ASSOCIATION FOR CONSUMER RESEARCH - EIGHTH ANNUAL CONFERENCE

October 13 - 16, 1977 - Chicago, Illinois

CONFERENCE COMMITTEE

H. Keith Hunt, Conference Chairman
Brigham Young University

* * * *

Jay D. Lindquist
Western Michigan University

William D. Perreault, Jr.
University of North Carolina

Earl W. Morris
Iowa State University

William L. Wilkie
University of Florida

Robert W. Pratt, Jr.
Heublein, Inc.

John Eighmey, Arrangements
Northwestern University

* * * *

Fred D. Reynolds
University of Georgia

Anthony F. McGann
University of Wyoming

Mary Winter
Iowa State University

George E. Brosseau, Jr.
National Science Foundation

EXECUTIVE COMMITTEE

Harold H. Kassarian, President
University of California, Los Angeles

Jerome B. Kernan, President-Elect
University of Cincinnati

David M. Gardner, Past President
University of Illinois

Kenneth L. Bernhardt, Executive Secretary
Georgia State University

William B. Locander, Newsletter Editor
University of Houston

Richard J. Lutz, Treasurer
University of California, Los Angeles

H. Keith Hunt, Conference
Brigham Young University

John Eighmey, Conference
Northwestern University

George H. Haines, Jr., Membership
University of Toronto

Mary Jane Schlinger, Publication
University of Illinois at Chicago Circle

James R. Bettman, Director
University of California, Los Angeles

Jerry C. Olson, Director
Pennsylvania State University

Gerald Zaltman, Director
University of Pittsburgh

Robert W. Pratt, Jr., JCR Policy Board
Representative, Heublein, Inc.

ADVISORY COUNCIL

Gwen Byers
Cornell University

Theodore F. Dunn
Benton & Bowles Advertising

Robert Ferber
University of Illinois

Stephen A. Greyser
Harvard University & Marketing Science Institute

Edward Heiden
U.S. Consumer Product Safety Commission

Stanley D. Shores
Procter & Gamble

Jay Schmeideskamp
Gallup Organization, Inc.

James R. Taylor
University of Michigan

Joseph N. Uhl
Purdue University

Frank D. Walker
Walker Research, Inc.

LIAISON REPRESENTATIVE FROM NATIONAL SCIENCE FOUNDATION

George E. Brosseau, Jr.

PREFACE

ADVANCES IN CONSUMER RESEARCH, VOLUME V, contains the papers presented at the Eighth Annual Conference of the Association for Consumer Research. The ACR annual conference provides a forum for the presentation of papers and discussion of topics which advance the state of the art in consumer research. This Proceedings contains 133 papers representing the contributions of 231 authors.

ACR annual conferences traditionally include three types of sessions: (1) competitive paper sessions featuring papers selected through a competitive double-blind reviewing process in which members of the Association serve as reviewers, (2) special topic sessions in which the topic and proposed participants of the session are competitively judged by the conference program committee, and (3) workshop sessions in which the topic and general area of discussion are competitively judged by the conference program committee. The papers appear in the proceedings grouped by the type of session of which they were part.

Conferences which make a contribution to the state of the art require the contribution of many people. First must go thanks to the authors and to the organizers of the special topic and workshop sessions. The lasting value of the conference and of the Proceedings will be due to their individual efforts. The reviewers also play a special role, both the program committee who review the workshop and special topics proposals and the competitive paper reviewers. Both groups are listed elsewhere in the Proceedings. Also deserving thanks are the many secretaries who provided camera-ready copy of papers for the Proceedings. And I especially appreciate the helpful hints of previous editors of these proceedings who shared their experience with me and encouraged me in this work.

As anyone who has ever edited a Proceedings knows, behind the editor is a super secretary who somehow keeps everything in order, cajoles and begs threatens to get papers in on time, and retypes and retypes and retypes. My special thanks go to Willyne Forsyth who was the person behind the conference details and behind the editing of this Proceedings.

Finally, I appreciate the support and understanding of my wife, Carolyn, during the weekends, late night, and even all night sessions while the conference and Proceedings were being put together. Her handling of family matters gave me the freedom to be involved in the highly enjoyable experience of being program chairman and Proceedings editor.

