed by Arnold and Tigert (1973), however, each of these techniques has significant problems. The major issue is their characteristic length and complexity. The semantic differential, for example, requires the respondent to rate each retailer on each attribute under study. The open-ended questionnaire, on the other hand, generally requires personal interviewing and content analysis of the responses.

Tigert (1976) has demonstrated that the measurement of store characteristics by the use of the "associative technique" is both reliable and valid, as well as discriminating. He contends, in fact, that the associative technique measures the world in a way which reflects the manner in which consumers go through the choice process.

Operationally, the associative technique involves asking each respondent which store (among a set of stores representative of a particular market) best answers each of a set of individual questions related to the stores. This technique has been employed in the analysis which follows.

Patronage Measures

Retail image researchers have, over the years, identified a large number of dimensions upon which consumers judge a store's performance and which therefore may conceivably contribute to the constitution of a

store's personality or image. For example, Lazer and Wyckham (1969), listed four major image dimensions, while Martineau (1958) suggested six traits, Stephenson (1969) described eight dimensions, Wyckham (1967) 30 dimensions, May (1971) 42 dimensions, Berry (1969) 44 dimensions and Shapiro (1970) 94 dimensions in a study of retail products among Boston consumers.

While these studies have focused on a variety of store types and product classes, many have dealt in some way with fashions. Based on these results, and on other fashion research over a period of several years, several "attitudes" or "image dimensions" have been found to consistently characterize retail fashion chains and as well to be useful for management decision-making. These dimensions in the question format of the "associative technique" and in the case of men's fashions are:

1. Which store is the easiest one to get to from your home?
2. Which store has the lowest prices?
3. Which store has the highest prices?
4. Which store has the most knowledgeable/helpful salesclerks?
5. Which store has the highest quality men's fashions?
6. Which store has the lowest quality men's fashions?
7. Which store gives you the best value for the money in men's fashions?
8. Which store gives you the worst value for the money in men's fashions?
9. Which store has the largest overall merchandise assortment/selection in men's fashions?
10. Which store is best for conservative, everyday men's wear?
11. Which store is best for current, up-to-date men's wear?
12. Which store is the best for the very latest, most fashionable men's wear?
13. At which store do you find the most exciting merchandise display of men's fashions?
14. Which store has the best fashion advertising?

In addition, two measures of share of shoppers should be employed in this approach, again using the "associative technique." They are:

1. Which store was visited the last time an article of men's wear was purchased?
2. Which store is shopped most often for men's wear?

Toronto: An Example

The results which are reported later in this paper represent an example of the implementation of the approach described here over several years in Toronto, Ontario, Canada for the expressed purpose of monitoring the retail fashion marketplace there. This research was conceptualized as a joint academic/industry project and has been operated and supported on that basis now for four consecutive years beginning in 1974. The example which is discussed below is based on data collected about the men's fashion market in Toronto and is repre-

sentative of other similar efforts elsewhere and in the women's fashion market as well.

Data Collection

The data for the Toronto Project has been collected each year (1974-1977) by mailed self-administered questionnaire from the Toronto Census Metropolitan Area (CMA). The samples have been obtained by telephone placement of questionnaires to adult male household heads. The samples were recruited to be in balance with city demographic profiles. Questionnaire administration has taken place in the spring of each year. A total of 615 usable questionnaires were mailed to each respondent complete with standard self-administration instructions. Each participant received a small gift for completing the questionnaire.

Store Selection

In attempting to understand the structure of the Toronto men's wear retail mass marketplace, it was first necessary to define a relevant set of retailers to present to respondents for their judgments. Since the analysis was to be concerned with the mass market, and was to be based on consumer judgment, it was important to include those chains which had sufficient market coverage and general recognition for respondents to judge them.

Ten stores and an "all other" category were listed as response alternatives in the survey, including the city's three major department stores. Each of the chains included in the analysis was operating at least six retail outlets in Toronto in 1975. In addition, it was estimated that each of the chains was obtaining gross men's wear sales in Toronto of at least \$5 million per year.

Fashion Interest Results

Table 1 presents the 1974-1977 fashion interest results for the ongoing Toronto project. These results can be interpreted in several ways. For example, those respondents

who perceived themselves to be in the first category (see question series), might be identified as innovators since they indicate that they keep their wardrobes up to date with fashion trends. However, perhaps a more important concern than the first category alone is the aggregated total of the first two categories. Pragmatically, those respondents who have responded in either the first or second level fashion interest categories might be classified as active in fashion interest, at least in terms of consistently monitoring, if not purchasing, new fashions.

By combining the first and second levels of fashion interest as indicated above, it is clear that approximately one quarter of the respondents over the four years can be classified as active in fashion interest and capable of influencing the mass population at least verbally, if not visually, with regard to changing fashion trends. This is true because those men responding in both the top two fashion interest levels keep informed of fashion changes and thereby could potentially be communicators of information. And, those individuals in fashion interest level one are also potentially visual influentials by virtue of the fact that they keep their wardrobes up to date and are therefore wearing the latest fashions for all to see.

Looking at the data another way, it appears that the majority of adult male Toronto consumers are not particularly interested in new men's fashions. And, in comparison to female and college student fashion interest statistics and even American adult male statistics (see Ring, 1977), Toronto has fewer change agents (categories one and two).

More importantly, from a market monitoring perspective, it appears some significant shifts have occurred in the level of fashion interest over the four year data base. For example, the drop in percentage reporting as fashion change agents from 1974 to 1975 represented a significant change in fashion interest level, as did the five percent increase from 1976 to 1977.² This kind of information might be particularly important to the firm which is mer-

TABLE 1
TORONTO MALE FASHION INTEREST

Statements Describing Degree of Fashion Interest ^a	1974 Toronto	1975 Toronto	1976 Toronto	1977 Toronto	Average
Read fashion news regularly and keep wardrobe up-to-date with fashion trends	4%	2%	1%	2%	2.25%
Keep informed of fashion changes but do not always follow	21	16	15	19	17.75
Check what is fashionable only if buying new clothes	24	28	28	30	27.5
Only pay attention to major fashion changes	26	30	36	33	31.25
Not at all interested in fashion	25	24	20	16	21.25
TOTAL NUMBER RESPONDING	100% (615)	100% (1,017)	100% (865)	100% (983)	100%

^aIdentical measures of interest used in all surveys.

*READ: In 1977, 2% of the sample said they read the fashion news regularly, and kept their wardrobes up-to-date with the fashion trends.

²The observed difference of 7 percent is greater than 2.4 standard errors from zero, while the 5 percent difference from 1976 to 1977 is 1.96 standard errors from zero. Both significant at the .95 level.

chandising primarily toward the top end of the fashion market as is demonstrated in the next section of this paper.

Fashion Interest by Store

The basic thesis in this analysis is that consumers differ in the fashion shopping behavior based on their self perceived fashion interest or involvement. To explore this question, the fashion interest measure need only be cross-classified with a measure of share of shoppers such as "store shopped most often."

The following example illustrates some rather dramatic differences between the self-perceived fashion interest level of the shoppers of a leading Toronto department store and a leading fashion specialty chain. In Table 2, it is clear that the fashion specialty chain shoppers perceive themselves as much more interested in men's fashions than do the department store shoppers. Taking 1975 as an example, fully 40 percent (levels 1 and 2) of the fashion specialty chain shoppers were regularly monitoring (if not purchasing) new men's fashions. In contrast, only 17 percent of the department store shoppers made a similar response.

These differences are important at any given point in time and also as they may change over time to the management of each chain. Satisfying the needs of the highly fashion interested clientele of the fashion specialty chain surely points to a different merchandising strategy than does satisfying the needs of the department store shopper. These results lead to an analysis of store patronage dimensions.

TABLE 2
TORONTO 1975
CROSS CLASSIFICATION ANALYSIS:¹
"CHAIN SHOPPED MOST OFTEN" vs. "FASHION INTEREST"

Fashion Interest: Reaction to Changing Fashion	Chain Shopped Most Often	
	Department Store	Fashion Specialty Chain
1. Read fashion news regularly and keep wardrobe up-to-date with fashion trends.	0.8%*	4.4%
2. Keep informed of fashion changes but do not always follow.	16.9	35.6
3. Check what is fashionable only if buying new clothes.	28.5	35.6
4. Only pay attention to major fashion changes.	34.1	22.2
5. Not at all interested in fashion.	19.7 100.0%	2.2 100.0%

¹The difference between department store consumer fashion interest and fashion specialty chain fashion interest were significant at the .001 level based on X² analysis.

*READ: Among those who shop most often at the department store, 0.8 percent said that they regularly read the fashion news and tried to keep their wardrobes up-to-date with the fashion trends.

Determinants of Patronage

The analysis of store patronage can proceed at two levels. Initially, the concern is with the share of shoppers mentioning each chain on each of the patronage dimensions. Secondly, however, it is important analyze the attitudes of each chain's shoppers on a chain-by-chain basis.

Table 3 continues the example of the department store and the fashion specialty chain for the year 1975. In this table the share of shoppers (of the overall sample) which mentioned each of the two stores as being best (or worst, highest, lowest, etc.) on each of the patronage dimensions have been presented. These results document the "image" of each chain as seen by the overall sample at a particular point in time (spring, 1975.)

TABLE 3
SHARE OF MENTIONS FOR TWO CHAINS
ON THE DETERMINANTS OF PATRONAGE QUESTIONS

Determinant of Patronage	Chain Mentioned	
	Department Store	Specialty Chain
1. Easiest to get to from home	18%*	2%
2. Store Last Shopped	29	5
3. Store Shopped Most Often	35	6
4. Lowest Prices	7	0
5. Highest Prices	3	48
6. Highest Quality	9	41
7. Lowest Quality	1	0
8. Best Value for the Money	28	4
9. Worst Value for the Money	3	7
10. Most Knowledgeable, Helpful Salesclerks	19	20
11. Largest Overall Assortment/Selection	30	6
12. Best Advertising	30	9
13. Most Exciting Display	14	22
14. Best for Conservative Everyday Men's Wear	31	5
15. Best for Current Up-to-Date Men's Wear	12	23
16. Best for Very Latest Most Fashionable Men's Wear	7	29

*READ: Eighteen percent of the total 1975 sample said that the department store was the easiest to get to from home, while only 2 percent said that the fashion specialty chain was the easiest to get to from home; 29 percent of the sample said that they last shopped at the department store, while 5 percent said that they last shopped at the specialty chain.

Market coverage in Table 3 has been measured by asking respondents which store is the "easiest to get to from their home?" Based on the percentage of respondents who identify a particular store as the easiest on to get to from home, a "trading area" can be defined for each store (chain). The discussion will refer to the trading area with the term, "market coverage." For example, the Department Store had a 18 percent market coverage because 18 percent of the respondents said that the Department Store was the easiest to get to from home. The Specialty Chain had only a 2 percent market coverage.

A more important concern than market coverage alone is the relationship between market coverage and share of shoppers (as measured by the "last shopped" and "shop most often" questions.) Twenty-nine percent of the sample last shopped at the department store compared to 5 percent which last shopped at the fashion specialty chain. Similar figures are obtained on the shop most often measure, indicating that a much larger percentage of the market shops at the department store than at the specialty chain.

However, the ratios between "market coverage" and the two share measures provide a slightly different perspective. The ratio analysis eliminates the differential market coverage across chains and expresses each chain's customer set as a ratio of coverage.

		Ratios	
		<u>Department Store</u>	<u>Specialty Chain</u>
1.	<u>Last Shopped</u> Market Coverage	1.6/1	2.5/1
2.	<u>Shop Most Often</u> Market Coverage	1.9/1	3.0/1
3.	<u>Lowest Prices</u> Highest Prices	2.3/1	0.0/1
4.	<u>Highest Quality</u> Lowest Quality	9.0/1	41.0/0
5.	<u>Best Value</u> Worst Value	9.3/1	0.6/1

Both of the chains in the above example have better than "one to one" ratios of the two share measures to market coverage. Interpretatively, these findings indicate that these two chains were performing better than could be expected based on their market coverage alone. Chains with ratios of less than the "one to one" would be drawing fewer shoppers than the percent who said the chains were closest to home--meaning some shoppers were driving past those chains to get to other, less accessible stores for some reason.

The ratio analysis can also be performed on the price, quality and value for the money measures since two data points were collected for each of those dimensions. A better than "one to one" ratio on each of these dimensions would indicate a positive price, quality, and value image from the overall sample. In this example, the department store is positive on all three dimensions, while the fashion specialty chain is positive on quality and "negative (or less than one to one) on price and value.

Looking at some of the other dimensions, the department store appears to have a larger percentage than the specialty chain in many, but not all, of the cases. This may, in part, be attributable to the fact that many more respondents shop at the department store, and all other things being equal probably tends to rate the store

shopped most often highest or best on each of the important dimensions. Consequently, to some extent the share of mentions on any given question often tends to mirror the share of shoppers for a given chain. Thus, if the results are examined only in terms of absolute percentages, a store with a large share of shoppers might be thought to be very strong on a particular dimension, while a store with a small share might be considered to be weak. This mistake can be avoided if the raw percentages are examined in comparison to the overall share of shoppers for the chain. For example, in terms of absolute percentages, both of the example chains appear to be equally strong on the best salesclerk question (question 10.) The department store obtains 19 percent of the mentions and the specialty chain obtains 20 percent. However, if these figures are compared to overall share of shoppers, it is clear that the department store is not performing particularly well on this dimension, while the specialty chain is extremely strong here. Only 6 percent of the sample shopped at the specialty chain but three times that many said the chain had the most knowledgeable, helpful salesclerks. In contrast, 35 percent of the sample shopped at the department store, but only 19 percent said that store had the most knowledgeable, helpful salesclerks.

Another method of understanding the strengths and weaknesses of each chain is to analyze how the shoppers of each individual chain rate that chain. This can be easily accomplished through the use of cross-classification analysis.

Cross Classification

Table 4 contrasts the shoppers of the two chains across 11 determinants of patronage. This analysis is based on the cross-classification of shoppers "most often shopping" each chain with each of the retail patronage dimensions. Given the fashion interest findings discussed earlier, the fashion specialty chain should be expected to be perceived as more fashion-oriented than the department store. In this example, that is the case.

Clearly, the shoppers of the department store have a different "image" of their "most often shopped" chain than do the fashion specialty chain shoppers of their "most often shopped" chain.

Although more sophisticated analysis techniques can be utilized (for example, see Ring, 1976), simply assigning the attributes to whichever chain obtained the higher percentage yields interesting results. What emerges is a statement of the strengths and weaknesses of the two chains as perceived by their own shoppers.

For example, consumers would appear to be shopping at the department store because of its good location, lower prices and higher value for the money, better merchandise assortment/selection, better (more) advertising, and a stronger orientation to conservative, everyday men's wear. The fashion specialty chain shoppers, on the other hand, are paying for higher quality, more salesclerk "stroking", an exciting merchandise display, and a current-to-very latest, most fashionable apparel mix.

These findings are consistent with the consumer self-perceptions of their own fashion interest as discussed previously. The department store was viewed as low on the fashion spectrum and its shoppers perceived themselves as only marginally fashion involved. The fashion specialty chain shoppers perceived themselves as much more highly interested in fashion and their chain as highly fashion oriented in terms of product offering.

TABLE 4
TORONTO 1975
CROSS CLASSIFICATION ANALYSIS:
SUMMARY OF DIAGONALS FOR DETERMINANTS OF PATRONAGE

Determinants of Patronage	Chain Shopped Most Often	
	Department Store	Specialty Chain
1. Easiest to Get to from Home	34%*	24%
2. Lowest Prices	17	0
3. Highest Quality	20	91
4. Best Value for the Money	64	40
5. Most Knowledgeable, Helpful Salesclerks	44	85
6. Largest Overall Assortment/Selection	58	27
7. Most Exciting Merchandise Display	31	86
8. Best Advertising	51	33
9. Best for Conservative, Everyday Men's Wear	61	23
10. Best For Current, Up-to-Date Men's Wear	27	75
11. Best for Very Latest, Most Fashionable Men's Wear	15	77

*READ: Among those who shopped most often at the department store, 34 percent said that the department store was easiest to get to from home, 17 percent said the department store had the lowest prices, and 20 percent said the department store had the highest quality, etc.

Monitoring Over Time

Thus far the discussion of store patronage and the fashion profiles of each store's shoppers has been discussed only as it related to one point in time, the spring of 1975. While this analysis in and of itself is obviously useful, it becomes even more relevant when it is done on a regular basis over a long period of time. The time series analysis permits management to observe its effectiveness at attempting to penetrate new market segments or to change its image from year to year. For example, one major Toronto department store had watched its market share and its image on many important dimensions such as display, assortment, and merchandise fashionability erode as competitors expanded their operations into new stores with more fashionable merchandise while the department store "let itself go" in anticipation of the eventual opening of a major downtown showcase flagship store and shopping mall. The data in Table 5 reflect this store's performance on selected dimensions over the four year period during which the Toronto project has operated.

Between the collection of data in 1976 and in 1977, this department store opened its new flagship store downtown. The upward shifts on the selected dimensions included in the table reflect the impact of the new store on the marketplace, and indicate the chain's image has improved over the year on each of these measures.

TABLE 5
SELECTED DETERMINANTS OF PATRONAGE FOR A
TORONTO DEPARTMENT STORE, 1974-1977

Determinant of Patronage	1974	1975	1976	1977
	1. Largest Assortment	34%*	29%	24%
2. Most Exciting Display	21	15	12	23
3. Best for Current Men's Wear	14	9	8	13
4. Best for Very Latest Men's Wear	13	7	6	12

*READ: In 1974, 34 percent of the respondents said this department store had the largest assortment, while only 29 percent made the same statement in 1975, 24 percent in 1976, and then back up to 28 percent in 1977.

Similar analyses have been completed for each chain on each of the patronage dimensions and on the fashion interest question for each of the four years. In addition, a number of other relevant dimensions have been measured as well, included demographics, fashion AIO measures, price and volume pointing measures, additional fashion involvement questions, media and information sources measures, and fashion item (suit, sports jacket, etc.) measures. In total, these results provide the basis for a complete diagnosis of the Toronto fashion market including patterns of buying behavior and determinants of patronage for major competing chains.

Summary

Earlier studies have documented major differences among consumers in terms of their fashion involvement and fashion consciousness. Other research has uncovered major differences in consumer perceptions of competing retailers and in the profiles of the customers of competing retailers

In the competitive fashion retailing milieu, these differences are of major decision-making importance. The established retailer inevitably has a store image which has attracted his existing clientele. That image may have been planned as a strategic maneuver, or it may have been generated fortuitously. Therefore, the retailer, in selecting his product line offerings, as well as in designing his entire fashion retail presentation, can buy product offerings which coincide with his present strategy and image, or select offerings or make image decisions purposively designed to attract other segments that he may not now service.

This paper describes a methodology for retail fashion market monitoring which applies fashion segmentation research techniques and retail image methods to the men's fashion context.

This methodology provides new input for the retailer in terms of identifying and profiling fashion market segment, in selecting his product lines, his merchandising approach, and in designing and targeting his entire retail presentation to specific fashion market segments.

Market monitoring permits the diagnosis of the market structure and the understanding of patterns of buying behavior over time and enables the retailer to precisely pinpoint his strengths and weaknesses as they currently exist and as they change over time.

Abstract

This paper presents a preliminary introduction to a survey research methodology for integrating some new techniques of fashion trend monitoring and retail store image/patronage monitoring into a retailing management information system. Selected preliminary findings from a two year longitudinal study of four separate random samples of consumers are used to illustrate the methodology.

Introduction

A new survey methodology for measuring retail store images and associated dimensions of store patronage has recently received increased use in retailing research (i.e. Arnold and Tigert, 1973; King, Tigert and Ring, 1975).

This methodology for market monitoring has been found to have a substantial degree of reliability and validity in describing the competitive positions of retail stores within a local market trading area. More recently the method has also proved useful for multivariate modeling and "mapping" of the structure of local retail markets (i.e. Ring and King, in press).

One use of this new methodology which has not yet been investigated involves integrating the methodology to some newly evolving techniques for measuring changing trends in consumers' product preferences and actual buying behavior. However, this represents the next logical step in the development of a comprehensive retail market monitoring system. Retailers need information not only on their competitive positions across general store image/patronage dimensions, but also on specific competitive products offered within their trading area. This type of data will ultimately be a key part of future retailing management information systems used by retailers as an aid in developing their general positions ("images") in the market and complementary product assortments.

Given these needs, the purpose of this paper is to describe a longitudinal survey research program which has merged the evolving market monitoring methodology with evolving techniques for measuring current and predicted future growth in consumer demand for specific products. The product category involved in this research is women's clothing fashions, which is one of the most difficult and yet crucial categories of products in which to measure consumers' current and predicted future preferences for consumption. This paper will present a brief overview on the development of the research methodology for the investigation. Some preliminary illustrative data on use of the integrated system will also be discussed.

¹Field administration of this study was funded by the Agricultural Experiment Station, Purdue University. Data analysis and computer programming was funded by the Department of Human Development and Consumer Sciences (pending), University of Houston. Mrs. Jacqueline McCullough was a doctoral researcher in one phase of this investigation.

Overview of the Methodology

The research was conducted in 1976 and 1977 in Lafayette, Indiana. In each year two separate random samples, one of college women at Purdue University and one of adult women in the Lafayette community, were mailed a questionnaire surveying their store patronage and fashion preferences. In the next paragraphs the store patronage measures, fashion preference measures, and administration of the study will be described.

The Store Image/Patronage Measures

The new retail image and patronage research methodology has been described in earlier cited references, and requires only brief introduction here. Basically, the methodology measures consumers' images of and preferences for retail store in their trading area across a variety of relevant patronage dimensions (i.e. store with the best location, best advertising, best assortment, most fashionable selections, store most often shopped, etc.). King, Tigert and Ring (1975) have developed a specific sequence of sixteen questions for use in clothing stores, and their sequence is used in the research reported in this paper.

A group of ten directly competitive clothing stores was selected for inclusion in the survey instruments, including 3 department stores, 6 specialty stores, and 1 chain store. The 10 stores had previously been identified in a pretest as among the most extensively patronized clothing stores in Lafayette. Each subject was asked to pick the best store on each image/patronage dimension from the list of 10 stores. Additionally, respondents were given a write-in for "other store," to measure instances when none of the 10 stores was perceived as best on a specific dimension.

The Fashion Preference Measures

The methodology for measuring consumers' fashion preferences and predicted buying behavior is relatively novel, and will be described in greater detail. The basic method was developed as a modification of techniques previously used by Baumgarten (1975). His method involved presenting subjects a series of slightly varied basic styles of dress (i.e. styles of pants, shoes), and asking each subject a series of consumption-related questions on each style. Those questions included number of items of each style currently owned, current popularity of each style, predicted future popularity of each style, and future buying intentions for each style. Selected measures were then statistically combined into measures of consumer innovativeness, and were used to identify fashion innovative consumers. However, it appears this type of methodology, with the appropriate modifications, can be used as a simple system of market monitoring and prediction of forthcoming fashion trends.

Since the technique for monitoring consumers' fashion preferences used in the present study represents a substantially different application of Baumgarten's approach, the development of this application will be described in some detail. The principal difference is that the technique is used to comparatively measure the current and changing fashionability of specific styles. Therefore, it is first necessary to validate the use of such a technique in discriminating between styles which are at different levels of current and predicted future fashion-

ability. A second major difference is that simple descriptive statistics (frequencies) are used to differentiate the fashionability of one style versus another. Thus the interpretation of findings is relatively uncomplicated and responsive to managerial needs.

To initially validate the use of this methodology in measuring stages and levels of fashionability for specific styles, a series of pilot pretests was conducted in the late Winter-early Spring of 1976.² In the first test, female college students were presented illustrations of over 150 styles of dress taken from various fashion periodicals, and were asked to classify each illustration into four categories.³ The categories can be described as follows:

- #1 -- The "newest" general fashion trend
- #2 -- Out of fashion
- #3 -- The "newest" college age/youth-oriented fashion
- #4 -- "Classic" (long established) fashion

For 42 styles which were placed in a single category by 50 percent or more of the first test subjects, a second test was run. This test used a group of junior-senior female students majoring in fashion retailing, who were used as "expert judges" to validate the categorizations done by the first test group. Based on the results given by this "expert" group, four dress styles and four pant styles representing the four categories were selected for use in the survey.

The selected styles were redrawn to the same size and scale on a neutral posed form, to control for any differences in appearances which could be attributed to anything other than the style itself (i.e. a model's pose, hair style, figure, facial expression). The redrawn styles were then subjected to a final validating test with female students. This test successfully validated each of the four drawings of dress and four drawings of pant outfits as fitting in one of the four categories of fashionability, though this test did indicate that minor redrawing of a few details on two outfits was needed.

To construct the questionnaire for this part of the survey, the four dress styles were randomly arranged in the left column of the page. The right column contained the four question sequence on consumption and perceptions of popularity for each style. The pant styles were then arranged in an identical manner on a separate page of the questionnaire.

Questionnaires containing the fashion preference and store patronage measures, as well as a variety of other measures not relevant to the present study, were mailed to separate random samples of 400 female students at Purdue, and 400 adults in Lafayette. The mailings were purposefully administered in the early part of the Spring 1976 fashion season, to obtain an "early season tracking" of fashion preferences. Additionally, the mailing was made to follow immediately after the pilot validation of categories for the four styles, thus avoiding the possibility that an abrupt change of fashion would invalidate any of the four categories.

²McCullough was a co-researcher and doctoral student who conducted the pretests. Also see McCullough (1977) for an analysis of fashion-conscious college students identified in the 1976 phase of this study.

³The concept of categorizing styles in a similar manner has previously been used by Reed (1973) in a study of clothing as a symbolic indicator of the self-concept of college women.

In the early Spring of 1977, questionnaires containing identical measures of fashion preferences and store patronage were mailed to random samples of 400 female students at Purdue, and 400 adults in Lafayette. Thus the survey administrations in 1976 and 1977 were directly comparable in terms of samples, questionnaire designs, and times of administration within the Spring fashion seasons of both years.

Other methodological details were as follows. In both the 1976 and 1977 surveys, the college student subjects included in the surveys were randomly selected from the Purdue registrar's list of full-time undergraduate female students. The adult subjects were randomly selected from the Lafayette telephone book. Representatives of the telephone company indicated that probably less than 5 percent of the Lafayette area households had unlisted phones or no phones; therefore, it would appear that the Lafayette telephone book was a relatively representative sampling frame for the purposes of this research. Finally, one methodological difference between the 1976 and 1977 studies should be noted. In 1976 the surveys were followed 10 days later by a reminder postcard which was used to stimulate increased response rates; however, the 1977 study involved a single mailing of a shortened questionnaire without use of follow-up procedures. This resulted in a difference in response rates in the two years of the study. The final response rates, in terms of returned usable questionnaires, was as follows:

1976 - College students	250 returns (62.5%)
1976 - Adults	174 returns (43.5%)
1977 - College students	198 returns (49.5%)
1977 - Adults	122 returns (30.5%)

From these results it would appear that the postcard follow-up yielded an increased response in the order of 10 percent or more. This was found to be the case in analyzing the returns in the 1976 study by date of return as compared to the postcard mailing date.

Findings

The following discussion focuses on a preliminary analysis of data on consumers' preferences for the four selected dress styles, and patterns of preferences across store patronage dimensions. These data illustrate the validity of this new methodology for measuring fashion preferences and identifying the predicted buying behavior of consumers frequently patronizing specific stores.

Tables 1 - 4 present descriptive data for the fashion preference measures, in terms of raw percentages of subjects in each sample who responded to each consumption-oriented question. The numbers #1 through #4 in these tables are keyed to the categories of fashionability described earlier in this paper. In general, the findings in these tables would significantly appear to validate the use of this monitoring technique in discriminating current levels of fashionability and perhaps in forecasting the forthcoming fashion trends. However, the latter point will require further research for more formal evidence on that point. Another point of interest is the divergence in preferences between the adult and college subjects. There are substantial differences in orientations toward fashion consumption of these two broadly defined market segments, and the surveys appear to discriminate these differences. This is especially notable in the measures of preference for style #3, which was categorized as a college or youth-oriented fashion.

Some of the more notable findings in Tables 1 - 4 are as follows. In the Table 1 data on ownership of the four styles, style #4 (the classic fashion) would appear to be the most widely owned style, particularly among adults. College students were significantly less likely than adults to report owning #2 (out of fashion). Finally,

TABLE 1
Ownership of Selected Dress Styles Among Adult and College Women,
1976 and 1977 Surveys

	Number Owned, By Styles	Adult Women		College Students	
		1976	1977	1976	1977
#1	None *	53.4%*	41.8%	45.6%	38.4%
	1 or 2 *	36.2%*	43.4%	42.0%	51.5%
	3 or more*	10.3%*	14.7%	12.4%	10.1%
#2	None	55.7%	56.6%	73.6%	77.8%
	1 or 2	28.7%	30.4%	22.8%	17.7%
	3 or more	15.4%	13.1%	3.6%	4.5%
#3	None	66.7%	67.2%	54.0%	46.5%
	1 or 2	24.7%	22.1%	32.4%	42.0%
	3 or more	8.6%	10.6%	13.6%	11.6%
#4	None	36.8%	23.0%	39.2%	39.4%
	1 or 2	42.6%	50.0%	46.4%	45.5%
	3 or more	20.7%	27.0%	14.4%	15.1%

*Read: 53.4% of adult women in the 1976 survey indicated they owned no items of style #1, 36.2% indicated they owned 1 or 2 items of style #1, and 10.3% indicated they owned 3 or more items of style #1. Percentages in each such group of percentages in Table 1, and in Tables 2 - 4, do not add to 100% due to missing responses and/or rounding errors.

TABLE 2
Current Popularity of Selected Dress Styles Among Adult and College Women,
1976 and 1977 Surveys

	Degree of Popularity, By Styles	Adult Women		College Students	
		1976	1977	1976	1977
#1	Extreme	45.4%	41.0%	72.8%	44.9%

		1976	1977	1976	1977
		#1	Definitely	10.9%	12.3%
	Possibly	35.1%	42.6%	52.8%	56.1%
	Will Not	51.7%	41.8%	24.8%	30.3%
#2	Definitely	3.4%	2.5%	2.4%	2.0%
	Possibly	22.7%	19.7%	9.2%	7.6%
	Will Not	70.7%	74.6%	86.4%	88.4%
#3	Definitely	4.0%	7.4%	12.0%	8.6%
	Possibly	16.7%	20.5%	40.0%	40.4%
	Will Not	77.6%	67.2%	47.2%	50.0%
#4	Definitely	9.2%	11.5%	8.8%	20.2%
	Possibly	35.1%	44.3%	33.2%	41.9%
	Will Not	52.3%	40.2%	56.8%	36.9%

growth in ownership of #1 (the newest general fashion) can be seen from the 1976 to 1977 studies for both the adult and student samples. Thus these ownership measures give a distinct picture of consumers' preferences in the market (this of course becomes even more true upon visual inspection of the line drawings for each style).

Tables 2 and 3 show consumers' judgments of current and predicted future popularity of each style. In the 1976 data of Table 2, it is clear that both the adult and college samples rated the category of fashionability of each style in the same general categories as identified in the pilot tests. This represents a significant validation of the methodology for discriminating current fashionability of styles based on using basic line drawings of the styles. In the 1977 data, results are similar, though there is a clear decline in popularity ratings for #1 and #3 (which were highly popular in 1976). The Table 3 data showing predicted popularity for each style in the next six months is also of considerable interest. Among adults the prediction is for #1 (the newest general fashion) and #4 (classic) to grow most significantly in popularity. In comparison, students clearly pick #1 and #3 (the youthful fashion) for the most significant growth. Finally, both adult and college groups indicate that #2 (out of fashion) is leveling out or declining in fashionability.

Table 4 presents data on consumers' purchasing intentions for each style. Although the preceding tables indicated many consumers would seem to have relatively well formed perceptions regarding popularity of each style, there is uncertainty as to what will actually be purchased. This is indicated by the high percentage of consumers responding they would "possibly" purchase each style in the near future. Only for style #2 (out of fashion) is the trend clear, and in this instance approximately 75 percent or more of consumers indicated they would not purchase the style. The styles most likely to be purchased by adults appear to be #1 and #4, while college students appear to be most positive about #1 and #3. It is also interesting to note the significant growth in students' purchase intentions for #4 (classic fashion) from the 1976 to 1977 study, as well as their apparent decline in intentions regarding #1 (newest general fashion in 1976).

Tables 5 and 6 exemplify how data from the fashion preference monitoring system described in Tables 1 - 4 can be integrated with data from retail store image/patronage measures. Tables 5 and 6 contain cross-tabulations of three stores which were identified by subjects as "most frequently patronized" versus the style preferences expressed by consumers choosing each store. The three stores selected for this example illustration include a well-known local department store (store A), a fashionable local specialty store (store B), and a national chain store (store C). These three stores were found to be among the most frequently patronized stores in the Lafayette area, and they collectively controlled a major share of the total clothing market. The three stores also represent different organizational structures, marketing strategies, and store images in the local market.

The percentages in Tables 5 and 6 represent the proportion of consumers choosing each store as most frequently patronized who rated each style as "high in current popularity," "will increase in popularity in next six months," and "definitely will purchase" this style. These percentages, when compared across styles, give an indication of the specific styles which would appear to be highest or growing in popularity, and which therefore should be emphasized in each store's inventory. The data also give an approximation of the proportion of inventory which might be committed to each style. The general finding of these tables is that consumers who have a "favorite" (most frequently shopped) store can

have different fashion preferences compared to those choosing other stores. A brief description of these differences in preferences, and their implications for the buying and assortment policy of each store, is as follows:

- 1) Store A - Department Store. The 1976 data indicate this store has substantial appeal to both adult and college markets. In adult-oriented departments, the data clearly indicate that emphasis should be placed on styles #1 and #4, perhaps including a balanced inventory of those styles. In comparison, the data indicate that college-oriented departments should carry styles #1, #3 and #4, with some weighting toward #3. The 1977 data indicate a general decline in styles #1 and #3, and a considerable growth in importance of #4, for both the adult and college segments of the market.
- 2) Store B - Specialty Store. The 1976 and 1977 data indicate this store appeals largely to the college market segment, with approximately 3/4 of the regular patrons coming from that market segment. The 1976 data indicate the store's inventory should be heavily weighted toward style #1, though a modest amount of #3 and #4 should be carried in stock. It is apparent that the emphasis on #1 would appeal not only to the college market, but also to the few adults favoring this store. In the 1977 findings there is a substantial shift in consumers' preferences, and it would appear that a relatively balanced inventory including styles #1, #3 and #4 would be best, though a slight over-representation of #3 and #4 would be acceptable.
- 3) Store C - Chain Store. In the 1976 data there are indications that this store has a substantial competitive appeal in both adult and college markets, and the market share of this store would appear to compare favorably to stores A and B. The data also indicate that this store should carry the widest variety of styles in order to appeal to its clientele. There are some clear indications that the most emphasis should be placed on style #1 (the newest fashion), but even style #2 (the out of fashion style) appears to achieve enough popularity and buying intentions to justify some modest representation in the store's inventory. The 1977 data also appear to support this policy of variety and balance for the chain store. It would thus appear that this chain store has some of the most complex inventory decisions to make, given its widespread appeal to the consumer market and the variety of styles appealing to those market segments. Considerable coordination between local store management and the centralized management of the chain would clearly be needed.

Discussion

This research has validated a mail survey technique for monitoring trends in consumers' fashion preferences. The technique involves presenting consumers with line drawings of basic styles, and obtaining consumers' rating of their ownership of each style, popularity (current and future) of each style, and future purchasing intentions. The data indicate that responses to these types of questions can be used to discriminate the current fashionability of each style. Predictions of future demand can also be extrapolated from the data, though the validity of those predictions has not yet been fully explored.

TABLE 5

*See interpretive notes at the bottom of Table 5.

The fashion preference monitoring technique can also be used to identify styles preferred by consumers who patronize specific stores most frequently. This type of information, when available to the retailer with the proper lead time, can be extremely useful as a merchandise management information system. Specifically, the data can be used to identify basic styles to buy, proportions of inventory to commit in each style, market segments for each style, and styles nearing the end of their period of fashionability. These types of information are crucial for effective and timely inventory management.

The fashion preference monitoring technique can be especially useful for longitudinal tracking of trends. In the present research a two year tracking was conducted, with studies conducted on an annual basis. However, to more precisely track changing trends, it is likely that more frequent studies would be necessary to fully respond to the needs of retailers. For example, a monitoring system keyed to major annual fashion seasons (Spring and Fall) might be more responsive to retailer needs. Furthermore, within any given season it would be useful to obtain an initial measurement of trends at the start of the season (as done in the present study), and then conduct a follow-up study at mid-season in order to monitor the trend and validate the earlier findings. Such accumulations of data, when compared to the store's actual results, could be very useful in precisely validating the predictive efficacy of the monitoring system for any given store.

Finally, it is important to note that the data presented in this paper are only one example illustration of how fashion preference and store patronage monitoring systems can be integrated into a management information system. In this example the focus was on the store patronage dimension of "store most frequently shopped." Similar comparisons such as those made in Tables 5 and 6 could also be made across other relevant store image/patronage dimensions (i.e. store last shopped, most fashionable store store with best assortment, store with best prices, store with the best location, and so on). In this manner a complete profile of consumers' fashion preferences and their view of the competitive market can be obtained. This type of competitive information can be crucial for retailers who wish to assess their position in the local market, and it can be absolutely vital to those retailers who need to reposition their images in order to maintain their share of the local market.

SEGMENTING LOCAL MARKETS FOR
ENTERTAINMENT SERVICES:
THE CASE OF DISCOTHEQUES

Daniel A. Emenheiser, Oklahoma State University
George B. Sproles, University of Houston

Abstract

There are many and varied entertainment services available today. Retailers of entertainment face problems and challenges concerning local market segmentation, focusing on recognizing and then satisfying the needs of their particular consumers. This paper presents an analysis of these problems and illustrates a method of segmenting local markets for such entertainment services, focusing on the segments patronizing two competitive discotheques in Indianapolis, Indiana. An effective profile of the "heavy user" market segments of these two discotheques is developed as a result of the research findings. There are some significant similarities between these segments, but there are also some very important differences between "heavy users" of the two discotheques, which lead to market segmentation implications.

Introduction

One aspect of retailing which receives little attention is the marketing of entertainment services. Nevertheless, the providers and promoters of entertainment services such as night clubs, discotheques, resorts, theme parks, health spas, tennis clubs and so on are very much in the business of retailing. They also face the retailer's classic problems of identifying local markets of consumers, analyzing consumer preferences, responding to changing services of their competitors, and developing retailing strategy for their local markets and market segments.

This paper presents an analysis of the marketing problems faced by retailers in the entertainment business, focusing on the segmentation of local markets for entertainment. An approach to segmenting local markets for a specific type of entertainment is described, using a combination of established and new techniques for market segmentation research. The specific example used is discotheques, a relatively new form of entertainment which has recently grown to become an important part of the contemporary market for entertainment. The questionnaires utilized measured variables including discotheque attendance, discotheque preferences, general discotheque interests, factors important when choosing a favorite discotheque, activities, general interests, and the respondent's personal situation.

The purpose of this research was to construct a comprehensive profile of patronage characteristics of the customers who frequent two selected discotheques in the Indianapolis, Indiana area. Emphasis is placed on constructing a complete profile of the "heavy user" of the selected discotheques, including demographic, life-style, and patronage preferences. This type of information on the market segments patronizing a particular discotheque is fundamental to the formation of discotheque retailing strategy.

Background

Within the past two years, the appeal of discotheques has been growing rapidly. This is evidenced by the ex-

treme success of the numerous discotheques that have come into existence. There are an estimated 10,000 discotheques in the United States today, and last year discos claimed a \$3.6 billion share of the entertainment market (O'Harro, 1976). Major leaders in the hospitality industry have been developing the discotheque concept and incorporating it into their establishments. For example, innovative disco marketing has been pioneered by Hilton Hotels, Ramada Inn, Interstate United (the Giraffe discotheque chain), Bobby McGee's, and Marriott. This growing industry also includes new chains and innumerable single proprietorships in large and small cities throughout the United States.

Zucaro (1976) has noted that the restaurant/discotheque has become a multi-function entertainment center which is capable of creating various atmospheres and handling many different types of events. Discos, like other forms of entertainment, must cater to their following, and a major consideration is the type of clientele sought. As described by Orth (1976) a contemporary disco is a place for people to relax and "let go," to be seen, and to watch; it is also an environment where technology allows an anonymity over insecurities and hangups. However, this perseverance goes far beyond the actual discotheque. It has created a popular emphasis on fashion, dancing, and many other areas of modern life. Discotheques have also profoundly influenced the tremendous popular-music industry by creating a dynamic disco sound (i.e., Motown's primary concentration right now is on "disco" music), a vast market for records and entertainers, and a new all-disco format for radio stations.

There are many reasons why these restaurant and hospitality operations are developing the disco concept. However, the primary reason is because of the high profit returns possible. Many lounges that previously relied on live entertainment are now being turned into profitable disco centers, thereby encouraging customers to remain in the units well after dinner hours. With the rising cost and uncertain availability of top name live entertainment, this appears to be a viable way to maintain continued business. Many discos operate adjoining restaurants, and some units are also experimenting with the new trend of offering a special limited late night breakfast menu when the disco closes.

Discos frequently offer a variety of attractions to their clientele. The "typical" disco features dancing to popular music, played from professional sound systems operated by a disc jockey. The disc jockey is usually situated near the dance floor. Often this person interacts with the patrons through remarks, requests, and various contests. Music selections are often mixed to appeal to all age groups. The total "product mix" of the disco will frequently include a combination of non-stop music, professional stereo sound system, a dance floor, pulsating lights, phenomenal decor, plants, liquor, food, and much more. Backgammon tables, huge TV screens, slide shows, pinball and other amusement machines may also dot the disco "dancescape."

Because of their emphasis on phenomenal decor and design by many discotheque operations, a considerable number of prominent interior designers and architects have become involved in this industry. Many discotheques throughout the country have received national and professional recognition for their design and decor. This combination facilitates and helps to promote the image of the discos, which is thought to be of tremendous importance in drawing a clientele. For instance, Funky's Discotheque of Evansville, Indiana, was once the Holtz Steamboat Foundry built back in the 1860's. The decor of Funky's today exhibits the skilled craftsmanship of the 19th century. Every article from the stained and cut glass to the ornate wood workings are original antiques. Funky's is in constant search of antiques of this sort, and they also offer some of their antiques for sale to their customers as their menu indicates. Another example is the Library, a tri-level discotheque in Atlanta, Georgia, which boasts a half-million dollar interior. The walls of the establishment are bookshelves lined with books, which customers are actually allowed to check out.

In addition to the emphasized phenomenal decor and dancing, a central and highly profitable attraction for many discos is their adjoining restaurant. Many of these operations are receiving recognition for their excellence in food quality and selection. Unique, interesting foods are being served as a part of the overall disco entertainment package. This gives the disco management further flexibility in developing the products and services to be offered to the various market segments. Given the growing significance of eating away from home, this dimension of the disco's "product mix" can in fact become a major key for long-term financial success of the disco concept.