TABLE OF CONTENTS

Association For Consumer Research Officers and Conference Committee	iii
Preface	iv
H. Keith Hunt, Brigham Young University	
Presidential Address	xiii
Harold H. Kassirjian, University of California, Los Angeles	

PART I: COMPETITIVE PAPERS

"On the Social Psychology of Giving: Door-in-the-Face and When Even a Penny Helps"	1
Peter H. Reingen, University of South Carolina	
"Selling a City: An Experimental Study of the Communication Effects of Message Tone"	5
Richard F. Yalch, University of Washington Margaret C. Dempsey, University of Washington	
"The Relative Effectiveness of One-Sided and Two-Sided Communication for Mass Transit Advertising"	12
Linda Golden, University of Texas, Austin Mark I. Alpert, University of Texas, Austin	
"Cola Preferences: Disguised Taste vs. Brand Evaluations"	19
Thomas J. Stanley, Georgia State University	
"Nonmetric Unidimensional Scaling of Consumer Preferences for Proposed Product Designs"	22
Murphy A. Sewell, State University of New York, Albany	
"Understanding University Choice: A Multi-Attribute Approach"	26
Ronald Vaughn, Bradley University Joseph Pitlik, Bradley University Behram Hansotia, Bradley University	
"An Exploratory Study of the Influences of Usage Situation on Perceptions of Product-Markets"	32
Rajendra K. Srivastava, University of Pittsburgh Allan D. Shocker, University of Pittsburgh George S. Day, University of Toronto	
"Assessing the Effects of Visible Consumption on Impression Formation"	39
Russell W. Belk, University of Illinois, Urbana-Champaign	
"Evoked Set Size as a Function of Number of Choice Criteria and Information Variability"	48
Joseph A. Belonax, Jr., Bowling Green State University Robert A. Mittlestaedt, University of Nebraska, Lincoln	
"Consumer-Oriented Versus Advertiser-Oriented Language: Comprehensibility and Salience of the Advertising Message"	52
Martin R. Lautman, Associates for Research in Behavior, Inc. Larry Percy, Gardner Advertising Company	
"Who Is the Deal Prone Consumer?"	57
Robert Blattberg, University of Chicago Thomas Buesing, University of Chicago Peter Peacock, Wake Forest University Subrata Sen, University of Rochester	
"Comparative Advertising: Issues and Problems"	63
Michael Etgar, State University of New York, Buffalo Stephen A. Goodwin, State University of New York, Buffalo	
"Mediating Effects of Cognitive Responses to Advertising on Cognitive Structure"	72
Jerry C. Olson, Pennsylvania State University Daniel R. Toy, University of Washington Philip A. Dover, Dartmouth College	
"The Organization of Product Information in Memory Identified by Recall Times"	79
Eric J. Johnson, Carnegie-Mellon University J. Edward Russo, University of Chicago	

"Low Involvement Versus High Involvement Cognitive Structures"	87
John L. Lastovicka, Temple University	
David M. Gardner, University of Illinois, Urbana-Champaign	
"A Study of the Interface Between Attitude Structure and Information Acquisition Using a Questionnaire-Based Information-Display Sheet"	93
Morris B. Holbrook, Columbia University	
Karl A. Maier, Ketchum, MacLeod & Grove, Inc.	
"Alternative Approaches to Assessing the Quality of Self Report Data"	99
Robert A. Hansen, Ohio State University	
Carol A. Scott, Ohio State University	
"An Evaluation of Telephone Sampling Designs"	103
E. Laird Landon, Jr., University of Houston	
Sharon K. Banks, University of Oregon	
"Whether to Agree-Disagree or Disagree-Agree: The Effects of Anchor Order on Item Response"	109
David Sheluga, Purdue University	
Jacob Jacoby, Purdue University	
Brenda Major, Purdue University	
"Nearest Neighbor Analysis: Inferring Behavioral Processes from Spatial Patterns"	114
Sanford L. Grossbart, University of Nebraska, Lincoln	
Robert A. Mittelsteadt, University of Nebraska, Lincoln	
Gene W. Murdock, University of South Dakota	
"Durable Accumulation: An Examination of Priority Patterns"	119
Robert F. Lusch, University of Oklahoma	
Edward F. Stafford, Jr., University of Oklahoma	
Jack J. Kasulis, University of Oklahoma	
"An Investigation Into the Causal Links Between Attribution Schema and Decision-Making"	126
Richard Mizerski, University of Cincinnati	
Stephen Green, University of Cincinnati	
"Some Issues in Designing Consumer Information Studies in Public Policy".	131
R. Bruce Hutton, University of Denver	
Dennis L. McNeill, Federal Trade Commission	
William L. Wilkie, University of Florida	
"Potential Contributions of Consumer Research to Antitrust Decision Making"	138
Paul N. Bloom, University of Maryland	
"Expectancy-Discrepant Information: Does Format Influence Effects?"	145
Debra L. Scammon, University of Utah	
"Shopping Time and Leisure Time: Some Preliminary Cross-Cultural Comparisons of Time-Budget Expenditures"	151
Douglass K. Hawes, University of Wyoming	
Sigmund Grønmo, Norwegian Fund for Market and Distribution Research	
Johan Arndt, Norwegian School of Economics and Business Administration	
"Personal Values: A Cross Cultural Assessment of Self Values and Values Attributed to a Distant Cultural Stereotype"	160
J. Michael Munson, University of Santa Clara	
Shelby H. McIntyre, University of Santa Clara	
"Correlates of Information Gathering and Evoked Set Size for New Automobile Purchasers in Norway and the U.S."	167
R. Neil Maddox, University of Missouri, St. Louis	
Kjell Grønhaug, Norwegian School of Economics and Business Administration	
Richard E. Homans, University of Missouri, St. Louis	
Frederick E. May, University of Missouri, St. Louis	
"Selecting Pareto Optimal Subsets from Multiattribute Alternatives"	171
James B. Wiley, Wayne State University and University of Florida	
"Four Methodological Problems in Multi-Attribute Attitude Models"	175
Michel Laroche, Simmons College	
"Measured Attribute Weights Can Make A Difference"	180
Richard A. Werbel, University of Illinois, Chicago Circle	
"Assessing the Impact of Increased Product Safety on Consumer Utility"	186
Stephen C. Burnett, Indiana University	