After interviewing prominent discotheque owners and managers, Tucker (1975) concluded that the secret to success for these professionals is to find something unique, something which will promote the "image" of their clubs. This virtually dictates the disco's emphasis on costly interiors, specialized decor, multi-level operations, high-powered sound systems, and special lighting. Some club owners are going to great expense to find the magic formula to satisfactorily meet the demands of the dominating affluent, young-executive market segment, but at the same time to have a disco that will bridge all age groups. This is possible because the versatility of discotheques is unique resolves Jarigue (1975). There are many possibilities available to management in developing the product/service mix for the discotheque. By developing a unique product/service mix, customers may be satisfied. But first management must know who comprises their market segments, the characteristics of these people, and what they really want from the disco. When management acquires this information, then each disco can develop its own formula to approach the desired market segment(s). Profitability of today's discos results in part from the special promotion and merchandising offerings and campaigns of each successful discotheque.

Delineated in the broadest of terms, the principal clientele of discotheques comprise what is sometimes referred to as the "Hungry Generation." The "Hungry Generation" represents the post-World War II bumper baby crop that is now growing into young adulthood, family life, and career employment. The largest part of this potential market appears to be young adults in their early to mid-twenties. However, a significant and perhaps growing segment is among established young adults ranging in age into the mid-thirties.

Nation's Restaurant News in an article titled "Feeding the Hungry Generation" (1971), has identified some specific attributes of the "Hungry Generation." These attributes include openness, involvement, spontaneity, and uninstitutionalism. Following through, today's "Hungry

Generation" is demanding choice and participation. They are looser and brutally honest. Other key orientations include impatience with tradition and refusal to be regimented. These characteristics suggest the hospitality and entertainment industry can increase its success in handling this young market by being less rigid and tradition-bound, and more flexible and innovative, in designing its product/service mix.

Discotheque and restaurant management must satisfy the desires stemming from these characteristics. Examples of some successful approaches include the implementation of salad bars, sundae bars, dance contests and lessons, contemporary decor, etc. Established chains have also adopted new restaurant images directed to the younger generation. A recent example of this occurrence is Howard Johnson's new restaurant system known as Ground Round. One would never know that a Ground Round is a converted "orange-roofer," but it is so successful (\$10,000 weekly sales are common) that the company is now building them from scratch. Although a Ground Round is principally a restaurant and bar, it has drawn upon the needs and desires of the "Hungry Generation" and has developed a product/service presentation which directly utilizes the characteristics of the discotheque concept. As Howard Johnson has done, many other established operations may continue their growth by finding fresh, new ways of expressing the new requirements that the young-thinking market segments are currently demanding.

Though discos have clearly achieved initial market acceptance among a rather young clientele, their market potential can be much broader. For example, Mr. Richard Chapman (1976), Assistant Director of Food and Beverage Planning and Development for Hilton International, remarks that, "The discotheque concept is a product, for which today's society in many locations has created a need. I feel that it is a product where the final mix must be finely attuned to the local market conditions. In general there is a trend away from the loud "rock" music to a more sophisticated and intimate level of operation. The former is more susceptible to the whims of fashion and appeals to the younger market, where spending powers are limited. The latter, perhaps requiring greater initial investment, appeals to the middle management mid-thirties age group." This suggests the importance of broadening the base of the disco's clientele whenever local market conditions permit.

Some notable attempts to broaden their markets have been made by various restaurant/discotheque operations. A principal emphasis is on diminishing the "youthful" image of discos, and making the modern disco a place where a variety of age/interest groups feel comfortable. Walton (1976), in a Nation's Restaurant News article titled "Hungry Generation Grows Up -- New Themes Aim at Wider Age Groups," points out several examples of this trend. For example, Bobby McGee's Conglomerate of discotheques considers customers aged 25 and up its basic target group and sees the concept's appeal as broad. Similarly, Steak and Ale views its market as "very broad," according to one company officer, and it has appealed to a 25-59 age group. Steak and Ale's Market Researcher, Albert J. Yesk, also identifies market segments within the population by values they hold rather than by age groups. Those expected to contribute to restaurant industry growth are "new values" people -- those whose interests and activities are not centered on home life. People, no matter what age, come to the discos to have fun, "to get away from it all" and to forget the hassles of everyday life. They do not come to get drunk, and they are mostly positive people as far as their entertainment and their social life go.

Disco operators who can fully understand the special identity and needs of the "Hungry Generation" will probably find themselves making extensive and more profitable uses of their capital investments. However, opera-

tors who can tap this "Hungry Generation" market will probably find it broader based than it first appears. Though the "Hungry Generation" may appear to be one homogeneously young "swinging" market, this is probably not the case. Rather, the disco market may contain many sub-segments, each having a relatively unique profile of personal characteristics and patronage preferences. In such a situation, disco marketing may be "tailor-made" to the special needs and wants of profitable sub-segments within this broad market.

Research Objective

Based on the preceding rationale, the basic objective of this research is to profile the characteristics of patrons of two major discotheques with restaurants in Indianapolis. The focus is on identifying the demographic, life-style, and patronage characteristics of "heavy users" of each discotheque. From these profiles it can be determined the extent to which the two clienteles of the discotheques are in fact different, and the extent to which the local market for discos can be segmented based on those differences. Finally, based on these findings managerial recommendations for planning a discotheque retailing strategy focused on the local market segments can be developed as an aid to managerial-decision making.

Methodology

Data were collected through a questionnaire which utilized dependent variables including, "About how frequently do you go to discotheques in the Indianapolis area?"; "Which disco do you patronize most often?"; and "When spending an evening in a discotheque, how much is your typical check?" Both life-style and demographic variables were included in the questionnaire to obtain specific descriptive data of the population and to aid in the development of a life-style profile of the "heavy user" of the discotheques.

The questionnaires used in this study were developed for application to discotheques based on previously conducted research. Discotheque preferences were measured using techniques developed by Arnold and Tigert (1973), and more recently modified by Charles King (Purdue University), Lawrence Ring (University of Virginia) and Douglas Tigert (University of Toronto). Questions from their instruments, which were designed to measure various patronage/store image dimensions for food and clothing stores, were adapted for the case of discotheques. Other sections of the questionnaire were adapted from the fashion and retailing research program of George Sproles (University of Houston) (Sproles, 1977).

As a preliminary exploratory investigation, an in-depth pre-test was conducted at three disco-type operations in Indianapolis on Wednesday evening, June 23, 1976 and on Saturday evening, June 26, 1976. Twenty pre-test questionnaires were distributed at each discotheque on each evening. Thus a total of 120 questionnaires were distributed for the pre-test. The pre-test questionnaire was randomly distributed to both males and females, after 9:00 P.M. until closing at all three operations simultaneously. At each discotheque on each evening, 10 questionnaires were distributed to men and 10 questionnaires were distributed to women. When customers were approached with a questionnaire, they were briefly informed of the purpose of the study, and then were asked if they would complete the questionnaire at their convenience. If they declined, they were thanked and no more was said. The process of distribution was designed not to disturb the clientele of the operations, and was done with cooperation of the management. The questionnaires were distributed along with an explanatory cover letter and an addressed, self-stamped return envelope.

Within thirty days the following response rates were obtained:

Discotheque A:	12/40 or 30%
Discotheque B:	12/40 or 30%
Discotheque C:	6/40 or 15%.

Overall, for the pre-test there was a 25% response rate, with a total of 10 male responses and 20 female responses.

Relevant information gained as a result of the pre-test was used to design a final questionnaire for the actual test. First, general response from the subjects and managers indicated that the length of the initial questionnaire kept a number of subjects from completing it. The original questionnaire was a four-page booklet, with questions on eight sides surveying the areas mentioned previously. Because of the length problem, the information contained on the first two pages of the questionnaire was shortened by the deletion of several of the discotheques. Several of those discos (other than the pre-test sites) went out of business between the pre-test and final test. These deletions allowed increased white space on the questionnaire, and aided in forming a shorter survey. The third page of the questionnaire which was concerned with certain aspects of personal attitudes and identity, the one requiring the most time to complete, was also deleted. With these changes, the actual questionnaire used still surveyed the principal research issues but did not appear nearly as lengthy or complex.

The pre-test results also resulted in a decision to remove Discotheque C from the final study, for several reasons. As indicated previously the response rate from Discotheque C was very low. This appeared to result from the fact that many of this disco's patrons were not true customers of the disco. Rather, many were dinner patrons and the disco or lounge area was often just a gathering or waiting place prior to dining. Consequently many of this disco's patrons felt they were not qualified to complete the questionnaire, and therefore they did not do so. Another reason for deletion of Discotheque C from the study was that the management did not add a dance floor to their lounge as they had planned at the start of the study. Therefore, this disco operation was not a true discotheque in the sense of offering the complete mix of music, dancing, and beverage service.

The pre-test also indicated the response of males in answering and returning the questionnaire was less than satisfactory. It was also tentatively found that there appeared to be minimal significant difference between the responses given by males and those given by females. Therefore it was decided to survey only the female patrons. This approach appears to have face validity, for many disco owners as well as the researchers believe that women are the crucial sex to satisfy in a disco retailing strategy. Likewise, Michael O'Harro (1976), one of this nation's leading discotheque consultants, supports the important role of women in the marketing process for hospitality operations. He suggests that if the women are satisfied and truly enjoy a given disco operation, then the male clientele will also be there, simply because the women are at the discotheque and are having a good time there.

The two competitive discotheques selected for final study are extremely successful discotheque/restaurant combinations. They are located in one of the affluent, upper-middle class suburban neighborhoods of Indianapolis. They are both located near popular shopping complexes, and are about a mile apart from each other. This close proximity makes them potential direct competitors for the same local market. For the actual test, 1,239 questionnaires were distributed to all cooperating female patrons who patronized either Discotheque A or Discotheque B during four survey nights. The nights were Wednesday-Saturday, July 21, 1976-July 24, 1976. Ques-

tionnaires were distributed by the same method used during the pre-test, from 9:00 P.M. until closing. Eight weeks were allowed for the return of the questionnaires.

The principal objective of this research was to identify the "heavy user" of the competitive discotheques. The dependent variable question "About how frequently do you go to discotheques in the Indianapolis area?", was used to identify "heavy users." Those who responded with "at least once every two weeks" were termed the "heavy users" of the discotheques. Additionally, another dependent variable question, "When spending an evening in a discotheque, how much is your typical check?", was used to identify "heavy spenders," a group of obvious interest to disco owners. The "heavy spender" was defined as that person who, when spending an evening in a discotheque, had a typical check of at least \$4.00 per person. The third dependent variable focused on the question "Which disco do you patronize most often?"

The "heavy user" of each disco was profiled across four major variable sets: 1) disco preferences, 2) disco image dimensions, 3) life-style activities/attitudes, and 4) demographics. Each profile variable was cross-tabulated against the selected "heavy user" dependent variable, using the .05 level for the test of significance. The following discussion will focus on a verbal summary of principal significant findings. See Emenheiser (1977) for a complete presentation of the data tables.

Results

A total of 1,239 questionnaires was distributed for the actual testing. A total of 754 questionnaires was distributed at Discotheque A and 485 questionnaires were distributed at Discotheque B. The greater number at Discotheque A resulted from the fact that the capacity of Discotheque A is greater than that of Discotheque B, and patronage was greater. After allowing eight weeks as a return period, 355 questionnaires were returned from the 1,239 which had been distributed, for an overall response of 29%. From the 754 questionnaires which had been distributed at Discotheque A, 192 were completed and returned, for a 25% response rate. From the 485 questionnaires which had been distributed at Discotheque B, 162 were completed and returned, for a 33% response rate.

A preliminary analysis indicated that 88.7% of the survey's 355 respondents have patronized Discotheque A, and 83.9% of the respondents have patronized Discotheque B. This provides assurance that the respondents are capable of effectively completing the questionnaire concerning these two competitive discotheques. It also implies (incorrectly as shown later) the market segments of the two discos actually view the two discos as competitive substitutes to one another.

Other initial findings were that the "heavy users" of the discotheques concentrate their patronage at one of the discotheques studied, as would be expected. However, the relation between the "heavy spender" and the variable denoting the disco patronized most often is more significant than is the relation between the "heavy spender" and the "heavy user" variables. This means that although the "heavy user" either patronizes Discotheque A or B most often, the "heavy user" is not always the one spending the most money at the disco. Thus it would appear that "heavy spenders" and "heavy users" of discotheques, as defined in this research, are not identical market segments.

The profile data on patronage preferences for "heavy users" of each disco yields some interesting findings. For each disco, "heavy users" said their chosen disco (A or B) was "best" across characteristics listed in

Table 1. However, competition between the two discos was high, as further analysis indicated. While "heavy users" of Discotheque A naturally rated it highly across most patronage dimensions, Discotheque B received the second highest number of "best" mentions across most dimensions. Likewise, among those preferring Discotheque B, Discotheque A receives second highest number of mentions.

TABLE 1
CHARACTERISTICS OF PREFERRED DISCOTHEQUE

is the easiest one to get to
has the lowest prices
has the most courteous service personnel
has the most efficient service personnel
has the highest quality food and/or beverage
gives you the best value for your money
is the most current, up-to-date
has the most exciting atmosphere
has the best selection of music
has the most enjoyable disc jockey presentation
has the best lighting system
has the best sound system
has their favorite dance floor

However there are some important differences in relation to other patronage dimensions. The patrons of Discotheque B believe Discotheque A is the disco with the highest prices, while they believe very strongly that Discotheque B has the most variety in food and/or beverage selection. The patrons of Discotheque A are evenly divided on this last factor. The patrons of both discotheques tend to agree that Discotheque A is the disco with the most exciting decor and most romantic atmosphere.

There are also a number of significant life-style/psychographic characteristics differentiating patrons of the two discos. Most interesting is the fact the "heavy users" of Discotheque A visit the disco for relaxation and enjoyment, while those at Discotheque B visit the disco to meet with friends and for entertainment. This goes along with the fact that the "heavy users" at Discotheque B frequently join in informal gatherings with friends. Those of Discotheque A do also but to a lesser extent. Other findings were that the "heavy users" at Discotheque A participate more often in outdoor activities than do those at Discotheque B. The "heavy users" of Discotheque B were also found to report lower levels of attending religious services or doing gardening. Finally, many patrons of Discotheque A perceived that they did not carefully watch how they spent their money, while patrons of Discotheque B were evenly split on this issue.

There are also a wide range of similarities in life-style orientations and patronage preferences of the "heavy users." All tend to go swimming regularly in the summer, to eat lunch at restaurants, and to go shopping with friends. There is a consensus among "heavy users" that the hours of operation of the local discotheques in Indianapolis are satisfactory. They believe that discotheques should have late night (after midnight) sandwich or breakfast type menus, and that good tips should be given for good service. The "heavy users" agree that a visit from a disco artist at the discotheque would be exciting. However, they do not seem to prefer the disc jockey's music to that of a live band. Nor do they usually stop at another restaurant, after leaving the disco, for a nitecap. Particular emphasis is placed on the importance of the disco's atmosphere, cleanliness, and efficiency and friendliness of the service staff. Also very important to the "heavy user" is dance floor space and hours for

reduced drink prices. Little importance is placed on the availability of pinball or other electronic games, backgammon tables, or slide presentations. Concerning other consumption-oriented interests of the "heavy user," the data indicate they do not perceive themselves to be opinion leaders in choices of fashions. However, the data indicate they keep their wardrobes up to date with current fashions by usually having one or more outfits of the very latest style. Finally, the "heavy users" appeared to not necessarily be heavy consumers of the albums or tapes of their favorite singers.

Demographic differences between "heavy users" of the two discos were not substantial. However, the age comparison does appear to be very important. Discotheque A had a greater proportion of patrons from the 25 to 34 age group than does Discotheque B, while Discotheque B tends to have more patrons from the 18 to 24 age group. This factor is a strong indication of the transitional differences between the "heavy user" market segments of the two operations. Otherwise, demographically the "heavy users" of the two discos are much the same. They tend to live in suburban Indianapolis in large apartment complexes. In general they are single and are employed.

Discussion

On the basis of significant data collected several market segments of the two discotheques can be described, including "heavy users," "heavy spenders" and disco most frequently patronized. However, most important is the market segment composed of the "heavy users" because they are the ones who are for many operations most important to the success of that operation. Even though their typical check averages may not be quite as high as those of the "heavy spenders," they are important for many reasons. They represent repeat business, they represent a large market segment, and they are excellent "promoters" of a disco, i.e., they tell their friends about their favorite disco and often even meet them there. As a result they are definitely a very profitable market segment to the operations. Often this market segment can become so loyal to a given operation that many discos become known as having a certain segment of people usually there, i.e., "the regulars" (many discos now offer memberships to such groups).

A rather effective profile of the "heavy user" market segments of the two discos emphasized in this research has been developed. There are some significant similarities between these segments. It has been noted that those patronizing either Discotheque A or B most often perceive their chosen disco to be "best" in a similar set of products and services (see Table 1). Along other lines, because "heavy users" of both Discotheque A and B are all broadly a part of the "Hungry Generation," it should not be surprising to find many of their attitudes, interests, activities, needs, and desires to be very similar. Further, because the two operations are competitive in location and in products and services offered, most of the customers have patronized both discos occasionally, though they clearly prefer one over the other. In short, the principal market segments of both discos have a relatively clear set of preferences, and their identifying characteristics overlap to a substantial degree.

However, there are some very important differences between "heavy users" of the two discos, and these differences suggest a basis for segmenting the local market. Most important is the age difference between the two segments. There are also important differences in perceptions of prices and variety of food/beverage selections. Finally, the patrons of one disco appear to go to it for "relaxation," while patrons of the other attend to "meet friends." Clearly the preceding dimen-

sions constitute a fundamental basis for segmenting any local market for entertainment.

The findings of this investigation make it rather apparent that both discos have generated a relatively loyal clientele, and have successfully offered a product and service mix satisfying their principal market segments. However, the findings also support some possible new retailing strategies that could be added as a part of their strategies to remain "unique." Both discotheques may want to assess the feasibility and profitability of offering lunch and late night (after midnight) sandwich or breakfast type menus (why not utilize those available kitchen facilities?). Results of the study indicated a demand for these services by disco patrons, and offering expanded meal service could broaden the retailing strategy of each operation. More promotional efforts could also be placed on encouraging evening patrons to come for dinner as well as dancing. It would also appear that "tie-in" promotions with other retailers (i.e., clothing stores) might offer unique opportunities for the discos which would be favorably received by their younger clientele. Many other "tie-ins" oriented toward the life-style aspects might similarly appeal to the young. Finally, it appears that both discos have their principal appeal to younger market segments, and both might therefore increase profitability and stability for the future by promoting their product/service mix to a broader range of the total adult market.

One final note regarding research methodology should now be made. The present study has adapted new retailing research techniques and some established market segmentation techniques to the special situation of segmenting local markets for entertainment. Relatively little of this type of research has previously been done by the entertainment and hospitality industry, but the need for such research in the modern competitive and fast changing services market is clear. The present methodology used in this study exemplifies one successful approach which has generated managerially-relevant information on disco strengths/limitations, the identity of principal market segments patronizing competitive discos, and new competitive ideas for disco retailing strategy. Such "marketing intelligence" is crucial in opening new markets for discos and to continually satisfy consumers' needs.

Conclusion

The contemporary discotheque has become one of the strongest, rapidly growing, and most profitable segments of the hospitality industry. The typical disco offers a combined entertainment product/service mix including food, beverages, music and disc jockey personalities. The potential market for disco entertainment is large, but centers on a younger clientele ranging from late teens to mid-thirties in age. The type of research summarized in this paper can be an aid to disco owners/managers in segmenting their local markets, identifying patronage characteristics of contrasting segments, and formulating "disco retailing strategies" focused on the needs and demands of their segments of the market.

LOCAL RETAIL MARKET MONITORING:
STRATEGIC IMPLICATIONS

Charles W. King, Purdue University

Abstract

Monitoring of the local retail market competitive structure for the retailer's particular product category and the retailer's position and store image within that competitive milieu is essential to the retailer's strategic planning. This paper discusses the retailer's strategic planning needs, the concept of local retail market monitoring as a routine research procedure and presents an example of pragmatic local retail market monitoring with a discussion of strategic implications.

Retailing: The Strategic Marketing Problem

The basic strategic marketing problem confronting the retailer centers around the classic issue of market positioning. The retailer's strategic objective is to develop an integrated marketing program encompassing a wide range of marketing elements to create a market position within his competitive environment.

To establish a market position, the retailer strives to develop store personality or image. The store image should be analytically defined and designed to appeal to and be compatible with the store's target customers. The store image is the product of a set of components or attributes that are important in determining customer patronage within a particular retailing competitive market.

Consumer perceptions of store images, however, are very time related. Store images can change significantly over time due to changing retailer strategies, new competitive entries or other exogenous market variables. The stability of store images over time can also vary sharply across product categories. Each week, for example, the price image of an aggressive supermarket is under scrutiny in its featured, end-of-week prices. Supermarket price image therefore, can be very volatile.

The fashion image of a major department store, by comparison, may change only modestly over several seasons. Even under heavy strategic focus, the fashion image of a retailer may be an extremely stable, difficult to change dimension of retail patronage.

The critical question is, how is the retailer's store image actually perceived by the target customers compared with the firm's competitors in the local market over time?

Local Retail Market Monitoring:
A Conceptual Overview

To address the issue of retailer market position and customer perceptions, the retailer needs an on-going local retail market monitoring program. The concept of local retail market monitoring is a direct extension of traditional store image research.

Historical Store Image Research: The State of the Art

Since the now classic Martineau (1958) conceptualization of the "store personality or image", store image research has become extremely topical among leading retailers and marketing academics. Over the past 19

years, great strides have been made in gaining management interest in the concept of store image as a key market variable and as a pragmatic strategic merchandising tool.

Over that period too, empirical store image research developed as well. Historical store image research, however, has been largely single sample survey and cross sectional in research design. The research has tended to be exploratory in topic content with too little historical linkage or futuristic continuity.

More importantly, across the store image research, there has been little standardization in field methodology or measurement instrumentation. Consequently, despite a relatively large literature, there has been only a limited amount of generalization across the field until recently.

From the historical store image research to date, however, has emerged an expanding research tradition. Analysis of that tradition indicates that:

- 1) A conceptual framework for understanding and researching store imagery has evolved;
- 2) A cadre of increasingly sophisticated empirical researchers in leading retailing organizations and in academia has entered the store image research arena;
- 3) The historical research has identified major "general" dimensions of retail patronage or store image such as merchandise selection or assortment, merchandise quality, merchandise pricing, locational convenience, merchandise styling(fashion), service(general) and sales-clerk service;
- 4) The research has indicated that the key determinants of retail patronage vary across product categories. Therefore, store image research, to be most effective to retailing management must be both "general" and tailored and focused to be product category "specific";
- 5) An operational field research design and measurement methodology for cross-study research comparability has evolved in the published literature.^{1, 2}

¹For representative and significant literature and industry trade practice reviews, see Wyckham, Lazar and Crissy (1971), Lindquist (1974-1975), May (1974-1975) and Ring (1977).

²Several leading research oriented retailers have made impressive progress in adapting this store image research tradition to their specific proprietary image monitoring needs.

The Concept of Local Retail Market Monitoring

Local retail market monitoring, as advocated here, is intended to produce a comprehensive analysis of the basic competitive retail market structure for a particular product category over time. The monitoring system must measure the retailer's historical and current market position and store image perceptions among its target customers.

Equally importantly, the monitoring system must also measure shifts in the relative positions of competitors in the local retailing arena as the market structure changes. The system must track both the number and market positioning of the major retailers and the changing strategies operative in the market over time.

In its ultimate form, the local retail market monitoring system would produce a comprehensive perceptual "image map" of a local retail market place. Based on that map, shifts in consumer perceptions and the resulting changes in retail market positioning could be tracked. The causes for the shifts could then be explored by more focused research.

More specifically, the local retail market monitoring methodology proposed here would expand and systematize the more traditional store image research. Within a particular product category, the local retail market monitoring research paradigm would:

- 1) Identify the major "general" and product "specific" determinants of retail patronage that should be monitored;
- 2) Develop and standardize an operational measurement battery designed to track consumer perceptions on those selected key dimensions;
- 3) Design an economically viable consumer survey research plan for soliciting consumer perceptions of retail store images;
- 4) Implement an on-going, systematic local retail market monitoring program using standardized field methodology and measurement instruments;
- 5) Based on the initial monitoring survey, prepare a comprehensive perceptual store image map--a based-line description--of the local retail market structure in the subject product category;
- 6) Routinely repeat the standardized market monitoring survey and analysis procedure to track changes in the perceptual store image map reflective of changing competitive conditions;
- 7) Based on changes in the perceptual store image map, direct more focused, in-depth research on specific problem areas and re-direct the retailing strategy accordingly;
- 8) Continue the routine market monitoring and retail market monitoring and retail strategy adaptation.

Local Retail Market Monitoring: A Pragmatic Example

The Toronto Male Fashion Research Program: On-Going Local Retail Market Monitoring

In 1974, the author launched exploratory research in the integration of traditional fashion adoption research with the developing area of store image and retail patronage analysis in the Toronto, Ontario, Canada fashion

retailing environment. Ultimately the 1975 Toronto Male Fashion Research Project was formalized and implemented.³

The 1975 research built on and integrated established research methodologies in the fashion segmentation, retail store image and lifestyle/AIO areas. The central thrust of the research focused on segmentation of the male fashion market ranging from the highly involved fashion change agent down to fashion disinterested/uninvolved consumer. Based on fashion interest/involvement segmentation measures, general and specific shopping/buying behavior was monitored across each of the major Toronto men's wear retailers.

A critical feature of the 1975 Toronto Male Fashion Research Project that had major impact on the strategic significance of the research was the author's commitment to retailer involvement. The major retailers who were to be subjects under study in the project were all solicited to contribute to the design and pragmatic analysis of the research results.

In terms of research funding too, the research effort was conceptualized as a joint academic/industry project. Purdue University and the University of Toronto contributed to the project through doctoral fellowships, University supplied computer time and professional support.

Industry funds, however, were solicited from local subject Toronto retailers to support the data collection and analysis costs. These costs were shared across all sponsoring firms. Therefore, to attract adequate field research funding from retailing management, the research design and analysis plan had to reflect strategic value to the sponsors at the outset of the research planning.

The basic field methodology involved two surveys of 1000 males each executed via a mail, self administered questionnaire based on area probability samples in Census Metropolitan Toronto. The two surveys were conducted in April - May, 1974 and April - May, 1975 to support longitudinal analysis of changes in store images over the 12 month period.

The concept of local retail market monitoring has been adopted by many of the major men's wear retailers in Toronto, largely as an out-growth of involvement in this research project. The 1975 project was launched as a one-survey extension of the 1974 pilot study. From that effort, a doctoral dissertation was produced (Ring, 1977).

At this point, however, the research effort has been syndicated as a commercial venture and expanded beyond its original academic objectives. The program is now entering its fifth year of operation and has proven the validity of local retail market monitoring as a pragmatic planning tool.

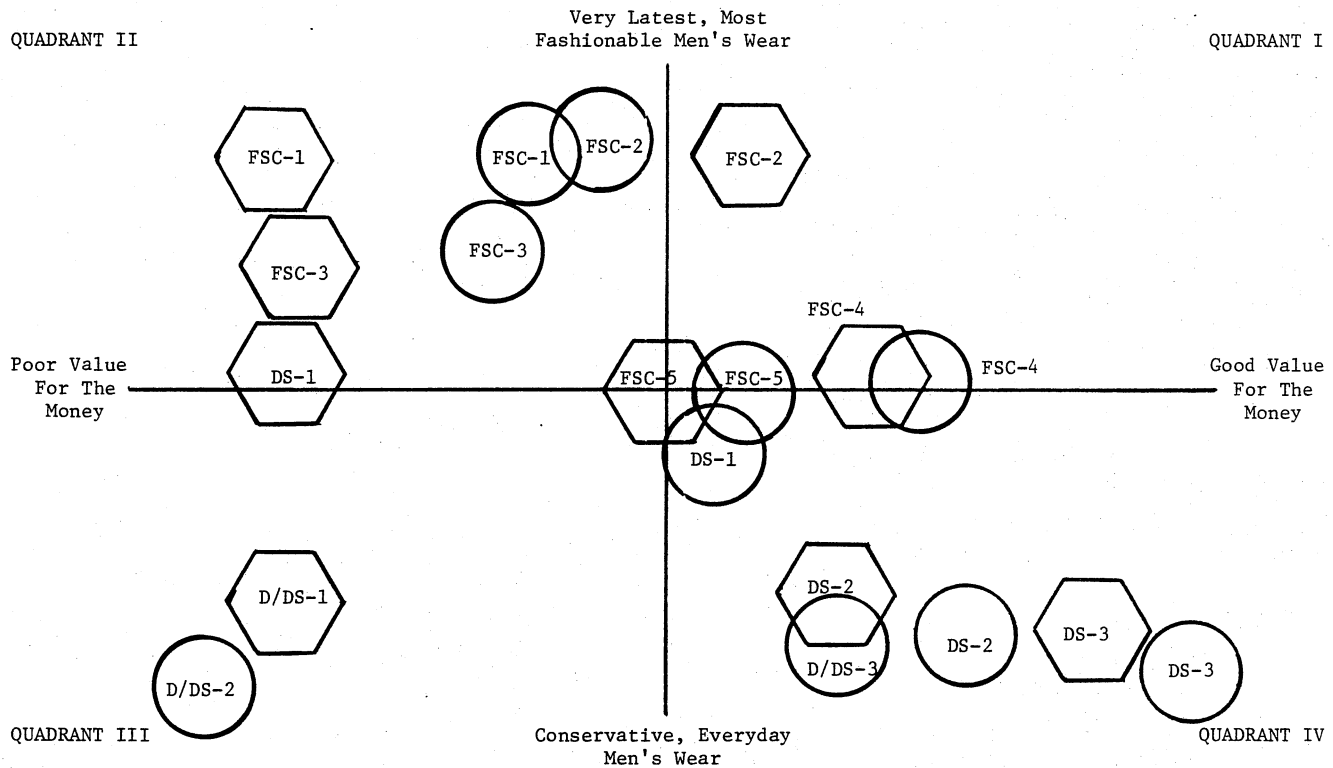

A Two-Dimensional Perceptual Store Image Map

The objective of this section is to present an illustrative example of the output of this local retail market monitoring research procedure. Recall the critical strategic question posed at the outset of this paper: how is the retailer's store image actually perceived by the target customers compared with the firm's competitors in the local market over time?

Toward that goal, a geometric representation--a two-dimensional perceptual store image map--has been prepared. The map presents consumers' perceptions of the major Toronto men's wear retailers on the two retail

³ For a discussion of the evolution of the Toronto Male Fashion Research Program, see King and Ring (1975)

patronage dimensions of store fashionability and value for the money over time from April-May, 1974 through April-May, 1975.

Store fashionability and value for the money were selected as the dimensions for the perceptual mapping example. These variables were identified as key determinants of retail patronage among consumers in this product category.

Methodologically, consumers were asked to select the store with the "best value for the money in men's fashions" from a pre-selected set of retail stores. Likewise, the consumers were also asked to rank the same retail stores in terms of the store "best for conservative, everyday men's wear", "best for current, up-to-date men's wear" and "best for the very latest, most fashionable men's wear."

The consumer responses on these two dimensions were analyzed for each store to define a specific retailer's store image on those two dimensions for 1974 and again for 1975. The positions of the stores in 1974 are designated by hexagon figures. The positions of the

stores in 1975 are designated by circles. In Figure 1, the 1974 and 1975 maps have been presented as an overlay. The shifts in retailer image and market position on these two dimensions over time are clearly visible.

Strategic Implications of the Perceptual Store Image Map: Retail Market Structure Analysis⁴

At the outset, the two dimensional perceptual map presented in Figure 1 is acknowledged to be a simplistic approach to data analysis. In that simplicity, however, lies its value. The basic concepts involved and the amount and direction of change are graphically presented and are readily understood by the retail manager.

More complex analytical procedures have also been employed on the same data. Ring and King (1977) used multiple discriminant analysis to produce a multi-dimen-

⁴Professor Douglas J. Tigert, University of Toronto and Professor Lawrence J. Ring, University of Virginia were co-researchers in the initial development and analysis of the two-dimensional perceptual store image map.

sional map descriptive of the competitive structure in the Toronto men's wear market. That analysis employs a much more sophisticated computational technique but the results agree very closely with the more simplistic two dimensional map. While the multiple discriminant analysis has more academic appeal, at the pragmatic strategic management level, the more complicated mapping technique may confuse the non-quantitative retailing manager.

Turning to the analysis of Figure 1, for ease of interpretation, Figure 1 can be viewed as being comprised of four distinct quadrants. Each quadrant represents a significantly different retail store image.

Quadrant I in Figure 1, the upper right hand quadrant included those retailers perceived as offering both high fashionability, "the very latest, most fashionable men's wear", and good value for the money. Quadrant II, the upper left hand quadrant, included those retailers perceived as offering high fashionability but poor value for the money. Quadrant III, the lower left hand quadrant, included those retailers perceived as offering low fashionability, conservative, everyday men's wear, and poor value for the money. Quadrant IV, the lower right hand quadrant, included those retailers perceived as offering low fashionability but good value for the money.

Several strategic implications immediately emerge from Figure 1. The overall market structure is well defined in the two dimensional fashionability/value for the money variable space. All of the chains except Discount/Department Store 1 and Fashion Specialty Chain 2 in 1974 and Discount/Department Store 2 in 1975 were positioned in either Quadrant IV, low fashionability and good value for the money, or Quadrant II, high fashionability and poor value for the money.⁵

Note that in both 1974 and 1975, Quadrant I, high fashionability and good value for the money was "under occupied." Only Fashion Specialty Chain 2 was positioned in that Quadrant in 1974 and the Quadrant was empty in 1975. The vacancy in that Quadrant clearly represents a unique market opportunity for store positioning.

The vacancy in Quadrant I, high fashionability and good value for the money, may be the result of various factors. Consumers may see an incompatibility between high fashion and good value for the money. In that case, it would be extremely difficult for a retail chain to develop the appropriate store image and occupy that market position. Alternatively it may be that no existing firm has made an overt strategical attempt to position itself as a retailer of very fashionable merchandise with good value for the money.

In either case, the strategic implication is that there is a potential opportunity in Quadrant I, high fashionability and good value for the money, for either new men's wear retailers or for a shifted positioning of existing retailers.

Looking further at the aggregate market structure, in 1975, the end points of the competitive market space are clearly marked by Fashion Specialty Chains 1 and 2, Department Store 3 and Discount/Department Store 2. Fashion Specialty Chains 1 and 2 clearly lead the high fashionability dimension. Department Store 3 occupies the end point position of the low fashionability and good value for the money store image dimension.

⁵ All of the retailers researched were chain operations with multiple stores. The term store and chain are used interchangeably in the text. The research, however, dealt with the overall perceptual image of the chain.

In 1975, Discount/Department Store 2 dominates the unenviable Quadrant III, poor value for the money and low fashionability. Interestingly, after the 1974 data were reported to the management of Discount/Department Store 1, the firm's management withdrew that operation from the Toronto market, closed or renamed the outlets and launched a new strategical store image development and market positioning program. The critical strategic question facing Discount/Department Store 2 is - is the discounter image of low fashionability with relatively poor value for the money a tenable strategic market position in the Toronto market?

While the end point positions are clearly differentiated, the store images of the retailers in the middle of the map are not well defined. This is particularly true for Fashion Specialty Chain 5 and Department Store 1 in 1975. These firms lack a clarity of offering. Neither of the firms have particularly strong positions on either the fashionability dimension or the value for the money dimension.

By comparison, the positions of Department Stores 2 and 3 have been relatively consistent across 1974 and 1975. Both department stores were well anchored in Quadrant IV, low fashion leaning toward good value for the money though both department store chains modestly improved their value for the money perceptions over the 1974-1975 period.

Adaptive Competitive Strategies by the Individual Retailer Over Time: A Longitudinal Example

The perceptual mapping exercise is also particularly useful in alerting a retailer to changing conditions in the market structure. In response to these identified market position shifts, a retailer can devise an adaptive competitive strategy to respond -- reposition himself.

The strategic positioning of Fashion Specialty Chain 1 over the 1974-1975 period is an illustrative case. In 1974 when the first exploratory, base-line study was reported to the cooperating retailers in the research program, the management of Fashion Specialty Chain 1 was surprised--stunned--at the store image and market position of their firm.

Fashion Specialty Chain 1 was perceived as offering high fashionability but poor value for the money. The firm, in fact, held an end point position of this store image.

In terms of relative competitive posture, Fashion Specialty Chain 1 was an arch rival of Fashion Specialty Chain 2. Fashion Specialty Chain 2, however, had been perceived by the consumer sample to be tied for the top position on high fashionability but with dramatically higher value for the money. Fashion Specialty Chain 2, in fact, was the dominant retailer in Quadrant I, high fashionability and good value for the money.

Over the 1974-1975 period, the management of Fashion Specialty Chain 1 developed and launched an aggressive competitive strategy designed to reposition the firm in relation to its key competitor, Fashion Specialty Chain 2. The strategic maneuver involved an integrated program of assortment modification, consumer advertising, price point realignment, salesclerk training and display merchandise modernization.

The end result of the extensive repositioning effort was reflected in the 1975 local retail market monitoring survey. Fashion Specialty Chain 1 had dramatically improved its value for the money position while maintaining its fashionability image. Likewise, over the ensuing year, Fashion Specialty Chain 2, the key competitor, had slipped from its position of 1974.

In 1975, Fashion Specialty Chain 2 did still hold a modest lead in value for the money. The responsive strategy of Fashion Specialty Chain 1 had been successful in repositioning the firm relative to the total market structure and, in particular, relative to its major competitor, Fashion Specialty Chain 2.

Conclusions

The major strategic problem facing the retailer involves market positioning. The retailer must develop an integrated marketing program to position his firm within his changing competitive environment. Local retail market monitoring is a key element in the retailer's strategic planning.

Local retail market monitoring is an extension of traditional store image research into an on-going, more systematic and standardized research program. Local market monitoring can produce a perceptual store image map of an aggregate retail market structure, locate the individual firm within that map, and identify opportunities unfilled in the market structure. Likewise, local retail market monitoring can track changes in the firm's position over time as a result of competition or as a result of purposive strategy changes by the retailer.

CROSS-CULTURAL RESEARCH METHODOLOGY
AS A CASE OF CONSTRUCT VALIDITY

W. Fred van Raaij, Tilburg University

Abstract

Cross-cultural consumer research witnesses an increasing interest of researchers, both for the managerial strategy of multinational companies and in order to establish the universality or specificity of theoretical construct and findings.

In this paper the validity of the hypothetical constructs is discussed in order to create functionally equivalent constructs across cultures and equivalence of samples from the cultures.

A theoretical structure in which a hypothetical construct is embedded serves as a manner for attaining the functional equivalence of instruments and constructs in order to interpret the findings and to implement managerial strategy.

Introduction

In 1889 Sir Francis Galton presided over a meeting of the Royal Anthropological Institute of Great Britain in which a paper was read using cross-cultural data. At the meeting Galton criticized this paper, raising the problem of independence of cases. Elder (1976) describes this as follows:

"If two societies exhibit the same juxtaposition of institutions or traits, how does one know whether these two societies represent two independent cases of that juxtaposition? What if society A "borrowed" the juxtaposition from society B, in which case the juxtaposition is historical rather than functional? What if A and B are merely variants of some common overarching society C? In either case, what appear to be two cases may actually be two illustrations of the same case, in which event the cross-cultural comparison has not produced any further evidence for the generalization of the juxtaposition than did the single-culture observation."

This illustrates the theoretical value of cross-cultural research: the generalization of findings and constructs across cultures, or better, following Popper (1959), the attempts to invalidate a theory or "behavioral law" as culture-specific.

From a practitioner's viewpoint, there exists the need for information on consumer behavior in other cultures and nations in order to develop international marketing operations. It's not the validation or invalidation of theories that is important here, but rather the answer on the question of applying a global or culture-specific marketing strategy.

Triandis, Malpass, and Davidson (1973) mention the following reasons for conducting cross-cultural research:

"To check the generality of behavioral laws; to increase the range of our observations on variables of interest; to determine the variations found in subjective culture variables in different settings; to take advantage of natural experiments involving combinations of variables (conditions) that cannot be obtained in the laboratory; to study the manifestation of psychological variables in different

cultural contexts; and to study cultures for their own sake."

Such research can serendipitously lead to a better insight into the communalities and specificities of consumer behavior in different cultural settings and the universality of behavioral "laws" and concepts across cultures (Poortinga, 1975).

Some introductory remarks make clear the ground for the remainder of this paper:

First, cross-cultural research as comparative research is not unique. All behavioral research is comparative; that is, it involves a comparison of experimental and a control group, e.g., samples of working and non-working wives, husband and wife roles, middle and lower social class consumers, users and non-users of a service, etc. Cross-cultural research is unique in that it considers different cultural settings or "geographical environments" (Koffka, 1935) that shape consumer behavior and are shaped by consumer attitudes and behaviors. Therefore, it means that we cannot control for the "disturbing" factors that may create unwanted differences between the samples under study, and it means that we cannot use the same instrument (questionnaire) for both samples in different cultures.

Secondly, consumer research is largely "made in the USA." Concepts and instruments have been developed in the United States and not in the "other" culture of the cross-cultural study. This may introduce "ethnocentrism" in the type of questions we address, the concepts we employ, and the explanations we give of the results. For instance, the study of "consumer satisfaction" is relevant in a western mass-consumption society but not, or in a different way, in a developing country. Another example is a book by Nieuwenhuijze (1963) reporting the results of an analysis of Islam, that was banned in Indonesia on the grounds that a non-Muslim could not properly examine either the history or the tenets of Islam. A last example is a questionnaire statement: "A good citizen is responsible for shoveling the sidewalk in front of his home" for measuring "social responsibility." This statement assumes private ownership of houses, one-family housing, and a climate with snow in winter, and is clearly not applicable in an African country. In that case, we have to measure "social responsibility" with another statement or set of statements.

Thirdly, the terms "cross-cultural" and "cross-national" are used in the literature. I prefer "cross-cultural" because this term reflects more possible differences in consumer behavior than "cross-national." In cross-cultural research we compare consumer behavior in different cultures, including subcultures, e.g. differences between French- and English-speaking Canadians; black and white subcultures; and minority ethnic groups with the majority ethnic group. Many of the problems and caveats that apply for cross-cultural research are also valid for market segmentation studies using the segmentation variables of race, ethnic background, and social class.

Cross-cultural studies on consumer behavior include: shopping behavior (Green and Langeard, 1975; Douglas, 1976), innovator characteristics (Green and Langeard, 1975), female role perception (Douglas, 1976), media

usage (Douglas, 1977), family buying decisions (Hempel, 1974), life-style research (Plummer, 1977), and information seekers (Thorelli, Becker, and Engledow, 1975; Anderson and Engledow, 1977; Becker, 1976). These studies compare a US sample of consumers with samples in France, England, Canada, Mexico, and Germany, all nations of the western world. Sheth and Sethi (1973) developed a theory of cross-cultural buyer behavior for the diffusion of innovations, and Dubois (1972) developed a framework for the study of the cultural factors that affect the rate of adoption of an innovation. Green and White (1976) give methodological considerations in cross-cultural consumer research. De Vos and Hippler (1969) and Triandis, Malpass, and Davidson (1973) review cross-cultural research in psychology.

History

Cross-cultural research is not new. A long cross-cultural tradition exists in anthropology. Benedict (1934) suggests that cultures - especially of small, isolated groups - are often integrated wholes wherein the parts coalesce around certain basic values. To extract parts from the wholes, compare them (out of context) with parts extracted from other cultures, and then conclude that one has found cross-cultural similarities or differences does gross injustice to social reality. Osgood (1967), using the semantic differential technique, demonstrated that persons speaking different languages have different subjective cultures. Arguments still continue over the degree to which language determines thought processes and thus subjective culture: The Whorfian Hypothesis (Whorf, 1956). The argument in anthropology is that cross-cultural data can be used primarily for the identification of cultural uniqueness or the establishment of cross-cultural contrasts, describing the contrasting cultures in their own context. However, in consumer research, our interest is not primarily the Eskimo of Northern Canada or the Temne of Sierra Leone (Berry, 1967). We study more-or-less similar cultures in Northern America or Western Europe. We may expect more culturally unique behavior patterns in the study of Japanese consumers or consumers in developing countries.

Borrowing the psycholinguistic terminology, a distinction will be made between an emic (culturally specific) and an etic (culturally universal) approach. In an emic approach (from phonemics) the behavior is described in terms and concepts of that specific culture and with internal criteria; hence cross-cultural comparison is difficult or impossible. In an etic approach (from phonetics) the behavior is described in universal categories and with external criteria. Cross-cultural comparison is feasible in the etic approach. Davidson (1977) criticizes the "emic-etic dilemma" and advocates the use of etic concepts (with which comparisons among cultures can be made) and emic ways of measurement (in the context of the culture under study). We will see that this is the central issue in cross-cultural methodology, also referred to as the functional equivalence of measuring instruments.

Another historical development is the evolutionary or revolutionary theory of socio-economic change. Cross-cultural contrasts are used to identify, in a quasi-experimental way, why socio-economic changes in one culture differ from those in another culture. Weber (1958) discusses why industrial capitalism developed in western Europe but not in China or India (Protestant ethic). Certain cultural conditions were different or absent in China or India, and industrial capitalism did not develop there. Hsu (1963) explained why clan, caste, and club emerged respectively in China, India, and the

United States. Implicit in Hsu's analysis is the counterfactual premise that if family structure had been different in the USA, clans or castes rather than clubs might have emerged.

Marx (1972) argued for a contextual view of social phenomena; the basic mode of production in a culture or nation determines social and cultural phenomena. Engels (1949) identified a sequence of politico-economic stages based on the means of production and the class relationship to the production means. Knowing these stages (feudal, bourgeois-capitalist, socialist) one can develop generalizations for societies in the same stage. Parsons (1966) distinguishes primitive, advanced primitive, archaic, advanced intermediate, and modern societies, identifying certain prerequisites as necessary but not sufficient conditions for a society's transition from one stage to another. Meaningful cross-cultural comparisons can only be made between societies at the same level of development (differentiation). Consumer behavior differs depending on whether it occurs in a capitalist nation, a dependent nation (colony) or a socialist nation.

Sampling

Cross-cultural research involves the comparison of samples from different populations (cultures). What type of sample we select depends on our research objective.

1. For a comparison of income and age distributions in different cultures one needs a random sample to employ statistical tests for the significance of differences.
2. For descriptive studies on attitude-value structures, attitude-behavior relationships, life-style, or opinion research sample representativeness is essential. This means that the sample has to be representative for the culture from which it is drawn. In this case, we study the relationships between variables in different cultures and we are not primarily interested in the absolute scores (distributions) of the variables as such.
3. In some cross-cultural studies we need functional equivalence of samples, e.g., comparing salesmen in an American and a Japanese department store. Here we try to find "similar" organizations and samples of the personnel of the organizations. Generalization of the results to the general culture, however, becomes hazardous.
4. For causal studies across cultures, we may employ "matched" samples with matching variables such as age, income, education, etc. One increases the power of the statistical test for the significance of differences using paired observations. But the danger exists that one eliminates real cross-cultural differences through the matching procedure. One has to have a theory to distinguish between the matching variables and the independent variables in a research design.

Except for the random samples, sampling procedures involve an a priori distinction between variables "that are controlled for" in sampling and "real" independent variables that are important from a theoretical viewpoint. To control for sampling inadequacies and to partial out covarying factors that could not be controlled for in the sampling procedure, the technique of analysis of covariance (ANCOVA) may be used. But one has to be aware of the dangers of these control procedures. Controlling for obvious variables such as age, income, and education in the sampling procedure may

create samples unrepresentative of the population. A sample from a culture in India with the same age, income, and education distribution as a US sample may be largely unrepresentative of the Indian culture.

Pretest data will often help to pinpoint the best sample. Pearlin and Kohn (1966) were interested in sampling people from equivalent class positions in the USA and Italy. Their preliminary data showed that income and education were not suitable for manifesting similar class positions, but that occupational prestige was. They approached the sampling problem by minimizing the extremeness of the groups chosen to be interviewed, finally selecting members of the middle and working classes. They concluded that "some intra-class variation is obscured by using only those two broad social class categories but what is lost in precision is gained in increased cross-national comparability" (p. 468).

Brislin, Lonner, and Thorndike (1973) advocate the plausible rival hypotheses approach. The differences or similarities that are found may be attributed to different sampling methods or to different qualities of the samples (age, socioeconomic status) rather than to "real" cross-cultural differences or similarities. A rival hypothesis may explain the obtained differences/similarities as well as the hypothesis one is interested in. In the research design one has to eliminate all plausible rival hypotheses that may explain the results from sampling inadequacies. It may be clear that "identical" samples in cross-cultural research are actually impossible; that the costs of random samples are often too high to justify their additional benefits. Essentially, equivalence of samples, based on the control of variables in a design that eliminates plausible rival hypotheses, must be the objective of sampling in cross-cultural research.

Rival hypotheses cannot always be ruled out in a design with only one sample from each culture. If we study the differences and similarities of French and American wives, it may be illuminating to include control samples of French and American husbands. How do the wives differ from the husbands (not necessarily their husbands!) in the two cultures, and an interaction (in the statistical sense) may exist between sex and culture. A good example is the 2 x 2 design by Douglas (1976), where she compares working and non-working wives in France and in the USA, using multivariate ANCOVA. Cross-cultural differences in Douglas' study prove to explain more variance than the differences between working and non-working wives.

Thorelli, Becker, and Engledow (1975), on the other hand, conclude that information-seeking consumers (higher education and higher income) are more similar across cultures (the USA and Germany) than the control group of non-information-seekers. Katona, Strumpel, and Zahn (1971) find more similarity across nations for white-collar than for blue-collar respondents.

Formal and Functional Equivalence

Formal equivalence of a questionnaire or a questionnaire item means that an identical questionnaire and respondent instruction are employed for all respondents involved in the study. Formal equivalence is the ideal of the survey technician but is impossible in cross-cultural research in nearly all cases. Translation problems and procedural problems such as whether to use a mail questionnaire or a personal interview, may arise. Formal equivalence can be attained to some extent through back-translation (translating the questionnaire and

instructions into the other language and then back into the original language by independent translators, and then comparing the two versions), the use of bilingual respondents, expert judges, and writing translatable English. See Brislin, Lonner, and Thorndike (1973, pp. 32-81). Formal equivalence is treated as an instrument reliability problem: How reliably does the instrument measure the variables in different cultural settings? It will be clear that we can easily attain formal equivalence in measuring behavioral variables (e.g., possession of durables; number of hours of TV watching; frequency of shopping trips). In these cases, we are interested in measuring and comparing behavioral variables as such. But as soon as these behavioral variables become an indicator or operationalization of a hypothetical construct, it becomes another case. "Frequency of church attendance" may be selected as an indicator of the hypothetical construct "religiosity." In this case, church attendance may be a good indicator of religiosity in one culture but not in another.

Functional or conceptual equivalence of instruments for measuring a certain construct is a validity problem. The survey methodologist strives for functional equivalence of instruments, i.e., the instrument must have a functionally equivalent meaning for the respondents in both cultures. Although questionnaire items may be different for different cultures the intention is that they measure the same hypothetical construct. "Religiosity" can be operationalized by church attendance in one culture while meditation may be an indicator of religiosity in another culture. In such cases, functional equivalence of instruments can only be attained through a theoretical a priori framework and pilot studies how a hypothetical construct becomes manifested in actual behavior or attitudes in the culture under study.

Straus (1969) distinguishes formal and functional equivalence of stimulus material (questionnaire, test, task) and of mode of quantifying. Instead of the terms "formally and functionally equivalent" he uses the terms "phenomenally identical" and "conceptually equivalent." Straus (1969) obtains the four possibilities of Figure 1, using our terminology.

Figure 1

A Taxonomy of Measurement Equivalence

Mode of Quantifying	Stimulus Material	
	formal equivalence	functional equivalence
formal equivalence	culturally universal (etic)	culturally modified
functional equivalence	culturally ipsatized	culturally specific (emic)

The mode of quantifying involves the development of norms for coding and scoring. A psychological test can only be used for a new population provided new norms are developed based on standardizing the test among samples of that new population (culture). The four quadrants have the following interpretation:

1. Culturally universal measurement refers to research methods that use identical stimulus materials in each culture, except for translation, and that record and

quantify the responses in identical ways. This means the formal equivalence of instrument and quantification of responses. This is the "etic" approach to cross-cultural research. It is likely that there are only a limited number of instances. The meaning and intention of this observable behavior, however, may be different across cultures.

2. Culturally ipsatized measurement refers to instances in which the identical instrument is used but the recording and/or interpretation of the responses are judged relative to others in that culture (internal criteria) rather than relative to external standards of scoring or interpretation. An attitude scale measuring "ecological responsibility," for example, may be identical across cultures but the norms for high or low scores may differ across cultures.

3. Culturally modified measurement refers to measurements in which the indicators for the hypothetical construct are altered in order to make them culturally appropriate but the original scoring is maintained. Przeworski and Teune (1966/67) provide an example in their cross-cultural study in the U.S.A. and Poland. The hypothetical construct "political activity" is measured in the U.S. with the indicators "contribute money to parties or candidates" and "place sticker on car," but in Poland they used the equivalent indicators "fight for the execution of economic plans" and "attempt to influence economic decisions." Przeworski and Teune (1966/67) also had a set of five identical indicators for both cultures.

4. Culturally specific measurement in the fourth quadrant represents the minimum formal equivalence in order to achieve the maximal functional equivalence. This is the "emic" approach to cross-cultural research, although it does not state the absolute uniqueness of cultures (Benedict, 1934). To measure the extent to which a sample of youth participate in an adolescent subculture, items of dress reflecting adolescent fads of the particular subculture might be used as a part of the index. In one subculture such indicators may be tight pants and in another subculture bell-bottom pants.

Straus (1969) provides four techniques for establishing functional equivalence of measures:

1. Use of expert judges to evaluate the appropriateness of the items, questions, and instructions. This procedure may help provide for the content validity of the instruments.
2. Revalidation and restandardization of the instrument in the culture in which it will be employed (ipsatizing).
3. Semantic differential procedure to obtain "psychological translation" of indicators. Blood and Takeshita (1964), as cited by Straus (1969), found that the word *deito*, a translation of the English "date", was not widely enough known in Japan to use it in the questionnaire. They therefore substituted the work "otsus ia" with connotations similar to "date."
4. Construct validation. Construct validity is determined by establishing that certain hypothetical constructs account to some degree for performance on a psychological test, or that the test accounts to some degree for performance on variables for which the test is taken as explanatory (APA standards). Zaltman, Pinson, and Angelmar (1973) define construct validity as "the extent to which an operationalization measures the concept (hypothetical construct) which is purports to measure." For instance, Blood and Takeshita (1964) measured the relative power of husband and wife in the Japanese family. The item "Who decides about what

type of car to get?" had to be eliminated and had to be substituted by some major purchase. Formal equivalence is given up for the sake of functional equivalence. The construct validation of such an instrument would consist of determining if the scores are related to other variables which theory or prior knowledge indicated should be related (Straus, 1969):

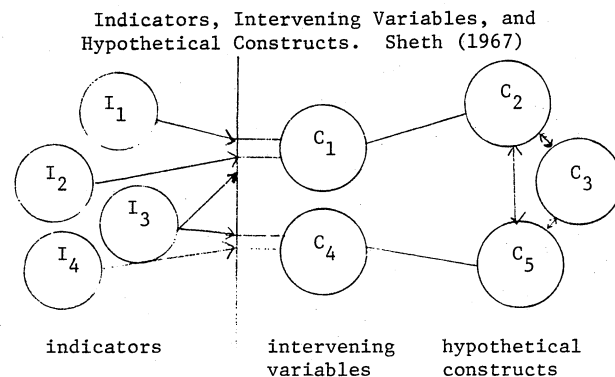

Another approach to functional equivalence of instruments is provided by Przeworski and Teune (1966/67) distinguishing between identical and equivalent indicators. An identical indicator is universal (etic) across cultures and an equivalent indicator is specific (emic) for a culture. We have seen the example of equivalent indicators in their study on political activity in the U.S.A. and Poland. By combining identical and equivalent indicators reliable and valid comparisons can be made. By this procedure a longer and more culturally relevant, and perhaps more valid, set of items is acquired. A set of items for a culture consists of universal and specific items. Inter-item correlation reveals that the specific items add to the universal items.

Green and White (1976) make a distinction between the functional equivalence of instruments, of phenomena ("shopping"), and of constructs ("Cognitive consistency"). However, an instrument is functionally equivalent across cultures if it measures the "same" construct.

Theoretical Structure

Construct validity is not only the extent to which an operationalization (set of indicators) measures the hypothetical construct which it purports to measure. It is also the relationship of the hypothetical construct with other hypothetical constructs and intervening variables in a theory. A theory is a set of propositions relating hypothetical constructs, formulated in such a way that testable hypotheses can be derived (de Groot, 1969). Maehr (1974) gives an example of the relationships of the hypothetical construct "achievement motivation" and other hypothetical constructs. Cross-cultural studies of "achievement motivation" suggest that the psychological dynamics underlying achievement behavior (e.g. entrepreneurial action) might not be the same across cultures. In other words, variables which

Figure 2

motivate individuals to be economically productive in one culture may differ from those motivating productive

work in another culture. These variables may be the need for affiliation, concern for the reaction of others, and strong obligations and identifications to one's group. In Japan the basic cultural value is

loyalty to one's group rather than the advancement of one's personal status. The hypothetical construct "achievement motivation" is conceptually different across cultures and even irrelevant in some cultures. We have to specify when and under what conditions achievement motivation will occur. Maehr (1974) proposes three theoretical structures in the study and prediction of achievement motivation.

1. In the first structure, social structure (SS) or, more specifically, the social learning experience provided by the milieu in which the person develops, influences the subjective culture (SC) or the assumed predispositions (attitudes, values, norms) and the personality traits (P) to respond in a given manner. SC determines achievement motivation (M) and achievement behavior (B). In a diagrammatical expression this may be indicated as:

This is the traditional approach by McClelland (1961) where the personal history of the individual determines his achievement motivation. Only through changes in SC/P achievement motivation may be changed.

2. A second structure may be diagrammed as follows:

where a situation or context (S) has demonstrable effects on motivation (M). Subjective culture (SC) and personality (P) are placed in parentheses indicating the relative unimportance of the attitudes, norms, values and personality variables. Here situational variables play a major role in determining achievement motivation. Maehr (1974) identified four situational dimensions that appear to be critical in determining achievement motivation and behavior. An individual achieves as a member of a social group and is influenced by the norms of his group. Another dimension is the locus of control. How much (internal) control has the individual over the outcomes (success or failure) of his behavior? Feedback about performance has to be communicated to the achiever through interpersonal contacts. A task dimension involves task difficulty and intrinsic task interest. The situational model implies that the above situational variables greatly affect achievement motivation and behavior. It is better changing the situation rather than the personality of the individual to enhance achievement motivation.

3. The third theoretical structure represents the most sophisticated analysis of achievement motivation:

This structure identifies both subjective culture/personality (SC/P) and situation (S) as simultaneously critical variables. This SC/P x S model goes back to Lewin; one of the prominent and highly developed of such models is the motivation model proposed by Atkinson (1964, Chapter 10). See also Van Raaij and Wandwossen (1978). The question becomes to find what situations match what motives in order to elicit a specific behavior such as achievement motivation. This theoretical structure requires considerable theoretical and methodological sophistication.

4. Not proposed by Maehr (1974) but as a counterconceptualization, Inkeles (1971) states that personality structure does not necessarily precede modernization and economic development. The influences may go in the opposite direction. That is, institutional changes may change the outlook of individuals exposed to them. According to Inkeles' theory modern social and cultural structures and systems may cause individuals' attitudes,

values, behaviors, and need dispositions to change in such a way as to make effective adaptation to these institutions by becoming increasingly "modern." The greater the degree of exposure and the longer the exposure time to the various modern institutions, the more the individual will shift toward the modern

direction on the psychological continuum. Inkeles' theory offers an alternative way for emphasizing the role of the individual in social institutions. The diagram becomes as follows:

The physical environment (PE) and/or the social structure (SS) expose an individual to situations (S) of modernization where achievement motivation (M) and behavior (B) are the best adaptive responses. M and B change the subjective culture (SC) and personality (P) of the individual afterwards making it consonant with behavior.

These four theoretical structures have consequences for the measurement and change of achievement motivation. In the first structure, projective personality tests have been used, and we may change M and B through changes in SC/P (personality change and attitude change). In the second theoretical structure, M and B are determined by situational dimensions. Group norms, locus of control, feedback, and task dimensions are indicators of M and B, and we may influence M and B by changing the situational dimensions. The interaction of SC/P and S determines M and B in the third structure. In the fourth structure, achievement motivation is the result of environmental factors (PE and SS), and is in fact adaptive behavior to the changing (modernized) environment. Personality and attitude (SC/P) measures are not a good predictor of M and B in a changing environment but the situation (S) itself may become an indicator of achievement motivation (M) and behavior (B). Maehr (1974) advocates a methodology of identifying settings in which achievement motivation occurs or does not occur in various cultures and then proceeds to characterize the nature of these settings. Much of the research that attempts to understand motivational patterns of (sub)cultural groups involves placing individuals in a "middle-class biased" or "western-biased" performance setting and then observing behavior. But instead, we have to devise a theoretical structure of achievement motivation for the culture under investigation and from this theoretical structure functionally equivalents may be derived for measuring the hypothetical construct of achievement motivation.

Cross-cultural Consumer Research

Triandis, Malpass, and Davidson (1973) distinguish classes of distal variables (PE, SS, O) which act as independent variables in studies in which classes of proximal variables (A, SC, P, B) are the dependent variables. These classes of variables are for consumer research:

- PE: physical environment: type of economy, distribution structure, climate, population density, GNP, transportation system, consumption level, health and education system. Sethi (1971) uses PE variables for clustering nations into eight groups.
- SS: social structure: social class, family organization, social and sex roles, social norms, language, socialization and education patterns. Sheth and Sethi (1973) call the PE and SS variables exogenous and treat them as givens or constraints of their model. These variables are not explained in terms of their structure or any changes over time.
- O: other persons: influence attempts, opinion leadership, social interaction, word of mouth, imitation, conformism/deviancy, cooperation/competition.

- A: persons' abilities: intelligence, cognitive style, cognitive development, memory, information-processing capabilities.
- SC: person's subjective culture: attitudes, values, personal norms, aesthetic judgments, opinions, life style, beliefs and stereotypes, meaning, satisfaction.
- PD: personality dispositions: self-concept, anxiety, aggression, alienation, achievement and affiliation motives, adjustment, cosmopolitanism, information-sensitivity.
- B: behavior: shopping, communication, consumption, and disposition behavior.

In cross-cultural consumer research, as indicated earlier, we cannot simply compare concepts from a class across cultures. We have to study the functional equivalence of these concepts (hypothetical constructs) across cultures through both their operationalization (indicators) and their relationship to other concepts in a theoretical structure. Maehr (1974) and Inkeles (1971) already provided four possible theoretical structures for the study of achievement motivation and economic behavior.

I will try to give some examples in consumer research of possible theoretical structures.

- The cross-cultural study of consumer satisfaction has to take into account the PE variables: type of economy, distribution structure, consumption level, transportation system, and income distribution, and the SS variables: social class, family organization, social and sex roles. If the cross-cultural differences of the PE and SS variables are great it becomes meaningless to compare consumer satisfaction scores. Consumer satisfaction is a function of the PE, SS variables and probably also of O and A variables.

PE → SS → A/O → SC

Consumer satisfaction as such may become functionally equivalent across cultures that differ on PE/SS variables but we have to employ a different (emic) set of indicators for each culture. Comparing the consumer satisfaction of a mass-consumption society with a developing country becomes a "tour de force" in finding sets of equivalent indicators. In a case of extreme differences, we better make cross-cultural comparisons of PE/SS variables only. If only slight differences on PE/SS variables of two cultures exist we may find sets of equivalent indicators in both cultures for the hypothetical construct "consumer satisfaction." The procedures may be largely emic in that they reflect the PE/SS structure in a culture but may become "psuedo-etic" in that a comparison is made between similar evaluative consumer reactions to the consumption system.

- Douglas (1976), Green and Langeard (1975) compare among other variables grocery shopping behavior in France and the U.S.A. Shopping behavior (B) can be thought of as a function of the PE variables: transportation system, private ownership of cars, distribution (retailing) structure, consumption level, and the SS variables: family organization, social and sex roles, working or nonworking housewives. Intervening variables from the O, SC, and PD classes may influence shopping behavior: social interaction, word of mouth, life style, attitudes, self-concept, and opinion leadership. Two theoretical structures can be hypothesized:

I: PE → SS → (O/SC/PD) → B,

II: PE → SS → B → (O/SC/PD).

PE/SS variables influence the O/SC/PD group, and O/SC/PD determines behavior, or PE/SS determines behavior and the O/SC/PD variables change into a direction to become consistent with behavior. Green and Langeard (1975) conclude that "most of the differences that we found (between samples of French and U.S. women) could be attributed to social and environmental that characterize the two nations. These finding emphasize the need for further theoretical and empirical cross-national work to achieve a better understanding of the relationships between buyer behavior and environmental forces." Douglas (1976) concludes in a similar fashion: "Retail environmental factors seem to play a key role in shaping and conditioning behavior patterns between countries may in many respects merely reflect current market conditions such as the availability of different products and services or the number of supermarkets or small, traditional retailers." She recommends further investigation of the role of retail environmental factors in influencing customer response patterns. Shopping behavior does not reflect "real" cross-cultural differences but reflects only the different distribution structures in France and in the U.S.A. Green and White (1976) add that shopping is not functionally equivalent in France and in the U.S.A. "In France shopping is reputed to be an integral part of the housewife's social life, whereas in the United States shopping tends to be considered a chore." Even a third theoretical structure is not ruled out, namely that the distribution structure reflects the social interaction patterns, the subjective culture, and personality dispositions of the customers:

III: (O/SC/PD) → (SS) → PE → B.

Does the "adaptive consumer" adapt his behavior to changes in the distribution structure (model II), or do we have to change the O/SC/PD cluster too before new shopping patterns develop? (model I). Or, do "adaptive retailers" change the distribution structure in line with changes in the O/SC/PD cluster? Most retailers want us to believe that model III is true because it reflects the marketing concept.

- Hempel (1974) found "a surprisingly high degree of cross-cultural similarity in household decision-making processes. In most instances, the differences between the roles perceived by husbands and wives within the same cultural setting were greater than the differences between cultures for either sex." Hempel compared samples in Hartford, Connecticut, and Preston-Lancaster, England, with nearly identical data collection methods, except for some minor adaptations to English word usage. Husband-wife interaction is a function of the SS variables: social class, family organization, social and sex roles, socialization and education patterns. A simple theoretical structure can be postulated:

(PE) → SS → O.

The United States and the United Kingdom are similar cultures in many respects. A valid cross-cultural comparison can be made and functionally equivalent instruments (no translation problem) are easily developed.

- Beginning with the pioneering study of Horton (1943), social scientists have attempted to find out why people drink alcohol. A correlation has been found between a PE variable, type of economy (hunting, fishing vs. agricultural), and a B variable, alcohol consumption. In general, hunting tribes drink more heavily than tribes that depend on agriculture:

PE → SS → (PD) → B.

But a number of variables may intervene the PE → B relationship. The degree of societal organization has received the strongest support as an intervening variable. In more highly organized cultures there are more social controls that inhibit drinking. The reflection of social organization on the individual disposition (PD) has been called alienation. The greater the alienation the more alcohol is consumed.

A recommendation for research designs is that if two hypothetical constructs are not comparable across cultures, i.e. are not functionally equivalent, the researcher needs to go to the next-higher order construct in the theoretical structure. If consumer satisfaction is an incomparable construct, compare the distribution system and/or the social system across cultures.

Construct Validity

Construct validity is the extent to which an operationalization (indicator) measures the construct which it purports to measure (Zaltman, Pinson, and Angelmar, 1973). Or alternatively, in order to show that an indicator applies to a construct, it is necessary to derive hypotheses from the theory related to the construct, that can be tested in reality (indicators) (Cronbach, 1964, p. 105). Thus, we have to include in the operationalization of a construct the theoretical structure in which the construct is embedded.

The validity of constructs across cultures can be attained through four essential procedures:

1. The operationalizations (measuring instruments, indicators) should measure the construct which they purport to measure. If identical indicators (etic measures) are not available, a set of identical and equivalent indicators (Przeworski and Teune, 1966/67), or equivalent indicators (emic measures) should measure the hypothetical construct.

2. The validity of a construct can be established in some cases through systematic variation with a criterion. Criterion-related validity is concerned with prediction (predictive validity) or with simultaneous performance of some other variable (concurrent validity). For instance, we measure the concept of "innovation-proneness" in several cultures using functionally equivalent indicators. The degree of adoption of an innovation may be the criterion measure. This means that we can validate our measuring instrument for the hypothetical construct only afterwards.

3. A hypothetical construct has relations to other constructs in a theoretical structure. Examples are provided in an earlier paragraph. Causal explanations for the obtained cross-cultural differences and similarities are proposed in a theoretical structure.

4. A last essential procedure of construct validity is the similarity of components of the construct across cultures. Frijda and Jahoda (1966) call this "dimensional identity." "Intelligence", for instance, consists of several components (verbal, numerical, etc.) obtained after factor-analyzing the concept. "Intelligence" is functionally equivalent across cultures if the same components are found in different cultures. "Perceived risk" may differ in its components (social, physical, financial risk, etc.) across cultures but that means that the construct validity of the hypothetical construct "perceived risk" is low. Especially in cross-cultural assessment (test) psychology, the componential similarity of a construct is stressed. However, we may study the components of "intelligence" in another culture with an emic approach, i.e. investi-

gating the unique componential structure of a construct in that culture.

Ethnocentrism

One of the biases in cross-cultural research has been called "ethnocentrism", i.e. bias arising from blindness for the unique and different characteristics of another culture. Consumer research is largely "made in the U.S.A." with all the risks that western-American- or middle-class biases pervade this type of research in the research questions we address, the concepts and theories we use, and the interpretations we give. We should encourage researchers in other cultures to study their own reality rather than to replicate American studies. Faucheux (1976) recommends a separate development of social psychology on the European continent. We may recommend the same for consumer research in order to become aware of the ethnocentrism and the blindness to other cultural values. A rationalistic tradition in Europe encourages theoretical speculation, sometimes at the cost of a proper care for empirical validation. This tradition produced scientists such as Freud, Lorentz, Piaget, Levi-Strauss, and Chomski, and does not have the illusion that a theory will spring from a gathering of "facts" and measurements collected with a preconceived idea. Some suggestions for avoiding ethnocentric biases are:

1. Double investigation: The researchers in a cross-cultural study perform their research or experiment in both cultures and compare their results.
2. Decentering of indicators: Questionnaire items are developed in both cultures are then an identical set and two equivalent sets are formed. See Brislin, Lonner, and Thorndike (1973, pp. 37-39).
3. Select and/or train the staff members in the other culture to introduce their own questions, concepts, and interpretations.

Galton's Problem and Evolutionary Theory

How do we get subclasses of cultures in which a valid cross-cultural comparison is possible? And if we want to generalize a finding, how do we get two or more cultures that are not simply two or more illustrations of the same case? This is Galton's problem. Evolutionary theory stated that only cultures in the same stage of differentiation can be meaningfully compared. In any case, we have to classify cultures or nations into diverse subclasses or types. Sethi's (1971) cluster-analytical approach may serve this purpose on a global scale. More refined classification is needed within the western cultures. To a certain extent, we may assume that concepts are functionally equivalent within such a subclass. Galton's problem, however, is to find mutually "independent" cultures (in different subclasses) to make universal generalization of a phenomenon possible, if one's hypothesis proves to be true for these independent cultures. We cite Elder (1976, p. 217):

"Galton's problem bears an interesting relationship to the problem raised by critics of universal cross-cultural generalizations, to the effect that one can meaningfully compare only cultures rather similar to each other in terms of size, structural complexity, etc. In both cases, the methodological goal is to identify cultural subsets to which specific cultures can be assigned. In the case of Galton's problem, the purpose of assigning cultures to subsets is to try to guarantee subsequently that cultures being compared

are drawn from different subsets, thereby permitting universal cross-cultural generalizations. In the case of the critics of such generalizations, the purpose of assigning cultures to subsets is to try to guarantee subsequently that cultures being compared are drawn from the same subset, thereby permitting limited but meaningful cross-cultural generalization."

Conclusion

From a theoretical viewpoint mere comparison of consumer responses to questionnaire items in different cultures does not guarantee meaningful and useful information for theoretical purposes and for managerial action. Functional equivalence of constructs and instruments has to be established in order to guarantee "real" cross-cultural comparison. Plausible rival hypotheses that also explain the obtained differences/similarities have to be ruled out by using equivalent samples, and functionally equivalent measures and quantification modes.

Cross-cultural research as comparative research creates some additional problems because of the non-equivalence of instruments that have to be employed. Only through (1) equivalence of indicators, (2) criterion-related validity of constructs, (3) a theoretical structure, and (4) componential similarity of constructs can the validity of hypothetical constructs be determined.

RESEARCH FOR CONSUMER POLICY FORMULATION:
AN EXPLORATION OF DIMENSIONS OF HOUSEHOLD ECONOMIC MANAGEMENT

Johan Arndt, University of Missouri-St. Louis
Oddvar Holmer, Norwegian School of Economics and Business Administration

Abstract

This study addresses a fundamental aspect of consumer behavior: administrative routines in the management of the economic affairs of the household. Several dimensions of economic management were uncovered, but the linkage of these dimensions to antecedent variables was weak.

Introduction

To date, most research on consumer behavior has been marketing management oriented and concerned with pre-purchase decision processes for brands. The relevant input to consumer policy formulation, however, is research with a more explicit "consumer economics" orientation. The study to be reported here is an example of such research, as it focuses on the fundamental problems in the administration of the economic affairs of the household. The study represents the pilot phase of a more comprehensive project.

The Household As A Small Business Firm

The conceptual framework underlying this study implies viewing the economic affairs of the household as a resource conversion process, in which the inputs are time, economic resources (income and capital), human capital, and service resources such as labor-saving appliances. The open-system organization of the household copes with the uncertainties and complexities of its market environment by developing information systems and by protecting its "technical core" with buffers of reserve money and reserve goods. To economize on time and effort, the household establishes, more or less formally and explicitly, administrative routines. These routines include rules for information acquisition, storage, and retrieval, and control procedures such as account keeping, budgeting, and advance planning, as well as mechanisms for conflict resolution. An important aspect of administrative routines is the organization of the household, particularly the delineation of authority and responsibility among its members for planning and implementation of purchases, contacts with finance institutions, etc.

The efficiency of the resource conversion process depends on the ability and willingness of the members of the household to plan and organize. And, in turn, this ability and willingness is believed to be related to background characteristics or antecedent variables of the household.

Method

The sample was not selected by any direct probability mechanism, but chosen in the following way: Four districts within the metropolitan area of Bergen, Norway were selected on a judgmental basis in order to ensure sufficient heterogeneity of the sample. In each district, a starting point was determined as a basis for selecting some 70 dwelling units by means of systematic sampling. Each household in the units selected received a structured questionnaire, which was collected on the following day. Of the 273 households contacted, 222 returned completed or partially completed questionnaires.

In the questionnaire, measurements were obtained for a set of 11 antecedent variables believed to be determinants of administrative routines. These variables included employment status of wife, age, household income, etc.

There were a total of 93 questionnaire items relating to administrative routines, categorized into three groups: convenience goods shopping, appliance purchasing, and items relating to financial management.

Findings

In this case it was desirable to search for the natural groupings occurring in the data rather than to rely on an a priori classification scheme. Therefore, factor analysis was used to track patterns of relationships and to reduce the data into basic dimensions of administrative procedures. The program used the VARIMAX in the SPSS package, extracted 32 factors, accounting for 73 per cent of the variance in the 93 items. However, as the contribution to explained variance dropped discontinuously after factor 7, only the first seven factors are included in the analysis.

These seven factors, which explained 36 per cent of the variance, were next related to the set of 11 antecedent variables using the factor scores for each factor as the dependent variables. This analysis was not successful, as the average proportion of the variance explained (in terms of the adjusted R^2 's) for the seven regressions was only .06. In the discussion of the factors below, antecedent variables not showing Beta coefficients significant at the 1 per cent level will not be discussed.

Factor 1 was clearly concerned with use of word of mouth information in appliance buying. High scores on this factor were positively related to the number of persons in the household and to the level of education, and both are possible indicators of a need for planning and the ability to plan.

Factor 2 covered cases in which neither husband nor wife was involved in administrative procedures.

The items loading highly on factor 3 were concerned with the use of shopping lists as a planning instrument. The factor was positively related to the number of persons in the household and to education.

The items showing the highest loadings on factor 4 related to spousal role differentiation in the financial management of the household.

The key dimension underlying factor 5 was the financing of major purchases "liberally", i.e. through instalment or bank credit rather than through saving or reducing other expenditures. Households living in the cheaper dwelling unit types such as small apartments were more inclined to use instalment credit, confirming that it is the economically less privileged consumer groups who tend to rely on credit. The negative correlation between scores on factor 5 and income adds further support for this interpretation.

Factor 6 seemed to reflect a "Make or buy" dimension, while the items loading highly on factor 7 related to the regular use of price deals or bargains in convenience goods shopping. The bargain hunters had smaller fixed expenditures per month (and were hence perhaps more likely to have more money at their disposal for bargains) and larger families.

Concluding Comments

The findings of an exploratory study such as the present one would be a shaky foundation on which to build sweeping generalizations. Instead, the results should be treated as hypotheses for future more rigorous study.

SESSION SUMMARY: CROSS-CULTURAL LIFE-STYLE RESEARCH

M. Venkatesan, University of Oregon

The Session Chairman, W. Fred Van Raaij, Tilburg University, pointed out that "cross-cultural" consumer behavior research is distinguished from "cross-national" research in the literature, but that he preferred the term "cross-cultural research," as the research not only can involve consumer behavior in different cultures but involves comparison of consumer behavior within subcultures. He pointed out that functional equivalence of constructs and instruments has to be established for real cross-cultural comparisons. The chairman pointed out other problems particularly relevant to cross-cultural consumer behavior research, viz., culturally ipsatized measurement problems, problems of operationalizations, "ethnocentrism" and the like.

suggesting possible uses of our findings for pragmatic business interests — "suffice at the present time that all involvement is indicated by our intellectual curiosity."

Johan Arndt, Norwegian School of Business Administration and Economics, focused on the ethnocentric bias manifested by the predominant marketing orientation to the study of cross-cultural consumer behavior because of almost all empirical studies have been conducted by U.S. academician or U.S. trained academicians. He emphasized, however, that properly conducted cross-cultural consumer behavior studies make it possible to validate findings obtained in one culture by replications in other cultures. The most important problem in Arndt's judgment was that of the unit of analysis in cross-cultural consumer behavior studies. While nuclear family may be an important unit of analysis in U.S. and some other cultures, the extended family unit may be the appropriate unit of analysis in many cultures.

Professor Eric Langeard, University of Aix-en-Provence pointed out that fairly similar types of situations can be studied with ease, such as opinion leadership for example, but he cautioned as the determinants of those situations might well vary across cultures even if the phenomenon is found to exist in consumer behavior contexts.

Professor G. van Veldhoven of Tilburg University focused on the problem of cross-cultural life style research. He pointed out that there are "conceptualization problems, and questions regarding "units of measurement." He illustrated such problems from his current study of life styles in Tilburg vs. Luill/Lille.

The discussant, Professor Venkatesan of the University of Oregon summed up the difficulties in conducting cross-cultural research. The main difficulties are: (1) assumptions of means-ends relationships; (2) problems of sample representativeness; (3) problems of validity and reliability of culturally ipsatized measurement, and (4) delineating micro and macro aspects of consumptive behavior. He cautioned against the use of instruments generated in the U.S. for purposes far removed from cross-cultural consumer behavior (e.g., AIDs generated in U.S. consumer studies). He also assailed the tendencies of researchers to "replicate" studies that were conducted in the U.S. without regard to the settings in other cultures, or without changing the instruments or generating new ones to suit the particular needs of these studies. However, he emphasized that cross-cultural consumer behavior studies can be conducted to test whether "procedures" utilized in U.S. consumer behavior studies work in other settings (cultures) and whether similar "manipulation" also work in different cultural settings. He concluded by pointing out that we are many many years away from

COMMENTS ON CROSS-CULTURAL CONSUMER RESEARCH

Johan Arndt, University of Missouri - St. Louis

Cross-cultural studies in consumer behavior are still in the early infancy stage. There is a paucity of published empirical studies; and worse, the few known studies suffer from methodological limitations. This not too encouraging state of the art is apparent in van Raaij's excellent comprehensive review in his "Cross-Cultural Research Methodology as a Case of Construct Validity."

Almost all empirical and theoretical consumer studies have been conducted in the U.S. by American or at least by U.S. trained academicians. This ethnocentric bias is manifested by the predominant marketing manager orientation and the focus on middle class consumers' problems in the mass-consumption society.

This occasion gives me an opportunity to reflect on the potentials and problems of cross-cultural consumer studies. The potential contributions should be self-evident:

1. Only cross-cultural studies may isolate the role of culture, a variable of interest in its own right as a determinant of consumer behavior.
2. Cross-cultural studies permit a more rigorous study of the role of various determinants of behavior by expanding the variation in them.
3. Cross-cultural studies permit extracting universals or trans-cultural concepts from idiosyncratic phenomena which are only the product of some unique historical or environmental factors.

The problems relating to cross-cultural research on consumer behavior may be divided into: (1) theoretical and conceptual problems concerning what to study and why; and (2) methodological problems relating to how to study the problems. As van Raaij has covered the methodological problems, particularly the problems of functional equivalence of samples and measurement instruments, in so much depth, the comments below will concentrate on the more fundamental problems of approach.

In the late 1940's and early 1950's, American business executives and academicians looked at the rest of the world mostly as a mission territory ready to accept the principles of modern business management and human relations. There is a danger that such "conceptual chauvinism" may repeat itself. Much current American consumer research is influenced by the perspective of the Marketing Concept, with its one-way control process conceptualization, and emphasis on prepurchase decision processes for brands and reliance on concepts such as "brand loyalty", "information overload", and "consumer satisfaction". To a Eastern European car buyer having just one brand to choose and little information, and to a poor Southeast Asian farmer such concepts may be meaningless. While in the U.S., much consumer behavior is an individual or nuclear family affair, the extended family may be the appropriate unit in other cultures.

Many cross-cultural studies give the impression of being opportunistic, a result of short-term sabbaticals abroad or sudden access to some secondary international data. Second, the research is reductionistic in the sense that the consumer behavior studied is not explicitly related to aspects of the consumers' resource situation and their market environment. Hence it difficult, if not impossible, to interpret the differences found.

In the future, perhaps the only feasible approach in cross-cultural consumer research, is the launching of larger scale projects operated by cross-national research teams. To explore the interrelations between political factors, the socio-economic environment, marketing institutions, and consumer behavior, one possible solution is more emphasis on detailed comparative case studies of selected marketing systems.

INFERENTIAL BELIEF FORMATION IN THE CUE UTILIZATION PROCESS

Jerry C. Olson, Pennsylvania State University¹

Abstract

The extant research on cue utilization is briefly reviewed. Generally, this research has ignored inferential processes by which beliefs are formed about concepts not present in the immediate environment. A model of the cue utilization process is presented which explicitly includes the inferential belief formation process. Memory schemata are proposed as the basic memory structure which enables inferences or attributions to be made. A discussion of how research on the inference process could be conducted follows, and the paper concludes by identifying several research issues that could be examined from the conceptual perspective provided by the model.

Introduction

How do people acquire and use information about their environment to make various types of judgement choices? What factors influence these processes? Issues regarding the cue utilization process have fascinated psychologists for many years. More recently, consumer researchers have become quite interested in how consumers use informational cues to accomplish various tasks. This paper briefly reviews the types of cue utilization studies and summarizes the typical approach taken. It is then suggested that most of the cue utilization research has ignored the potentially important process of inferential belief formation. A flow-chart model is presented which illustrates how inferential processes might be included in the cue utilization process. The paper concludes by briefly discussing several research topics which could be investigated from the perspective provided by the proffered model.

Overview of Cue Utilization Research

Define somewhat loosely, the cue utilization process may be considered to encompass the cognitive processes involved in obtaining information from the external environment and in using the information (in a cognitive, information processing sense) to produce a particular behavior, e.g., an evaluation or a choice. Defined at this broad general level, the cue utilization process is involved in virtually all information processing phenomena.

Given this broad perspective, then, a wide variety of research areas can be seen as focussing on aspects of the cue utilization process. Included are research areas such as impression formation (Asch, 1946; Wyer, 1974; Zanna and Hamilton, 1977), decision theory and judgment formation (Slovic, Fischhoff, and Lichtenstein, 1977; Kahneman and Tversky, 1973), integration theory (Anderson, 1971), attribution theory (Frieze and Weiner, 1971; Fishbein and Ajzen, 1975), syllogistic relationships among beliefs (Henninger and Wyer, 1975; McGuire, 1960), or social inference (Gollob, Rossman and Abelson, 1973; Wyer, 1975). Although there appears to be relatively little cross-communication between these fields, each research area deals, in the broad sense suggested above, with how people use informational cues. That is, the investigator in each research area is interested in how

people select and comprehend environmental information and possibly use the information in forming the response requested (usually an evaluative judgment or overt choice behavior).

In the consumer research literature, cue utilization research is not quite so compartmentalized, although studies in virtually all of the above-mentioned research traditions have been published. Essentially, just three major research areas have evolved. The largest part of consumer-oriented research is focused on informational effects on consumers' product judgments, usually of quality (see Olson, 1972), and particularly on the effects of price cues on such judgments (Monroe, 1973; Olson, 1977). Another rapidly developing research area involves study of consumer information acquisition behavior by Jacoby and his colleagues (cf. Jacoby, Chestnut, Weigl, and Fisher, 1976). A third research area which involves cue utilization processes seeks to identify the combinatorial "rules" used by consumers to integrate or combine various items of information in order to accomplish some task (cf. Bettman, 1970; Wright, 1975; Scott and Wright, 1976; Sheth and Raju, 1974).

Despite the specific focus of most of this research, it is clear that the cue utilization process is involved in virtually all behavioral phenomena. That is, nearly any behavior will require processing of informational cues selected from the external environment. Thus, the process of cue utilization is of broad importance. However, for purposes of this paper, our attention is restricted to those controlled situations in which the subject is given a particular task to accomplish that requires cue processing, as in an experimental study of cue utilization behavior.