"Transportation Attitudes Over Time: A Longitudinal Approach"	194
Mark I. Alpert, University of Texas, Austin Linda L. Golden, University of Texas, Austin	
"Energy Conservation, Price Increases and Payback Periods"	201
William H. Cunningham, University of Texas, Austin Brondel Joseph, University of Illinois, Chicago Circle	
"An Experimental Examination of Deception in Labeling: Consumer Research and Public Policymaking"	206
Philip G. Kuehl, University of Maryland Robert F. Dyer, George Washington University	
"Evaluation of Food Labeling Policies Through Measurement of Consumer Utility"	213
Roger Best, University of Arizona Jim McCullough, University of Arizona	
"Consumer Processing and Use of Supplementary Drug Label Information"	220
F. Robert Dwyer, University of Arizona	
"A Multiple Discriminant Analysis Approach to the Development of Retail Store Positioning"	227
Lawrence J. Ring, University of Virginia Charles W. King, Purdue University	
"A Hierarchical Model of Source Effect in Retail Newspaper Advertising"	235
James G. Barnes, Memorial University of Newfoundland	
"An Examination of Consumer Grocery Store Choice: Considering the Attraction of Size and the Friction of Travel Time"	243
Daniel J. Brown, Oregon State University	
"Perceptions of Unfair Marketing Practices: Consumerism Implications"	247
Gerald Zaltman, University of Pittsburgh Rajendra K. Srivastava, University of Pittsburgh Rohit Deshpande, University of Pittsburgh	
"A Comprehensive Study of Consumer Satisfaction with Durable Products"	254
Stephen B. Ash, Indiana University	
"Consumer Response to Dissatisfaction with Services and Intangibles"	263
Ralph L. Day, Indiana University Muzaffer Bodur, George Mason University	
"Catastrophe Theory as a Model for Describing Consumer Behavior"	273
Terence A. Oliva, Louisiana State University Alvin C. Burns, Louisiana State University	
"Testing Competing Models of Consumer Decision Making in the Preventive Health Care Marketplace"	277
Richard L. Oliver, University of Iowa Philip K. Berger, University of Kentucky	
"An Examination of an Alternative Form of the Behavioral Intention Model's Normative Component"	283
Michael J. Ryan, Columbia University	
"The Market for Personal Growth Services"	290
Philip Kotler, Northwestern University Lenore Borzak, Northwestern University	
"Sparks and Tucker Revisited: A Reanalysis and Replication"	295
Charles M. Schaninger, University of Massachusetts V. Parker Lessig, University of Kansas	
"Perception of Marital Roles in Decision Processes: Replication and Extension"	300
E. H. Bonfield, Temple University	
"An Examination of Innovative Communicators, Opinion Leaders and Innovators for Men's Fashion Apparel"	308
Elizabeth C. Hirschman, University of Pittsburgh William O. Adcock, Georgia State University	
"Individual Time Orientation and Consumer Life Style"	315
Robert B. Settle, San Diego State University Pamela L. Alreck, San Diego State University John W. Glasheen, San Diego State University	
"Belief Systems and the Differential Role of the Self-Concept"	320
George E. Belch, University of California, Los Angeles	

"Masculinity and Feminity Factors in Product Perception and Self Image"	326
James W. Gentry, Kansas State University