Summary of Cue Utilization Research

Much of the cue utilization research in marketing must be characterized as simple. Many studies involved presenting consumer subjects with task environments containing only one relevant cue (e.g., Leavitt, 1954; Peterson, 1970). More recent quality perception studies have tended to provide more cue stimuli and, thus, have created somewhat more complex and ecologically valid task environments (see Olson, 1977). Consumers have been provided with two cues (Enis and Stafford, 1969; Valenzi and Andrews, 1971), three cues (Szybillo and Jacoby, 1974; Wheatly and Chiu, 1977) and four cues (Jacoby, Olson, and Haddock, 1971) in an environment with the task to evaluate the quality of one or several alternative brands. The research on cue weighting in the integration process has used task environments containing even greater numbers of cues, as many as 10 or 11 (see review by Scott and Wright, 1976). In most of these cue utilization studies, the consumer's task has been to give evaluative judgments of the product (e.g., menu appeal, Green, Wind, and Jain, 1972). Thus the typical dependent variable has traditionally been a rather simple evaluative scale such as good-bad, like-dislike, or high quality-low quality. Essentially then, many of these studies may also be considered as examining the attitude formation process.

¹Associate Professor of Marketing.

A Simple Model of the Cue Utilization Process

In sum, the cue utilization process can be considered to

involve two basic processes--(a) the acquisition of cues and (b) the integration of the information derived from the cues to form the desired response (Olson and Jacoby, 1972). Actually, however, this view is highly simplified and, in fact, tends to hide several complex information handling sub-processes that may occur upon exposure to stimulus cues in a task context. Current interest in the cognitive states and processes involved in information processing (cf. Jacoby and Olson, 1977) suggests that several hierarchically-arranged stages are involved. Figure 1 presents a simple model of some of the stages involved in cue utilization. This model should be considered only as a convenient illustrative scheme to communicate some of the complexities involved. Most of the extant research on cue utilization can be described within the confines of this model.

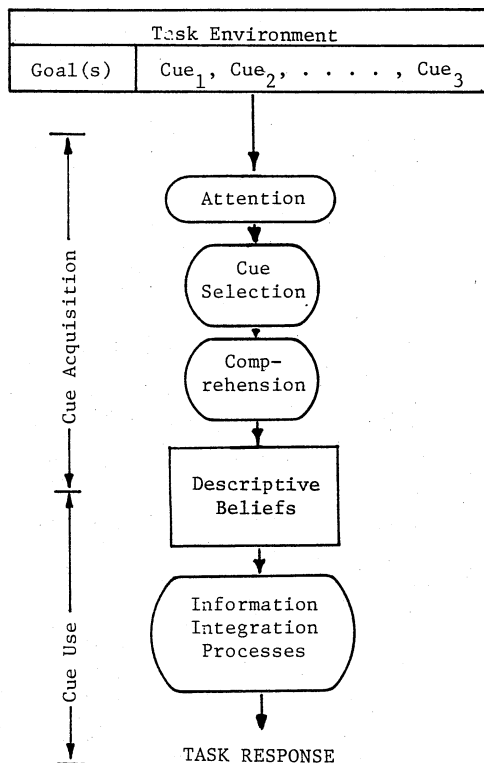

Figure 1. A SIMPLIFIED MODEL OF THE CUE UTILIZATION PROCESS

Briefly, presentation of a task goal (Which brand do you think is of highest quality?) and a task environment (four brands of shoes with price, brand name, and other informational cues), focuses the attention of the consumer/subject and initiates the goal-oriented cue utilization process. The initial sensory processing of the environment is probably extremely rapid, especially for familiar task environments, and may not be available to conscious awareness. Therefore, this stage typically goes unrecognized and unreported (Broadbent, 1977). One can think of this preconscious processing as orienting the organism to the general class of stimuli. This will be elaborated later in the paper.

Following, relatively more conscious selection of specific informational cues (dimensions, attributes, etc.) occurs.

These specific cues are subjected to further processing, the outcome of which is the comprehension of the selected cues, i.e., the assignment of categories of meaning to each cue. This meaning--now encoded information--may be stored as descriptive beliefs about the object. Descriptive beliefs encode the perceived association between the task concept and specific attributes or dimensions present in the task environment. These beliefs may then be integrated together or combined to accomplish the task, such as rating the quality of each brand.

Several points about the cue utilization process are made obvious by Figure 1. First, the cue utilization process is probably highly selective of certain cues. Interestingly very few studies have examined factors which may influence the cue selection process (cf. Cox, 1962; Olson, 1972). Second, the outcome of the integration sub-process is highly dependent upon the precise encoded informational form of the selected cues, i.e., the specific beliefs about the stimulus concept (Olson, in press). That is, environmental cues may be transformed during encoding and assigned a meaning that may or may not be similar to the physical form of the cue. For instance, a price of 29¢ may be encoded as "cheap," rather than "29¢," and integrated with other product information in the "cheap" form (Jacoby and Olson, 1977). Third, certain complex informational cues may not be encodable in a meaningful way by a perceiver (e.g., nutritional cues, Jacoby, Chestnut and Silberman, 1977), and thus may have little effect on the task response. For the most part, these three points have not been clearly recognized nor explicitly considered in previous cue utilization research.

Inferential Belief Formation

A fourth implication, implicit in Figure 1, involves the formation of inferential beliefs, a process that has generally been ignored in cue utilization research. That is, it is possible that in processing the given cues from a task environment, one might develop beliefs about other aspects of the task stimuli not represented by environmental cues. This is the process of inferential belief formation (see Fishbein and Ajzen, 1975). The importance of this process is that both the descriptive beliefs (directly related to environmental cues) and the inferential beliefs (inferred from the environmental cues) will, according to the basic expectancy-value theory, both influence global evaluation of attitude toward the concept of interest (cf. Fishbein and Ajzen, 1975; Lutz, 1975).

Although as yet not explicitly studied in the consumer behavior literature, there have been several empirical demonstrations of inferential belief information. For instance, Mazis and Adkinson (1976) found that exposure to a corrective ad about a mouthwash's inability to block colds and sore throats also changed beliefs regarding the brand's ability to "kill germs." Informational cues regarding killing germs were not present in the task environment and thus the latter beliefs must have been formed via some inferential process. Lutz (1975) found that a persuasive message regarding a single attribute of detergent affected the strengths of other beliefs about the product. As a final example, Mitchell and Olson (1977) found that an ad containing only a symbolic visual image and the brand name created stronger beliefs about the symbolically-communicated product attribute than an explicit verbal claim about the same attribute. In this case, the beliefs were inferred from a pictorial cue. Fishbein and Ajzen (1976) describe many other studies from the social psychology literature that also demonstrate the formation of inferential beliefs.

In sum, it is clear that people may form beliefs about the task object/concept that are not represented by cues in the task environment. This phenomenon is termed inferential belief formation. The next task, then, is to develop

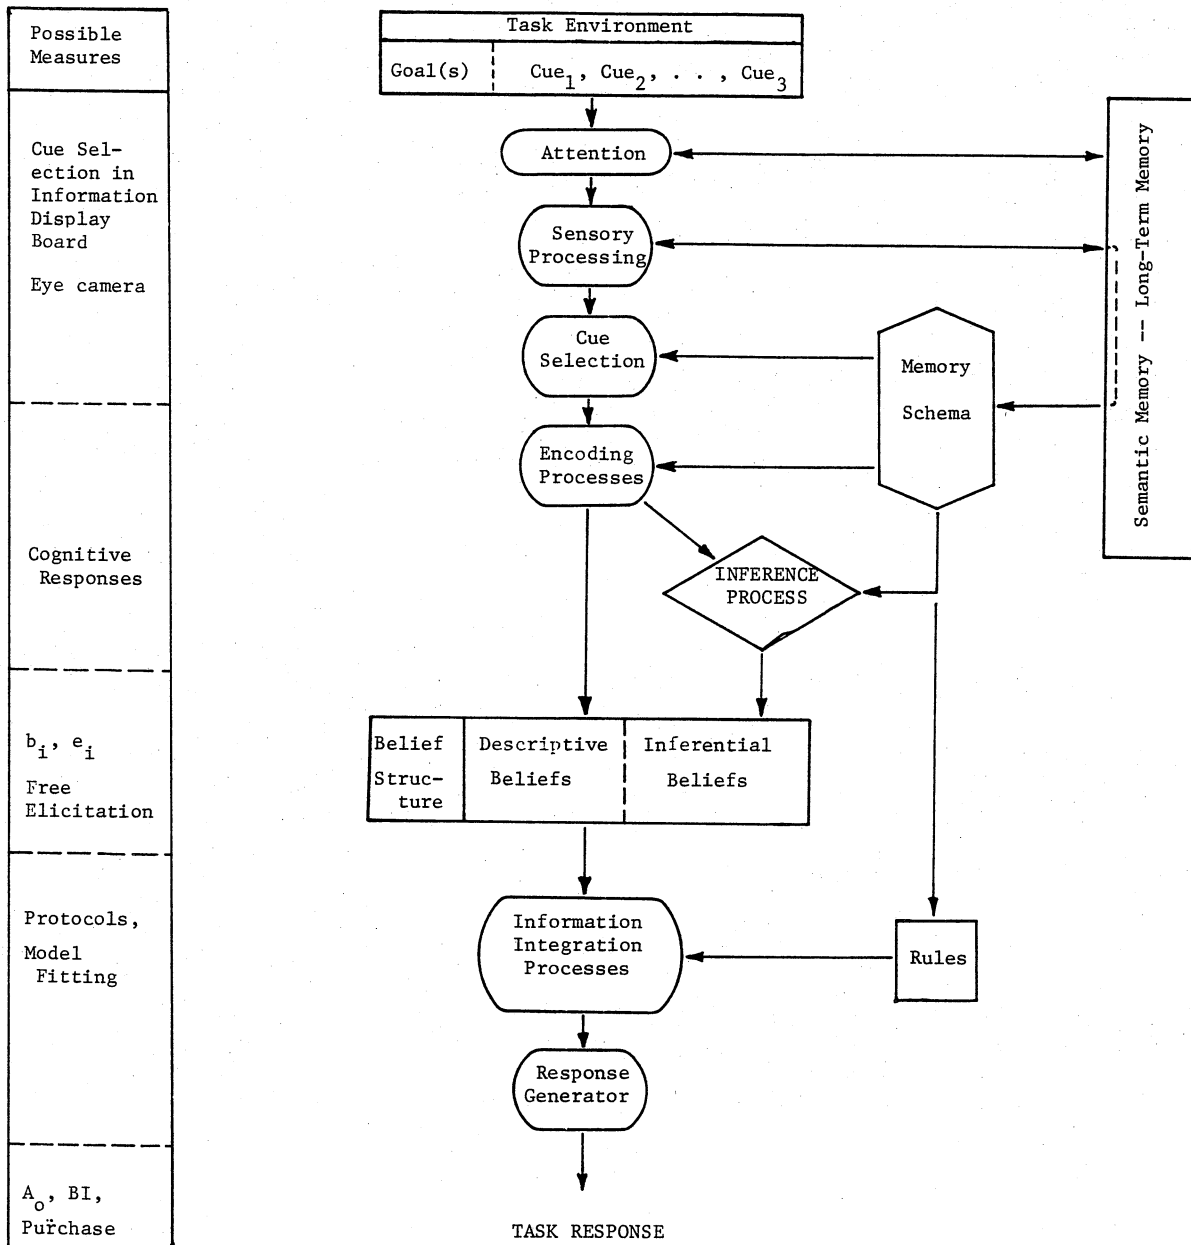

Figure 2. CONCEPTUAL MODEL OF THE CUE UTILIZATION PROCESS, INCLUDING THE INFERENCE BELIEF FORMATION PROCESS

a theoretically-based model of the cue utilization process which can logically account for such phenomena.

Inferential Belief Formation in the Cue Utilization Process

It is obvious that an explanation for inferential belief formation requires a consideration of previously learned information upon which one can logically base, or from which one can derive, inferences. That is, an adequate model of the cue utilization process must account for the influence of memory on the inferential belief formation process. Fortunately, the cognitive psychology field has developed numerous memory concepts and models. Several of these ideas appear useful in developing such a more theoretically complete model of cue utilization process--one that includes the possibility of inferential belief formation (cf. Olson, 1977).

Memory Schemata

Perhaps the most useful concept for the purpose of this paper is that of memory schemata. Norman and Bobrow (1975; Bobrow and Norman, 1975) developed this idea of highly organized substructures of knowledge stored in semantic memory. Schemata for products or brands would

²Tulving (1972) suggested a distinction between episodic memory (memory for past events in our lives) and semantic memory (stored knowledge about the world). It would seem that inferential processes about products are more likely to be influenced by semantic than episodic memory. This is particularly so given the perspective of focusing on specific product characteristics followed by most product perception or multi-attribute research. It would seem that semantic memory, in which is stored the meanings linked to the concept via its associated attribute/characteristics, is likely to influence the formation of inferential beliefs.

contain previously learned knowledge about the concept, plus, the interrelationships between these items of knowledge, stored in an organized logical framework. Interestingly, schemata may also contain "rules" for responding to the stimulus concept--e.g., a learned tendency to favorably evaluate a high price for a particular product. In this sense, schemata are "active" cognitive units which can influence behavior rather "directly," once activated. A schema may be activated simply by exposure to the stimulus representing to concept-context combination. Thus, schemata tend to be highly context specific. One might find different knowledge and different "rules" stored in the schemata for (a) toothpaste to use in the morning and (b) toothpaste to use before a social engagement.

Figure 2 represents an initial attempt to model how schemata may be integrated into the cue utilization process in a way that may explicate the inferential belief formation process. In Figure 2, the process begins with an experimental setting in which a subject is given a specific task (goal) and an informational cue environment within which to accomplish the task. Consider the previous example of evaluating the quality of four pairs of men's dress shoes given a set of cues about the shoes. The early attentive and sensory processing will activate (make available for conscious processing) the relevant schema, in this case the schema for men's dress shoes. This, of course, presumes that the subject has acquired a schema for men's dress shoes. If the consumer has not developed a special knowledge structure for dress shoes, the task environment might activate a more general schema for men's shoes.

Once activated, the schema "controls" the processes of cue selection and cue comprehension or encoding. For instance, if a relevant component of the schema for men's dress shoes is leather soles, a desired feature, then the consumer may "be directed by the schema" to select cues regarding the composition of the soles for the alternative brands. Once a cue is selected, the encoding/comprehension process also proceeds "in light of" the activated, hopefully relevant schema. For instance, a price of \$49.00 may be encoded as "about average" given one consumer's schema for dress shoes. Another consumer may interpret the same price as "excessively excessive"--due to a difference schema for dress shoes. Moreover, the same \$49.00 price might be encoded differently by the same consumer when associated with casual sports shoes than with dress shoes if a different schema has been activated. Clearly, how we encode incoming informational cues, i.e., the meaning we assign to cues, is a function of our past experiences (cf. Fishbein and Ajzen, 1975). The schemata concept can be seen as a theoretical representation of the cognitive structure created by those past experiences.

Now, as a result of selecting and encoding some or all of the informational cues in the task environment, beliefs are formed. Those directly related to environmental cues are termed descriptive beliefs to distinguish them from inferential beliefs. It may be that no inferential beliefs are formed. For example, in the case where one desires whole wheat bread, one may acquire and encode only those cues related to the grains used in manufacturing the bread and select the first whole wheat alternative found. Other beliefs about the breads may not be formed. However, in most situations it seems likely that inferential beliefs will be formed. In fact, for cases involving activation of well-developed schemata, the inferential process may proceed without much conscious analytical thinking, apparently automatically.

The inferential process itself, although still not completely explicated, can be likened to an attributional process in which incoming encoded information from the

task environment is compared/fitted into the established knowledge structure of the schema and inferences drawn about other concepts not present in the immediate environment.

Both descriptive beliefs and inferential beliefs (if any) form the cognitive content upon which the integration process operates. As noted above, the schema may also provide the combinatorial "rules" for integrating the information. The resultant cognitive state created by integrating the information is then "passed" to a "response generator process" which converts the cognitive state into the appropriate response called for by the experimental task--e.g., a check mark on a 7-point product quality scale.

The Inference Process

Now that the stages represented in Figure 2 have been discussed, let us examine more closely how a memory schema may allow inferences to be made regarding product attributes not represented in the immediate task environment. Part a of Figure 3 illustrates a portion of a memory schema for the generic product category, winter coats. This schema contains a consumer's knowledge regarding coats that are insulated with goose down. This knowledge is stored in a highly organized framework represented by distinct associations between concepts. Thus there are linkages (logical associations, or beliefs) between the concept, down-filled, and the product attributes of weight and warmth. These concepts associated with winter coats and their interrelationships were previously acquired/learned via classical and/or instrumental learning principles (cf. Fishbein, 1967; Olson and Mitchell, 1975) as a function of one's past experiences. In one sense, these associations between the knowledge components of the schema are very much like general product expectations (Olson and Dover, 1976). Now, suppose that this particular subject possessing this schema is exposed to a task environment and instructed to evaluate a particular winter coat. Assume, moreover, that the only cue provided by the environment is that the coat is down-filled. Upon processing (acquiring and encoding) this cue, the subject will form a belief, probably a strong belief, that this brand does indeed possess the attribute, "down-filled" (see Part b of Figure 3). In addition, exposure to the task environment will probably activate the previously-learned schema of winter coats illustrated in Part a of Figure 3. When the descriptive belief that the coat is down-filled is "fitted into" the schema, the previously learned relationships "enable" the consumer to infer certain other qualities of the coat. This inferential belief process is represented in Part c of Figure 3, which illustrates that the two beliefs (represented as subjective probabilities) P_{XB} and P_{BA} , about the associations between concept X and B and B and A , allow an "inference" to be made about the association between X and A , P_{XA} . This latter probability is the inferential belief about a product attribute not explicitly present in the task environment.

In other disciplines, notably social psychology, numerous studies have focused on peoples' ability to form inferences and of the factors which influence that ability. Some years ago, McGuire (1960) developed a probability model of the relationships between syllogistically-related beliefs. More recently, Wyer (cf. 1974) has extended this model (Wyer and Goldberg, 1970). Wyer has shown in several studies (cf. Wyer, 1975) that peoples' subjective estimates of some of the associations between concepts in a syllogism predict with considerable accuracy the strength of the other association in the syllogism.

A Probability Model of the Inference Process

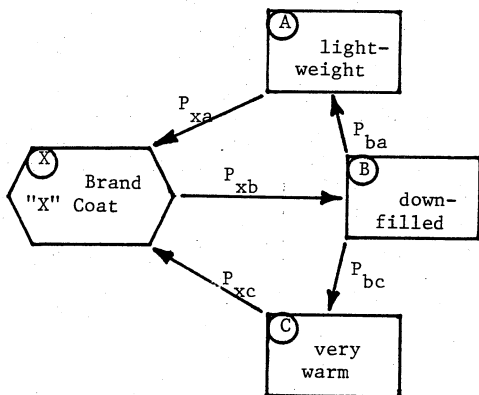

The McGuire-Wyer model appears useful in explicating how

a. MEMORY SCHEMA FOR GENERIC PRODUCT -- WINTER COATS

b. BELIEF FORMATION (P_{xb}) CAUSED BY PROCESSING CUE "B" FROM THE TASK ENVIRONMENT

c. BELIEF STRUCTURE (P_{xb} , P_{xa} , P_{xc}) CREATED THROUGH INFERENCE (arrows indicate theoretical causal flow).

Figure 3. THE INFLUENCE OF A MEMORY SCHEMA ON THE INFERENCE BELIEF FORMATION

a memory schemata can account for inferential belief formation. Figure 4 illustrates a schema containing three concept, A, B, and C. Also illustrated are some of the logical links or associations between the concepts, stated in probabilistic terms. For example, the subjective estimate of the likelihood of C given A ($P_{C/A}$) is .60. The likelihood of C in the absence of A ($P_{C/A'}$) is only .20. These subjective associations indicate that concept "C" is perceived to be somewhat contingent upon concept A. In contrast, Figure 4 indicates that concept B is not perceived as highly contingent upon the presence of A--note that $P_{B/A'} = .70$, only .10 less than $P_{B/A} = .80$. Further, suppose that exposure to an experimentally-controlled task environment creates a strong descriptive belief that concept X possesses concept A--e.g., $P_{XA} = .90$. The question of interest involves the belief strengths of the two inferentially-created beliefs, P_{XC} and P_{XB} .

Figure 4. PROBABILISTIC RELATIONSHIPS BETWEEN THREE CONCEPTS STORED IN A MEMORY SCHEMA.

The McGuire-Wyer Subjective Probability Model of Cognitive Functioning (or Inferential Belief Formation), allows predictions of P_{XC} and P_{XB} . The model, based upon conditional probability theory; is as follows:

$$P_{xc} = P_{xa} \cdot P_{c/a} + (1 - P_{xa}) \cdot P_{ca'} \quad (1)$$

Verbally, the association strength between X and C is equal to the strength of association between X and A times the conditional probability of C given A, plus the probability of no link between X and A times the conditional probability of C given absence of A. This model produces the following prediction of the inferential belief, P_{xc} :

$$P_{xc} = (.90)(.60) + (.10)(.20)$$

$$P_{xc} = .56$$

Likewise, the inferentially-formed belief regarding the association between concepts X and B can be estimated by the same model:

$$P_{xb} = P_{xa} \cdot P_{b/a} + (1 - P_{xa}) \cdot P_{b/a'} \quad (2)$$

$$P_{xb} = (.90)(.80) + (.10)(.70)$$

$$P_{xb} = .79$$

Once estimated, these belief strengths can be compared with direct ratings of the perceived associations. In several studies, Wyer (cf. 1974) reported reasonably strong relationships between model predictions and independent ratings.

Using this probabilistic approach, one can study the organization of stored knowledge in schemata held in semantic memory, as well as the use of that stored information in the process of inferential belief formation. Briefly, the procedure could be as follows. First, using a relatively non-reactive method such as a free elicitation procedure ("say everything that comes to mind when I say _____"), identify the concepts stored in semantic memory that are associated with the concept. Then, ask consumers to subjectively rate the strengths of associa-

tion (perhaps in both directions) between pairs of concepts. These procedures will yield a probabilistic view of the content and structure of the knowledge stored within a memory schema for a particular object concept. With this data, one should be able to predict the inferential beliefs and the strengths of those beliefs created by an experimental message directed at one of the target concepts within the schema. Certainly, this type of approach should be examined in future research.

Other Research Issues

Product Familiarity

The model proposed in Figure 2 has implications for phenomena other than inferential belief formations. For example, the concept of "product familiarity" has frequently been used by consumer researchers as an "explanation" of some observed data or as a blocking variable in experimental designs. "Product expertise" is another concept commonly used in similar ways. Seldom, however, is either concept precisely defined in clear conceptual terms, and virtually never in terms of the cognitive state associated with each variable.

However, the notion of memory schemata, which possess varying degrees of complexity in terms of amounts of stored knowledge and "interrelatedness" of the stored information, may be used to represent the cognitive state created by degrees of "familiarity" or "expertise" with a product category. It should be noted that the relationship between amount of past experience and complexity of memory schemata is not clear. It may be that familiar, expert customers have in fact, less complex cognitive structures (schemata) than moderately familiar consumers (cf. Hayes-Roth, 1977; Olson and Dover, 1978). Although the degree of complexity is in doubt, it is essentially an empirical question that appears determinable with relative ease. In any case, the schemata of the expert, whatever their complexity, should lead to differential cue utilization behavior compared to a non-expert, and these differences should be predictable once the schemata are measured. This approach to issues of product familiarity/expertise has promise of providing deeper levels of understanding of these important concepts.

Development of Schemata

A variety of important related issues involve the development of memory schemata. We might ask, "What types of product information and experiences lead to the acquisition of well-developed, complex schemata that are useful in reacting to a product in varying circumstances and settings? How much overt, conscious, cognitive analysis is necessary in schemata development? Do low-involvement products have simpler schemata? Does "low involvement processing" lead to non-complex schemata? These questions focus on the fascinating issues involved with the processes of schemata development (cf. Olson, in press) and certainly warrant future research attention.

Activation of Schemata

A final issue to be briefly discussed involves the activation of a schema for conscious processing. A critical question to be answered is, "What cues trigger or activate a schema?" Are purchase context cues or broad purchase goals critical factors in determining the precise schema that is activated? For instance is "buying for self" vs. "buying for a gift" a distinct cue to activating different schemata for products such as ball-point pens or table wine? Or, is the price level a broad cue for activating a particular schemata for certain product categories such as automobiles or men's shirts. Such questions (and many others unstated) are of high rele-

vance to marketers and must be addressed in future research before the schemata concept can be widely useful.

Summary

This paper presents several ideas intended to broaden the approach taken in cue utilization research. It was suggested that inference processes may be involved in the cue utilization process which may create beliefs about concepts not present in the task environment. A model was presented which positioned the inferential belief formation process within the cue utilization process. The concept of memory schemata was proposed as a basis for a viable theoretical explanation for the inference process. The issues raised by this perspective are of interest to consumer researchers for both theoretical and applied reasons. This paper will serve its intended purpose if others are stimulated to study the inferential belief formation process, its effects, and the factors which affect it.

SELF-PERCEPTION PROCESSES IN CONSUMER BEHAVIOR:
INTERPRETING ONE'S OWN EXPERIENCES

Carol A. Scott, The Ohio State University

Abstract

Although consumer behavior has been conceptualized as dynamic in nature, little empirical work has been done on the process by which behavior in one time period forms the basis for subsequent attitudes and actions. Recent developments in self-perception theory, however, provide the analytical tools necessary for investigating this process. The basic postulates of and evidence for self-perception are reviewed, and current research issues are identified and discussed in this paper. Implications for consumer research are then considered.

Introduction

Consumer behavior has been conceptualized traditionally as a dynamic process in which actions are affected by what is learned from previous behavior as well as by information from external sources (e.g., advertisements, friends, relatives, etc.). This property of dynamism is incorporated implicitly in most research (e.g., studies which control for past experience by using new or fictitious brand names), and explicitly in theoretical statements which include feedback loops from behavioral to cognitive variables (e.g., Engel, Kollat & Blackwell, 1973; Howard & Sketch, 1969; Nicosia, 1966) and in research utilizing Markov, linear learning, or stochastic models of brand choice (e.g., Bass, 1974; Kuehn, 1962). While this link between past and future behavior is acknowledged, little research attention has been focused on the process by which behavior in one time period forms the basis for subsequent attitudes and actions.

Recent theoretical developments provide the analytical tools necessary for exploring this rich and exciting area. Specifically, self-perception theory (Bem, 1965, 1972) attempts to explicate how an individual interprets his own behavior, how he assigns meaning to that behavior, and under what conditions the individual accepts experiential information as valid and worthy of incorporation into his attitude and behavior set. Self-perception theory's central province is the feedback loop, often postulated by theory and often neglected empirically.

Although self-perception theory has been developed within social psychology, it has major implications for the study of consumer behavior, and this is the primary focus of this paper. First, the basic postulates of self-perception theory are reviewed. Next, basic evidence for the theory is presented. Several current issues of relevance to consumer researchers are identified and research related to them are discussed. Finally, the implications of this work for consumer behavior theory and research are considered.

Self-Perception Theory

Self-perception theory (Bem, 1965, 1972) can be viewed as one portion of a general set of propositions commonly referred to as attribution theory. Like other attributional paradigms (see Kelley, 1967 on object attribution, Jones & Davis, 1965 on other person attribution, and Kelley, 1973 for an integrated view of all three paradigms), self-perception theory is phenomenological in character. That is, self-perception theory takes the perspective of the actor. It attempts to explain

and predict how individuals come to understand the causes of their own behavior, and to specify the consequences of this causal assignment.

The basic postulate of self-perception theory is that:

Individuals come to "know" their own attitudes, emotions, and other internal states partially by inferring them from observations of their own overt behavior and/or the circumstances in which this behavior occurs (Bem, 1972, p. 2).¹

Self-perception theory postulates the mechanism and the conditions under which a person uses his own behavior as data to make inferences about himself. For behavior to be used to infer individual characteristics, it must be a credible indicator of his internal state. In order to be credible, it must be perceived by the person as resulting from his internal motivations or true reactions to a stimulus, i.e., it must be attributed to properties of oneself as opposed to controlling aspects of the environment.² Thus, perceived causality of behavior is a primary determinant of the belief inference process.

Perception of causality, as indicated by Bem's proposition, depends partially upon the circumstances in which behavior is enacted. According to the discounting principle (Kelley, 1971), "the role of a given cause in producing a given effect is discounted if other plausible

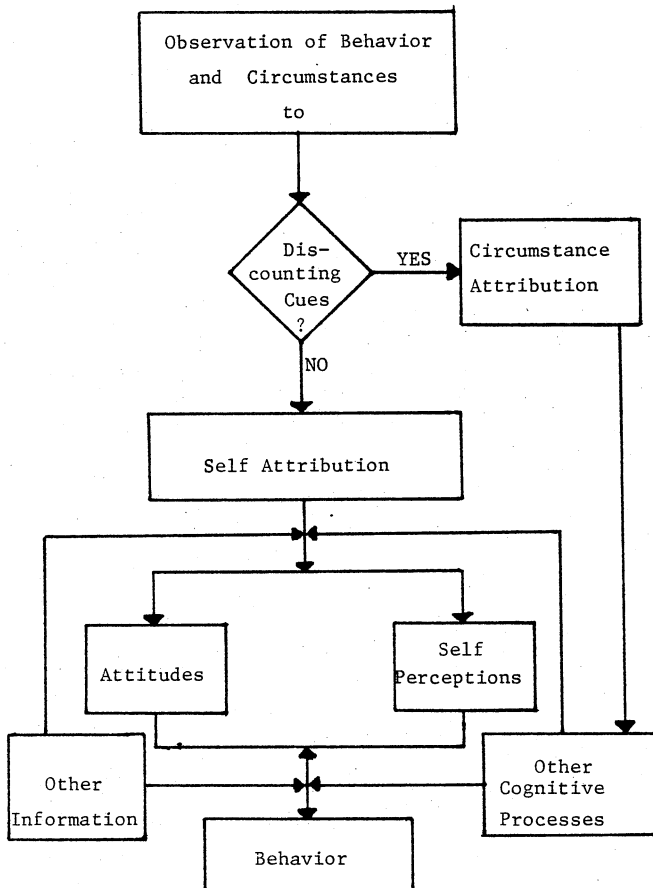

¹ A second postulate of self-perception theory is that individuals are functionally in the same position as an outside observer who must rely on external cues to infer the individual's inner state (Bem, 1972). While this proposition has caused a substantial amount of controversy because it implies that individuals have no more information about their feelings than observers, it has been shown to be tenuous at best (see Jones and Nisbett, 1971). Negation of this second postulate, of course, does not invalidate the first one which has received widespread support.

² A note on terminology should be made here. Many authors refer to this process as internal (self) versus external (situational contingency) attribution, while others (notably Nisbett and Valins, 1971) prefer the terms stimulus (perceived intrinsic properties) versus circumstance (factors external to the stimulus). The difference is more apparent than real. Behavior that is perceived to be elicited by the person's intrinsic feelings about the stimulus (stimulus attribution) implies internal motivation or causality. Behavior elicited by a desire to gain a particular reinforcement or to avoid punishment or by some other aspect of the circumstances (circumstance attribution) implies external causality. For simplicity, the terms "internal" and "external" will be used here.

ble causes are present" (p. 8).³ The presence of plausible external causal factors such as reward/cost contingencies, lack of volition, and the like should induce discounting of internal motivations as the cause of behavior. If a person performs an act for a large reward, for example, he would attribute his behavior to the reward rather than to his own positive attitude toward the act. When attributions are made to such external situational contingencies ("I was paid to do this"), no belief inferences would be made, and no link between behavior in one situation and behavior in another is expected. On the other hand, attributions to oneself ("I did this because I wanted to") are postulated to result in belief inferences ("I must believe in this issue") and subsequent behavior consistent with the initial behavior and internal attributions.

This attribution process is diagrammed in Figure 1. The relationship between past behavior, discounting cues, and future attitudes and actions has received the most empirical attention, and this body of literature provides the strongest support for the theory. The other parts of the process have received less attention, and these relationships are the source of current issues in self-perception research. The next section provides brief overview of this work.

FIGURE 1
A Schematic of the Attribution Process

³ Circumstantial factors can enhance the probability of self-attribution. Behavior enacted under inhibitory conditions (e.g., purchase at a premium price) should enhance the perception of internal motivation and result in strong belief inferences (augmenting principle, Kelley, 1971). These factors have been investigated only rarely, and thus are not discussed here.

Evidence relevant to self-perception theory can be discussed by first examining those studies which focus on the effects of past behavior, and then examining those that deal with the effects of perceived causality of behavior derived from Bem's (1972) central proposition. Several questions regarding the self-perception process emerging from these basic works and preliminary findings pertinent to them can then be discussed.

Effects of Past Behavior

At a minimum, two conditions must be demonstrated if the basic postulate of self-perception theory is valid. First, it must be shown that individuals do use their own behavior to infer their attitudes and/or to guide subsequent behavior. Second, it must be shown that circumstances surrounding the enactment of behavior affect this inference process.

The first of these conditions has been illustrated by several laboratory and field experiments in which a behavior is induced and subsequent attitudes and/or behavior are measured (e.g., Bandler, Madaras, & Bem, 1968; Freedman & Fraser, 1966; Pliner, Hart, Kohl, & Saari, 1974; Snyder & Cunningham, 1975; Valins, 1966). In a laboratory study (Valins, 1966), for example, male subjects were allowed to hear what was ostensibly their own heart beat while viewing pictures of nude females. Pictures associated with a (falsely manipulated) quickened heart rate were subsequently rated as more attractive and were frequently chosen as ones the subjects would like to keep than others. Similarly, in a field study utilizing what has become known as the foot-in-the-door paradigm, people were contacted at home and asked to display a small sign promoting a social cause in their window (Freedman & Fraser, 1966). Two weeks later, these individuals and a control group of subjects not contacted previously were asked to comply with another very large request. When both the issue and the task were similar across requests, 76% of the experimental participants as opposed to 16.7% of the control participants agreed to comply with the large request. Apparently, the initial behavior was self-attributed, causing subjects to draw belief inferences which enhanced the likelihood of subsequent compliance.

Effects of Perceived Causality

The second necessary pattern of data has been reported in numerous experiments which show that behavior enacted under discounting cue conditions does not persist in future time periods and may even decline in frequency (Bem, 1966; Davison & Valins, 1969; Calder & Staw, 1975; Deci, 1971; Kruglanski, Freedman, & Zeevi, 1971; Kruglanski, Alon, & Lewis, 1972; Kruglanski, Riter, Arati, Agassi, Montequio, Peri, & Peretz, 1975; Lepper, Greene, & Nisbett, 1973; Lepper & Green, 1975; Storms & Nisbett, 1970). Using an overjustification paradigm,⁴ for example, Lepper et al. (1973) found that children who expected and received a reward for engaging in a playtime activity subsequently spent less time engaging in that activity than a control group of children, even though they had previously evidenced considerable interest in it.

More recently, both of the two necessary conditions have been demonstrated in the consumer behavior literature. Scott (1976) asked individuals to take a two-week trial

⁴ Overjustification situations are the converse of insufficient justification ones, are those in which there are both internal and external motivations for engaging in an activity.

subscription to a weekly community newspaper either at the regular price (discounting cue absent) or at various discounted prices (discounting cues present). After the trial period had expired, these participants and a control group of subjects not receiving the trial offer were called and asked to subscribe on a regular basis. The results supported self-perception predictions in that large incentives for trial produced no more regular subscriptions than did the no-trial control condition. No or very small incentives, however, did have a positive effect on subscription behavior.

The negative effect of monetary incentives on subsequent behavior has been replicated in a social marketing context (Scott, in press) and in an interview request situation (Reingen & Kernan, 1977). And, Tybout (in press) and Dholakia & Sternthal (1977), using essentially the same foot-in-the-door paradigm, have shown that high credibility of the source of a message or request also acts as a discounting cue which attenuates subsequent behavior. Finally, Hansen (in review) has found that while monetary inducements to respond to a mail survey do not adversely affect response rate, they do result in lower quality of responses.

These studies provide considerable support for the self-perception thesis, and demonstrate the applicability of the self-perception framework for many consumer behavior contexts. However, they and other experiments conducted more recently raise some fundamental questions regarding the self-perception process and indicate areas where theoretical extensions and empirical research are needed to clarify our understanding of the link between past and future behavior. Six of these issues and preliminary data relevant to them will be discussed next.

Research Issues

Many areas of the self-perception process remain relatively unexplored. Following the diagram in Figure 1, these areas may be categorized as relating to the strength of the behavior-behavior link, the definition of past behavior, the relationship between the magnitude of discounting cues and behavior, the mediating role of attributions, the outcomes of self-perception processes, and the way in which experiential information is combined with other types of information. Research issues in each area and their implications will be briefly considered.

Issue 1: Strength of Self-Perception Effects

A very basic issue relates to the strength of the link between past and future actions. In their seminal study, Freedman and Fraser (1966) suggest that an initial behavior has a rather dramatic and persistent (two weeks) effect on subsequent actions. However, only behavioral intentions to comply with the large request were measured. Actual behavior was measured by Pliner et al. (1974), but the requests were made only one day apart, and difficulty of the behavior (e.g., donation to charity) was a dependent variable rather than an independent one. Scott (in press) varied second request task difficulty and measured both behavioral intentions and behavior in order to assess directly the strength of the initial behavior effect. The findings replicated those of Freedman and Fraser (1966) in that behavioral intentions to comply with the very difficult task were positively affected, but behavior was affected only when the second task was moderately difficult.

These studies show that an initial behavior does have a positive influence on subsequent behavior, but that this effect may be limited by the difficulty of that subsequent action. It seems likely that a series of requests could be used to gain compliance with very large requests, but this speculation has not been tested

empirically. Thus, the strength of influence strategies based on this paradigm is still unclear at least in the case where the two requests are made on two different occasions and where behavioral intentions are not synonymous with behavior. Other studies have examined the effects of size of the initial behavior on subsequent behavior, and these are discussed next.

Issue 2: What is Past Behavior?

In the field studies discussed previously (e.g., Freedman & Fraser, 1966; Pliner et al., 1974; Scott, 1976, in press), the initial behavior consisted of behavioral intentions to comply with a request. Two other types of experiments have varied this definition of past behavior. The first examines the effect of merely relabeling or reinterpreting some behavior that has already occurred, while the other focuses on enhancing the behavior-behavior link by increasing the level of difficulty of an initial, induced behavior.

Labeling studies manipulations are often no more than the provision of a belief-relevant label or interpretation for behavior that has already occurred. In a study by Tybout and Yalch (in review), for example, individuals responded to a survey about voting behavior. Half the individuals were then told that they were more likely to vote than the average person, while others were told that they were about average in their likelihood of voting. Examining records of a local election one week later, the authors found that more individuals given the "above average" feedback had indeed voted than individuals given the "average" feedback. These findings replicate those of Kraut (1973) who found that labeling individuals as charitable or uncharitable resulted in subsequent behavior consistent with these labels, and of Miller, Brickman, and Bolen (1975) who showed that labeling children as non-litterers or math achievers enhanced subsequent behavior relevant to that label. All of these results are consistent with self-perception assumptions about the cognitive status of attitudes and empirical evidence which indicates that people often do not know what their attitudes are (e.g., Ross, Insko, & Ross, 1971). They are also congenial with findings that attitudes are inferred from behavior only when behavior is perceived as belief-relevant, or belief expressive (Kiesler, Nisbett, & Zanna, 1969). That is, labeling affects behavior because it implies a link between past actions and beliefs, and makes this link salient to the individual.

All of these studies, however, have utilized a personal contact to deliver the label. Extending this work, Allen (1977) tested the relative effectiveness of a labeling message versus a typical persuasive message using television advertisements. The results were equivocal, but suggest that under some conditions people are sensitive to the explicit positive label ("You are the kind of person who...") of the labeling message and the implicit negative label of the persuasive message ("You ought to be..."). Too little is known about the qualifying conditions of labeling effects and the cognitive meaning of labels to reach definite conclusions, but the question of the situations in which labeling or persuasive messages are most effective is an intriguing one for consumer researchers.

A second type of study takes an approach opposite that of labeling, and seeks to test methods of strengthening the effect of an initial behavior by increasing its difficulty or size. Seligman, Bush, and Kirsch (1976), for example, found that very small behaviors had no effect on subsequent actions, while Pliner et al. (1974) found no differences between groups performing different levels of initial behaviors. It is clear from even a cursory examination of these discrepant findings that we actually know very little about what kind of an initial behavior is required for the self-perception process to become

operative, nor do we know along what dimensions this initial behavior should be classified. It may be that size of the request is not as important as degree of involvement, for example. These questions must be answered before influence strategies predicated on the paradigm can be used confidently.

Issue 3: Magnitude of Discounting Cues and Behavior

The definition of discounting cues as well as the definition of past behavior is an issue of particular relevance for consumer research. In many previous studies, a discounting cue is either present or absent. In contrast, consumer choice contexts often involve an initial behavior or trial of a product induced by a monetary incentive (e.g., coupons, cents-off deals, etc.) which may be of a variety of sizes. While self-perception theory does not specifically hypothesize a relationship between magnitude of the discounting cue and the likelihood of subsequent behavior, a reasonable derivation is that this relationship should be negative. Scott (1976; in press) addressed this issue empirically by including several levels of monetary incentives as treatments. Two findings are of interest. First, small incentives did not produce discounting in a commercial setting (Scott, 1976). Second, the relationship between magnitude of the incentive and subsequent behavior appeared to be negative, but not linear, in both a commercial (Scott, 1976) and a social issue setting (Scott, in press).

The first of these findings suggests that monetary incentives as discounting cues may have different effects in commercial than social settings. In commercial contexts, small incentives for trial may be perceived as so intrinsic to behavior that they are not perceived as salient causes of behavior. Kruglanski (1975) has shown that rewards intrinsic to the task (e.g., stock market choices) do not result in decreased interest or behavior as they do when the rewards are not intrinsically related to the task (e.g., a social game). Thus it may be that small monetary incentives do not lead to discounting of internal motivations in commercial contexts. It is only when they become very large, or when they are used in an unusual setting (e.g., a social program), that they are perceived as salient causes of behavior and discounting occurs. The findings of a single experiment should, of course, be regarded as the only tentative evidence at best. However, researchers need to be sensitive to areas where cross-situational generalizability may be problematic.

The second finding indicates that incentives as discounting cues may carry different meanings and thus activate different processes than other forms of discounting cues. That is, they not only provide contextual cues about behavior, but also specify the terms of an exchange in which perceptions of equity (Adams 1965) are relevant. When incentives are very large relative to the task, the person may feel that he has been inequitably rewarded and is obligated to do something in return to restore equity. An attempt to investigate this issue would be characterized by an experiment including several levels of incentives and measures of attitudes and perceptions of inequity as well as behavior. If the speculations about equity are correct, behavior would be curvilinearly related to levels of incentive, but attitudes would be negatively related and perceptions of inequity positively related to the magnitude of incentives. This type of research on the meaning and effects of monetary incentives is of central importance in understanding much marketplace behavior.

Issue 4: The Mediating Role of Attributions

Many self-perception studies merely assume the presence of an attributional mechanism from behavioral findings

consistent with attribution predictions. However, varying the presumed antecedents of self-perceptions and observing the outcomes is not sufficient to demonstrate the efficacy of the theory (see Burnkrant, 1975). Direct assessment of attribution is necessary since competing theories often make the same behavioral predictions.

Among studies which do include measures of cognitive processes, a frequent finding is significant behavioral effects, but no or only slight effects on cognitive variables assumed to mediate behavior (e.g., self-perceptions, attitudes, attributions). An interesting theoretical rationale for these results is one proposed by Nisbett and Valins (1971) who postulate that self-attributions and the corresponding self-perceptions or beliefs have a cognitive status similar to an hypothesis. That is, performance of a behavior causes individuals to attribute it to themselves, and this attribution in turn causes the individual to form an hypothesis about his beliefs, which is then tested out in subsequent actions. The behavioral effects demonstrated in previous studies then result from a desire to test this attributional hypothesis by gaining more information rather than to act consistent with stable attributions and attitudes.

The hypothesis-testing proposition is compatible with the results of several studies. For example, Barefoot and Straub (1971) were able to replicate Valin's (1966) false heartrate feedback findings only when subjects were given sufficient time to examine the pictures. Apparently the quickened heartrate caused subjects to view the pictures more closely and confirm that they were indeed more attractive. Similarly, Valins (1974) and Ross, Lepper, and Hubbard (1975) have demonstrated that merely debriefing subjects about the falsity of the feedback had no effect. Again, it seems that feedback stimulates an individual to gather more information to confirm the belief hypothesis. Once confirmed, the falsity of the feedback is irrelevant to the belief.

A recent experiment tested this attribution process directly (Scott & Yalch, in press). Subjects were asked to test a new soft drink under incentive or no incentive conditions. After making this choice, half the subjects were allowed to visually examine the product. All subjects then tasted the product which was manipulated to provide either a good, neutral, or poor experience. When subjects were allowed to examine the product, the familiar discounting results were found in the neutral and poor taste conditions; incentives undermined subjects' attitudes toward the drink, behavioral intentions to purchase it, and actual choice of it relative to no-incentive conditions. The reverse effect of incentive was found when no examination opportunity was given. It appears that individuals do infer their beliefs from their own behavior, but only when they have an opportunity to persuade themselves of the veracity of the experimental information.

The hypothesis-testing proposition and related empirical work represent beginning attempts to outline the conditions under which attributional hypotheses are translated into beliefs and behavior. Unfortunately, this begs the question of what starts the attribution process in the first place. That individuals do not always engage in causal analyses is suggested by findings from Tybout (in press). In her study, the predicted discounting cue effects were obtained only when subjects' attention was drawn to their behavior by a question asking why they behaved as they did.

The issue is not really whether individuals do or do not engage in attributional analyses, but rather is "under what conditions do they perform these analyses." The answer may be found in terms of individual difference characteristics (e.g., absence of self-schema on a dimension as in Markus (1977), internal versus external

locus of control as in Shaver (1976) or low education as in Tybout, in press). Or, it may be found in terms of the characteristics of the context of behavior (e.g., expectation of future consequences as suggested by Berscheid, Graziana, Monson, & Denmer, 1976, and relevance of the behavior to beliefs as in Kiesler, Nisbett, & Zanna, 1969). Unfortunately, little evidence exists to answer this question conclusively although the literature certainly provides some hypotheses. It is critical that future research address this issue since self-perception theory will have little applicability to consumer behavior if it turns out that only a small segment of the population engage in these analyses spontaneously and that there are no methods to encourage such analysis. In sum, the external validity of the self-perceptions process must be defined and demonstrated.

Issue 5: The Cognitive Consequences of Self-Attributions

Related to the issue of when attributions are made and their cognitive status once they are made is the issue of what happens as a result of self-attributions. Much evidence exists which demonstrates a behavior change, but we know very little about the cognitive changes that occur. In interpreting their results, Freedman and Fraser (1966) offered the following possibilities:

Once he has agreed to a request, his attitude may change. He may become in his own eyes, the kind of person who does this sort of thing, who agrees to requests made by strangers, and who takes action on things he believes in, who cooperates with good causes (p. 201).

Thus behavior may change a person's perception of himself in general, or may alter attitudes specifically related to the behavior, or both. And, there is some evidence to suggest that other cognitive activities occur as well.

With regard to the self-perception versus specific attitude question, a few studies indicate that one's self-perception is most affected. Freedman and Fraser (1966), for example, reported positive (but not significant) effects of past behavior even when the issue and task were different across requests. Similarly, significant positive effects of behavior on subsequent actions have been observed when the issue was different across requests (Snyder & Cunningham, 1975). These studies provide indirect evidence that issue-specific attitude change is not solely responsible for the behavioral effects.

Direct evidence for an effect on self-perception is found in Scott (in press). Attitudes and perceived personal activism were both measured in this study, with larger (although not significant) effects found on activism than on issue-specific attitudes. Some methodological problems exist in this design, however, and the results must be viewed as tentative. And, attitudes of the subject population were already favorable, so a ceiling effect may have been encountered.

Future research is needed which clarifies the cognitive effects of self-attributions since this will be a critical factor in determining the applicability of self-perception based strategies to consumer settings. If issue-specific attitudes are not affected, the applicability of the theory to choice decisions among similar alternatives is problematic. On the other hand, there are also many situations in which attitudes are already favorable but behavioral enactment of these attitudes is low (e.g., everyone believes that conservation of energy is important, but few take action), and changes in self-perceptions may provide an energizing force on behavior.

Finally, there is evidence to suggest that the attribution process may affect other cognitive variables indirectly. Several studies show that providing feedback about one's behavior, or making that behavior salient instigates a search for information (e.g., Taylor, 1975; Berscheid et al., 1976). And, other experiments indicate that the provision of rewards or incentives for behavior also have this effect. Using a Bayesian framework for analyzing the value of information, Yalch and Scott (in review) and Scott and Tybout (1977) have found that subjects who agreed to test a product under incentive (reward) conditions responded more to information provided them after this choice.

Issue 6: Combining Experiential and Other Types of Information

Self-perception theory offers fairly clear specifications of when an individual uses his own behavior to formulate attitudes and guide behavior. Other attributional paradigms (e.g., object and other person) suggest other types of information that may be used to form judgments. Specifically, distinctiveness of response, consistency of response, and consensus information may be used when the person forms judgments over time (see Kelley, 1976; 1973). It seems likely in most consumer contexts that individuals will have access to at least some of these types of information as well as to information from their own experiences. We know that self-perception induced beliefs can affect both the quantity of information and the perception of the content of that information at least when it is somewhat ambiguous (e.g., tasting a "new" soft drink as in Scott & Yalch, in press). The question now is whether these beliefs will be given greater or lesser weight than information of another type.

Burnkrant and Cousineau (1975) have shown that individuals' judgments of product quality are influenced by the degree of consensus exhibited by others. The greater the apparent consensus, the more an individual is influenced by this information. These authors did not, however, examine the relative influence of experiential and consensus information. That is, they did not induce a self-perception based belief and observe changes in those beliefs as a function of consensus information. Research by Nisbett, Borgida, Crandell, and Reed (1976) indicates that individuals often ignore consensus information and rely more heavily on their own experiential data, and Scott and Tybout (1977) found that the timing of consensus information presentation as well as whether discounting cues are present affect the acceptance of consensus information. That is, rewarded subjects showed a primacy effect in that they were more influenced by consensus information when it preceded actual product experience. Unrewarded subjects generally were less responsive to both consensus and actual product experience.

The process by which information sources are combined is undoubtedly a complex one which will require much research to unravel. It seems clear, however, that a merging of the paradigms is necessary to extend the external validity of the research questions posed and the experimental designs used in consumer behavior research.

Implications and Conclusions

Self-perception theory and research promises to add much to our understanding of how consumers learn from their own experiences and the consequences of this learning for future actions. The phenomenological focus of this framework forces one to examine not only behavior itself, but also to examine how the individual perceives the behavior. The meaning an individual assigns to his experiences is of critical importance in predicting and explaining subsequent actions. Self-perception theory

acknowledges that learning from past behavior is not a simple, automatic response. Rather, it is a complex process in which what is learned from previous experiences is dependent upon many interacting factors. While situational factors affect the perception of the outcomes of consumer behavior, for example, it is also likely that some outcomes will affect the perception of situational cues.

Self-perception theory (and attribution theory in general) is inherently dynamic, and thus it orients researchers to examine behavior over time. Situational characteristics, in self-perception terms, affect behavior in both immediate and future time periods. Investigation of only the immediate impact of situational variables tells only half the story. Similarly, strategies designed to modify behavior must be evaluated at several points in time since their long-run effects may vary from their short term ones.

Caution must be exercised, however, in expecting too much of self-perception theory as developed thus far. Consumer researchers must be aware of the unresolved issues surrounding the self-perception process, and must be vigilant for conditions which may limit its cross-situational generalizability. As noted in this paper, we have only just begun to examine the self-perception process in any depth. And, consumer researchers must be careful even in applying the knowledge gained in other contexts. In consumer contexts, it may be that some product decisions involve attributional processes more frequently than others, that some individuals utilize attributional analyses more than others, or that special strategies must be developed to encourage attributional processes.

It should be clear from this paper that much research remains to be done in explicating the self-perception process and its implications for consumer behavior. Given its potential for shedding light on that ubiquitous feedback loop, however, such research seems well worth our time and resources.

A TWO-STAGE THEORY OF INFORMATION PROCESSING IN PERSUASION: AN
INTEGRATIVE VIEW OF COGNITIVE RESPONSE AND SELF-PERCEPTION THEORY

Alice M. Tybout, Northwestern University
Brian Sternthal, Northwestern University
Bobby J. Calder, Northwestern University

Abstract

Cognitive response theory is presently not a sufficient explanation of the information processing underlying persuasion. Initial opinion, one of the key constructs in cognitive response theory, is not well specified. This paper uses self-perception theory to specify the nature of the initial opinion construct. This integrative view emphasizes the importance of message related behaviors as cues utilized by consumers.

Introduction

During the last decade cognitive response theory has emerged as the most viable explanation of how individuals process persuasive information. The theory, however, is not a sufficient explanation of the persuasive process; it relies on the construct of initial opinion without fully specifying the nature of these opinions. Self-perception theory complements the cognitive response view, suggesting the process by which individuals acquire initial opinions. In this paper a common language is developed which links these theories. This integration provides a comprehensive theory which is sufficient to account for persuasion. In this integrative theory, initial opinion is a fully specified construct. An important implication of the theory is that persuasion depends on cues provided by message related behaviors as well as by the message itself.

This paper is divided into three sections. First, cognitive response theory extended to include memory structure is described. Next, an integrated theory is developed by incorporating the self-perception process into the cognitive response view. In the final section, implications of the comprehensive theory are outlined.

Extended Cognitive Response Theory

According to the cognitive response formulation, much of persuasion is self-persuasion. In response to a persuasive communication, individuals generate and rehearse their own repertoire of thoughts as well as those included in the information presented. The thoughts generated and rehearsed depend to a large extent on information recipients' initial opinion toward the position being advocated (cf. Greenwald, 1968). Those who are initially opposed to an advocacy are likely to rehearse counterarguments to it. And the more extensively people rehearse counterarguments, the more likely these thoughts are to become part of their attitudinal disposition toward the issue, and the less likely people are to be persuaded to adopt the advocated position. In contrast, those individuals who have a favorable initial opinion toward an issue are likely to generate and rehearse support arguments, thus enhancing the probability of their being persuaded by the information presented. (Petty, 1977; Sternthal, Dholakia and Leavitt, in review).

The description of cognitive response as a mediator of persuasion underscores the theoretical importance of the initial opinion construct. Initial opinion guides the generation of thoughts that ultimately affect persuasion.

However, for initial opinion to have integrity as a construct, the mechanism by which it influences processing must be described rather than merely stated. This can be achieved by extending cognitive response to include concepts related to memory structure (cf. Calder, 1978). More specifically, this view suggests that processing entails a short-term memory store and a long-term memory store. Short-term memory holds information which is being processed actively. Long-term memory holds most, if not all, of the information an individual has ever processed. To proceed further, the information held in long term memory must be retrieved and transferred to short term memory. In terms of cognitive response, memory structure implies that information from a message as well as other incoming information is initially represented in short-term memory as cognitive responses. In turn, these cognitive responses trigger the retrieval of further information from long-term memory and its registration in short-term memory.

An Integrative Theory

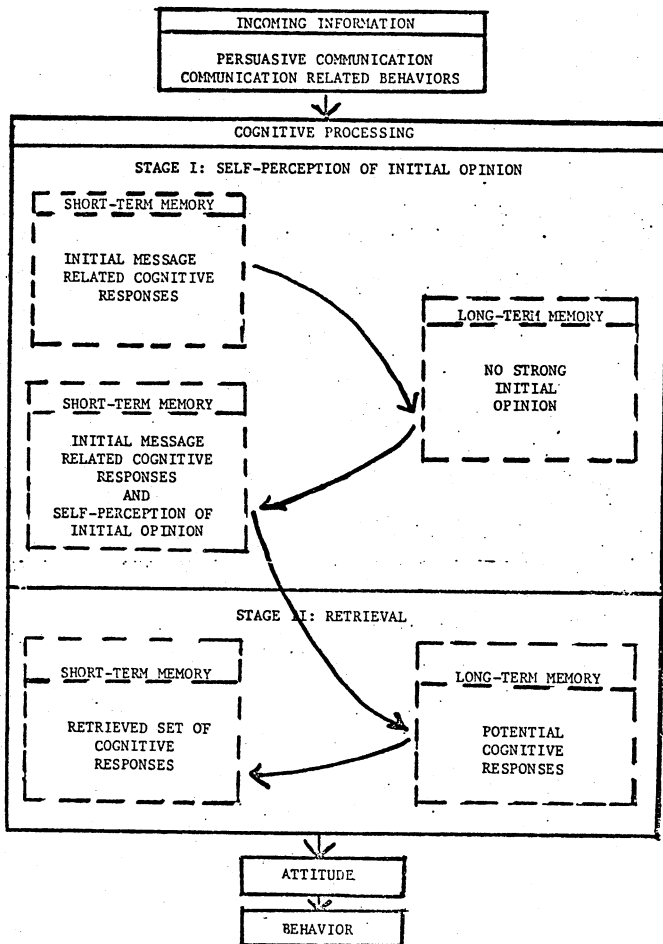

The extended cognitive response theory presented above implies that the role of initial opinion in current cognitive response theory may be equated with retrieval from long-term memory. The initial cognitive responses in short-term memory determine whether long-term memory will be searched for support or counterargument thoughts. It may be appropriate to think of persuasion as a two-stage process. In the first stage, incoming information is represented more or less faithfully in short-term memory. If a person already has strong general thoughts in long-term memory (perhaps as the product of self-perception), these thoughts will be triggered at this point and also entered into short-term memory. It is these cognitive responses which form an initial opinion that guides further retrieval from long-term memory. This subsequent retrieval is the second stage of the process.

Consider a second and more problematic case for cognitive response theory. What occurs if no strong general thoughts are already stored in long-term memory? That is, what if the message triggers no existing initial opinion. Cognitive response theory is not sufficient to explain the persuasive process in this instance, unless it is bolstered by self-perception theory. This latter theory describes the process by which individuals infer the causes of their own behavior when they do not have strong initial opinions. These inferences then guide subsequent action. When a person cannot attribute his/her actions to external causes, an internal disposition is inferred (e.g. liking a product). This disposition, in turn, may guide subsequent action. When a person's behavior is attributable to external causes such as social pressure or monetary incentives, no inference about internal states will be drawn with certainty. As a result, a disposition toward the behavior is unlikely to be formed and behavior will persist only in the presence of the external cause. Support for these self-perception predictions has emerged both in studies using the foot-in-the-door technique (cf. Freedman and Fraser, 1966;

Pliner, Hart, Kohl, and Saabi, 1974; Reingen and Kernan, 1977; Snyder and Cunningham, 1975; Scott, 1976; Tybout, 1978) and labeling (cf. Kraut, 1973; Miller, Brickman, and Bolen, 1973; Tybout and Yalch, in review).

In situations where the message triggers no initial opinion, individuals will examine behaviors associated with the message to infer their initial opinion (Figure 1, Stage I). The self-perception process ensues; if no external cause for the behavior is salient, an initial opinion consistent with the behavior is inferred. This opinion guides Stage II of the process (Figure 1). A final set of cognitive responses is retrieved from all of the potential cognitive responses in long-term memory.

FIGURE 1
SCHEMATIC DIAGRAM OF THE INTEGRATED THEORY
For the Case of No Initial Opinion

In an experiment pertaining to the persuasive effect of source credibility, Dholakia and Sternthal (1977) presented subjects with a communication requesting their compliance with a request attributed to either a high or low credibility source. Subjects' compliance was measured either before or after the administration of an attitude battery. Because message recipients were unfamiliar with the issue, it was expected that the highly credible source would induce a more positive attitude toward his advocacy than a low credibility source when attitude measures were administered prior to behavior. In this situation, a high credibility source was more likely to inhibit the retrieval and transfer of counterarguments from long to short-term memory than a low credibility source. Of greater interest in the present context is the source credibility effect when subjects behavior (i.e. compliance with the request) was available as a cue. Here, it was found that the low credibility source was more persuasive than the highly credible communicator.

To explain this result, we must invoke the common language. Consider for example those subjects who complied with the communicator's request. When the source was highly credible, individuals were likely to consider this stimulus as a likely cause of their compliance and therefore discount personal reasons. The relatively neutral initial opinion resulting from this attributional work would thus stimulate the retrieval and transfer of few support arguments and counterarguments to short-term memory when subjects were called upon to express their attitude toward the issue advocated. As a result, subjects' attitude would not be highly favorable or highly unfavorable. In contrast, those who complied in the low credibility condition could only plausibly attribute that behavior to a positive initial opinion toward the issue. In turn, this positive initial opinion would stimulate the retrieval and transfer of arguments supporting the advocacy to short-term memory when subjects were subsequently asked to complete the attitude questionnaire. Thus, attitude would be highly positive. These predictions were confirmed by Dholakia and Sternthal (1977).

Conclusion

As noted at the outset of this paper, cognitive response theory is possibly not a sufficient explanation for persuasion. The driving force in cognitive response theory is initial opinion. Yet the source of this opinion is not fully specified. While consumers may have stored opinions about some products/issues (possibly derived on the basis of their past behavior, circumstances surrounding that behavior etc.), for many products/issues no strong stored opinion may exist. In such instances, the individuals' self-perception of any message-related behaviors may provide the driving force for information processing. Our integration of cognitive response and self-perception theory provides a model which accounts for information processing regardless of whether or not an initial opinion exists. (See Table 1).

This integrative view is perhaps most important in underscoring the need to go beyond examining just the message in consumer research. Equally important may be the behavior and the perceived causes and significance of behavior associated with the message. On this view, consumer research has been myopic in investigating the non-message cues utilized by consumers.

In sum, we are suggesting that by developing a common language to link cognitive response and self-perception we can explain consumer behavior phenomena that cannot be adequately explained by either theory alone. Self-perception does not address the mechanism by which individuals process information. This is described by cognitive response. On the other hand, cognitive response does not consider a key source of initial opinion which may mediate persuasion, namely message related behaviors. This is addressed by self-perception theory. The importance of developing a common language may be illustrated with a recent investigation.

TABLE 1
POSSIBLE STATUS OF INITIAL OPINION

CASE	HYPOTHESIZED PROCESSING
Pre-existing initial opinion	Retrieved from long-term memory and used in retrieval of subsequent cognitive responses
No initial opinion, self-perception possible	Self-perception based on message related behaviors used in retrieval of subsequent cognitive responses
No initial opinion, self-perception not possible (i.e. behavior discounted)	"Random" retrieval

CUE UTILIZATION IN PRODUCT PERCEPTION

Robert E. Burnkrant, University of California, Berkeley

Abstract

Cue utilization in product perception is viewed as complex information processing. It involves a process of making inferences about products from the configuration of cues available. It is maintained that this type of information processing is more likely to be engaged in with complex rather than simple products. It is also suggested that the consistency in meaning of cues associated with a product is directly related to the intensity of the perception of that product. Preliminary results of a study to test these hypotheses are briefly reviewed. The relevance of attribution theory to product perception is discussed.

Much of the information people acquire about products comes from the processing of product related cues. These cues provide a basis for making inferences about the product and give it meaning which frequently goes beyond and departs from the specific arguments made in advertising appeals. As such, they become important determinants of how people behave toward products.

An individual in a purchasing context is frequently faced with the problem of evaluating the worth of a product which he cannot possibly objectively evaluate from physical manipulation and observation of its characteristics alone. Among the strategies employed by the consumer is processing information contained in messages (i.e., advertisements) about the product. This has been given considerable attention in the literature. Much less attention has been devoted to another strategy. The consumer may turn to cues given by the product, the context in which it is found and the people who use it. These cues can provide a basis for inferring the characteristics of the object under consideration. This information processing involves making inferences about the product from the selective processing of product related cues.

It is important for marketers to come to grips with some of the factors which will determine the extent to which inferences will be made in particular situations and to identify cues people utilize when they make inferences. This will permit marketers to employ cues more consciously and appropriately with products and in situations in which these cues are likely to have an affect on consumers' product evaluations. This requires that we determine which types of products and situations will lead to cue processing. It requires a concerted effort to determine which product and other related factors are used by people as cues. It is also necessary to consider how various combinations of these cues will affect the inferences people make. The study to be described here addresses two of these issues. It attempts to identify a product dimension which will be directly related to the use of cues in product evaluation, and it attempts to assess the affects of variations in cue consistency on product evaluation.

The author would like to acknowledge the support of the Center for Research in Management Science, the Committee on Research and the Institute of Business and Economic Research of the University of California, Berkeley. He would also like to thank Mr. Scott Vitell for research assistance provided this project.

The process of inferring the characteristics of an object from indirect information is clearly more complex (i.e., involves more cognitive effort) than the direct processing of observable product attributes. As a result, it would be expected to be engaged in only when available direct information is insufficient to permit satisfactory performance on the impending task. The assessment of product differences in cue utilization naturally turns, then, to a consideration of dimensions which will distinguish between products requiring the individual to infer from indirect information and those which do not require this type of information processing.

Product familiarity has been found to be related to cue utilization in product evaluation. Monroe (1976) found that price played a greater role when subjects were unfamiliar with the brand than when they were familiar with it. Similar findings were also obtained by Smith and Broome (1966). In Jacoby, Olson and Haddock (1971) the influence of price ceased when price was paired with an already known brand.

It is suggested that if we control for familiarity, the tendency to make inferences from such cues as price should be directly related to product complexity. What is meant here by product complexity is the typical or mean number of dimensions by which the product is represented in the minds of its potential customers. It is expected that some products are largely represented in only very few, perhaps one or two, dimensions. These products are considered to be relatively simple. On the other hand, some products are likely to be represented by most people in several dimensions, and these products are considered to be complex.

This treatment of product complexity is adapted from work focusing on cognitive complexity. Researchers concerned with this topic have treated cognitive complexity as an individual difference variable and have made predictions about the effects of complexity on information processing (e.g., Kelly, 1957; Schroder, Driver and Streufert, 1967). It has been found that "most persons are relatively 'complex' in some areas of cognition and relatively 'simple' in others" (Gardner and Schoen, 1962). It follows that most people may be "complex" with regard to some products and "simple" with regard to other products. If this is true this distinction should have implications for information processing, including the tendency to base a products' perception on inferences.

Schroder, Driver and Streufert (1967) point out that "the more judgmental space contains dimensions of information that are not objectively or directly given by the situation (for example, as instructions or as direct outputs from the environment), the more we can assume the presence of higher and more flexible levels of integration" (p 27). The reverse should also be true. That is, the more complex the perception the more it should contain dimensions of information not objectively or directly given by the situation. This indirect information must come from an inference process. As a result, we would expect that an inference process plays a greater role in the formation of perceptions about complex products than simple products. If people have employed an inference process more readily in the evaluation of complex products than simple products, we would

expect, based on learning, that people would more readily make inferences from indirect information about complex than simple products.

It is necessary, in order to test this proposition, to distinguish between products in terms of their complexity. Cognitive complexity has been measured in a number of different ways (c.f., Vannoy, 1965). One of the most frequently employed techniques has been Kelly's Role Construct Repertory Test (Rep Test). People are asked to provide the ways in which known stimuli (i.e., parent, teacher, child) are similar to and different from one another. People who provide many differences in response to this task are considered more cognitively complex regarding this stimulus domain than those who provide only few differences. Bieri, et. al. (1966) modified the Rep Test by providing bi-polar adjective scales rather than having the subject employ his own construct dimensions. Their results with the modified test have been consistently positively correlated with the results obtained from Kelly's original instrument. This modified Rep Test will be employed here to measure product complexity.

Product Related Cues

If we are interested in determining the effects of cues on product perception we must employ cues which do not, by their very presence, bring to mind previously formed, well-defined product perceptions. In studying cue utilization we are interested in determining the effects of cues on the formation of product perceptions. Use of these types of cues will permit us to explicate the nature of the process by which cues are combined to give meaning to the goods and services in the consumer's environment. Two cues which seem to meet these criteria are price and advertising. While the former has traditionally been employed in studies of product perception the latter cue is new.

Price

It has generally been found that, when price is the only cue, the subject perceives the higher priced product as being higher in quality (i.e., Tull, Boring and Gonsior, 1964; McConnell, 1968). When price is combined with other cues an interaction is frequently obtained (i.e., Andrews and Valenzi 1971; Jacoby, Olson and Haddock, 1971; Valenzi and Andrews, 1971).

Advertising

Nelson (1974) suggests that one of the most important pieces of information the consumer takes from advertising is merely the understanding that the brand is advertised. He contends, "the consumer believes that the more a brand advertises the more likely it is to be a better buy" (p 732). That is, he suggests consumers make inferences about a brand from knowledge of the magnitude of advertising support afforded that brand. The magnitude of advertising support given a product may be viewed, therefore, as a cue which permits inferences about that product without directly conveying product beliefs.

In the natural environment this belief that one brand is more heavily advertised than another is the result of exposure to many more advertisements for one brand than another. Nelson's contentions about the effects of this varied exposure could be subjected to experimental investigation by providing subjects in one condition with many advertisements for a brand while providing those of another condition with only a few or no advertisements. If actual advertisements were provided, however, the cue properties of advertising magnitude would be confounded with specific beliefs presented in the advertisement. One way to avoid this problem would be to give people

information about the magnitude of advertising support without actually showing them the advertisement. This is the procedure which will be followed here.

Theoretical Orientation

It has been maintained that product perceptions are formed by cue processing in accordance with a general inference process. Therefore, theories which account for the conditions under which and the extent to which people make inferences should be relevant to the prediction of product perception. Attribution theory is appropriate to this spectrum. While it has been used primarily to account for inferences made to other individuals, it is equally applicable to inanimate objects. That is, a person should employ the same process when making inferences about objects that he uses when attributing characteristics to other individuals. One of the most basic principles emerging from work in attribution theory is that attributions are directly related to the consistency of the meaning of cues associated with that object (c.f., Kelley, 1967). A stronger inference will be made when the attributional implications of the cues are consistent than when they are inconsistent. If high price is combined with high advertising support we would expect a stronger inference than if it is combined with low advertising or if only one cue is provided. We would expect then that a stronger, more extreme attribution will be made when cues are combined consistently than when they are combined inconsistently or when only one cue is provided.

Dependent Variables

If we view price and advertising as cues that people use to attach meaning to the products in their environment, it seems that dependent variables employed in the assessment of these products should give the consumer an opportunity to provide this meaning.

Osgood and his associates have found across a large group of studies, that the meaning of an object can be accounted for by the first three factors derived from a factor analysis of responses to a set of bi-polar adjective scales (i.e., Osgood, Suci and Tannenbaum, 1957). The object's position in a space comprised of these three dimensions is considered to be the object's meaning. The intensity of a person's position on a dimension is indexed by the distance of his position on that dimension from the midpoint. It is suggested, therefore, that the individual's position will be more extreme when cues are combined consistently than when they are combined inconsistently or when only one cue is provided.

Method

A pilot study was performed in order to select products differing significantly in complexity. This was followed by a laboratory experiment in which the implications of the previously suggested hypotheses were tested. In both studies the subjects were females recruited from civic organizations in the San Francisco Bay area. They volunteered in return for a donation made in their name to the civic organization or group from which they were recruited. The donations were \$1.50 each for those participating in the pilot study and \$3.00 per person for those taking part in the experiment.

Initial Study

Questionnaires were administered in a group setting to 61 subjects. Each subject received an instrument designed to measure cognitive complexity. Brands of black and white television, headache remedy, toothpaste and soft drink were used as stimuli. The brands of each product

class were placed on rows in a separate rating matrix. The columns of the matrices were occupied by bi-polar adjective pairs. The matrices provided the vehicle for measuring product complexity. They were developed in accordance with the procedure set out by Bieri, et. al. (1966). The order in which matrices were presented was randomized.

Experiment

Subjects arrived in the laboratory at the time of their pre-designated appointments in groups of up to eight people. After a general introduction by the experimenter, they proceeded to their cubicles. All treatments and questionnaires were administered individually on laboratory terminals while subjects were in these cubicles.

Subjects. One-hundred forty-four female volunteers participated in the experiment. Of this total, 118 subjects completed the task. The remainder failed to complete the experiment due to computer breakdowns and other malfunctions.

Independent Variables. Three levels of price (low, high and no-information control) were combined with three levels of advertising support (low, high and no-information control) and four products (black and white television, toothpaste, soft drink and headache remedy). Each subject evaluated each product under one of the price-by-advertising conditions. The order in which products were presented was counterbalanced.

Subjects were told that a new brand (in each of the given product classes) was about to be introduced to the local market. Variations in price and advertising support associated with this brand constituted the manipulations of the independent variables.

Price was manipulated by providing subjects with information about the suggested retail price of the new brand. Subjects in the high condition were presented with a price which was found to be higher than most brands in the given product class. Subjects in the low price condition were presented with a price which was found to be lower than that charged for most brands in the given product class. The control condition was given no price information.

In the low advertising condition it was stated that the brand will be "only lightly advertised." It was pointed out that advertisements will appear occasionally in local newspapers. In the high advertising condition it was pointed out that the brand will be "heavily advertised" and that it will appear frequently on "national network television" and in "national news and women's magazines". The control condition was given no information about advertising.

Product was manipulated by providing subjects with four different product classes. The products employed were chosen to represent both high and low complexity.

Dependent variables. After receiving a product description subjects were asked to evaluate the product on a set of 7-point bi-polar adjective scales. This was followed by a question which asked how likely they would be to buy the product if they were in the market for it. Finally, they were asked to provide their feelings about how high or low the product's price was and how lightly or heavily it was advertised.

This procedure was repeated three times (once for each remaining product). Subjects were then asked to respond to a series of post-experimental questions. These included a number of probes for demand characteristics.

After leaving their cubicles the subjects gathered in a

second waiting area. Their reactions were elicited. The purpose of the experiment was explained to them and any misperceptions were corrected. They were thanked for their participation and asked not to divulge anything about what went on during the experiment.

Results

Manipulation Checks

Complexity. The data from the pilot study were scored for cognitive complexity in accordance with the procedure developed by Bieri, et. al. (1966). Cognitive complexity is measured by comparing each rating in a row with the rating adjacent to it (i.e., for the same brand) in the other rows of the matrix. A score of one is given for every exact agreement of ratings on any one brand. This matching procedure is carried out in the same way for all possible pairwise comparisons in the matrix. The scores for each comparison are totaled to yield a final complexity score on the product class for each individual. Given an 8x13 matrix, the maximum, or simplest score obtainable would be $(13(13-1)/2)8$ or 624.

A cognitive complexity score was calculated in this manner for each subject and each product class. Orthogonal comparisons were made across products using multiple t-ratios. TV ($\bar{x}=140.3$), and soft drink ($\bar{x}=159.5$) were found to be significantly ($p < 0.001$) more complex than headache remedy ($\bar{x}=242.3$) and toothpaste ($\bar{x}=208.8$).

Advertising. After evaluating a given brand, subjects were asked how heavily advertised they believed the brand would be relative to other brands in the given product class. Responses were recorded on a 9-point equal appearing interval scale which varied from "Very Heavily Advertised" at the high end to "Very Lightly Advertised" at the low end. An analysis of variance was performed for each product class on the responses to this question. The manipulation of advertising was found to be significant ($p < 0.01$) in the expected direction for toothpaste, soft drink and headache remedy. It was found to approach significance ($p < 0.10$) for television.

Price. Subjects were asked how high in price they believed the test brand would be relative to other brands in the given product class. Responses were recorded on a 9-point equal appearing interval scale with the endpoints labeled "Very High" and "Very Low" respectively. Analysis of variance was performed for each product class on the results of this question. The manipulation was found to be significant ($p < 0.01$) in the expected direction for each of the four product classes.

Experiment

A principal components analysis was performed on a within-cell correlation matrix of bi-polar adjective scale scores. This adjusts the correlations to remove treatment effects. The components analysis was performed separately for each product class with varimax rotation of the first three components. Items loading more heavily than 0.500 on a given component were taken as representing that perceptual dimension. Items representing each of the first three factors for each product are shown with their loadings in Table 1. They represent the meaning or perception a la Osgood, Suci and Tannenbaum of each given product.

Individuals' scores on each factor were derived by summing their scores on items representing each factor. The items were scored +3 to -3, but, due to the fact that the earlier hypotheses concerned intensity or strength of perception, absolute values were summed to provide the dependent scores.

A separate 3x3 (advertising by price factorial multivar-

				Factor 2	1.269	.286
				Factor 3	5.191	.007
Television	Price	2.152	0.047	Factor 1	0.225	.799
				Factor 2	0.597	.553
				Factor 3	5.750	.004

¹Only significant effects are shown.

iate analysis of variance was performed for each product class. The dependent variables were individuals' scores on each of the three factors. A significant ($p < 0.01$) price main effect was obtained for television and for soft drink (see Table 2). No other significant main or interaction effects were obtained. Univariate analyses show that in both cases the price effect was due to factor 3. Multiple comparison tests (i.e., Tukey's Test, Kirk, 1968) indicated that the effects were due to the difference between the control and high price conditions. This can also be seen by referring to the table of means (Table 3).

Discussion

These preliminary results provide some support for the contention that cue utilization in product evaluation is directly related to product complexity. Price was related to product perception only for the two products found to be relatively complex. Further work is necessary, however, to substantiate this finding.

The results failed to support Nelson's contention that the amount of advertising provided a product is a cue to the product's value. The advertising manipulation check was found to be significant for three of the four products. Even though subjects differed significantly in their belief about how heavily the product was to be advertised, this difference did not affect their perception of the product.

The failure to find a significant cue effect for advertising prevented the testing of the hypothesis suggested earlier that the strength of the inference is directly related to the consistency in meaning of provided cues.

It would be desirable to employ a multi-method approach to the measurement of product complexity. The results provided by the Bieri, et. al. method could be compared with those obtained when other methods are employed. This could provide evidence to support the convergent

TABLE 3
Marginal Means For Significant Effects

Product	Price Treatment: Factor 3		
	Control Price	Low Price	High Price
Soft Drink	3.15	3.24	4.29
Television	2.23	2.85	3.33

validity of an instrument to measure product complexity. Vannoy (1965) found some evidence to support the convergent validity of instruments used to measure cognitive complexity. Work is in progress comparing results of the Bierl, et. al. approach with those obtained through factor analysis.

Further assessment of differences in cue utilization across product complexity levels would also be desirable. This could be accomplished by assessing the effects of cues on subjects' evaluations across a larger sample of products found to vary in terms of product complexity. If supportive results were obtained in these other studies it would make an alternative hypothesis that the results are due to product differences other than the typical complexity of its representation in cognitive structure less likely than it is from an assessment of only four products.

The failure to obtain stronger results in the study may be due, in part, to use of non-student women as subjects. These women, many of whom were older did not seem as comfortable and familiar as are students with the environment and tasks to which they were subjected. Most studies of price effects have employed students as subjects (Olson, 1976). It is likely, however, that different groups of people differ in their use of cues. It is also likely that complexity of a product's representation in cognitive structure differs by group. It is, therefore, important in this type of study to employ subjects representative of the target market for the chosen products. The women employed in this study seem to fit this criterion.

Olson (1976) has maintained that a theoretical orientation to future product perception research is necessary if we are to gain an understanding of cue utilization in product perception. It is believed here that attribution theory can contribute to this goal. Our consideration of the implications of cue consistency represents an initial basic hypothesis related to attribution theory. Many other hypotheses are also derivable from this work. In future research the theory could be adapted in a much more complete fashion. This could contribute greatly to our understanding of how, when and with what effect people employ cues in product evaluation.

Kelley (1967, 1973) employs four criteria in his treatment of attributional validity:

1. Distinctiveness: the impression is attributed to the thing if it uniquely occurs when the thing is present and does not occur in its absence.
2. Consistency over time: each time the thing is present, the individual's reaction must be the same or nearly so.
3. Consistency over modality: his reaction must be consistent even though his mode of interaction with the thing varies.
4. Consensus: attributes of external origin are experienced the same way by all observers. (Kelley, 1967, p 197).

Subjects in attribution studies are typically given a behavior sequence such as: John is the only person who laughs at the clown (i.e., McArthur, 1972). Subjects are then asked to attribute John's behavior to something about John (a person attribution), something about the clown (an entity attribution) or something about the situation (circumstance). When consensus (hardly anyone else laughs at the comedian) and distinctiveness (John also laughs at most other comedians) are low and consistency is high (John has almost always laughed at the comedian) an attribution will be made to the person. When consensus (almost everyone laughs at the comedian), distinctiveness (John does not laugh at almost any other

comedian) and consistency are high an attribution will be made to the entity (McArthur, 1972).

We may view an entity as a product (or brand). A product attribution will then be most likely when consensus, consistency and distinctiveness are high. Similarly we may expect the strongest product attribution when consensus, consistency and distinctiveness are high. If everybody buys brand B (high consensus); if John, for instance, does not buy any other brand (high distinctiveness); and if John always buys brand B (high consistency) then a strong attribution should be made to brand B. Presumably, the attributor would conclude that brand B is the best brand to buy.

We may adapt the theory even further by viewing consistency (in meaning) of cues related to the product as consistency over modality. That is, if every cue associated with the product provides a consistent implication then we have an instance of high consistency over modality. We may also wish to consider product class heterogeneity to represent distinctiveness. If high consistency and high distinctiveness are combined with high consensus we would expect a strong attribution to the product.

Further research would, of course, be necessary to substantiate these propositions. If people make inferences about products the way they do about other people then attribution theory should be relevant to the prediction of these inferences. Research directed at providing support for the propositions made here should contribute to a greater understanding of how and when people use cues in their evaluation of products. It should permit the marketer to do a better job of consciously and appropriately employing cues.

FAD FOOD USE AMONG ANGLO- AND MEXICAN-AMERICANS:
AN EXAMPLE OF RESEARCH IN CONSUMER BEHAVIOR AND HOME ECONOMICS

Joel Saegert, The University of Texas at San Antonio
Eleanor Young, The University of Texas Health Science Center at San Antonio
Merry Mayne Saegert (student), The University of Texas Health Science Center at San Antonio

Abstract

To home economists, consumption of fad foods is a behavior inconsistent with nutrition research data. The dynamics of belief in food fad benefits have not been satisfactorily explained by demographic or psychographic studies. The present study compared fad food use in two American ethnic groups. Suggestions for interdisciplinary cooperation in the study of food faddism are discussed.

Introduction

Both the American public and their public service representatives are becoming increasingly interested in the nutritional consequences of the products they consume. While such an increase in nutrition interest is a long-sought goal of home economists, some of the nutritional concern has manifested itself in the form of what nutritionists refer to as "fad foods." These products are considered to be a serious problem by many authors in the nutrition area (e.g., Bruch, 1974). Thus, the problem of fad food consumption seems to be an obvious area for cooperation between researchers in consumer behavior and home economics.

The nutrition research community has long refuted claims made by fad food advocates, either by showing that such claims have not been confirmed empirically (e.g., Anderson and Reid, 1974) or by pointing to research that shows that some fad foods can actually be harmful (e.g., Herbert, 1974). From the standpoint of nutrition education, the problem has been that fad food beliefs are held with what appears to be a very high degree of intensity (by certain segments of the population) and also that such attitudes do not seem to be susceptible to conventional educational attempts at combating ignorance and misinformation.

In the area of product attitude formation, consumer researchers have amassed a sizable literature on the multitude of variables postulated to be related to consumer purchase decision-making processes. It seems reasonable therefore to consider the problem of fad food consumption in the light of the theory and methodology which have been developed to study the formation of attitudes about general consumer behavior.

The Problem of Food Faddism

Fad foods, to the nutritionist, include a wide range of products and techniques which are offered to the public through various marketing activities. Some of these include "organic," "natural" or "health" foods, megadoses of vitamin and/or mineral supplements, quick weight loss diets, and more exotic items such as hair restoratives and sexual potency enhancers. In nearly all cases, such products are viewed by the nutrition research community as being harmful or as having little or no value, other than placebo effects, to consumers; these views are based on a broad foundation of scientific research and are supported by Federal agencies such as the Department of Agriculture and the Food and Drug Administration (e.g., Fusillo, 1974).

Numerous speculations have been offered to explain the consumption of fad food products in spite of lack of empirical verification of their value. Early hypotheses suggested that the fads were mainly used as "last resorts" by people who were desperately ill or aging and who had not responded to conventional medical treatment (Bruch, 1974; Jalso, Burns and Rivers, 1965). Recently however, researchers have argued that the demographic and psychological characteristics of fad food users "hardly confirm a stereotype of the rigid, stubborn and irrational 'health food nut'" (Calvert and Calvert, 1975). Typically, food faddists have described themselves as young, at least high school educated and in good or excellent health (Rhee and Stubbs, 1976). At least two studies have indicated that faddists cannot be classified as having bizarre or dogmatic personality characteristics (Calvert and Calvert, 1975; Saegert and Saegert, 1976). Thus, to both nutrition and consumer behavior scholars alike, the apparent paradox of an irrational purchase behavior being maintained by people with normal, middle-American background characteristics presents a challenging enigma for study.

An Example of Consumer Behavior/Home Economics Cooperation in Fad Food Research

One possible hypothesis concerning fad food use is that it is in some way associated with a middle-American value system which embraces such beliefs as the need for preventive maintenance and the utility of technological innovation to solve potential problems such as aging or future illness. If so, fad food use can be predicted not to be as prominent in cultural groups which stereotypically do not identify strongly with American middle-class values. For example, it is possible that Mexican-Americans may not subscribe to fad food beliefs in the same degree as Anglo-Americans of equal education and socioeconomic level.

Rhee and Stubbs (1976), in a study of 600 heads of households in two Texas cities found that Mexican-Americans did not differ from Euro-Americans in their use of fad foods. However, the random telephone sample used in their study contained only 3% (N=18) Mexican-Americans. To further study the hypothesis that Mexican-Americans do not use fad foods as frequently as Anglo-Americans, a larger sample was studied in another large southwestern metropolis which has a large (53%) Mexican-American population.

Method

Sample

Approximately equal numbers of Mexican- and Anglo-American shoppers were surveyed at a large shopping mall complex. The mall was chosen on the basis of its location near sizable middle socio-economic level neighborhoods of both ethnic groups. In all, 400 shoppers were interviewed; ethnic origin was determined by the interviewers as each questionnaire was administered.

Sampling was done on two weekends in the spring of 1977. Half of the interviewers were members of an undergraduate class in marketing research and half were members of an undergraduate home economics class in nutrition. A total of 16 interviewers participated.

Questionnaire

Shoppers were asked to fill out a questionnaire which contained items concerning several areas; among these were questions about fad product usage, general nutrition practices and demographic classification variables. Six items on the questionnaire were intended to provide information about usage of example products and purchasing practices which are typically associated with food faddism (Bruch, 1974): vitamins C, E, and B complex, "organic" foods, foods purchased at "health" food stores and "other" food supplements (examples were given as lecithin, minerals, etc.).