Terrence V. O'Brien, Kansas State University	

PART II: SPECIAL TOPICS PAPERS

"Attitude Maturation: Changes in Related Belief Structures over Time"	333
Jerry C. Olson, Pennsylvania State University	
Philip A. Dover, Dartmouth College	
"Carryover Effects of Corrective Advertising"	343
Alan G. Sawyer, Ohio State University	
Richard J. Semenik, University of Utah	
"Attitudes as Actions: Social Identity Theory and Consumer Research"	352
Barry R. Schlenker, University of Florida	
"A Functional Approach to Consumer Attitude Research"	360
Richard J. Lutz, University of California, Los Angeles	
"New Directions in Attitude Research: A Critical Evaluation"	370
Joel B. Cohen, University of Florida	
"Short and Long Term Cost Consequences of Government Regulations to Consumers"	377
Rachel Dardis, University of Maryland	
"Industry Response to Government Regulations"	380
David Hillier, American Textile Manufacturers Institute	
"Issues in Analyzing Consumer Satisfaction/Dissatisfaction with Clothing and Textiles"	383
George B. Sproles, University of Houston	
Loren V. Geistfeld, Purdue University	
"The Process of Setting Standards and Some Current Issues in Standards"	392
L. J. Sharman, Consumer Product Safety Commission	
"Human Values: A Historical and Interdisciplinary Analysis"	396
C. Joseph Clawson, University of Southern California	
Donald E. Vinson, University of Southern California	
"Values and Consumption Patterns: A Closed Loop"	403
James M. Carman, University of California, Berkeley	
"The Europeanizing of America: A Study of Changing Values"	408
Donald L. Kanter, University of Southern California	
"Consumers' Reactions to Sex in TV Commercials"	411
Deborah K. Johnson, Needham, Harper & Steers Advertising, Inc.	
Kay Satow, Needham, Harper & Steers Advertising, Inc.	
"Sex on Television, More or Less"	415
William S. Rubens, National Broadcasting Company	
"Men and Women on the Tube: Sex and Sex-Stereotypes on Television"	419
Susan Hesselbart, Florida State University	
"Energy Conservation and Travel Behavior"	422

PRESIDENTIAL ADDRESS, 1977:
ANTHROPOMORPHISM AND PARSIMONY

Harold H. Kassirjian, University of California, Los Angeles

This is the eighth meeting of the Association for Consumer Research and the seventh time that members of the association have had to suffer through a farewell address by a president. On this particular occasion, I am particularly fortunate for in the audience sit previous presidents of this association and therefore at least they appreciate that if such addresses are insufferable to the listener, they are even more threatening to the speaker. I am here because Keith Hunt ordered me to give a presidential address at this place and at this time with the simple request that it be significant, visionary, important, memorable, and interesting: a milestone in the consumer research literature. What he meant was, "keep it mercifully short." Not too sure of what a visionary milestone was, I turned to previous addresses.

In 1970 our first leader, and father of this association, Jim Engle, stood here and spoke about the developing organization and its exciting future. Bob Perloff continued in the same vein. In 1973 Joel Cohen was optimistic and excited perhaps because the Journal of Consumer Research had been conceived during his administration and would soon be born. Cohen, however, did comment on his perceptions of the trivial nature of the problems we had been studying.

Bob Pratt again sat back and offered us his perspective of ACR, where it had been and the challenge ahead for the fledgling adolescent. That year will best be remembered for the wave after wave of laughter caused by a film he presented. By the time Jack Jacoby presented his sharp perspective and criticism we had matured, we had our own literature, we had our own research tradition, we had several media to disseminate our work.

And so, the tradition of a presidential address that was to be somewhat different from those of other associations began to emerge. As Gardner pointed out last year, rather than the presentation of a major research inquiry, rather than a significant contribution to the research literature that is common in our sister association; our presidential address was to be an overview, a perspective, a self criticism of our field and our association.

And now it is my turn. I would like to focus on two problems I see in the field of consumer behavior: that of anthropomorphism and our lack of concern about parsimony.

Anthropomorphism

First let me turn to anthropomorphism. As you know, pet owners often see in their animals a thinking, reasoning, information processing creature--a cat that ambles with disdain, an arrogant dog, a wise goldfish. More than one psychologist experimenting in animal laboratories has wondered whether his highly trained rat is thinking out a response, pondering a decision or has become "lost in thought." And children often wonder about the emotional feelings of a flower or the memories of a rock that has seen so many centuries pass before his (or is it her?) senses. To project human activities, emotions, motivations, and adjectives onto animals or inanimate objects is an error we all make, even in our professional work.