Earlier studies (e.g., Food and Drug Administration, 1972) have indicated that fad food habits are generally practiced without medical consultation. In the present survey, several items were included to insure that the food behaviors indicated by the respondents were not intended to correct diagnosed metabolic disorders. (Most of the interviewees, 72%, said that their use of the various products had not been prescribed by a physician.) It was also clearly stated on the questionnaire that vitamin usage should include only those products taken over and above "multi-vitamins."

The shoppers were approached in a systematic random manner (every "Nth" person to pass a specified point was approached). Approximately 10% of both ethnic groups declined to be interviewed. Usage rates of the six example fad foods and practices were measured by a four-level classification; the levels were "no use," "occasional use," "weekly use," and "daily use."

Results

The percentage of respondents in each response category for the two ethnic groups is presented in Table 1. As can be seen, significant differences ($p < .05$) were found for use of vitamins C and E; the difference in use of B vitamins approached significance ($p = .08$). In all three cases, the direction of the differences was as predicted; i.e., product use was less frequently reported by Mexican-Americans. Significant differences were not observed for use of organic foods, health food stores, or other food supplements.

Thus, slight differences in usage rates were observed for three of six example fad food practices considered in our survey. However, we also observed that there were some small but significant differences between the two ethnic groups on demographic variables, especially age, income and education level. These differences were such that the Anglo sample reported themselves slightly older, more educated and of higher income level (all p 's $< .02$ by Chi square test). In order to control for these differences, we felt that it would be useful to combine the product usage rates for the six fad items to provide a single overall index of food faddism. This score could then be subjected to an analysis of covariance which would compare ethnic groups using income, education level, and age as covariates.

Because of the low frequency of the "weekly use" response alternative, this category was combined with the "occasional use" category to yield a three-point scale. "No use" was assigned a value of zero, "occasional or weekly use" was assigned a value of one and "daily use" was assigned a value of two. The six scores for each respondent were summed to provide a scale which varied from zero (no use of any fad items) to twelve (daily use of all six products or practices). A slight difference in mean total food faddism score between ethnic

TABLE 1

Incidence of Fad Food Practices in Two Ethnic Groups

		No use	Percentage Responding			χ^2 (df=3)	p
			Occa- sional use	Weekly use	Daily use		
Vitamin C	Anglo-Americans	59	19	2	20	8.63	.03
	Mexican-Americans	60	26	3	10		
Vitamin E	Anglo-Americans	75	12	1	13	8.34	.04
	Mexican-Americans	76	12	4	8		
B Complex	Anglo-Americans	68	16	2	15	6.77	.08
	Mexican-Americans	76	12	4	8		
Other Food supplements	Anglo-Americans	82	10	2	7	5.31	.15
	Mexican-Americans	82	10	5	3		
Organic foods	Anglo-Americans	58	33	4	6	3.24	.36
	Mexican-Americans	50	37	7	8		
Health food stores	Anglo-Americans	74	22	2	2	5.44	.14
	Mexican-Americans	76	15	4	4		

groups (Anglo-American $\bar{X}=2.51$; Mexican-American $\bar{X}=2.38$) was found to be non-significant in the analysis of covariance ($F<1.0$). Thus, it must be concluded that overall fad food usage, as reported by the respondents in our survey, was equivalent for the two ethnic groups, even though a few differences were noted on three specific vitamins (before age, income and education were adjusted). It is not known whether this indicates that the two groups were equivalent in subscribing to middle-American values or that there is simply no relationship between "value system" and fad food practices (as hypothesized above).

Discussion

The present survey data fail to provide evidence of a difference in fad food use among two American ethnic groups. This demonstration of the null hypothesis is not startling when considered along with other research in the fad food area. Relatively few empirical comparisons have been made between fad food users and non-users, but those which are available have failed to isolate specific reasons for subscription to fad food beliefs. Moreover, there is no reason to suspect that fad food users are other than healthy, youthful, affluent, educated, normal Americans; the present study merely adds ethnic origin to the list of factors which cannot be used to explain the phenomenon of fad food use.

Such results are also not surprising to students of consumer behavior. Although it is intuitively obvious that demographic and/or psychographic variables are related to purchase behaviors and product attitudes, the consumer behavior literature is notoriously full of reports of failures to pinpoint simple relationships (e.g. Frank, Massey and Lodahl, 1969).

Rather than dismiss the, as yet, unfathomable phenomenon of fad food use by the American public as insuperable, the area can serve as an example of the need for combined effort through inter-disciplinary cooperation. The following suggestions are some areas in which such interdisciplinary efforts may be useful.

Increased use of Empirical Research and Statistical Analysis

While the literature in home economics and nutrition has provided a wealth of theoretical speculations on the dynamics of fad food use (Bruch, 1974; McBean and Speckman, 1974; Schafer and Yetley, 1975), relatively few empirical studies have been undertaken. Also, some of those which have been conducted have not taken advantage of analytical techniques which might tease out explanatory relationships. For example, an important study by Calvert and Calvert (1975) used a standardized measure of the socio-psychological variable of dogmatism to investigate the degree to which fad food users were characterized by irrational belief systems. Unfortunately, the study did not compare food faddists to a control group of non-fad food users nor were the percentages of users holding rational vs. dogmatic beliefs in various categories tested for statistical significance. This study would have been substantially more useful if more rigorous procedures of research design and analysis had been used.

Increased use of Modern Multivariate Analytical Techniques

Marketing theorists have often pondered the relatively low correlations found between personality traits (as measured by standardized tests) and usage of specific products. The answer must lie in the fact that such relationships are too complex to be found through

simple one-to-one correlational techniques. In what is now a classic study on personality and product use, Sparks and Tucker (1971) used canonical analysis, a technique which considers complex relationships between sets of dependent variables and sets of independent variables. They found that relationships of relatively high magnitude emerged when patterns of personality traits were compared with patterns of product usage behavior. For example, the trait "sociability" was correlated with one set of products in one personality trait milieu, but was correlated with an entirely different set of products in the context of a different milieu.

Such complex relationships obviously exist in the case of fad food usage. The employment of such multivariate techniques as canonical analysis, factor analysis, discriminant analysis and multidimensional scaling should reveal underlying relationships which can be used to understand food faddism.

Increased use of Consumer Information Processing Models

Recent theory in the area of consumer behavior has seen the development of cognitive information-processing models to try to integrate the complex network of factors which must underlie consumer decision-making. Such models have taken diverse forms; some examples include Howard's recent assessment of consumer behavior from the standpoint of cognitive psychology theory (1977), Bettman's decision-net model (1974) and Kuehn's linear learning model of brand choice (1962). Variables often included in such models are attention and memory, advertising media influence, susceptibility to novel ideas, psychographic factors, and economic market conditions.

Fad food behavior can provide interesting data for consideration in such models. For example, advertising processes for fad food products seem to be different from those of other products. Since the benefits claimed for fad products are not substantiated by empirical evidence, touting such benefits in advertisements is precluded by false advertising laws. Therefore, promotions in ads for fad foods only provide notice of their availability and price, rather than of their proposed benefits or advantages. Claims of powers for such products often appear in articles in health food periodicals but it is left to the consumer to make the connections between the benefits advocated in the articles and the advertisements for the products. Understanding how such processes fit into models of advertising effectiveness would make an interesting contribution to both the consumer behavior and nutrition education areas.

Conclusion

It is suggested that the phenomenon of fad food use is merely an example of a much broader problem in American society. This problem is one in which the "establishment" sources of information, i.e., scientific researchers, government agencies and the food industry, maintain one position with respect to available evidence, while a sizable group of consumers have chosen to ignore or deny that view. Such behavior is observed in beliefs ranging from the benefits of Laetrile, the safety of food preservatives, and the benefits of acupuncture to such entertaining but widely discussed beliefs as unidentified flying objects, pyramid power and the Bermuda Triangle. The issue involves the overall relationship between consumer attitude-formation and traditional, research-based information. Cooperation among researchers in the fields of home economics and consumer behavior can provide insight into the mechanisms behind such conflict between data and belief. However, we should obviously not expect substantial

breakthroughs in understanding this problem without a great deal of concerted collaboration among researchers in consumer behavior, home economics and a host of other disciplines.

THE PROBLEMS, PITFALLS, AND OPPORTUNITIES IN INTERDISCIPLINARY APPLIED CONSUMER RESEARCH

Joseph Barry Mason, The University of Alabama
Helen Goetz, The University of Alabama

Abstract

This paper explores the problems and opportunities inherent in the pursuit of interdisciplinary research and outlines various strategies for encouraging faculty involvement in such activities.

Introduction

The problems of interdisciplinary research are discussed infrequently in the published literature and few empirical studies have been published on the topic. Thus, few role models exist. One exception is the work being pursued at the University of Washington under a National Science Foundation grant as part of the Research Management Improvement Program (e.g., Birnbaum, 1975; Gillespie, 1976; Mason, 1975).

Further, the concept and practice of interdisciplinary research is fraught with myths and misconceptions. Also, few persons have invested the time and energy necessary to establish truly interdisciplinary research activities. Disagreement even exists on the meaning of the term "interdisciplinary." The terms interdisciplinary, multi-disciplinary, and transdisciplinary are often used interchangeably by colleagues discussing the subject. For the sake of clarity the following definitions are presented.

- Discipline..... A specific body of teachable knowledge with its own background of education, training, procedures, methods, and content areas.
- Multidisciplinary.. Juxtaposition of various disciplines, sometimes with no apparent connection between them. e.g.: music + mathematics + history.
- Pluridisciplinary.. Juxtaposition of disciplines assumed to be more or less related. e.g.: mathematics + physics, or French + Latin + Greek: "classical humanities" in France.
- Interdisciplinary.. An adjective describing the interaction among two or more different disciplines. This interaction may range from simple communication of ideas to the mutual integration of organising concepts, methodology, procedures, epistemology, terminology, data and organisation of research and education in a fairly large field. An interdisciplinary group consists of persons trained in different fields of knowledge (disciplines) with different concepts, methods, and data and terms organised into a common effort on a common problem with continuous intercommunication among the participants from the different disciplines.
- Transdisciplinary.. Establishing a common system of axioms for a set of disciplines, e.g., anthropology considered as "the science of man and his accomplishments." (Centre for Educational Research and Innovation,

1972, pp. 25, 26).

Most persons probably agree that the major problems of contemporary society are increasingly interdisciplinary in nature, but neither interdisciplinary research nor education are simple processes, especially given the discipline-oriented university and the mission oriented society of today. Ideally, interdisciplinary research efforts involve pooling the talents of several faculty members from various disciplines who integrate their knowledge in conducting research on a problem that individual researchers working alone could not effectively resolve. Too often, however, multi-disciplinary research is the end product, not interdisciplinary research. As noted, "multi-disciplinary research... can be performed by experts with interdisciplinary backgrounds, but who work separately, not necessarily in the same environment or within a mutual confrontation, exploring different aspects of a central problem. Results of multi-disciplinary research may be integrated by one of the researchers or by someone else (Nilles, 1976, p. 80; also, Segner, 1973).

The lack of ready acceptance of interdisciplinary research efforts is at least partially due to the nature of the university. Disciplinary structures are the basis of the university and of the professions engaged in teaching and research. The arrangement provides a convenient breakdown of knowledge into readily identifiable parts. However, disciplines as we know them today do not represent a preordained order of knowledge. The dynamics of social phenomena forces interchange between disciplines and even creates new disciplines. "The inter-discipline of today is the 'discipline' of tomorrow" (Centre for Educational Research and Innovation, 1972, p. 9).

Unfortunately, most persons experienced in interdisciplinary research agree with the statement that "a principle feature of interdisciplinary research is not necessarily profound scientific development, but an improvement in human relations to overcome the intolerance, bigotry, and barriers not only among individuals, but within and among disciplines" (Mar, 1976, p. 65; also, Sherif and Sherif, 1969; Piaget, 1970).

The discussion that follows reflects our joint experience in interdisciplinary research, graduate and undergraduate teaching, development of interdisciplinary curricula, and the direction of interdisciplinary masters theses and doctoral dissertations. The thoughts presented also reflect the experiences of colleagues at other institutions with whom we have discussed this area.

Potential Problems in Interdisciplinary Research

Colleague support of interdisciplinary research activities. The quality and worth of much interdisciplinary research is suspect in the eyes of many colleagues. This often occurs because of the blending of concepts from two or more disciplines in an interdisciplinary research activity, but typically not the use of frontier concepts from either discipline. Thus, the research activity is likely to reflect breadth of knowledge, perhaps more than depth of knowledge. Faculty members are trained in doctoral programs and selected for faculty appointments on the basis of their knowledge

of and research skills appropriate to a particular discipline, not because of interdisciplinary skills. Thus, suspicion of the unknown is to be expected.

We have clearly seen the suspicion with which interdisciplinary research is viewed by various professional associations. For example, a session focusing on consumer education at the secondary school level was recently proposed to the program committee of a major national consumer association with an avowed interdisciplinary thrust. The proposed session, including three empirically based papers, was not accepted because the program committee felt that the topic was not appropriate for sponsorship by the organization. Likewise, when two of our marketing colleagues presented a paper at the American Council for Consumer Interests meeting a few years ago and approached the problem from a marketing perspective--development of marketing strategies for reaching consumers--instead of from the home economics perspective--consumer welfare--criticisms of the paper and the approach were both intense and vocal. Much progress in the recognition of the value of interdisciplinary research remains to be accomplished.

Recognition and support by administrators. Faculty members who pursue research activities outside their own primary area of expertise face the possibility that this will be viewed as contrary to the goals of their college and to the goals of the individual faculty member, defined as achieving excellence in a particular discipline. For example, we know of a young home economics colleague who, with the support of the department chairman, began to pursue interdisciplinary research with young faculty members in the marketing department of a college of business. The chairman of the marketing department also supported this effort. The result yielded several quality articles which were published in such journals as the Journal of Social Psychology. However, the Dean of the College of Home Economics indicated to the young faculty member that this activity was largely a waste of time as it did not contribute to the visibility of the College of Home Economics or contribute to the conceptual and technical skills of the individual in terms of solving problems unique to home economics. As part of the process of chastisement, support to the individual in the form of research monies and computer time were lessened. Also, it was made clear the research accomplishments in no way contributed to progress toward promotion and tenure.

Finally, one further example illustrates the point. One of the authors recently collaborated with a young faculty member in writing an article from the young person's doctoral dissertation. The logical publication outlet for the article appeared to be the new British journal, the Journal of Consumer Studies and Home Economics. However, the young faculty member indicated that he preferred not to have the article published in this journal because the publication would be viewed by his colleagues and his dean as a relatively insignificant contribution which would not be acceptable by a marketing journal. These narrow viewpoints and outright prejudices against interdisciplinary research can be very disheartening.

In summary, interdisciplinary research in a university setting often faces major human relations problems and requires a continuing education of other faculty members and administrators on the value of such activity. In the absence of support by peers and administrators, the path is particularly fraught with difficulties for a young faculty member in a promotion and tenure track. However, the benefits to the individual and society can be tremendous, and these comments are not designed to frighten people away from interdisciplinary research efforts but simply are offered to point out some of the pragmatic realities which often exist today.

Ways of Generating Interdisciplinary Research

The following discussion reflects on the various activities in which we have engaged over the past ten years and which have been useful in developing and encouraging an interdisciplinary research environment in our departments. The various approaches are relatively easy to implement and can yield significant benefits.

Strive for better communication. Communication is probably the fundamental problem in interdisciplinary research. The persons involved must understand the different viewpoints focusing upon a central research problem. Without this appreciation, which requires a high level of tolerance and patience, good interdisciplinary research simply cannot occur. Establishing adequate communication is a time consuming process even under the best of circumstances and may well take several years. Otherwise, what happens is a multi-disciplinary effort.

Each discipline has its own sophisticated jargon which can only be understood over time. To many people, this process of establishing constructive communication may seem scientifically unproductive. We have observed that persons who are strongly committed to a narrow academic specialization have difficulty in participating in interdisciplinary research for this very reason.

Further, it is necessary to recognize that disciplines often have intolerance for other disciplines. Representatives of each discipline are likely to claim superiority or intellectual distinction over the others. For example, we probably all have heard a colleague ask the question, "What can a home economist possibly tell me about consumer behavior?" or "Those faculty members in marketing are simply interested in finding ways to help businesses exploit the consumer; they have no interest in consumer welfare."

How, then, can communication be encouraged? The following possibilities seem to work fairly well.

Cross-listed courses. One of our major breakthroughs occurred when Professor Joseph Uhl, an agricultural economist at Purdue University, taught a graduate consumer behavior course at the University of Alabama which was cross-listed between home economics and marketing. Students from both disciplines enrolled in the course. The resulting dialogue was lively and instructive. At least one doctoral dissertation emerged as a result of the discussions in the course, and a heightened awareness of and interest in interdisciplinary problems emerged on the part of both students and faculty members.

Interdisciplinary curricula. In 1970, the consumer sciences curriculum in the College of Home Economics was revised at both the graduate and undergraduate levels to require or encourage consumer science students to take courses outside the College of Home Economics. Even though our joint interests in interdisciplinary activities extend back to 1968, the curriculum revision which occurred accelerated the interest and placed several graduate and undergraduate home economics students in the marketing curricula on a regular basis.

Colloquia. Several seminars for graduate students and faculty have been conducted in recent years in which research ideas and research findings have been presented. Also, focuses on common methodological concerns have been a part of these discussions. Lastly, areas of common consumer research interests are likely to emerge.

Joint appointments. Joint appointments, if more than simply an arrangement on paper, can be especially useful in encouraging an appreciation of the values of interdisciplinary research. Such arrangements allow

badly needed dialogue at faculty meetings, give a measure of credibility to the activities of the faculty member which would otherwise be lacking, and encourage broadened dialogue with graduate students and faculty members who share joint interests in a given area of research.

Masters theses and doctoral dissertations. Two interdisciplinary doctoral dissertations have been completed under our joint direction. The focus of one was on evaluating the effectiveness of consumer education at the secondary school level, and the second dealt with consumer cognized distance and the factors which affect distance perception. Five or six masters theses on diverse aspects of consumer behavior have also been completed under our supervision in recent years.

Students and faculty members have to be selected carefully for participation in this process. For example, students must be capable of tolerating a higher level of ambiguity than is normal because of the complexities of working with faculty members from more than one discipline. Also, we have found that the senior faculty members involved have to be constantly on the alert so that the student is not "used" by a faculty member from one of the disciplines in generating research which is primarily disciplinary in nature, but which is conducted under the guise of interdisciplinary research. Intellectual snobbery often occurs when a young faculty member makes disparaging remarks about the other discipline involved.

Interdisciplinary doctoral programs. We have been successful in structuring one doctoral level curriculum and one masters program in the last few years which have been truly interdisciplinary. These were housed in the Graduate School of the University to avoid the problem of departmental barriers. These vehicles are useful in allowing students to select courses from a wide array of disciplines such as marketing, economics, consumer sciences, psychology, geography, sociology, and other areas which are appropriate to a particular area of study. The result is a stronger conceptual and methodological base for conducting research.

Interdisciplinary research committees. The two of us have made a continuing effort to serve on committees which are evaluating possible areas for interdisciplinary research. These have included activities related to the Center for the Aging, Center for the Study of Drug and Alcoholism Abuse, the New College of the University, the Health Care Management Advisory Committee and similar programs or institutes. These arrangements provide a unique opportunity for advocating quality interdisciplinary efforts.

Advantages of Interdisciplinary Research

Development of a broader philosophy. Inevitably, interdisciplinary research activities will lead to a greater understanding and appreciation of the philosophies underlying the respective disciplines of marketing and consumer science. The horizons of the participants are expanded. Problems are more readily viewed from a variety of different perspectives and a greater tolerance for diverse viewpoints occurs. Also, entirely new dimensions of rather conventional research problems emerge. As recently noted, for example, marketers often treat the "consumer not as the subject, but as an object to be affected in order to realize their behavior goals" (Arndt, 1977, p. 13). Interdisciplinary research helps overcome this bias.

Language barriers are overcome. As a result of interdisciplinary efforts, faculty members will benefit by becoming able to read a greater variety of journals.

Language barriers are resolved and levels of heightened intellectual awareness and appreciation occur.

Development of new conceptual frameworks. The value of differing conceptual frameworks for focusing on a given problem is quickly realized. Alternative assumptions and viewpoints emerge which make one more sensitive to the nuances of language and of the need for developing shared meanings to permit linking of insights into the disciplines involved. An interdisciplinary focus also fosters the convergence of the two disciplines in developing more comprehensive consumer interest and public policy perspectives and helps conceptualize public policy on matters of broad social concern.

Current Research Activities

This paper is not primarily designed to report on our ongoing research. However, a brief discussion of how the research originated and its focus will help to reveal some of the everyday realities of interdisciplinary research. The focus of our current research effort is the senior citizen and the marketplace. Funding was provided by the Center for Aging on the University of Alabama campus. It quickly became apparent to us that an interdisciplinary focus on senior citizens shopping behavior was badly needed. Thus, the specific areas of focus of the research include the shopping behavior of the senior citizen, information seeking activities, food consumption patterns, and satisfaction and dissatisfaction with various products or services and complaint behavior, nutritional adequacy of diets, and the adequacy of physical facilities within the senior citizen household.

Logical Areas for Interdisciplinary Research

Numerous opportunities exist for meaningful interdisciplinary research between the Colleges of Business and Colleges of Home Economics. A few areas quickly come to mind and include various dimensions of public policy, metrication, consumer education, quality of life, the handicapped, use of leisure time, improving consumer competence, and family resource use. For example, a recent conference at the University of Nevada identified the following areas of research in the generally defined area of "improving consumer competence in family resource use":

- A. Comparison shopping studies for both goods and services.
- B. Family expenditure for food, clothing, shelter, services.
- C. Assessment of non-food items charged to the food budget.
- D. Comparison of convenience foods and/or prepared foods with those made at home.
- E. Evaluation of information available to consumers in relation to potential purchases.
- F. Comparison of costs in different retail outlets.
- G. Assessment of knowledge regarding consumer credit.
- H. Attitudes and values of different groups about money and financial management.
- I. Knowledge of credit costs and available information about credit.

Summary

Truly, the opportunities for and the values of interdisciplinary research are many. However, persons contemplating such activities should be fully aware of the potential pitfalls and frustrations and the large amount of time necessary to establish communication links which are necessary for an atmosphere of mutual trust and support. Finally, one needs to be prepared to answer questions about the relevance and quality of the research from persons in both disciplines.

However, the potential problems are well worth the benefit, particularly for persons who are well established in their respective disciplines and who can afford to pursue interdisciplinary research even in the face of some uncertainties and risk. As noted, "working outside the conventional structure is costly in time, energy and general strain. Its only conceivable justification is that it opens up educational territories that could otherwise remain unexplored" (Southern Regional Education Board, 1972, p. 6).

Really, an interdisciplinary focus is a mental outlook and a desire for self fulfillment through different approaches to problems. It necessitates openmindedness and requires continuing practice and flexible mental patterns. Properly approached, it can be a new stage in the development of scientific knowledge as is reflected in the papers presented in the recently released Association for Consumer Research publication entitled The Broadened Concept of Consumer Behavior (Zaltman and Sternthal, 1975).

Strong support and recognition of the value of interdisciplinary research, such as shown by the development of this forum, also is a vital and necessary force for effectively overcoming disciplinary barriers and rigidities. Clearly, peer recognition at the national level of the value of such activities is a fundamental requisite, given the realities of promotion and tenure guidelines in most major universities today.

SOURCE SIMILARITY AND FASHION NEWNESS
AS DETERMINANTS OF CONSUMER INNOVATION

Karen Kaigler-Evans, The University of Texas at Austin
Clark Leavitt, The Ohio State University
Lois Dickey, The Ohio State University

Abstract

Using a 4 x 4 x 4 fractional replication, the research combined 4 different fashion ideas, in each of 4 levels of newness, and four pictured sources rated from highly similar to dissimilar to the population from which the 48 subjects in the experiment were chosen. For each subject one idea from each newness level was attributed to each source immediately before the subject rated her agreement with the idea. The main effects of both source similarity and fashion newness were significant as hypothesized.

Introduction

The diffusion of innovations and the adoption or non-adoption of new products and ideas is an area that has been cultivated by several disciplines including home economics, rural sociology and marketing. The related topic of social influence has occupied the attention of sociologists particularly. Most of the research studies in these areas have been field studies that have structure variables that underly diffusion such as social strata and homogeneity of membership groups or the role of key individuals in relaying information and influence: innovators and opinion leaders, for example.

At the same time social psychologists also have been interested in the adoption of new ideas under the guise of attitude change and persuasion. However, the research paradigm, unlike that of home economics, has included the laboratory rather than a field setting and has been concerned largely with the individual processes underlying the adoption of new attitudes and beliefs. Social psychologists, together with students of mass communication, have been interested in the role of mass media in social influence and have dealt in this context with two general classes of independent variables, those related to the source and to the message.

There has been remarkably little cross-fertilization between these two research traditions of innovation and attitude change. The home economists' concern with innovation or education is essentially an application problem in need of conceptual enrichment while attitude change research has been characterized by a great deal of theory, but is unseasoned by serious attempts at application. The research reported here is an attempt to combine elements of both traditions. It uses the laboratory paradigm of attitude change research while attempting to enrich the independent variables in a way most appropriate to the research tradition familiar to the home economist, particularly that of social influence and fashion adoption. Primarily we have attempted to meld variables from both disciplines and have taken over only the necessary minimum of conceptualization from either field. Before describing the experiment, we shall review the ideas from each field that might interact profitably with those from the other.

Social Influence and Fashion Adoption

Three kinds of studies may be mentioned briefly: the psychological significance of clothing and fashion; population trait distribution related to innovators and opinion leaders, and the relation of social structure

to adoption behavior. Each provides evidence for the relevance of the variables used in this research.

Studies in the literature of home economics deal with the function of clothing as both a cue used by others to make social judgments and as a means of expressing the wearers own internal needs or values (Gibbons, 1969; Compton, 1962; Douty, 1963; Rosencranz, 1962; Connor, et al., 1975). This research is only indirectly relevant here: it makes clear that clothing is rich in personal meaning and that it can also be ambiguous as to what it can mean for the self.

There has been a sizeable body of research on social influence both in relation to fashion and to other products and ideas. Informal influences or word-of-mouth activities have long been of interest to social scientists. The two-step flow of influence proposed by Lazarsfeld and Merton, (1954), is a classical attempt to explain the lack of an immediate, obvious effect of mass media by invoking informal networks as leveraging agents. Most of this research has attempted to identify the kind of people who are influential in adoption and who adopt early in the life cycle of an innovation. In particular, King, (1963), has used such research to challenge the traditional concept of fashion as a vehicle for status differentiation that "trickles down" from higher to lower strata. Instead he emphasized the importance of peers or similar others as sources of fashion information (see Grindering, 1967).

More recently a different set of constructs has been invoked to examine the spread of ideas in informal communication. These are variables applied to communication networks, in particular the interconnectedness and the homogeneity of an individual's network. A person's network of social contacts can vary from homogeneous interconnectedness to a state of more heterogeneous, looser connections. At some point between these two extremes, conditions are right for maximum influence.

Any particular person is more likely to be exposed to new ideas when interacting with a person who is different, but at some point the difference will become so great that communication will break down or fall off. The balance point of greatest effectiveness between these competing tendencies has been called the point of optimal heterophily, a term originally introduced by Merton, (1957) and made current by Rogers, (1976). Similar concepts underlie other field studies. Laumann, (1973), found that men in interlocking networks were less open-minded with respect to non-conformity than those in radial networks. Interlocking networks are more homogeneous in respect to religious and occupational status while the radial networks represent weaker ties and greater heterogeneity. The idea that we learn more or are similar to us has been the subject of other field studies. Granovetter, (1973), and Liu and Duff, (1972), have attempted to demonstrate what they called the "strength of weak ties" for the diffusion of innovations. People are more likely to accept suggestions from others with whom they have only weak ties.

Studies of Source and Message in Attitude Change

Much of the research mentioned above has been concerned with specific products or fashions. Most studies also

are concerned with the characteristics of the person who influences others. These two variables are paralleled by message and source determinants in persuasion studies. We shall not review message research here except to point out that innovations and fashions are characterized by newness which is a frequently used variable in psychology, both in terms of familiarity and novelty seeking. It is often regarded as an underlying determinant of cognitive arousal.

Source variables have been approached in two ways that are relevant here. First, basic perceptual dimensions of the source of communication have been studied as interpersonal perceptions. Typically three dimension appear: expertise or competence, trustworthiness or safety, and attraction or dynamism (Giffin, 1967). (A similar approach has been used with message variables in which case novel and useful seem to emerge as basic dimensions.)

The second source variable of relevance here is similarity of the source to the receiver. Two contrasting interpretations have been made regarding the role of similarity. Byrne and others have demonstrated a relation between similarity and attraction which lends credibility to the "myth of super-representativeness" (Simons, 1973). This refers to the popularly held notion that influential speakers are seen as being similar to the audience -- "one of us." Clearly, however, an expert source would not be similar to the receiver -- the more expert, the less similar. Alpert and Anderson, (1973), found a curvilinear relation between similarity and influence -- not surprising in light of these considerations.

Whichever the direction of relation in any particular case, the variables of similarity of source and of newness of the idea are highly relevant to the problem of describing the underlying dynamics of consumer innovation. This is especially the case in view of the recent trend toward examining social influence and communication in terms of peer groups and homogeneous networks. The experimental procedure followed here not only used these variables but attempted to operationalize them in as representative a manner as possible in a laboratory setting.

In an experiment done to find the point of "optimum heterophily," Alpert and Anderson, (1973) used 3 students as presumed sources of statements about air travel. They were presented in photographs and varied from normal appearing to deviant and were shown to student subjects drawn from the same population (business administration). The pictured source that was most influential (evoked most agreement with statements attributed to him) was the one that was intermediate in magnitude of similarity to the subjects as measured by profile similarity on a series of rated personal traits.

The present study extends these findings to fashion suggestions and also varies the degree of newness of the suggestions. More important, it defines similarity in a more general way using self/similarity ratings of a group of independent judges to preset the source values. To the extent that this method is judged to be successful the results raise the question of whether similarity to the self is the critical variable or whether it is an artifact of group representativeness stemming from group similarity ratings.

We hypothesize that the relation between source similarity and influence or agreement with suggestions made by the source will be curvilinear with middle level sources being most influential (the so-called inverted U curve) as would be predicted by the notion of optimum heterophily.

Method

While the experiment to be reported here was straightforward, several auxiliary studies were done beforehand to prepare the experimental materials and some additional measures were gathered on the subjects themselves in a later session. We shall first describe the preparation for each of the two experimental manipulations: the source of the innovations and the message about the innovation itself.

Selection of Persons for Sources

In an effort to maintain some of the naturalism of field studies, we used as sources of the fashion suggestions snapshots of actual coeds taken on the campus of a large midwestern university where the experiment itself was to be carried out. The photographs had a casual look as though taken impulsively by a friend, although the size, background and camera angles were relatively uniform. Forty photographs were taken in as unsystematic a way as possible using different times and places and types of subjects.

From this pool, sixteen pictures were selected that seemed to represent the range of women typical of home economics undergraduates. A group of 63 home economics undergraduates, none of whom knew the women in the snapshots, were asked to judge each photographed woman on a five point scale, ranging from "extremely similar to you" to "not similar at all." Using the method of summated ratings, the sixteen photographs were scaled and four were chosen covering equal intervals of the scale (3.53, 2.85, 2.42 and 1.98 were the actual values of the mean similarity ratings).

The scale represents group similarity because the self ratings of similarity to each person in the group, when combined, become an index of the similarity of the photographed person to the entire group. (We felt that a direct rating of similarity to the group would be a meaningless task.)

Selecting of Fashion Suggestions

Although it would have been possible to bring actual fashion innovations into the laboratory, such a strong manipulation would have overwhelmed the source variable. In any case, influence is most often manifest in talking about innovations before the actual trial. To maintain realism in representing the fashion object we asked women from undergraduate classes to write down fashion suggestions that they actually had heard recently. The term "suggestion" was not given a limited interpretation but included all forms in which comments might be made such as "I like ...". A total of 78 women contributed 352 items. After editing and eliminating duplication there were 58 acceptable fashion comments.

Next we asked a panel of five buyers from local stores catering to students to rate each statement for the extent to which it was a new idea for local college women. They sorted fashion comments into four groups from extremely fashionable to not-so fashionable. The four levels of fashion newness included such statements as "Long dresses are fun to wear to parties" and "Shoes with rope trim are comfortable." Sixteen statements were selected, four from each newness level, for presentation to the subjects in the experimental treatments. All but one statement lacked unanimous agreement concerning the newness level.

Subjects

The main experiment was carried out with 48 undergraduate women enrolled in home economics. None were used in any of the previous steps. Each was assigned to one of 4 groups in a Latin square design pairing each of the 4

items at each newness level with one of the 4 photographed sources using a different combination in each of the 4 groups. Thus each of the sixteen items was paired with each source an equal number of times, the order being counterbalanced in the Latin square design. The photographed source was shown using a 35 mm slide projected on a screen in front of the subjects.

When the picture of the source was projected on the screen the subject indicated on a five-point scale her agreement with the fashion opinions attributed to that source. Each subject made judgments about 16 items, four from each source.

A second session of the experiment required all subjects to rate each source on a series of trait descriptors. In this session, following the main experiment by one week, each subject was given a personality scale to measure open versus cautious information processing (Leavitt and Walton, 1975), a measure of affiliation or liking for each source (Hayes, 1972), and the series of adjective ratings to describe the sources (reported in detail elsewhere).

Results

Complex analysis of variance was used to determine the significance of the results using Plan 12 of Winer (1962, page 571). This is a 4 x 4 x 4 balanced fractional replication Latin square in which the treatments are assumed to be fixed and subjects within groups are a random variable. The three main effects are the four sources, the four newness levels and the four replicated fashion suggestions within each newness level (assumed to be identical in the design of the study). The results are contained in Table 1.

The main effects of sources and newness level were significant. Their interaction was not significant for all groups combined, but when the groups are considered separately they have a significant interaction. Replicates by groups interaction is also significant indicating that response to the individual items was determined not only by newness level and source pairing but also by their unique qualities. This failure to achieve uniform response to items within newness levels -- while not surprising -- makes the interactions in the study difficult to interpret.

The mean agreement level for the four sources is shown separately for each newness level in Figure 1. Even though the first order interaction is not significant, combining the newness levels may be misleading. It can be seen that the effect of similarity is most unequivocal for the two extreme newness levels while the two middle levels show the inverted U curve found in previous research.

The overall effect of the group similarity of the four sources is curvilinear in roughly the same manner as the two middle levels of newness. The mean agreement from most to least similar was 3.6, 3.4, 3.7, and 2.9. The exception to the trend was source II. In order to investigate this further, the scores were plotted separately for the thirteen subjects who scored highest and the eleven subjects who scored lowest on the open processing scale given in the post session. This is a measure of the extent to which the person adopts an open, constructive attitude toward innovation. The results are graphed in Figure 2. Clearly it is source II that distinguishes the two types of processors.

To explore this difference further, the average rating for all four sources on the 26 trait ratings made by all subjects in the post session was computed. The strong and weak traits for each source are listed in Table 2. It can be seen that source II and source III are almost

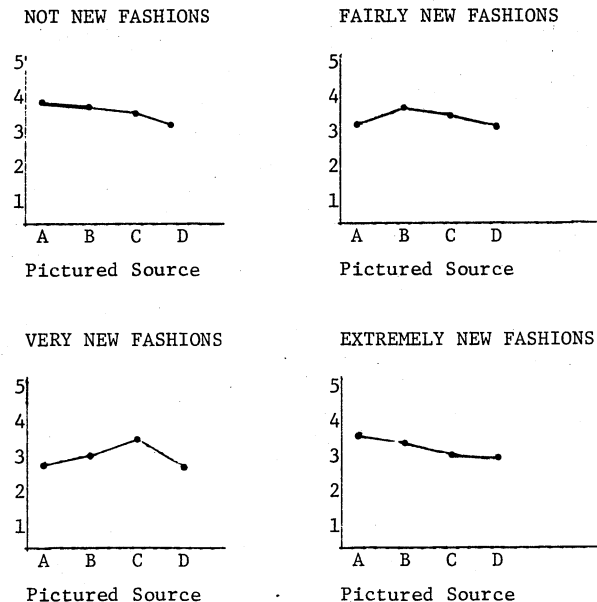

mirror images. Source II is high on anxious and aggressive and low on conventional and trustworthy while source III is the reverse except for conventional.

TABLE 1

FIGURE 1

AGREEMENT OF SUBJECTS WITH FASHION INFORMATION VARYING IN NEWNESS ACCREDITED TO FOUR PICTURED SOURCES (Source A is most similar and 5 is agree extremely well)

This is interpreted as indicating that open subjects are less dependent on conventional credibility cues such as expertise and more likely to respond to a source who is somewhat controversial as a source per se, but more representative of the group with which the subject identifies.

FIGURE 2

TABLE 2

PERCEIVED PERSONAL TRAITS OF THE SOURCES

Source	Strong Traits	Weak Traits
Source I	active sophisticated innovative aggressive	anxious conventional introverted
Source II	anxious aggressive	conventional trustworthy
Source III	trustworthy expert introverted	anxious aggressive
Source IV	anxious conventional introverted	active sophisticated innovative expert

Conclusion

What do the results tell us about the psychological processes underlying consumer innovation? They clearly demonstrate the importance both of characteristics of the source and of the innovation itself for acceptance of fashion ideas. The attempt to ground laboratory experimentation in the real world by using naturalistic manipulations -- snapshots and "overheard" fashion ideas -- was only partially successful since the realistic flavor of the fashion items seemed to increase the "noise level" of the analysis: the four replicates within each newness level contributed significant interaction variance in the design. This could have been avoided by constructing

sterile phrases designed to produce response only in terms of the one aspect of interest -- newness. Also, the effects of the photographs were more difficult to interpret than would they have been if only one dimension were varied -- hair color for instance. But, all-in-all, these individualistic variations give us more faith in the generalizability of the results than would have been the case if a less naturalistic stimulus variation had been used.

Our measure of similarity was more generalizable than Alpert and Anderson's, but the operation that makes it so -- independent judgments -- raises the question of whether the essential variable is similarity of source to the individual receiver or to the group as a whole (super-representativeness). Further research will be required to unconfound these two interpretations.

CLOTHING DECISIONS: A DECISION PROCESS ANALYSIS OF FOCUSED GROUP INTERVIEWS

Roger D. Blackwell, The Ohio State University
Jo Ann Schickel Hilliker, The Ohio State University
(On leave from the Kentucky Cooperative Extension Service)

Abstract

The purpose of the research was to gain a comprehensive understanding of variables and the processes involved in the purchase of selected garments of women's clothing. A decision process approach was used to analyze ten focused group interviews conducted in varied geographic and demographic populations.

Introduction

The purchase and use of women's garments has been investigated by many researchers. Generally, these investigations have concentrated on only one or a few of the variables such as information sources (Stauffer, 1972; Arbaugh, 1974; Orsini, 1972; Martin, 1971-1972), confidence and perceived risk related to satisfaction (Sproles, 1969), physical characteristics such as color or fiber content (Wylie, Grown, and Morris, 1977; Schultz and Phillips, 1976) racial and socioeconomic factors (Braguglia and Rozencranz, 1968; Patson, 1971; Sturdivant, 1971; Schickel, 1970), social class (Warning, 1956; Roach 1960; Kundel, 1976), quality/price relationships (Stafford and Enis, 1969; Sims, 1969), and numerous other evaluative criteria such as laundering qualities, appearance and style, durability, fit and so forth (Borrell et al., 1964; Nolan and Levine, 1959; Shelly, Goldberg and Clayton, 1968; Clayton and Sherman, 1972; Jenkins and Dickey, 1976). Many studies have also focused on complaints and satisfaction (Whitlock et al., 1959; Conklyn, 1971; Steiniger and Dardis, 1971; Ayers et al., 1963; Wall, Dickey and Talarzyk, 1976).

The investigation of each of these variables provides important clues to understanding purchase and usage decisions but the clues are limited only to partial explanations. A more comprehensive approach is needed to integrate all of these variables, or even to determine what variables are relevant. Ryan (1966, p. 178) has commented on the need for understanding a wide range of variables and their interrelationships:

We can have a better understanding of what will be satisfactory to the consumer if we know: why people choose the clothes they do; how society influences them in their selection; the relationships between personal values, interests, attitudes, self-concepts and personality factors and the effect of clothing on individuals.

The research reported in this paper takes an integrated approach to understanding clothing decisions, using a comprehensive model of consumer decision processes as an aid to collecting and analyzing data. This study involves qualitative data and must be regarded as exploratory in nature. However, it is based on an approach designed to discover major variables important in clothing decisions which may later be subjected to more quantitative approaches. The results, though exploratory, do describe how some consumers make clothing decisions and may therefore be useful both to management interested in marketing clothing and to home economists interested in maximizing satisfaction from the use of clothing.

Research Methodology

This research involved focused group interviews analyzed by reference to the Engel-Kollat-Blackwell (EKB) model of decision processes. (Engel, Kollat, Blackwell, 1973). The results are reported in this paper, using the EKB model as a framework for presentation.

Data Collection

Ten focused groups were conducted in varying geographic regions. Each group consisted of six to twelve women (average of 10) selected by commercial marketing research organizations using random recruiting techniques and screening questions to obtain balanced groups. The screening question given to randomly selected women on the telephone consisted of a statement in which respondents were asked to rate themselves as "very interested, somewhat interested, or not interested" in fashion. Only those who were very interested in fashion were asked to participate. Other questions established the woman's age, dress size, and socio-economic characteristics. Each group consisted of a balanced composition of age and socio-economic characteristics and three racial groups. Thus, because of recruiting specifications in this study, the women wore average clothing sizes and possessed a greater than average fashion interest compared to the population as a whole.

The interviews were conducted in Atlanta, Boston, Columbus (Ohio), Daly City (California) and San Antonio. All interviews were tape recorded and conducted in specially equipped facilities of commercial marketing research organizations. Half of the interviews were conducted by the senior author and half by another investigator experienced in group interviews.

Focused Group Approach

The purpose of the focused group approach is to provide a sampling of the decision elements in clothing decisions. No attempt is made to develop a statistical description of the proportion of consumers in the population possessing specified attributes. The qualitative approach of focused group interviews does not supplant statistical description but rather provides an important prior step by discovering variables that are important and generating hypotheses for investigation in quantitative studies (Cox, Higginbotham, Burton, 1976).

An interview guide was used in conducting the focused group interviews. This generally enhances the efficiency of the technique in collecting the maximum amount of relevant information but at the same time has the potential of arresting discussion that might generate topics not previously considered by the researchers and may force discussion of topics that are not meaningful to the group participants (Merton, Fiske, Kendall, 1975). These problems were recognized by the interviewers who, being sensitive to the problems, attempted to allow and encourage the discussion into areas not covered in the interview guide (but relevant to fashion and clothing topics) and to move to other areas of discussion when topics failed to generate meaningfulness to the participants.

Theoretical Framework for Analysis

The Engel-Kollat-Blackwell (EKB) model of consumer

decision making was used for analysis of the data and as the theoretical framework for the study. For each garment analyzed in the study, separate analysis pages were prepared containing headings corresponding to stages of the EKB model (problem recognition, internal search, etc.). Each of the authors independently listened to all tapes of the interviews and recorded each comment relating to a stage in the EKB model. Other comments that did not "fit" in the model but were of interest in understanding fashion and clothing purchases were defined as follows:

Problem recognition is the consumer decision stage which is caused by recognition of unmet needs. Problem recognition results when a consumer recognizes a difference of sufficient magnitude between what is perceived as the desired state of affairs and what is perceived as the actual state of affairs. It leads to doing something about this feeling or recognition.

Internal search and alternative evaluation is the consumer's use of existing attitudes to identify and evaluate alternative solutions. The consumer identifies the pertinent evaluative criteria based on past experience.

External search and alternative evaluation is the consumer's use of various sources of external information such as mass media, personal sources and marketer-dominated sources (advertisements, dealer visits and so on) to learn about the number of alternative solutions to the perceived problem. The characteristics and attributes of these alternatives and the relative desirability of each is reviewed and weighted by the consumer.

Purchase process is the customer in-store environment interaction. Purchase process behavior can be precipitated by two events. One, it can be problem oriented in the sense that the consumer visits a retail outlet in order to purchase a product or service that satisfies some perceived problem. Second, other factors such as desire to get out of the house, a desire to get away from the spouse and children, a desire to engage in fantasy may motivate a visit to a retail store.

Outcome refers to consequences of a decision and the various forms of resulting behavior. Two outcomes are specified: (1) triggering of new behavior, and, (2) post purchase evaluation.

A second objective of the study involved understanding contemporary conceptions of fashion and understanding of the relationship between such conceptions and clothing purchases is necessary to predict future trends that may occur in fashion conceptions and clothing purchases.

The remaining portion of the paper describes the results from the focused group interviews. Following a general discussion on the concept of beauty and role of clothing, the results concerning decision stages are reported for each garment analyzed in the study. These garments include a good dress, skirts, casual clothes, pant suits, bras and panties. Due to the overlap between some garment categories, only the results which relate to distinguishing attributes or decision elements are reported for some garment categories.

Contemporary Conceptions of Beauty and Clothing

Contemporary women viewed beauty and fashion in diverse ways and the only consensus position was that a beautiful woman is one who looks healthy, clean, well-postured and appears to take care of herself. Among young women, this usually meant a "natural" look but among middle-aged women, there was more tolerance for "some help for nature."

The women in this study consistently defined beauty more as "personality" or the inner qualities of a person rather than external appearance. The quality of a relationship with a person or a person's attitudes toward life and other people were increasingly viewed as beauty -- a position that de-emphasized the role of clothing in achieving "beauty."

When pressed to describe women of physical beauty, two different models emerged. One was of the contemporary, natural women. She has a free spirit, is liberated, and wears both casual clothing, such as jeans and casual shirts, or wears exotic dresses with extreme cleavage, no bras and often back-less design. The other model of beauty was the woman who appeared healthy and had a good body. She wears attractive clothing but not exotic clothing.

The Role of Clothing

Clothing was worn to fit into women's peer groups or her life style. Clothing was much more individualistic in the sense that fashions were determined by many types of groups or segments rather than one fashion for the society as a whole. A typical comment reflected this view: "People notice clothing because it explains a lot about your personality." Another woman amplified this view when she said, "You can't judge a book by its cover but clothing gives a good clue about which people are alike."

A Good Dress

Respondents indicated that a good dress was not as important in their lifestyles as it once was. Pants have replaced the dress for many occasions.

Problem Recognition

Varied comments were made indicating the recognition of a need for a new dress. The purchase process for a dress was usually initiated by a special occasion or by a recognition of new fashion look. Career women, however, often walk through a store and see a dress which triggers the decision process.

Many women mentioned that they purchase a dress for a special occasion such as a wedding or funeral or to wear to a special place such as a nice restaurant. In general they felt a dress was expected or more appropriate than pants for such occasions.

Some comments seemed to indicate that fashion is one reason for recognizing the need for a new dress. Several women stated that in spring or fall they feel the need to look for new clothing. The recognition of this need appeared to be a combination of boredom with their present clothing and an awareness of the "new" fashions.

Several of the younger women indicated that they bought a dress because they did not have one. The recognition of a need for a dress may have been prompted by two influences. First, at the time the interviews were conducted (1975), the pants fashion had been important for several years. It had reached a peak and had begun a decline as the "fashion." Skirts and dresses were beginning to appear. Since the women interviewed possessed above average interest in fashion, they probably were picking up a trend. In other words, the eye was becoming accustomed to a new look. Secondly, several women said their purchase of a dress was influenced by husbands or boyfriends. A typical expression offered by one woman was, "My husband said, Why don't you buy a dress? I always see you in pants." Several respondents stated a belief that men were pleased to see legs. Their beliefs support Laver's theory of shifting erogenous zones in women's dress (Laver, 1964).

Career women reported that dresses were still appropriate for office wear, at least two or three days a week, or for special "dress up" days. High school students reported that dresses were worn by some to school but mostly by the straight kids who were "out of it" or by the very stylish, country club kids. There was considerable agreement that students who wore a dress all the time were considered "strange."

Internal Search

The criteria for evaluation of a dress varied with each woman. It appeared that most women went shopping with an idea of what they intend to buy but looked at several dresses to find the one that met most of their criteria. Whether the individual liked the dress when in the store was an important criterion. Color was also very important in the selection of a dress.

Women reported that they must try on quite a few dresses to find the right fit. Some stores were viewed as never having anything that fits or that is appropriate while others do.

Price was also important. Women usually had a price range in mind and did not deviate much from it. Some women made a point to browse through sale dresses.

The care of the dress was also a consideration. Some women would only consider buying washable garments; other preferred dry cleanable ones. One woman said that since she owned only one dress, she preferred to have it dry cleaned.

Several women expressed concern related to the construction of the garment. Several inspected the garment to determine if it was durable. They expected the dress to last a long time. Comments were also made concerning the thread, buttons and size of seams. The women most concerned with construction appeared to be homesewers.

External Search

Few women relied directly on mass media for information on dresses. A few girls indicated that they liked the clothes of Mary Tyler Moore and Cher on television. Most women consulted personal sources of information such as a sister, mother, boyfriend, or husband. High school girls indicated that the popular people at school were significant influences.

Purchase Process

The comments related to purchase process fell into two categories -- store related and product related.

Store related. The store considerations concerned its location, the sales personnel and whether or not an individual "likes" the store. Only a narrow range of stores appeared to be considered. The respondents desired a store that was easy for them to get to. Career women reported that they often do their shopping during lunch hour and choose a store convenient to work.

Various attitudes toward salespeople were expressed. Some women indicated a positive attitude toward sales women but most expressed a desire to look at the dresses and not be helped by salespeople. A typical comment was expressed by one young woman, "Clerks bug you. They always say that a dress looks so cute even when you know it looks crappy."

The product. Two types of dress shoppers were revealed in this study. One is the woman who likes to shop in large department stores for a good selection. The other is the woman who prefers small, unique shops. The latter type disliked shopping in department stores because

"you see yourself on the street."

SKIRTS

Most of the comments made concerning a good dress also applied to skirts. The primary attraction of skirts was the variety in skirt lengths, which made skirts a desirable change from pants.

There was a general concensus among the women of all ages that mini skirts were out of fashion even for younger girls. Respondents stated a belief that short skirts became accepted because of the youth revolution, liberalism, freedom and new sexual attitudes; however, they believed that now the mood is more conservative, resulting in more skirts of long and moderate lengths.

Several women indicated that for special occasions they selected the floor length or maxi skirts because they were "fun to wear" and made them feel "special". These women appeared to be very receptive to the fashion trend toward long skirts for "at home" wear or for entertaining.

The women were also concerned about the fit of skirts. Some tall girls reported that it was easier to find skirts to fit than pants that fit. Others indicated difficulty in finding skirts that fit around the waist and hips.

CASUAL CLOTHES

Casual clothes were defined by the researchers as clothes appropriate for home or leisure activities. Almost all women referred to jeans or pants with assorted tops as casual clothes. Other possible clothing items, such as culottes or shorts, were not included in the current definition of casual clothing by most women.

Jeans were recognized as the favorite of younger women although several women over 30 commented on their pleasure in wearing jeans, too. It appears that jeans will be included in wardrobes for many years in the future. Some typical comments of respondents illustrate the probable future in jeans:

"We'll still be wearing jeans twenty years from now."

"They are trying to get skirts back instead of jeans but it won't work, except maybe long skirts, because jeans are so comfortable."

"I like jeans because you can wear anything with them. It doesn't matter if you get a stain on them. You can just keep wearing them every day -- and they are accepted everywhere."

"I wear jeans around home 95% of the time," (Ex-school teacher, age 35).

"We'll never stop wearing jeans."

Problem Recognition

Pants and jeans were perceived to be ideal for contemporary lifestyles. They were worn almost everywhere and were described as the most "comfortable" garment. Almost all women owned at least one pair. The wardrobe of some younger women contained only pants or jeans; no dresses or skirts were included.

Pants and jeans were purchased when old ones wore out. As a woman's inventory became depleted, she became more receptive to purchasing jeans or pants in routine

shopping. The women were also sensitive to special sales and special displays or other stimulants to sales.

As with dresses, the purchase of pants or jeans was also prompted by a need related to an activity. The role for pants and jeans has expanded to include all activities including work, parties, dinners on the town and even religious activities. The style of pants or jeans varies with the activity.

Internal Search

Jeans were important to women and they were willing to expend considerable effort to find jeans or pants that match their evaluative criteria. There were specific features that women looked for, such as type of cuff, durability, fit.

Fit was the most important evaluative criteria. Women wanted jeans and pants that fit. A major problem for many women was to get jeans to fit around stomach. Some respondents reported loyalty to some brands because of fit but others said that even the same brands changed so often in fit that brand loyalty does not help. Women reported searching for jeans that fit and finding few that do.

Several women commented on the pros and cons of all cotton versus cotton blend jeans. All cotton jeans were liked because of the softness, however, they wore out quickly. Other women desired cotton blended jeans because of their durability.

A small but distinct group of women indicated that they liked jeans because they could embroider favorite designs on them. They particularly liked to express their own individuality in the designs chosen. This group tended to be younger women who disliked their clothing to be like everyone else.

External Search

Store displays were credited with influencing the type of casual clothes purchased. Husbands and family members were also important influences. An older woman explained that she had not worn pants for 50 years but that at the instigation of her 20 year old daughter she began wearing them for yard work. Now she likes them so much she wears them every place and stated that now they could not be taken away from her.

Purchase Process

Jeans are bought everywhere. Selection is an important factor in determining which store is shopped. Stores appealing to youth -- such as those on campuses -- were perceived to have better selection.

Quite a few women reported the need for shopping in several stores in order to find jeans or pants that fit. The respondents reported that they always tried on pants to check the fit. The exact fit desired depended on the individual. Some women wanted jeans not too tight; others wanted jeans that would shrink to fit their bodies. Some women complained that jeans were too tight in the hips and too loose at the waist, requiring something to be worn over the waist to cover it up. Several respondents stated the male jeans fit better because they could buy the correct leg and waist measurements.

PANT SUITS

The respondents indicated that the use of pant suits varied with age. The younger women felt that pant suits were worn only by older women. Several high school girls indicated that their mothers and grandmothers wore pant suits almost everywhere -- to work, parties, movies

and other places. Their fathers were credited with influencing the mothers to wear pant suits. The younger women emphasized that they preferred the mix and match quality of jeans or pants and tops rather than the coordinated suit. Pant suits were generally considered to be too "dressed-up" for younger women.

The older women interviewed indicated that they liked the freedom and comfort of pant suits. Pant suits were perceived as "right" for the office. An older woman explained that pant suits were for older women over 25 who wanted to be neat and who would not wear jeans but did not want to wear a dress. They were believed to be good for lifestyles involving either work or bridge in the afternoon.

BRAS

Attitudes toward bras have become more realistic and more individualistic. Respondents viewed a bra as something to be worn if a woman needs it rather than simply because every one else wears one or does not wear one. If a woman is small, she may not need one but a larger woman probably needs one, especially in active situations such as sports. A few years ago when some women stopped wearing bras, it was considered a "showy" thing with shirts or blouses that made it obvious that no bra was being worn. Today, it is less for show and more a matter of individual preference.

Problem Recognition

Buying a new bra usually occurred for one of two reasons. First the woman became increasingly aware the bras she owned did not provide support, had sagging straps, were discolored, or did not make her feel as she wanted to feel. If the situation was really serious the woman might make a special trip to a trip to a department specialty store. By the time she entered the store she had determined the need for a new bra. Thus, she was particularly susceptible to ads or special promotions in the store.

The second reason that often resulted in the purchase of a new bra was the purchase of outerwear that required a different type of bra. Sometimes the purchase of an especially nice dress caused feelings that it was wrong to wear an old bra with a special occasion dress. A new bra might be purchased at the same time as the dress.

Internal Search

The criteria with which women evaluated and selected bras were varied and reflected a highly segmented market. There was nearly complete disagreement or absolute polarity reflected by respondents' comments about what they wanted in a bra. Bra features considered included total disagreement about whether straps should be elastic (so they don't "cut" you and allow active movement) or non-elastic (so they don't stretch out of shape). Some women asked for wider backs because it was more comfortable; others preferred the opposite because wide straps interfered with current fashions. Some women preferred the seamless bras which gave a natural, soft, rounded appearance. The women who liked seamed bras indicated that these bras lasted better and gave better support in contrast to the seamless which became flimsy with a few washings.

The women agreed that the "pointy" look was undesirable and in decline. There was also general agreement that bras must be easily washable in automatic machines without discoloring or falling apart.

Prettiness was an attractive feature for bras but not sufficient reason to cause women to buy the bra or become a satisfied customer. The appearance of the bra

may have caused the woman to try it on or give it consideration but other criteria were used in making the purchase.

The two criteria used most often by women in the actual purchase of a bra were fit and comfort. Each woman may define these two criteria differently.

Women may look at the same bra and have very different evaluations on these criteria. Some women look at underwire support bras and say, "How awful. That would just kill me." Other women look at the same underwire bra and say, "That has a good underwire and looks like it would give me enough support to be comfortable."

External Search

As a result of the decision to purchase a bra made prior to entering a store, women often wait for sales or shop for special sales before purchasing. The need for a new bra may be evident but time is usually not crucial.

Younger women were influenced by their friends and their preferences in bras. The women indicated that as their figures matured, each woman relied more on her personal evaluative criteria.

Purchasing Process

Women bought bras in stores that offered a large selection. Middle-aged women were more brand loyal than young women. Young women were more likely to select in bargain basements, specialty stores, chain department stores (Sears, Penneys) and some discount stores. They looked at the prettiness, price, color, and so forth before selecting. The middle-aged woman bought the same brand and style purchased before if satisfied with it and it was available. Several women complained that the styles changed frequently and that they were unable to repurchase a favorite style.

Women felt that they must try on a bra before buying it. The exceptions were young women of moderate (usually B cup) size who were able to buy the one size soft bras and the D cup woman who had limited selection, and such precise requirements that she became a repeat purchaser of one style and brand.

Women were divided in their opinions about the helpfulness of sales clerks in the foundation departments of retail stores. Many women reported that few clerks were helpful with fit problems and style substitutions.

PANTIES

Panties were considered a "fun" product for most young women rather than a product to be taken seriously. Most women reported that they wore briefs and preferred a lot of variety in applied decoration and color.

Problem Recognition

Panties were purchased when the ones owned wore out. Store displays or sales frequently reminded the consumer that her inventory was low.

Several younger women stated that when the hip hugger pants became popular they purchased panties with the lower waist to wear with the new pants. Most women expressed great dislike for wearing natural waist panties with lower waist pants. Many women have continued to wear bikini panties even though outer garments now have natural waists.

Internal Search

Women reported that they liked pretty panties and were

heavily influenced by appearance. They usually bought inexpensive panties but occasionally received more expensive ones as gifts from relatives.

External Search

Evaluative criteria used by women when selecting panties were appearance and comfort. As stated before, most women selected panties from those available in stores based on their appearance. Most women preferred panties in a variety of colors or with an applied decoration such as embroidered flowers. A few women preferred white panties.

Women considered comfort important, too, but seldom tried on panties before purchasing. Comfort was judged by visual inspection. Dislike was expressed for elastic that became either too tight or too loose after washing and for seams that scratched. Some women expressed their dissatisfaction with the performance of nylon panties that were dried in a dryer.

Girlfriends or peers were sometimes influential in the selection of panties. The older women indicated that husbands or boyfriends influenced what they purchased.

Purchasing Process

Most women reported that they bought panties in department stores and to a lesser degree in specialty stores. They usually made selections from the tables of panties on display. Some women indicated that they purchased a specific brand such as Sears because they were pleased with previous experiences.

CONCLUSIONS AND FUTURE RESEARCH

A decision process approach revealed substantial insight into the variables that are important in purchase decisions for selected garments. Analysis of focused group interviews, using the Engel-Kollat-Blackwell model, permits a sampling of decision elements in garment decisions and suggests many hypotheses that might be investigated with quantitative or statistical methodologies.

In addition to the specific descriptive elements that might be further investigated, the following general questions are generated from this exploratory research and may be fertile areas for further investigation:

1. The women in this study (who because of selection procedures have above average interest in fashion) appear to be very aware of fashion trends and have well-developed opinions about such trends. Could groups such as these be isolated and with proper statistical controls be used reliably to predict future fashion acceptance and trends?
2. Substantial differences in opinions were expressed by younger and older women regarding some items of clothing. Will the younger women continue to express the same attitudes and beliefs as they grow older (attitude stability) or will their attitudes and beliefs become more consistent with the older women's as they mature? (attitudinal assimilation)
3. Practically every garment was discussed in terms of its comfort by respondents. What is the meaning of comfort? Do women use "comfortable" to describe clothes because it is socially acceptable comment or are physical and performance reasons underlying comfort more important?
4. The current definition of a beautiful person appears to minimize physical features and the clothing worn. Is this definition valid among the entire population?

Will this definition decrease the importance individuals place on clothing? Is this belief in what a beautiful person may be, reflected in the clothes chosen by an individual?

RESEARCH PRIORITIES

Elizabeth Y. Davis, CSRS/U. S. Department of Agriculture
 R. J. Ritchey, Virginia Polytechnic Institute
 & State University
 Francille M. Firebaugh, Ohio State University

Introduction (Elizabeth Y. Davis)

"It is most important to decide what it is you really want to do, and then be realistic enough to recognize how feasible it is to achieve it, and what it takes." This is a direct quotation from the speech by Dr. Walter L. Fishel at the HERAPP Workshop in Washington last spring. HERAPP is the acronym for Home Economics Research Assessment, Planning and Projections. Some of you attended that workshop, or participated in one of the many activities included in the assessment, planning and projections of research.

HERAPP is a product of the ideas and energies of many people. In the summer of 1975 there was a very successful conference where priorities for research in food and agriculture were set through a modified Delphi technique. The Conference was an activity of ARPAC, the Agricultural Research Policy Advisory Committee, made up by joint agreement with the U. S. Department of Agriculture and the National Association of State University & Land-Grant Colleges. In other words, ARPAC represents State University-Federal research relationships. ARPAC is an active committee, and functions as a research planning group in the broadest sense.

When home economics presented their plan for research assessment, planning, and setting of priorities, to ARPAC, it agreed to co-sponsor the project with AAHE (Association of Administrators of Home Economics.)

The relationships among the various organizations represented in the HERAPP project are illustrated below:

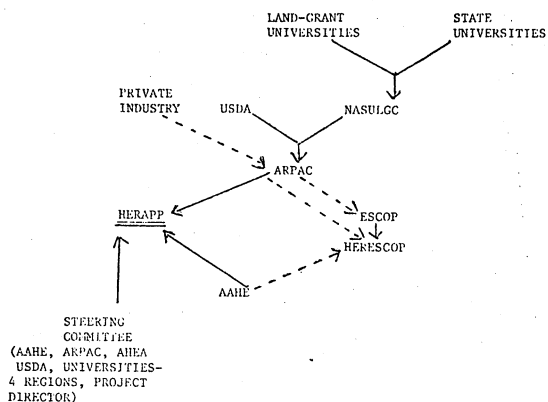

FIGURE 1. Organizations represented in HERAPP project.¹

¹ Abbreviations used are AAHE, Association of Administrators of Home Economics; AHEA, American Home Economics Association; ARPAC, Agricultural Research Policy Advisory Committee; ESCOP, Experiment Station Committee on Organization & Policy; HERAPP, Home Economics Research Assessment, Planning and Projections; HERESCOP, Home Economics Research Sub-committee of Experiment Station Committee on Organization & Policy; NASULGC, National Association of State Universities and Land-Grant Colleges; USDA, United States Department of Agriculture.

The Cooperative State Research Service in the Department of Agriculture developed a cooperative agreement with Virginia Polytechnic Institute and State University to support the project, with Dr. S. J. Ritchey as Project Leader.

Where are we now?

To develop background for setting priorities for home economics research, the administrators of Home Economics Research programs were asked to submit names of scientists and users of research who might prepare statements about the state of the art, or situation statements, in a particular area. There were originally 35 areas included in the initial request. With 35 areas no one can say Home Economics is not multidisciplinary! Requests for preparation of papers were made to five people in each area. The ideas in each area were collated into one paper which was returned to the original authors for review and statements of priority researchable problems; suggestions were incorporated into the working papers prepared for the HERAPP workshop. Nearly 200 people, representing many disciplines and viewpoints attended the Workshop, worked through the papers, and established research priorities.

The most important problems in all areas, as set by the Workshop, were listed in random order and mailed to about 4500 persons including a randomized sampling of members of the American Home Economics Association, those who attended the HERAPP Workshop, and administrators of home economics, to set priorities across areas.

At the same time two other activities were in process. One was to assess the current research actively in home economics and related areas, and to relate these activities. The other activity was a questionnaire sent to all State Experiment Station Directors in order to gain knowledge about the climate for home economics research in experiment stations. A preliminary report on the results of these activities are in the next section of this paper.

The products of the HERAPP exercise will be two published reports. One will include the statements of research and the priority researchable problems and results of the assessment. Projected funding needs in each area will be a part of that publication. The other publication will be a short summary for use in public policy activities.

Many of us who have been working with HERAPP over the past couple of years feel that it is a tool for us to accomplish some of the things in research we want to do -- that we think need to be done -- if we are really dedicated to improving the quality of living for people through research on the family. We also think HERAPP is a tool which is helping us to recognize how feasible it is to achieve those things.

Consumer Research and HERAPP
(S. J. Ritchey)

Consumer research in the broad area of home economics is being evaluated and assessed through a project sponsored by the Cooperative State Research Service, USDA, the Association of Administrators of Home Economics, and AHEA. Preliminary findings can be useful in the context of this workshop and your future endeavors in research.

At the present time, research in all areas of home economics is supported through appropriations to the agricultural experiment stations and the Land-Grant system. Though there is a long history of home economics research in this particular arena, support is quite limited. Support for all home economics research is less than 3 percent of total research through the experiment stations. Moreover, much of the total is expended on food and nutrition, leaving between 1-1.5% for all other areas of home economics. Except for foods and nutrition the number of projects, personnel and financial support are quite limiting.

In almost every measure of support, home economics research lags behind research in the experiment station. Technical and clerical support per scientist, funds per scientist, and funds per projects in home economics lag behind other subject matter areas. This may reflect the poor performance of researchers in home economics and probably reflects the notion that much of the home economics research, particularly the social and economic aspects, do not mesh with the primary mission of the agricultural system. However, administrators perceive home economics as a group of disciplines with potential for service through research. Further, they recognize that research in home economics must be improved by increased funding support, by improving the productivity of researchers, and by improving the available facilities.

In the future, home economics research must receive a higher priority. Our researchers must be more productive, must be more aggressive in seeking funding through the experiment stations and through other granting agencies, both governmental and private. Recommendations from the HERAPP project are that numbers of personnel and funding be increased by factors of two and three, respectively, in the next 10 years. A variety of mechanisms may be important to achieve this goal and the leadership group within home economics must be active in the search for funds, the passage of necessary legislation, the increased productivity of present researchers, and the education of a new generation of outstanding young scholars.

Implementation in Relation to
Interdisciplinary Research Efforts
(Francille M. Firebaugh)

Any planning process is just that -- implementation is not inherent in planning. Research planning can give increased visibility for topics. For researchers, information on priorities can provide impetus for the project development. Administrators will continue to look to researchers to justify areas of high and low priorities with the hope of stimulating an orientation to high priority areas.

Research planning leads to another end -- a delineation of research needs which can be presented to help legislators and others know of our research direction. In working to increase support for our research related to home economics, the need for planned research efforts is

great. Response to legislators concerning research needs for formulating legislation can be stronger as a result of this planning effort.

A research program should include as a primary ingredient the researcher's capabilities and interest, with a clear analysis of importance of the research problems in relation to the needs of society. In 1977, an author proposes: ". . . the problems of society always and necessarily involve many disciplines in their study and solution . . . the best research can be done only in the context of the whole problem" (5:29).

Ten years earlier, another author suggested: "Problem-focused research can be disciplinary: in the sciences of man there is probably not a single discipline that has been able to develop without taking account of the needs of practical action, or being concerned with big social problems" (1:203). I believe contributions can continue from both single disciplines and interdisciplinary efforts.

Research funding has been changing for some period of time. Referring to the shift from grant research to contract research, Rist and others propose:

- 1) ". . . as the Federal government has been able to sharpen its priorities in a number of policy related areas, the scientific community has not kept pace and increasingly has responded in inappropriate ways in terms of proposed research . . . While the demands within agencies for focused research have grown, the academic community has continued to operate in a private, entrepreneurial manner" (4:264).
- 2) ". . . from the Federal view, the assumption is that researchers do not care from where their funds come, so long as they get them and are then left alone" (4:264).
- 3) limited research accountability in grants has influenced the shift to contractual agreements (4:264).

We have seen the RFP (Request for Proposals) come into its element in recent years -- with the statement of the research problem, the target population, and the methodological approach specified. I submit to you that part of that which has come through our ignoring needs of policy makers. We have also seen the rise of contract houses, not associated with university groups who can and do move with greater ease in hiring than universities without the "distraction" and "enrichment" of students and other responsibilities, and with built-in interdisciplinary teams or "purchased" teams. Rist makes a fourth point which seems appropriate for our thinking today:

- 4) "The primacy of the model of the single academic working to locate support for his/her particular project will have to be de-emphasized if academic research is to continue to have Federal support on any scale comparable to that it enjoyed until relatively recently. Cooperation among researchers, the effective use of the supporting services of one or more universities in concert, and the willingness to engage in research that is not oriented toward the development of important contributions to theory or method all appear essential" (4:267).

Political and socio-economic factors affect the extent of scientists participation in policy making in the executive branch of government. "Some have argued that political factors (interparty competition, demands, forms of government, policy-makers' attitudes, etc.) explain more variations in policies" (6:243).

Within marketing, Dyer and Shimp suggest that "policy makers need empirical evidence, and they are receptive to it as long as it captures the full thrust of the issues" (2:67).

We want to be both a part of solutions to problems which are heavily influenced by public policy and we want to be a part of the accumulation and generation of knowledge which depend on continuous contributions to theory.

I would like to differentiate single disciplines, multidisciplines, interdisciplinary and development of new disciplines.

Discipline: Much of the development of knowledge and theory building has come from single disciplines. Perhaps there are individuals who can best function in a single discipline with a broad view of the problem to be researched -- a person with a "cosmopolitan" outlook of the problem but a specific approach which is productive due to the focus.

Multidisciplinary: Boundaries between and among disciplines remain intact, even though cooperation and common attention is focused on a problem or issue. "Mission-oriented work which is so managed as to break down a mission-oriented problem into separate (typically disciplinary) components to be carried out by separate investigators with different skills (possibly) at different sites (5:30). Roy suggests further that multidisciplinary work may take place in widely spread geographic areas: individuals may write reports separately (5:32).

Multidisciplinary

Interdisciplinary: Boundaries are shown here as fading between disciplines as a genuine meshing of ideas takes place. There is a "day-to-day interactive mode of research (or study) where, in order to do the best work, each researcher's work demands the use of ideas, concepts, materials, or instruments from one or more other disciplines. Such research is usually directed to a specified goal or mission" (5:32). Magrabi defined interdisciplinary research as directed toward problems, the solution of which requires application of theories and specialized methods from several disciplines.

It is fair to ask if it is even possible to determine the research problem as an interdisciplinary group or is it best formulated by one person who seeks help and forms a team. Some have been able to do it, others have not. Luszki, who wrote the classic reference about interdisciplinary team research methods and problems back in 1958 cites four strengths when interdisciplinary groups

formulate research problems:

- 1) resulting research problem should be broader and richer than individuals could construct;
- 2) research problem should be inclusive of important issues which might be overlooked by single researchers;
- 3) research methods from a number of vantage points should be better than those known or experienced by one person; some new concepts may evolve from pooling ideas about the research;
- 4) formulation of problems should assist a researcher in knowing if there is a contribution for him or her to make (3:146).

"When an interdisciplinary team begins work together, difficulty is often experienced in the initial attempt to develop a theoretical framework . . . there may be a tendency to take a set of hunches of hypotheses constituting a loose conglomeration of possible factors and glorify this as theory construction" (3:167). "If the group is successful in developing a theoretical framework to which all participants can subscribe, it changes from a team representing separate disciplines to a cooperative group of individuals with different and overlapping training, concentrating on a common problem" (3:167-168).

In interdisciplinary research, two or more individuals often unite papers or reports together. Roy proposes that program management must be local, "interaction among individual researchers is essential" (5:32).

Interdisciplinary

Where does interdisciplinary work lead us? Eventually to new disciplines as noted by Mason earlier today.

New disciplines: "After a generation of concentration of interdisciplinary, concrete issues, new constellations of technical problems will be abstracted out to serve as the foci of new disciplines; and these will then need about thirty years to develop their own specialized theoretical ideas and techniques to the required pitch of excellence, before they in turn are reapplied by a more practically minded generation to the concrete human problems of their time" (7:160).

New disciplines

In summary, the Home Economics Research Assessment, Planning, and Projections effort contributes to:

- 1) the stimulus for researching complex issues
- 2) increased visibility of research needs
- 3) foundation for seeking increased funding support
- 4) researcher and administrator information on priorities from several vantage points
- 5) exchange of ideas among researchers -- a starting point for discussion
- 6) recognition of the difficulties of bringing together ideas through brief face-to-face work periods and long distance exchange, with the special challenges of geographical separations and unresolved basic theoretical and vocabulary differences.

Implementation of the research planning will be accomplished by many means, including single, multi- and interdisciplinary programs of research.

CONSUMER RESEARCH

Administration and Funding of Interdisciplinary Consumer Research
 Keith N. McFarland, Dean, College of Home Economics
 University of Minnesota

ABSTRACT

Departmental goals and faculty reward systems oriented to department colleagues and activities often impede interdisciplinary efforts in research. Administrative leadership can provide positive reinforcement. Searches for interdisciplinary research funding require institutional, unit administrator and researcher cooperation. The field effort in home economics research is at a relatively underdeveloped stage.

An administrator new to a home economics program quickly becomes sensitive to interdisciplinary endeavor, since the field rationale focuses upon the interrelationship of man and the various aspects of his near environment. Undergraduate courses appear to reach across disciplines in various degree. Interdisciplinary research appears to be more honored in the abstract than in execution. To launch into interdisciplinary endeavor the researcher must form the relationships that permit planning across departmental lines and have the determination that overcomes the added burdens incurred by work outside the department or discipline.

Let's look at some administrative considerations relative to interdisciplinary research. Fred Harvey Harrington describes the department as a "major obstacle to change within American Colleges and Universities."¹ And, indeed, the typical departmental structure poses special problems to those seeking cross-disciplinary outlets. Department goals and individual researcher interest do not always coincide. Staffing needs may be met with choices more appropriate to the disciplinary concerns of the department than to the cross-disciplinary expressions fundamental to a mission-oriented institution. At a time when staff evaluation for tenure, promotion, and salary adjustment purposes is increasingly centered in departmental

¹ Harrington, Fred Harvey, "Structuring of Conventional Departments," from *Academic Departments*, ed. by Dean McHenry, Jossey-Bass Publishers, Inc., San Francisco, CA, 1977.

colleagues, the risks encountered by the cross-disciplinary worker operating "outside the pale," so to speak, are magnified. Seldom are two departments at the same stage of readiness to attack a problem of mutual concern. Other assignments or priorities lay claim to time and resources of those with willingness to work across lines. Those who work in interdisciplinary research must, in a sense, command two or more "languages." In crowded daily routines the time and energy required in setting meetings and in traveling across the campus to work with colleagues of another discipline may be just enough to quell the urge. Outlets for results may be less available for cross-disciplinary material, though this may be changing. The delicate question of who receives the credit in shared research can complicate the scene. When one has limited time for research, efficiency favors its use on matters close at hand. Because cross-disciplinary work may be interpreted as being

peripheral to departmental objectives, the resources of the department may be less available for its promotion.

Some administrative considerations probably necessary to the conduct of interdisciplinary research include the following:

- a) The department must be encouraged to sketch its objectives with sufficient breadth as to include interdisciplinary research as a completely appropriate and, indeed, an expected activity.
- b) The department seminar and project review systems should encourage cooperative interchange with scientists in related disciplines. Joint discussions are useful in legitimizing joint endeavors.
- c) Staff members should be asked to outline research intentions in annual reviews. Discussions attendant to these reviews can lend encouragement and support to new directions in research.
- d) The faculty load must permit the use of reasonable blocks of time for research or for project development and proposal writing. Staff members can be encouraged to get out and make contacts, both professional and funding related. This should be expected behavior. Some travel funds must be available to bring the scientist face-to-face with the potential funding agency. It may be useful to consider redirecting funds presently used in attending society meetings to more focussed visits to funding sources.
- e) The resources of the institution should be utilized to identify possible sources of funding as a preliminary to follow-up visits by the researcher to the agency.
- f) Interest in interdisciplinary research might well become a criterion in faculty recruitment.
- g) Public or private funding agencies need to be made aware of problems of major public interest. Out of this aroused concern should come fiscal response to attractive research proposals. This is a continuing process, never ending.

Funding sources are in the eye of the beholder. Courage, aggressiveness and imagination do on occasion produce strange and wonderful results for the seeker of funds. The researcher in the land grant colleges may have access to Agricultural Experiment Station funds, both federal and state in origin. State funding (legislative specials) is most likely to relate to defined problems and those of interest to legislators who are very close to their constituencies. At the federal level the more comprehensive questions may be treated, and over time one might assume that more funding for consumer research will stem from federal or private than from state sources.

Funding agencies tend to put their money where there is power in program. This works to the disadvantage of new thrusts or of groups just moving into research endeavor. Experienced researchers note the need for

"something to sell" in going to funding sources, this including defined rationale, pilot study results, and the promise of pay-off in ultimate outcomes. Here again the researcher's need for time for planning and for opportunities to meet with funding agencies is evident.

Your workshop planners were interested in the experience of the AHEA Commission of Family Research Act of 1975. The then Senator Walter Mondale had introduced the Family Research Act of 1975 (S2250), with intent to provide funding through the Cooperative State Research Service, USDA for research on the family and to provide assistance to land grant colleges of a kind and duration that would lead to the development of a larger corps of family researchers. It was the commission's role to assist in marshalling such support as we could for this legislation. The commission familiarized itself with the bill and met with the Senator and his staff with respect to language and interpretation. We reviewed our relationships with other interested organizations and agencies, began to structure support groups within each state through the various state Home Economics Associations, and gave thought to potential hearings on this legislation. It quickly became clear that we needed answers to several key questions before testimony could be given with confidence. What is the history of home economics research? What problems are attracting attention? What research would follow funding if the bill were to be enacted? What research of similar nature was being funded by other federal agencies? This information was not at hand.

Land grant college administrators of home economics were asked to report on research programs in progress and to note problems of interest, were funding to be available. Returns were fragmentary, but several interesting findings came to view:

- a) Home economics researchers are few in number. A late inventory of researchers in Agricultural Experiment Stations in 1975 revealed only 153 scientist year equivalents in home economics research endeavor.
- b) The majority of researchers reported investing but limited time in research. The majority of projects reported were of small scale. There was little indication of powerful thrusts in defined areas.
- c) The research projects proposed, were funding to become available, were miscellaneous in nature, and not of a type that would arouse major sponsor support. There were few suggested projects of size and scope. Home economics researchers do, it appears, tend to "think small."
- d) Little was known of the amount of home economics related research funded by other federal agencies.

The fate of the Family Research Act of 1975 (S2250) was sealed by the massive attack launched by various bodies upon the Child and Family Services Act, of which Senator Mondale was also a principal author. Because of the similarity in titles, it was likely that S2250 would, if pushed, attract a parallel attack from conservative groups, hence no hearings were held on S2250 and the bill received no action.

The need for more information on home economics research efforts did lead to the initiation of a study entitled "Home Economics Research Assessment, Planning and Projection" (HERAPP), this funded by the Cooperative State Research Service, USDA, in cooperation with the Association of Administrators of Home Economics and the Agricultural Research Policy Advisory Committee, USDA and NASULGC. The work was headed by S. J. Ritchey and Elizabeth Davis. From their efforts

will come a listing of researchable problems, in priority order. So, too, will the study survey other sources of funding for home economics researchers.

It is quite clear that, in general, home economics researchers have not been aggressive in exploring sources of funding other than that of the Agricultural Experiment Stations. Sources appear to exist. A hasty survey of July and August, 1977 issues of Commerce Business Daily and the Federal Register, reveals 30 requests for proposals and grants in home economics related areas, from USOE, NIAA, NIDA, HEW, NIMH, DOL, PHS, and the U.S. Army. The more complete census being accomplished as a part of the HERAPP study will do much to guide home economists as they look to their research funding future.

The home economics profession has enjoyed some successes in influencing public policy in recent years, yet its history is one of reacting, rather than initiating. This climate is changing.

What lessons did the commission learn from its experience with the Family Research Act?

- a) That a continuing relationship to funding sources needs to be developed and to be maintained over time,
- b) that requests for legislative funding need to rest on a strong information base, be realistic, and promise information useful in dealing with questions held to be important by the funding sources,
- c) that the faculty member needs time to plan, to develop projects and to follow leads to sources,
- d) that the race goes not to the meek or the conservative,
- e) that credibility of the petitioner grows out of action, and that research success breeds success.

Funding of public institutions of higher education increasingly rests upon measures of teaching load. In a future where research will be largely separately funded, the home economics researcher will have to be skillful in seeking research support. Preliminary results from HERAPP suggests that research funding relating to home economics interests is available from a number of Federal Agencies, but that the home economics researcher has to this time concentrated largely upon funding from the CSRS, USDA. A more aggressive inquiry and request program is in order.

EXPERIENCES IN INTERDISCIPLINARY CONSUMER RESEARCH

Sarah L. Manning, Purdue University

Abstract

Experience in two inter-regional interdisciplinary research groups brings out two reasons for doing interdisciplinary research: (1) economic, by pooling funds and costs, and (2) talent-complementing talents and abilities. Frequent problems are (1) communication due to different concepts and word meanings; (2) ego problems with talking prima donnas. Also discussed are publication, administrations, attitude, and concepts/methods problems.

My experience with interdisciplinary research has come from involvement in two regional projects under the Agricultural Experiment Stations of several states. My own field is family economics and management. Other researchers on the committees have been from child development, family studies, housing, and sociology, with some minor nuances of those more interested in management than in economics, or vice versa, those interested in aesthetics rather than sociological or economic factors of housing, those interested in family processes more than the sociology or psychology of the family.

The first committee I was a member of was NC 90, an interdisciplinary, inter-regional research committee to study "Factors Affecting Patterns of Living in Disadvantaged Areas". As this research area was originally conceived to involve more than one discipline, a call went out to all the Agricultural Experiment Station Directors to send a representative if the director and a researcher was interested in being involved. Support for the project came from the several states and also from federal money channeled through the states. One state director was asked to be our administrative advisor. I will quote from the foreword he wrote for the joint publication or basebook we produced:

"It was a rare privilege for me to watch this project develop from the early stages of overcoming the language barrier of diverse disciplines, through the multiple agonies of preparing a common instrument acceptable to all and coordinating the collection and processing of data, to the triumph of the Committee in presenting these data so painstakingly recorded."

Herbert Kramer, Administrative Advisor

Language barriers, multiple agonies, triumph. Herb Kramer's words capture some of our experience. Several members of that committee, believing that we'd been through the language barrier bit already, volunteered to work on a second interdisciplinary committee: NC 128, "Quality of Life as Influenced by Area of Residence." We are currently in the data collection stage, having come through the conceptualization, the development of the instruments and the sampling procedures. My remarks on interdisciplinary research are based on my experience and observations.

First, and also most important, in home economics we are concerned with the family. However you define "family" and its functions, it is a many sided entity, a system composed of subsystems which interact, and a system which interacts with its environment. An interdisciplinary research approach approximates the family better than any one-sided approach can ever do. This is not to

denigrate the one-sided approach; we need researchers going in depth in isolated areas to help develop the building blocks to fit these subsystems together. But the interdisciplinary research offers the best, perhaps the only, way to fit pieces together. As a family economist, I must recognize that, powerful as economics is in shaping family decisions, it is not the only motivating force. My economic analyses may be complete in themselves but they have to take as given tastes, values and social structures. Therefore, as a researcher I welcome the opportunity to work with others who can supply my deficiencies.

Second, on a more practical or personal level, what are our reasons for doing interdisciplinary research?

Economic reasons. We all are constrained by lack of funds. But in NC 90 we were able to obtain thirteen samples totaling 2650 families, with a wealth of detail no one researcher could probably hope to obtain. We decided on central computer processing for our overall analysis. This was done at the University of Missouri for an approximate cost of \$5800. Dr. Edward Metzger estimates that the same processing, done at each of the states, would have cost each of us \$3500 to \$3800 for the computer and other direct costs. We each paid Missouri \$300, so Missouri had to pick up the rest of the tab but even so, Ed estimates that the net cost to Missouri was about \$2200, less than it would have cost them to go it alone. These figures do not cover faculty time and I am sure there was considerable saving of total faculty time over what it would have been without the central processing.

Talent reasons. We each bring to interdisciplinary research our own bag of tricks, our own talents and abilities. Within the committee we find others who complement us by their differences in abilities. The ones who can develop the best conceptual frameworks may not be the ones who have the deepest understanding of computer analysis. The synergistic results are greater than each working alone could have accomplished.

What problems occur in this kind of research? And how can we deal with them?

Communication. As I reflect back to our first formative meeting here in Chicago, I recall that each person acted very protectively for his own research area. There were subtle attempts to put the others down in order to enhance one's own position. In the early meetings we often used the same words and only time showed us that we had different meanings attached to them. How did we overcome this? We read each other's papers and references. We fought with each other, in meetings and over dinner. We liked each other and respected each other so we could bring our differences out into the open. We still haven't arrived at that point where I can say we always resolve our differences, because we haven't. But our meetings have been characterized as "lively". Communication is still a problem but much less so than several years ago.

Ego problems. In commenting on Regional Research in the Southern Cooperative Series, Bulletin 212, October 1976, J.D. Jansma wrote "Faculty members are inherently prima donnas convinced that "their approach" is the preferable one." Not only prima donnas but talkative prima donnas, I believe, for the most part. It takes a firm hand of

chairman to control some of this, and constant checking and rechecking to make sure someone hasn't gone off in his own direction assuming the rest of us are following him. Or not giving a hoot whether we are or not.

Publication problems. Today the pressure is on as never before (and it wasn't negligible before) to publish research. When each state collects data, every researcher wants to work up his own data and get it published. He also would like to pick pieces from the other states to publish. Who has priority when the data came from several or all states involved? In NC 90 we evolved a simple one page form to be sent to each other state when we wanted to ask permission to use any state's data other than our own. This form indicated what parts of the data we wanted, the objectives of the research to be done, the nature of the use or publication and the anticipated completion date. The state wanting the data had 10 days to respond. No response indicated agreement with using the data. Sending to all committee members kept us all informed about what kinds of analyses were being done. If it were something we wanted to do we could either cooperate or shift our emphasis so we didn't have uneconomic duplication. This seemed to solve the problem of individuals publishing by giving them freedom to do so without destroying the unity of the project.