I can't help but wonder, if much too often we do not project too much onto the consumer: because we care about brands, or packaging, or information processing, we assume that the average consumer also cares. As consumer researchers, this group happens to be highly educated, extremely intelligent, and as individuals we pride ourselves on being wise, rational consumers not burdensomely influenced by advertising campaigns, or skillfully deceptive labels. If anyone is a "thinking, reasoning, problem solving organism capable of transforming, storing, and evaluating sensory inputs", this audience must qualify as that type of person. For if humans can be classified into motivational or personality types, this audience must qualify as the cognitive man.

And from that, we have assumed, perhaps much too often, that other people, consumers in general, are also extremely wise, problem solving rational organisms every time the purchase decision is made for a pound of coffee, a tube of tooth paste, or a can of peas. We have often assumed that labels are read, products are compared, prices are utilized, and a rational decision is made, when we know it is not usually so.

Of course, there is no question that under some conditions for the purchase of some goods and services, the consumer is sometimes a thinking, information processing individual. Important or expensive, high risk, high involvement, psychologically or socially or ego related products, may under certain conditions, lead to highly sophisticated actions and decisions. Thus our complex theories, and our model of the cognitive man occasionally seems to be rewarding.

But, of the dozens, if not hundreds, of mundane decisions made each day by the average consumer, I wonder just how many are important to him, just how many are significant or high involvement decisions. For example, the work by Tom Robertson, and Mike Ray, and of course, the classic studies by Krugman, and several papers at this conference clearly indicate that behavior toward the low involving product is quite different than behavior toward the high involvement, high risk, important product. And the world is mostly full of insignificant decisions and unimportant solutions.

Yet, because to us a brand of toilet paper may be important, we have projected that belief onto the consumer. A one percent share of market can mean thousands of dollars of net profit to a company. That one brand has greater shearing strength or is more quickly biodegradable, or has more sheets per roll may be quite important to the consumerist, to the environmentalist, or to the readers of Consumer Reports. That panel data on the purchase of toilet paper over a seventeen year period exists may be titillatingly exciting to the academic researcher, but the average consumer who blithely purchases, consumes, and discards the product, most likely could care less. Unconcernedly he or she makes the purchase, switches brands, ignores commercials, and worries about the important decisions in his life and not the purchase of toilet paper.

For these countless thousands of insignificant decisions that are made by the consumer, to assume a thinking, reasoned, attitudinally influenced decision may well be a classic example of anthropomorphism.

Parsimony

In a similar vein, we have developed complex theories in the attempt to understand, explain, and predict the behavior of the consumer, as had psychology many years before. In psychology, the all encompassing extremely complex views of Sigmund Freud were called upon as well as those of Adler, Jung, Fenichel, and Horney; and, of course, Clark Hull and Tolman and Kurt Lewin.

But, in time, psychology turned from the complex theories to the much simpler middle range theories that Merton had been calling for. Lately, in psychology, an even simpler theory has been quite dominating. From clinical psychology to counselling, from social psychology to learning, we see more and more the impact of behaviorism and the work of Skinner, stressing not the mystical beliefs of the ancient Greeks or of the turn of the 20th century Germans, but rather the simple concepts of repetition, reward, reinforcement, and shaping behavior.

To this point, the work in consumer behavior has not followed that pattern, from the all encompassing view to the middle range theory to the simpler theory -- but rather has been quite the opposite in its short history. For example, the original work by Howard in his marketing management textbook started with a very uncomplicated view of consumer behavior theory. Behavior could simply be explained by drive, response, cue, and reinforcement. In less than a decade, this simple parsimonious view has been expanded, developed, flow-charted, sophisticated, and complicated. Meanwhile, in marketing and advertising, from the simple behavioristic views that sales or advertising effects were related to repetition and reinforcement, we found researchers turning to middle range theories such as cognitive dissonance, and personality, perceived risk, multi-attribute attitude models, and attribution theory. By stringing several of these middle range theories together, the flow-chart models were to emerge.

And in our journey from the simple to the more and more complex, we lost our basic theoretical need for parsimony. Three years ago, Frank Bass, frustrated that the complex theories we created could not predict much of behavior, proclaimed in a Journal of Marketing Research article that, "it will never be possible to provide good predictions of individual choice behavior for separate occasions," and that man is substantially stochastic. Bass assumed that there is a homonculus in the brain that throws dice, and that behavior is dependent upon that stochastic turn of events. Perhaps Bass's view is too simplistic, and certainly it is not new, for it has been around since the early days of the mathematical learning theorists three decades ago. Nevertheless, the view deserves more of a hearing than it received in consumer behavior this time around. But apparently it was just too simple for us. Our cherished middle range theories, our complex deterministic views of reality were not prepared to accept a simple approach. It may be true that stochastic approaches have not predicted the behavior of the consumer in the marketplace very well, but they have had no less success than the unparsimonious approach of the grand theories of behavior. Having been personally schooled in psychoanalytic theory, having been weaned on Gestalt and Lewinian Field theory, and never much having liked the views of Bush and Estes, of Mosteller and Burke, I find it quite difficult to defend stochastic thinking and to condemn a deterministic view of reality. Certainly I do not believe that a Bass or Skinner can explain the selection of a spouse, the purchase of a home, the ownership of a new car or the decision to commit suicide; but it is possible that with the