That satisfied the individual researchers, but we still had the obligation to produce a total report from the project. For this purpose we all worked on sections, partially by subcommittees, and then were fortunate to have one committee member who was retiring. She pulled all our parts together into a unified whole. In cooperative research this is a real problem, especially when the committee is large. No one researcher may want to devote so much time to writing the major report when he appears as only one among many authors. Incidentally, one colleague has reported to me that in his university, promotion and tenure committees look at the number of authors and give credit for one third of a refereed article when there are three authors! Not much support for interdisciplinary research evident there.

Administration. This can be either a problem or a help. In general, when interdisciplinary research results from the individual interests of the researchers who see gains to be made either for their field or for themselves, the research will go forward. If it is purely an administrative decision, it seldom works. One administrator several years ago told me that interdisciplinary research did not work because no one took primary responsibility for it; it was always the other fellow's job. This would be less likely to happen if the researchers had initiated it. We have had some people attend our committee meetings who were sent by their Stations. But because there was no time released for them to do research, they dropped out. Or sometimes the administration failed to allocate adequate funds.

Attitude. Any one going into interdisciplinary research would be wise to adopt a cooperative attitude. One must share his ideas, his data, his expertise for the good of the project. This is one of the costs of getting input from others in order that the whole may be greater and that the individual can advance in his field. Compromise is also necessary. Often each of us knows we could go faster or in a deeper direction without all those others we must compromise with. But the synthesizing potential is far greater than going it alone; and without compromise no other researcher worth his salt would be willing to work with you.

Problems of concepts and methods. These differ among various disciplines, and my only advice is to focus on your similarities and your differences until all sides understand. The learning process can sometimes be painful; I hope one of my colleagues from another

discipline has forgiven me for messing up one of his sets of questions in NC 90 when I altered the format to agree with the rest of our questions.

One advantage home economists have in interdisciplinary research is the broad base they already have in their education and orientation. The basic disciplines are fine but we do have this edge, if we are good researchers.

What could improve interdisciplinary research?
Three suggestions:

- 1) Money, of course.
- 2) Time may be more important, however, time to work on the research. Time to interact with one's colleagues on the research team.
- 3) More WATS lines so we could iron out problems faster when we are apart.

INTERDISCIPLINARY RESEARCH NEEDS AND OPPORTUNITIES IN CONSUMER BEHAVIOR AND EDUCATION

J. Barry Mason, University of Alabama
A. William Gustafson, University of Alabama
Mary Harrison, University of Florida
Norleen Ackerman, University of Wisconsin
Roger Swagler, University of Tennessee
Rose Davis, University of Kentucky
Beatrice Petrich, University of Wisconsin
Nancy Miller, University of Wisconsin
E. Thomas Garman, Virginia Polytechnic Institute and State University
Robert Mittelstaedt, University of Nebraska, Lincoln
Terrje Assum, Cornell University

The topics assigned to this ACR/AHEA subgroup for discussion were (1) consumer behavior and satisfaction, (2) family economics, and (3) home economics education, redefined as consumer education. Consumer behavior in the context of the household was the focus of the discussion. The group sought to translate specific aspects of the above three topic areas into a series of researchable topic statements. These statements were then ranked in terms of 1) their need for research and 2) their appropriateness for interdisciplinary research. The background for the three topic areas and the specific research topics agreed upon are presented below.

Consumer Behavior and Satisfaction

Objectives of Research

To strengthen understanding of consumer behavior so as to improve consumer competencies and satisfactions.

Current Situation

One goal of consumer behavior is to maximize satisfaction. Choices by consumers affect the quality of their lives, but many consumers are not adequately informed about the bases of choices or the consequences of decisions. The effects of factors such as governmental regulation, technological developments, and cost and availability of information on consumer satisfaction are not fully known.

Much of the research on consumer satisfaction serves only to determine preferences for brands of products and not whether the product is needed or whether a needed product is available. A better understanding of consumer values and goals and relative degrees of satisfaction would provide a basis for more efficient use of resources. An index of consumer satisfaction, for example, would provide producers and policy makers with new directions for decision making. Policy makers could also be guided in attempts to provide incentives for consumer decisions that conserve nonrenewable resources (for example, through tax credits and deductions) by the results of research on energy use in alternative lifestyles. In an economic system presumably guided by the ideal of maximizing consumer welfare, goals and satisfactions should be the focus of concern in evaluating societal progress.

Researchable Topics

The following topics were identified as those most in need of additional research. (1) The development of a comprehensive conceptualization of the meaning of cost/benefit in the context of consumer protection: (2) the development of measurement tools reflective of the benefits and costs of consumer protection to the consumer: (3) analyze the cost/benefits at the household level of specific consumer protection legislation--i.e.,

fair packaging and labeling, equal credit opportunity and similar legislation.

The most viable interdisciplinary research topics agreed upon were: the same as those developed above as most in need of additional research.

Family Economics

Objective of Research

To analyze the components of economic well-being and evaluate their contribution to the family's overall well-being.

Current Situation

Families are faced with the necessity of reevaluating their expectations with respect to changes in real income and material levels of living. Since World War II families and individuals have experienced a fairly continuous rise in the level of real income. Expectations have developed that this trend will continue bringing possibilities of continued improvement in families' material levels of living. In the past few years, however, the U.S. economy has been faced with both inflation and unemployment which have threatened the maintenance of our currently high material level of living. Also, large numbers of families and individuals in the United States still live in poverty. Whether the size of the economic "pie" continues to increase or remain the same, alternative government programs for income redistribution need to be evaluated.

In addition, the economic significance of family composition and structure is greater today than ever before. The rise in the number of female-headed families, fewer elderly people living with relatives, and fewer couples having children affect the economic well-being of today's family unit.

In the above context, development and use of human capital in the labor market and in the home affect the economy and the individual family unit. Rapid increases in the cost of education, changes in job skills, and increases in female participation in the labor force have repercussions on the economic well-being of families.

Finally, evaluation of economic position, a concept broader than money income, is important, especially because of the increase in the use of credit for consumer purchases and since much of the material level of living is based on possession of durable goods. Economics position of the family, which includes not only the level of money income but debts and savings, and other monetary income are important in determining economic well-being.

Researchable Topics

The following topics were identified as those being most in need of additional research: (1) development of operational definitions of income adequacy and equivalence in order to review appropriateness of poverty thresholds, income supplements, income maintenance and related concepts; (2) studies of economic responses by families to aggregate economic changes including inflation, recession, stagflation, economic dislocations, changing productivity, unemployment and taxes; (3) assessment of the components of levels of well-being of families; (4) an investigation of the impact of public programs and policies on consumption patterns (housing, day care, income supplements, consumer education).

The most viable interdisciplinary research topics were identified as follows: (1) the study of the economic responses by families to aggregate economic changes including inflation, recession, stagflation, economic dislocations, changing productivity, unemployment and taxes; (2) development of operational definitions of income adequacy and equivalence in order to review appropriateness of poverty thresholds, income supplements, and maintenance; (3) study of changes in economic behavior of various groups of families experiencing changes in money income as a result of changes in family composition/circumstances such as multiple job holders and working wives.

Consumer Education

Objectives of Research

To strengthen the system for delivery of knowledge, strengthen the integrative forces within various consumer related disciplines and to improve the education of consumer educators and the public generally.

Current Situation

Consumer education serves individuals and families through professionals who work in such educational areas as:

- 1) higher education: undergraduate and graduate programs
- 2) vocational and technical education: in secondary, post-secondary, adult and paraprofessional programs
- 3) secondary education: in consumer and homemaking, occupational, and general programs
- 4) early childhood and elementary education: in pre-school, kindergarten, primary and middle school programs
- 5) extension, continuing education, and other nonformal programs
- 6) research: in higher education, business, and government
- 7) other, such as in government, business and international programs

Researchable Topics

The following topics were identified as being most in need of additional research: (1) the establishment of systems through which professionals can identify competencies and needs of individuals and families as a base for consumer education programs and devise, validate, and evaluate instruments for use in the systems; (2) determine the characteristics related to the needs of specific learners that can be met by consumer education programs; evaluate models to meet educational needs of these special groups such as displaced homemakers, the elderly, the physically handicapped and institutional (mentally ill) populations; (3) establish systems through which professionals can identify competencies and needs of individuals and families as a base for consumer education programs; devise, validate, and evaluate instru-

ments for use in the system.

The most viable interdisciplinary research topics were identified as: (1) study educational approaches which impede or facilitate change in the consumer behavior of individuals and families in consumer economics related areas (e.g., energy conservation, sex stereotyping, and food habits); (2) determine the characteristics related to the needs of specific learners that can be met by consumer education programs; evaluate models to meet educational needs of special groups such as displaced homemakers, the elderly, the physically handicapped, and institutional (mentally ill) populations; (3) evaluate alternative educational delivery systems in consumer education in relation to such characteristics as purposes, audience, cost, and societal pressure.

Research Topics for ACR/AHEA 1978 Workshop

The following two topics were selected as the subjects for papers to be presented at the ACR/AHEA meeting in June 1978: (1) sources and utilization of information and correlates of satisfaction/dissatisfaction in complaining behavior about food marketing practices at the retail level by the elderly consumer. Authors: Ackerman, Assum, Gustafson, Harrison, and Mason (Hunt and Swagler later joined this group); (2) delineation of professional and subject matter competencies of teachers in consumer education programs. Authors: Davis, Garman, Miller, and Petrick.

PRIORITY OF TEXTILE AND CLOTHING PROBLEMS
FOR INTERDISCIPLINARY CONSUMER RESEARCH

Gloria Williams, University of Minnesota
Betty Crown, University of Alberta
Marjorie Wall, University of Guelph
Billie G. Murphy, University of North Carolina, Greensboro
Lois Korslund, University of Missouri, Columbia

Six areas were identified in the Home Economics Assessment, Planning and Projections (HERAPP) papers as potentially workable for interdisciplinary research for the Textile and Clothing (T & C) sub group. The areas are (1) clothing--social and psychological aspects, (2) economics of textiles and clothing (3) historic clothing and textiles, (4) design and aesthetics of clothing, (5) special needs for clothing and (6) textiles. Included within each area was a statement of the current situation, a broadly stated research objective, specific research problems of greater and lesser importance and identification of current activity with respect to each problem represented. These papers served as the basis for group discussion.

Suggestions provided by the workshop organizers directed the attention of the Textile and Clothing group to tasks which were primarily evaluative in nature. Initial focus centered on the adequacy of each situation statement--its timeliness, relevance and need for modification. The statement of specific problems for research, the concepts and concepts in relation were the second area of examination. Criteria for assessment included 1) the importance and precedence of research problems within and between the six areas, 2) the significance of the concepts identified, 3) the critical need for research solutions of problems 4) the appropriateness of problems and concepts for interdisciplinary thrusts and 5) the likelihood and necessity of interdisciplinary input into the problem area(s). In addition to suggesting ways in which cooperation among different and interested disciplines could be attained and enhanced, our final task was to identify the significant research problem area(s) or topic(s) within which each group member--separately or together--could develop papers for presentation at the continuing workshop at the 1978 AHEA Conference in New Orleans.

This report addresses itself to the above tasks.

Situation Statements

The subdivisions and titles for T & C areas reflect a traditional approach to categorization of research interest areas in the home economics field. Thus, the possibility of stimulating and attracting interdisciplinary input may be limited. Alert to this likelihood in critical analysis of the situation statements, the following observations and assumptions seem reasonable to make.

1. Current and traditional interests of scientists and educators in the textile and clothing area are reflected in the situation statements. Each, however, has been conceptualized in a manner which lends itself to interdisciplinary input. For example, in AREA I, Clothing--Social and Psychological Aspects,
 - a. attribution theory, function theory and other social interaction theories are implicit in the statement.
 - b. focus is on clothing use which can be conceived as an aspect of general product usage, as an

area of consumer decision-making in post-purchase processes, as a component of non-verbal communication and as a broad area of human behavior (or action) with respect to clothing.

2. Each statement explicitly or implicitly refers to problems connected with theoretical and methodological issues as well pragmatic aspects. It is therefore understood that these issues cannot be separated but must be considered parts of a total perspective for an applied science concerned with consumer research.
3. A stronger practical problem-orientation is apparent in the situation statements of some areas rather than others. For example,
 - a. in AREA VI, Textiles, reference is made to problems connected with (1) inter-and intra-information delivery systems among government, manufacturers/distributors and consumers of textile products, (2) energy resources, use and conservation in the design and recycling of textile structures, (3) the analysis of costs, benefits and consequences of government regulations and standards for producers/distributors and consumers.
 - b. in AREA IV, Design and Aesthetics of Clothing and AREA V, Clothing for Special Needs, attention is directed to problems associated with aesthetic and functional clothing designs for general populations and especially for those populations with special needs--the elderly, children, disabled and obese. Overlap is apparent between these two areas. Marketing problems are evident in production and distribution of clothing for special populations.
 - c. in AREA III, Historic Clothing and Textiles, emphasis is primarily on methodological issues, the need to organize and integrate past knowledge as a basis for describing and explaining the current social-economic-cultural situation and predicting the future along with the importance of preserving these artifacts as a part of our social and cultural heritage.
4. Timeliness and relevance are reflected in certain of the situation statements. For example, emphasis in society on (a) the dignity and worthwhile of individuals and the quality of life experiences (in clothing use, choice and protection) (b) special interest groups--the disabled-elderly, elderly and poor (with respect to special clothing design and quantity needs), women and other minority groups (the stereotypic reflections of appearance and clothing in media presentations and other interacting situation) (c) the proliferation, resistance and acceptance of public policy intervention (in regulating manufacturers and distributors of apparel, home furnishing and other textile products).

Research Problems and Concepts

Taking into consideration the first few research problems identified as more or less important for each subdivision for the T & C group, the following statements seem reasonable:

1. Problem areas as delineated are complex in nature. Contained within each are many concepts and relations between them which are perceived as associative and/or causal; multivariate rather than simplistic relations are to be considered.
2. Some problem areas may be better managed by industry or groups other than those in the disciplines currently represented, e.g., medical and biological teams may be required for some problem areas; some problem areas in textiles are concerned with basic research and development of fiber, yarn, fabric properties.
3. Some problems seem to lean more toward theoretical and methodological issues which seem somewhat removed from providing immediate solutions. Attention to these problems has consequences for building knowledge in the discipline and are basic to solving practical problems.
4. Problem areas through their concepts not only tap different disciplines but different interest and expertise.

In order to tap differences in training, interests and expertise of group members and to provide a means for individual commitment, one approach taken was

1. to develop a matrix which would take into account
 - a. significant and prioritized problem areas on one axis,
 - b. different units of analysis, e.g., consumers, manufacturers, distributors, government, on the other axis and
 - c. interaction between the units and the problem areas
2. to review the lists of researchable problems to see if the concepts and relations exemplified in the problem statements fall more naturally into one cell or another within the matrix.
3. to use the matrix as a basis for subsequent discussion, assessment, commitment and reporting.

The matrix and list of problems for which interdisciplinary research effort is required for problem solutions is attached. (See Appendix).

Individual Topic/Problem Commitment

Reflection on the HERAPP papers, the matrix and activities of the group showed a groping and constant search for a way to capitalize on individual resources and talents as well as manage our tasks of prioritizing research problems and assessing their usefulness for interdisciplinary thrusts. It became apparent in ensuing conversations that each of us was interested in focusing broadly on problems associated with some aspect of the consumer (individuals or families) as the unit of analysis, and his behavior (e.g., use, dressing-undressing) interrelated with aspects of the structure and characteristics of the clothing or flexible product. Consideration would have to be given to conceptual, methodological and pragmatic aspects of the broad problem area or subareas. Three broad subareas were identified for individual pursuit.

1. Problems associated with individual dispositions (i.e., motivations, attitudes and values) with respect to clothing use.
Gloria M. Williams
2. Problems associated with aesthetic and functional clothing design needs with respect to special populations.
Lois Korslund
3. Problems associated with consumer attitudes toward textile product performance and standards.
Betty Crown and Marjorie Wall
(working jointly on product safety)
Billy Murphy

Each of us is aware of the continued and necessary critical assessment of the research problem area and concepts in relation to the specified criteria. In addition, each of us is attuned to the implications of these topics (or areas) for intra- and inter-disciplinary consumer research and possible ways of attaining and enhancing cooperation between disciplines.

Members of the T & C Committee:

- Betty Crown
- Lois Kroslund
- Clark Leavitt
- Billy Murphy
- Fern Rennebohm
- Marjorie Wall
- Gloria Williams

Appendix A

This group identified three main problem areas for which the identification of solutions requires an interdisciplinary research effort (Figure 1). In each area, research is needed to obtain information about consumer needs, values, motives, attitudes and behavior; information about the design, production and distribution of textile and clothing products; and information about government involvement. In addition, there is a need to know more about methods of disseminating the above information among consumers, designers, producers, distributors and government agencies.

Dissemination of Information
(6, 23, 24)

PROBLEM AREAS	Consumer needs, values, motives attitudes and behavior	Designers Manufacturers Retailers	Government
Energy/resource use and conservation	*1, 2, 3, 4, 5, 6, 7,	16, 17, 18	2, 22
Product Safety (or more generally, product performance)	8	19	22
Special Needs/Functional Problems	9, 10, 11, 12, 13, 14	16, 20	
	7, 15	21	

Figure 1. Research Problems for Interdisciplinary Consumer Research.

*Numbers in each cell refer to problem statements listed on the following pages.

Problem Statements

Twenty-four sub-problem statements from the HERAPP Draft Working Paper were selected and revised to fit within the framework of Figure 1. The sub-problems thus arrived at are listed below.

1. Examine the effect of fashion on the consumption of clothing and textiles, including prices, quantities of items purchased, and frequency of replacement.
2. Measure the impact of environmental controls on the cost and availability of textiles and clothing; economic implications for clothing from industrial constraints; cost of enforcing and administering the controls; cost and use of care labelling.
3. Examine textiles and clothing consumption from a theoretical view; analyze the clothing and textiles consumption process including cost, discard, and other aspects; relate to demographic and other variables.
4. Analyze consumer demand for clothing and textile products; prices consumers are willing to pay in light of particular product attributes.
5. Develop ways of conserving energy by a use of innovative textile structures in clothing and household textiles and b) modification of care techniques.
6. Evaluation of information delivery systems for transfer of knowledge concerning textile products to the consumer.
7. Determine consumer knowledge and values concerning textile characteristics, and criteria for selection, use and care.
8. Determine consumer knowledge and value systems concerning "trade-offs" involved in textile production, cost, performance (including special properties) and trade resulting from government mandated programs related to consumer and worker safety, environmental protection, and care labelling.
9. Investigate the use of clothing in adapting and adjusting throughout the life cycle.
10. Investigate the interrelationships between textile properties, human anatomy, garment cut, and structure as they affect the comfort, function, and aesthetic quality of garments.
11. Develop measurement methods for assessing garment comfort.
12. Analyze disabilities which create special clothing needs of adults and children and identify problem areas; develop and evaluate solutions to the problem areas identified.
13. Develop a classification system based upon disabling conditions for the synthesis and integration of information about clothing for disabled.
14. Investigate the interrelationships between textile properties and garment design as they affect the physiological and psychological aspects of comfort in varied environments.
15. Develop appropriate techniques for measuring values, attitudes and behavior associated with clothing.
16. Investigate the potential of innovative construction techniques with new fibers and fabric structures for development of new design forms for apparel.
17. Determine the comparative amounts of energy consumed in the production of various types of textile structures.
18. Develop methods for recycling textiles which are profitable economically in order to conserve finite resources.
19. Determine aspects of textiles which affect consumer safety. These include fabric and product flammability as well as the allergenicity, toxicity, mutagenicity, and carcinogenicity of textile additives, dyes, and finishes.
20. Develop a predictive method of shaping and adjusting garments to varied body shapes.
21. Analyze the structural and aesthetic trade-offs made by apparel producers in the interests of controlling production costs and meeting regulations.
22. Determine effects of government policies and regulation relating to textiles on their cost, availability, performance, and selection as well as upon the domestic-international trade balance.
23. Examine the interaction of consumers and retailers in terms of consumer practices, retailer response to these practices, transmission of information and feedback of consumer preferences to producers.
24. Evaluate methods of disseminating to the disabled information on selection, adaptation, and construction of clothing to meet special needs.

INTERDISCIPLINARY RESEARCH GOALS FOR FOOD,
HUMAN NUTRITION, AND HEALTH

Jim McCullough, University of Arizona
Karen Morgan, Michigan State University
Joel Saegert, University of Texas, San Antonio

Problems in the area of Food, Human Nutrition and Health are, by the nature of the field, multidisciplinary, since the disciplines involved in the study of this area are both numerous and diverse. Effective analysis of these problems requires not only multidisciplinary research in which the many disciplines consider a problem from their unique position, but also interdisciplinary research in which both the concepts and viewpoints of the various disciplines are blended to achieve a unique, more complete perspective of the questions in a global setting.

Rather than a single discipline placing emphasis on indepth study of problems drawn from multidisciplinary areas, some segments of the academic community are beginning to recognize the value of an interdisciplinary approach to the study of these problems. It was interest in merging disciplines for the purpose of problem identification that led to the interdisciplinary workshop held by the Association for Consumer Research (ACR) and the American Home Economists Association (AHEA) during the ACR meetings in Chicago.

The purpose of this workshop was to stimulate an interdisciplinary approach to the identification of problem areas from among research issues drawn from several disciplines. One approach to this task is discussed in this paper.

Appropriateness of Problems

Research involving food and nutrition involves numerous disciplines. Table 1 shows some of the disciplines which could make contributions to problem solving in this area of research. Among the 16 fields mentioned in Table 1, only four, i.e., Food Science, Marketing, Psychology, and Economics, were represented by the members of the team preparing this paper. Therefore, many problems, particularly those of a technical nature in the areas of food safety and nutrition, were rejected as inappropriate for treatment by this team.

TABLE 1

Disciplines Related to Food, Human Nutrition, and Health

	<u>Physical Science</u>	
Chemistry		Food Science
	<u>Biological Science</u>	
Biochemistry		Pharmacology
Biophysics		Microbiology
Physiology		Nutrition
	<u>Social Science</u>	
Economics		Anthropology
Sociology		Political Science
	<u>Behavioral Science</u>	
Psychology		Marketing
Management		Dietetics

A three element screening criterion was used to identify those research priorities most suitable for analysis by this particular group. The problem areas most suitable for additional assessment by this team were determined to be:

1. Problems of cognition and perception of food and nutrition
2. Problems of group and individual behavior towards food
3. Problems of attitudes, values and beliefs concerning foods and nutrition.

Problems outside these categories could be better approached by individual scientists in specialized areas or by interdisciplinary teams with greater competence in the more technical areas of food and nutrition research. As a part of an on-going program to establish research priorities in Home Economics, the Home Economics Research Assessment, Planning and Projections (HERAPP) prepared a listing of areas of current research and important problem areas which require additional research. These were screened by the interdisciplinary team using the three element criterion. Since the earlier workers had divided the area of Food, Human Nutrition, and Health into six sub-areas, the problems were examined and classified by the interdisciplinary team under these headings as shown in Table 2. In each area, several problem areas could be appropriately handled, and in most cases, the previously identified major problem areas were found to be feasible concerns. The scheme of classification, however, failed to provide a research frame suitable for systematically identifying appropriate significant research questions for interdisciplinary work; therefore, additional tools were selected.

TABLE 2

Assessment of Problems

<u>Area</u>	<u>HERAPP Problems</u>	<u>Suitable Problems</u>	<u>Most Critical Questions</u>
Food Quality	11	5	Education and Provision of Information
Food Safety	15	2	Education
Food Service	12	10	Energy Conservation Education
Nutrient Requirements	23	4	Biological Requirements Testing
Nutritional Health of Population	9	5	Standard Development, Theory of Behavior
Human Nutrition, Health Education, and Applied Programs	12	12	Theory of Behavior Education

Taxonomy of Projects

Evaluation of the substantive questions underlying the research priorities deemed appropriate for interdisciplinary research resulted in a taxonomy of research areas. This taxonomy is outlined in Table 3.

TABLE 3

A Taxonomy of Problem Areas

- 1) Theoretical Issues Underlying Choice, Habits, and Behavioral Change Relative to Food.
- 2) Analysis of the Vehicles of Change
 - a) information
 - b) intervention
 - c) institutional modification
- 3) Evaluation Criteria

The research proposals from HERAPP deal heavily with methods for change; furthermore, they tend to concentrate on education. Unfortunately, the theoretical bases for these desired changes are not well understood. Consumer information processing and food distribution systems are areas of marketing research which are actively pursued and are areas particularly suitable for interdisciplinary work. The establishment of standards and evaluation criteria must be done in an interdisciplinary fashion if there is to be any real meaning to the results.

The most serious question, however, is the lack of a well-balanced interdisciplinary base from which research may commence. The research question with which this particular team will begin the literature review is "the identification of the factors influencing consumer choices in the food marketplace." This will then serve as a broad base for examination of more specific research questions.

ENERGY MANAGEMENT FOR CITIZENS IN A CONTEMPORARY WORLD

Merlene Lyman, South Dakota State University
Maryann Paynter, University of Kentucky
Emma Auer, Purdue University
Raedene Combs, University of Nebraska
Patricia Tripple, University of Nevada, Reno
Judy Van Name, University of Delaware

Abstract

Work group five, Energy, Shelter and Community, was composed of six persons who explored the assignment and tentatively agreed to compile annotated bibliographies of research related to energy management for citizens in a contemporary world.

Introduction

Work group number five was organized informally during the Friday morning session. Francis Magrabi, co-chairperson of the ACR-AHEA Interdisciplinary Research Workshop, asked conferees to declare a preference from the five research areas she listed. The six persons who chose "Energy, Shelter and the Community" met together to select a discussion leader and recorder as suggested. They held several discussions Friday afternoon and Saturday morning to select and revise research priorities using the preliminary draft of a project report entitled, "Home Economics Research, Assessment, Planning and Projections" (HERAPP).

The research topic areas from the HERAPP project assigned to group five included:

1. Housing and Energy
2. Energy Management in Housing
3. Management and Resource Use
4. Community Development

Initially, participants in this section expressed tentative concerns about:

1. the limited interdisciplinary composition;
2. the assumption that these persons represented the expertise necessary to select and revise the research priorities from the HERAPP project;
3. the scarcity of knowledge concerning the origin or selection of the HERAPP lists (Many participants had access to this information from their institutions but were not aware that this was to be the basis for their deliberation at the workshop); and
4. the lack of direction about how this segment of the workshop was to function during the time before it was expected that they would present a review-of-literature-and-theory paper at the AHEA meeting in New Orleans in June 1978.

Research Priorities

After reading and studying the HERAPP document, suggestions were presented for research priorities. Most of the group favored ranking energy use related to housing as the first priority; others voted for community development or involvement in public policy as a means of influencing consumer energy management.

It was not possible in the time provided to evaluate and re-order all the HERAPP items. However, the following topics were given some precedence over the others.

1. Alternate housing forms
2. Barrier-free housing for elderly and disabled
3. Constraints on achieving home ownership
4. Energy management in the home
5. Extent of discrimination and problems of enforcing laws for ensuring human rights to housing
6. Impact of utilization of home computers
7. Influencing public policy for housing
8. Investments in human capital, new life styles
9. Life cycle cost analyses for housing, furnishings and appliances
10. Other political, economical and social aspects of housing
11. Promotion of democratic decision-making in the home
12. Relationship of public and private energy costs
13. Solar heating and other energy alternatives
14. Spatialization and design of housing

Commitments

Incidences of completed or current projects related to several of the HERAPP researchable problem areas were cited. However, since they were not funded through agriculture funds, it was understood why they were listed. Duplication of these studies did not seem reasonable. Hence, it was decided that each researcher would begin by compiling an annotated bibliography of research using a variety of sources from many disciplines. These are to be sent to Merlene Lyman by February 1, 1978.

Topics selected for the literature search and persons tentatively committed to compiling the annotated bibliographies were:

1. Cost and Availability of Energy for Housing; Adaptation of Technological Advances--
Merlene Lyman, South Dakota State University
2. Contemporary Spatialization and Design of Housing--
Judy Van Name, University of Delaware
3. Relationships Between Public and Private Energy Consumption--
Raedene Combs, University of Nebraska
4. Public Policy Related to Public and Private Energy Management--
Patricia A. Tripple, University of Nevada, Reno
5. Coping Behavior for Managing Family Energy Resources--
Maryann Paynter, University of Kentucky
6. Alteration of Life Styles for Energy Management--
Emma Auer, Purdue University

J. J. Persensky, National Bureau of Standards

"Safety Research — You and Your Lawn Mower"

BREAK 10:30-10:45

Parlor A-B

CONSUMER BEHAVIOR AND HEALTH CARE CHANGE

Chairmen: Thomas S. Robertson, University of Pennsylvania
Lawrence H. Wortzel, Boston University

Thomas S. Robertson, University of Pennsylvania
Terry C. Gleason, University of Pennsylvania
John R. Rossiter, University of Pennsylvania

"Children's Conceptions of Health and Medicine: The Role of Advertising"

M. Venkatesan, University of Oregon

"Nutritional Behavior and Preventive Medicine"

Lawrence H. Wortzel, Boston University
Robert A. Clarke, Boston University

"Consumer Behavior Aspects of Encouraging Non-Smoking"

Irving Wolf, NIMH

"Consumer Behavior and the Prevention of Alcohol Abuse"

BREAK 10:30-10:45

Icarus/Davinci/Montgolfler Room

CONSUMER RESEARCH APPLICATIONS IN PUBLIC POLICY

Chairman: Donald Hempel, University of Connecticut

Discussion Leader: Michael Mazis, Federal Trade Commission

R. Bruce Hutton, University of Denver
Dennis L. McNeill, Arizona State University
William L. Wilkie, University of Florida

"Some Issues in Designing Consumer Information Studies in Public Policy"

Paul N. Bloom, University of Maryland

"Potential Contributions of Consumer Research to Antitrust Decision Making"

Debra L. Scammon, University of Utah

"Effects of Expectancy-Discrepant Information on Consumers"

BREAK 10:30-10:45

Chanute/Bleriot Room

CROSS CULTURAL RESEARCH

Chairman: Donald Hendon, Texas A & I University

Discussion Leader: Roger Blackwell, Ohio State University

Douglas K. Hawes, University of Wyoming
Sigmund Gronmo, Norwegian Fund for Market and Distribution Research
Johan Arndt, Norwegian School of Economics and Business Administration

"Shopping Time and Leisure Time: Some Preliminary Cross-Cultural Comparisons of Time-Budget Expenditures"

J. Michael Munson, University of Santa Clara

"Personal Values: A Cross-Cultural Assessment of Self Values and Values Attributed to a Distant Cultural Stereotype?"

R. Neil Maddox, University of Missouri, St. Louis

Kjell Gronhaug, Norwegian School of Economics and Business Administration
Richard E. Homans, University of Missouri, St. Louis
Frederick E. May, University of Missouri, St. Louis

"Correlates of Information Gathering and Evoked Set Size for New Automobile Purchasers in Norway and the U.S."

BREAK 10:30-10:45

Saturday Morning Sessions 10:45-12:15

Terra Firma Room	Parlor A-B	Icarus/Davinci/Montgolfier Room	Chanute/Bleriot Room
CHILDREN'S INFORMATION PROCESSING AND CONSUMER BEHAVIOR #	ASSESSING AND EXTENDING MULTIATTRIBUTE MODELS*	RESEARCH ON PROGRAMS IN THE PUBLIC SECTOR*	RESEARCH ON LABELING OF CONSUMER PRODUCTS*
Chairmen: Lawrence J. Gianinone, Needham, Harper & Steers, Advertising Paul Zuckerman, Needham, Harper & Steers, Advertising	Chairman: Steve Baumgarten, University of South Florida Discussion Leader: Kenneth W. Kendall, Dalhousie University	Chairman: Betty Diener, Case Western Reserve University Discussion Leader: Richard Reizenstein, University of Tennessee	Chairman: Valerie Valle, University of Pittsburgh Discussion Leader: John Miller, University of Colorado, Colorado Springs
Bobby J. Calder, Northwestern University	James B. Wiley, Wayne State University	Stephen C. Burnett, Indiana University	Philip G. Kuehl, University of Maryland Robert F. Dyer, George Washington University
"Review of Studies on Children's Consumer Socialization"	"Selecting Pareto Optimal Subsets from Multiattribute Alternatives"	"Assessing the Impact of Increased Product Safety on Consumer Utility"	"An Experimental Examination of Deception in Labeling: Consumer Research and Public Policymaking"
Ellen Wartella, Ohio State University	Michel Larocque, Simmons College	Mark I. Alpert, University of Texas, Austin Linda L. Golden, University of Texas, Austin	Roger Best, University of Arizona Jim McCullough, University of Arizona
"Understanding Children's Consumer Socialization"	"Four Methodological Problems in Multiattribute Attitude Models"	"Transportation Attitudes Over Time: A Longitudinal Approach"	"Evaluation of Food Labeling Policies Through Measurement of Consumer Utility"
Marvin Goldberg, McGill University Gerald Gorn, McGill University	Richard A. Werbel, University of Illinois, Chicago Circle	William H. Cunningham, University of Texas, Austin Brondeil Joseph, University of Texas, Austin	F. Robert Dwyer, Jr., University of Arizona
"Television's Role in Promoting Good Eating Habits in Children"	"Measured Attribute Weights Can Make A Difference"	"Energy Conservation: Price Increases and Payback Periods"	"Consumer Processing and Use of Supplementary Drug Label Information"
Discussant: Jim Bettman, UCLA			

LUNCH 12:30-1:50 Galaxy Ballroom

Business meeting will commence during the second half of lunch. Those not interested in attending the annual business meeting should feel free to leave whenever they wish.

Saturday Afternoon Sessions 2:00-3:30

Terra Firma Room

ACR-AHEA INTERDISCIPLINARY RESEARCH WORKSHOP #

Group reports on research priorities for ACR-AHEA interdisciplinary research.

Parlor A-B

RECENT DEVELOPMENTS IN STUDYING CONSUMER INFORMATION PROCESSING #

Chairman: James R. Bettman, UCLA

Jacob Jacoby, Purdue University
Robert Chestnut, Columbia University

"Behavioral Process Technology: Selected Measurement Characteristics"

David Arch, U.C.L.A.
James R. Bettman, U.C.L.A.
Pradeep Kakkar, University of Pennsylvania

"Subjects' Information Processing in Information Display Board Studies"

J. Edward Russo, University of Chicago

"Eye Movements Can Save the World: A Critical Evaluation"

John W. Payne, Duke University
E. K. Easton Ragsdale, University of Chicago

"Verbal Protocols and Direct Observation of Supermarket Shopping Behavior: Some Findings and a Discussion of Methods"

Peter Rip, Stanford University
Peter Wright, Stanford University

"Product Profile Evaluation Tasks in Consumer Judgment Studies"

Meryl P. Gardner, Carnegie-Mellon University
Andrew A. Mitchell, Carnegie-Mellon University
J. Edward Russo, University of Chicago

"Chronometric Analysis: An Introduction and An Application to Low Involvement Perception of Advertisements"

BREAK 3:30-3:45

Icarus/Davinci/Montgolfier Room

RETAILING APPLICATIONS OF CONSUMER RESEARCH #

Chairman: William Locander, University of Houston

Discussion Leader: Ray Marquardt, University of Wyoming

Lawrence J. Ring, University of Virginia
Charles W. King, Purdue University

"A Multiple Discriminant Analysis Approach to the Development of Retail Store Positioning"

James G. Barnes, St. John's University of Newfoundland

"A Hierarchical Model of Source Effect in Retail Newspaper Advertising"

Daniel J. Brown, Oregon State University

"An Examination of Consumer Grocery Store Choice: Considering the Attraction of Size and the Friction of Travel Time"

Chanute/Bleriot Room

CONSUMER SATISFACTION, DISSATISFACTION AND COMPLAINING BEHAVIOR #

Chairman: C. P. Rao, University of Arkansas

Discussion Leader: Earl Morris, Iowa State University

Gerald Zaltman, University of Pittsburgh
Rajendra K. Srivastava, University of Pittsburgh
Rohit Deshpande, University of Pittsburgh

"Perceptions of Unfair Marketing Practices: Consumerism Implications"

Stephen B. Ash, Indiana University

"Rate of Purchase, Importance, and Satisfaction: A Comprehensive Analysis of Durable Goods"

Ralph Day, Indiana University
Muzaffer Bodur, Indiana University

"Consumer Response to Dissatisfaction with Services and Intangibles"

BREAK 3:30-3:45

BREAK 3:30-3:45

Saturday Afternoon 3:45-5:15

Terra Firma Room

ACR-AHEA INTERDISCIPLINARY RESEARCH WORKSHOP # (continued)

Journal editors report their interests in interdisciplinary research.

Uses and funding of ACR-AHEA interdisciplinary research.

Next stop: New Orleans, 1978 AHEA Conference, where the workshop will be continued.

Parlor A-B

RECENT DEVELOPMENTS IN STUDYING CONSUMER INFORMATION PROCESSING # (continued)

Icarus/Davinci, Montgolfier Room

"NEW" MODELS FOR CONSUMER RESEARCH *

Chairman: Gerald Hills, University of Tennessee

Discussion Leader: Ivan Ross, University of Minnesota

Terence A. Oliva, Louisiana State University
Alvin C. Burns, Louisiana State University

"Catastrophe Theory as a Model for Describing Consumer Behavior"

Richard L. Oliver, University of Iowa
Philip K. Berger, University of Kentucky

"Testing Competitive Models of Consumer Decision Making in the Preventative Health Care Marketplace"

Michael J. Ryan, Columbia University

"An Examination of an Alternative Form of the Behavioral Intention Model's Normative Component"

Chanute/Bleriot Room

REPLICATIONS AND EXTENSIONS *

Chairman: George Brooker, State University of New York, Albany

Discussion Leader: Mary Winter, Iowa State University

Philip Kotler, Northwestern University
Lenore Borzak, Northwestern University

"The Market for Personal Growth Services"

Charles M. Schaninger, University of Massachusetts

V. Parker Lessig, University of Kansas

"Sparks and Tucker Revisited: A Reanalysis and Replication"

E. H. Bonfield, Temple University

"Perception of Marital Roles in Decision Processes: Replication and Extension"

COCKTAIL HOUR 6:00-7:15 Cash Bar Terra Firma Room

DINNER 7:30-9:00 Galaxy Ballroom

Sunday, October 16, 1977

Sunday Morning Sessions 9:00-10:30

Terra Firma Room

INTERNATIONAL PAPERS

Chairman: Kenneth P. Uhl, University of Illinois

W. Fred van Raaij, Tilburg University
Kassaye Wandwossen, Tilburg University

"Motivation-Need Theories and
Consumer Behavior"

Solveig Wikstrom, Stockholm University

"Consumer Problems and Consumer Policy
—A Panel Assessment"

Gary Baumgartner, Universite des Sciences
Sociales de Grenoble
Alain Jolibert, Universite des Sciences Sociales
de Grenoble

"The Perception of Foreign Products in France"

Eric Langeard, University of California, Berkeley

"Measurement of Interpersonal Communication
Audiences of Artistic Performance"

Parlor A-B

VISUAL IMAGERY AND ADVERTISING

Chairman: John R. Rossiter

Kathy A. Lutz, U.C.L.A.
Richard J. Lutz, U.C.L.A.

"Illustration and Imagery: Implications for
Advertising"

John R. Rossiter, University of Pennsylvania
Larry H. Percy, Gardner Advertising Co.

"Visual Imaging Ability as a Mediator of
Advertising Response"

Bobby Calder, Northwestern University

"Is There Such A Thing As Imagery?"

Wright/Farman Room

METHODOLOGICAL ASPECTS OF THE ORGANIZATIONAL BUYING PROCESS

Chairman: Robert Spekman, University of
Maryland

Kjell Gronhaug, Norwegian School of
Economics and Business Administration

"Participation in Organizational Buying:
Some Conceptual and Methodological
Problems"

David Wilson, Pennsylvania State University

"Research Approaches to Multi-Participant
Decision Processes"

Arch Woodside, University of South Carolina

"Observations and Organizational Buying
Processes"

Gerald Zaltman, University of Pittsburgh

"Methodological Issues In The Study of
Innovation Adoption by Organization"

Bobby Calder, Northwestern University
Robert Spekman, University of Maryland

"The Collective Level of Analysis: A Crucial
Aspect of Organizational Buying Behavior"

Jerry Wind, University of Pennsylvania

"The Interface Between Organization and
Consumer Buying Behavior"

Icarus/Davinci/Montgolfier Room

NEW DIRECTIONS IN RETAILING RESEARCH: LOCAL MARKET MONITORING

Chairman: Charles King, Purdue University

Douglas Tigert, University of Toronto

"Forecasting Market Shares Through Retail
Image Research"

Larry Ring, University of Virginia

"Defining Market Structures"

George Sproles, University of Houston

"Fashion Preferences and Store Patronage:
A Longitudinal Study"

Dan Emmerheiser, Oklahoma State University
George Sproles, University of Houston

"Segmenting Local Markets for Entertain-
ment Services: The Case of Discoteques"

Charles King, Purdue University

"Strategic Implications of Retailing
Image Research"

BREAK 10:30-10:45

BREAK 10:30-10:45

BREAK 10:30-10:45

BREAK 10:30-10:45

Sunday Morning Sessions 10:45-12:30

Terra Firma Room

CROSS-CULTURAL LIFE STYLE RESEARCH #

Chairman: W. Fred van Raaij, Tilburg Univ.

Johan Arndt, Norwegian School of Economics and Business Administration

Christian Pinson, INSEAD

Manfred Scholer, University of Mannheim

Titles to be announced at session

Discussant: M. Venkatesan, University of Oregon

Parlor A-B

CUE UTILIZATION AND INFERENCE IN CONSUMER BEHAVIOR #

Chairman: Robert E. Burnkrant, University of California, Berkeley

Jerry C. Olson, Pennsylvania State University

"Inferential Belief Formation in the Cue Utilization Process"

Carol A. Scott, Ohio State University

"Self Perception Processes in Consumer Behavior: Interpreting One's Own Experiences"

Bobby Calder, Northwestern University
Alice Tybout, Northwestern University

"New Directions in Attribution Research"

Robert E. Burnkrant, University of California, Berkeley

"Communitization in Product Perception"

Wright/Farman Room

INDIVIDUAL INFLUENCES ON CONSUMER BEHAVIOR *

Chairman: Gerald Alba, University of Oregon

Discussion Leader: Nils-Erik Aaby, Pacific Lutheran University

Elizabeth C. Hirschman, Georgia State University
William O. Adcock, Georgia State University

"An Examination of Innovative Communicators, Opinion Leaders and Innovators for Men's Fashion Apparel"

Robert B. Settle, San Diego State University
Pamela L. Alreck, San Diego State University
John W. Glasheen, San Diego State University

"Individual Time Orientation and Consumer Life Style"

George Belch, U.C.L.A.

"Belief Systems and the Differential Role of the Self-Concept"

James W. Gentry, Kansas State University
Mildred Doering, Kansas State University
Terrence V. O'Brien, Kansas State University

"Masculinity and Femininity Factors in Product Perception and Self Image"

Icarus/Davinci/Montgolfler Room

NEW DIRECTIONS IN RETAILING RESEARCH: LOCAL MARKET MONITORING # (continued)