unimportant, uninvolved, insignificant, minor decisions that are made in the marketplace everyday, we do not need a grand theory of behavior. In unimportant, uninvolved, unemotional, non-cognitive, low commitment instances, unparsimonious complex explanations are often just not necessary. Although it is quite hard to accept the extremely simplistic views of the mathematical theorists and stochastic models, perhaps we also do not need the complication of intervening variables and hypothetical constructs for explanatory power when studying low commitment purchases. Skinner's shaping behavior is perhaps more than enough in the low commitment marketplace; reinforcement and repetition may well be sufficient.

As Markin and Nayarana pointed out in a 1975 ACR paper, "the fact that so much consumer behavior is shaped in an operant fashion perhaps even refutes the notion of the cognitive consumer. Such a traditional concept may well reflect a tragic misunderstanding of our notions regarding consumer's intelligence, rationality, and intellectual autonomy."

Although the Markin position is quite extreme, if we divide the world into important, high involvement, high commitment decisions and into insignificant trivial decisions, it may well be that the theories to explain these two kinds of behavior are quite different. Whereas complex deterministic theories involving series of intervening constructs are necessary for the high involvement case; for the insignificant ones, those with relatively low risk, simple Skinnerian behaviorism, operant conditioning, or maybe even stochastic thinking may be more than sufficient.

It is too bad that so few of us have chosen to study learning theory in consumer behavior in recent years, and so few of us have turned to the study of low involvement behavior. Whether we like it or not, low involvement, low risk, the unimportant, is what much of consumer behavior is all about. Whether or not we anthropomorphize our own values onto the consumer, and whether or not we chose to be unparsimonious in our thinking, the facts do not change that under most conditions, for most types of goods and decisions, the behavior of the consumer is just not important from his point of view.

There is a subset of us that is, in fact, not really interested in consumer behavior, per se; but rather is interested in human behavior; and happened to choose human behavior in the marketplace as their specialty. It is here that the grand theories of consumer behavior properly reside. And, these people are making some important contributions to the world of science and knowledge.

But, for the rest of us, our strength and our contributions may be even greater. We, not pure economists, or pure psychologists, are the experts on the thousands of insignificant and trivial decisions in this world. It is here that we have made our greatest contributions to date and here lies our greatest potential for future contributions.

There is a lot more in the world that is low risk and low involvement than there is major and important. But these are decisions nonetheless. It is we that know more than any other sub-set in the scientific community on this topic. Perhaps if we have it, we should flaunt it.

ON THE SOCIAL PSYCHOLOGY OF GIVING: DOOR-IN-THE-FACE
AND WHEN EVEN A PENNY HELPS¹

Peter H. Reingen, University of South Carolina

Abstract

Four strategies of inducing people to comply with a request to donate money were investigated in a field experiment: A concession approach where a requester first asked a target person for an extreme favor and, after being refused, retreated to a smaller favor (the one that was desired from the outset); an approach that avoided the dilemma of small requests by legitimizing rather than directly requesting compliance with a small request; a combination of the previous two approaches; and an approach utilizing the standard plea for funds. The prediction that the standard approach would be the least effective was confirmed. However, contrary to predictions, the approaches involving a concession did not significantly increase compliance with a (third) request for subsequent help. Possible processes that could explain these results are discussed.

Introduction

There has been a recent upsurge of interest in methods for obtaining behavioral compliance with minimal pressure. The door-in-the-face technique, first formally investigated and confirmed by Cialdini, Vincent, Lewis, Catalan, Wheeler and Darby (1975), has received particular attention. This technique is based on the simple notion that the probability of obtaining compliance with a request that has a low a priori probability of agreement can be increased substantially by first inducing noncompliance with an extreme request. Cialdini et al. (1975) and Cialdini and Ascani (1976) argue that a requester's movement from an initial, extreme request to a second, more moderate one is viewed by the target person as a concession. Based on the societal rule of reciprocation of concessions that states "You should make concessions to those who make concessions to you," normative pressures are brought to bear that tend to compel a target person to move from his/her initial position of noncompliance with the extreme request to a position of compliance with the more moderate second request. Cialdini and his coworkers found this rejection-then-retreat approach effective in increasing compliance with the rather large request of chaperoning a group of juvenile delinquents on a day trip (Cialdini et al. 1975) and increasing compliance with a request to donate blood (Cialdini and Ascani, 1976).

One of the purposes of this study was to test the concession procedure in a request context other than the ones employed in previous research. Subjects (college students) were asked in a naturalistic setting to contribute money to the Heart Association in accordance with one of four conditions. In the first, the control condition, a standard request for funds was made. In the second, the extreme-then-donation request condition, subjects were first asked to perform an extreme favor (to give three dollars every month for at least one year) and, having refused, were asked the standard request. It was predicted that subjects exposed to the concession procedure would be significantly more likely to decide to contribute than those exposed to only the

standard request. This part of the study, then, simply replicated the work by Cialdini et al. In so doing, it was hoped to (a) test the generality of the concession procedure as a compliance induction mechanism, (b) obtain further evidence concerning the hypothesized mediator of the effect, (c) apply the technique in a context that is of considerable interest to both practitioners and consumer researchers, and (d) investigate the power of the technique by employing student subjects.

The purpose of the third condition was to test the relative effectiveness of the concession procedure by including in the experimental design a procedure that did not involve a concession. In this third condition, the standard request was followed by the sentence, "Even a penny will help." While the research evidence (e.g., Wagner and Wheeler, 1969) suggests a strong relationship between a subject's compliance with a request and the cost of performing the request, the clear dilemma of small requests per se is that they produce high levels of compliance but low levels of reward for a requester (Cialdini and Schroeder, 1976). The phrase "Even a penny will help," however, implied that a small contribution was acceptable without suggesting, as small requests normally do, that it was what the requester desired. In other words, by implying that a small favor is acceptable but not necessarily desirable, a requester would make it difficult for a target to refuse and would make it unlikely that a target would offer a small donation (Cialdini and Schroeder, 1976). In the fourth condition, the phrase "Even a penny will help" was added to the extreme-then-donation request manipulation. Since this approach would appear to reap the benefits of both the concession approach and the even-a-penny-will-help strategy but not the disadvantages of small requests, it was expected to be an especially effective compliance induction mechanism. That is, it was predicted that subjects exposed to the last approach would be significantly more likely to decide to contribute than those exposed to just the request addendum, "Even a penny will help," but that each of these two approaches would be superior to the standard request. In addition, based on the above, it was hypothesized that the average donation would not differ significantly between conditions.

Finally, the fund-raising context provided an opportunity to examine another kind of compliance of considerable interest, namely compliance with a request for subsequent help. Subjects in the extreme initial request conditions and a control condition were asked to become a fund-raising volunteer for the Heart Association. It was predicted that the subjects in the extreme initial request conditions would be more likely to comply with this (third) request than the control subjects. This expectation was based on evidence produced by studies of bargaining behavior suggesting that a concession strategy in negotiation leaves the target of such a strategy with more positive feelings about the interaction outcome (e.g., Benton, 1973), and on more direct evidence provided by Cialdini and Ascani (1976) showing that subjects in an extreme-then-blood donation request condition were more likely to agree to donate blood again than control subjects.

¹The author would like to thank the Heart Association of South Carolina and especially Mary Wright for her considerable assistance. This paper reports a portion of a larger study.

Method

Subjects

Subjects were 160 (80 male and 80 female) students at the University of South Carolina. Only those students were selected who were walking alone along university walkways during the hours 10 a.m. to 6 p.m., and no subjects known to an experimenter were selected.

Procedure

The naive experimenters, four male and four female college students, approached only same-sex subjects who met these conditions. Experimenters, thoroughly instructed in training sessions, were equipped with the identification badges, information brochures and donation envelopes in fund-raising drives by the Heart Association of South Carolina. An experimenter initiated interaction by introducing him- or herself as representing the Heart Association. After the common introductory remarks, subjects were randomly assigned to one of five conditions according to a treatment schedule that varied randomly across experimenters. An experimenter completed exactly four replications per condition.

Donation-request-only control condition. Subjects in this condition (n=32) were asked by the experimenter to comply with the request to donate money. Specifically, the experimenter said:

As part of our annual campus fund-raising drive, I'm collecting money for the Heart Association. Would you be willing to help by giving a single donation?

If a subject consented, the experimenter took the donation and put it in the donation envelope. Thus, two measures of helping were taken: (a) whether a subject gave a contribution, and (b) size of contribution.

Extreme-then-donation request condition. Subjects in this condition (n=32) were initially asked to perform a very large favor which all subjects refused. Specifically, the experimenter said:

As part of our annual campus fund-raising drive, we're currently asking students to become involved in our Long Term Donor Program. Long term donors are those students who pledge to give 3 dollars per month for a period of at least 12 months. Would you be willing to enroll in our Long Term Donor Program?

(After the subject declined, the experimenter continued.) Well, maybe you'd be interested in another activity we're asking students to participate in. I'm also collecting money.....

The remainder of the procedure was identical to that of the donation-request-only control.

Even-a-penny condition. Subjects in this condition (n=32) were delivered the standard (control) plea for funds, but the experimenter added, "Even a penny will help." The remainder of the procedure was identical to that of the donation-request-only control.

Extreme-then-donation request, even-a-penny condition. Subjects in this condition (n=32) were administered the procedure identical to that of the extreme-then-donation request condition, except that "Even a penny will help" was added to the standard plea. All subjects but one refused to comply with the extreme initial request.

Volunteer-request-only control condition. Subjects in this condition (n=32) were asked by the experimenter only to comply with the request to become a fund-raising

volunteer. Specifically, the experimenter said:

As part of our annual fund-raising drive, the Heart Association is looking for volunteers to solicit funds from the public. Would you be interested in becoming a Heart Association fund-raising volunteer?

If a subject consented, the experimenter wrote down his/her telephone number and indicated that the Heart Association would contact the subject if his/her help was needed. Thus, the dependent measure was the subject's verbal compliance. The subjects in the extreme initial request conditions were also approached with this volunteer request but after they had received the donation request.

Results

Donation Request

A preliminary Chi Square analysis on frequency of donation within each condition showed no significant differences due to sex of the target subject (and thus sex of the experimenter), with levels of significance ranging from .28 to 1.00, and no significant differences between experimenters, with levels of significance between .36 and .89.² Hence, the compliance data were relatively free of sex effects and experimenter effects, and the subsequent analysis could therefore be performed on collapsed data.

Table 1 presents the results for frequency of donation, total amount donated, and average amount donated. The predictions concerning compliance rates seemed most appropriately tested by a set of three orthogonal contrasts.

TABLE 1

Donation Results

Condition	% of Compliance	\$Total	\$Average
Donation-request-only	19(6/32)	3.07	.51
Extreme-then-donation	34(11/32)	6.75	.61
Even-a-penny	47(15/32)	4.64	.31
Extreme-then-donation, even-a-penny	44(14/32)	5.60	.40

The first tested the donation-request-only control against the combination of the extreme-then-donation request condition, the extreme-then-donation, even-a-penny condition, and the even-a-penny condition. It was predicted that the three experimental conditions would be superior to the control in compliance to donate money, and this was confirmed ($X^2 = 4.52$, d.f. = 1, $p = .03$). The second contrasted the extreme-then-donation, even-a-penny condition and the even-a-penny condition. The prediction that the extreme-then-donation, even-a-penny approach would be superior to the even-a-penny treatment was not confirmed ($X^2 = 0.00$). The last compared the extreme-then-donation and the combination of the extreme-then-donation, even-a-penny and the even-a-penny groups and also found no significant difference ($X^2 = .65$, d.f. = 1, $p = .42$).

With respect to mean donation per active contributor, no significant difference was expected. While this prediction was confirmed ($F = 2.08$, d.f. = 3/42, $p = .12$),

²All Chi Square tests reported in this paper were corrected.

there was a consistent tendency for the "even a penny will help" additions to produce a somewhat smaller average contribution. However, an a posteriori test based on Scheffé's procedure involving the relevant comparison resulted in a p of only .25.

Volunteer Request

Table 2 presents the proportion of subjects in the three relevant conditions who were willing to comply with the volunteer request. Contrary to expectations, it is clear that the principal orthogonal comparison (volunteer-request-only control versus the combination of the extreme-then-donation and extreme-then-donation, even-a-penny conditions) is highly insignificant.

TABLE 2
Volunteer Results

Condition	% of Compliance
Volunteer-request-only	6(2/32)
Extreme-then-donation	0(0/32)
Extreme-then-donation, even-a-penny	9(3/32)

Discussion

These results are of significant practical value for anyone wishing to elicit compliance with a request to donate money. The experimental conditions were significantly more effective in producing compliance with the donation request than the control. In addition, the average amount donated did not differ significantly among the conditions. Thus, it is not surprising that along the practical dimension of total funds obtained, the even-a-penny condition produced 1.5 times, the extreme-then-donation request, even-a-penny condition 1.8 times, and the extreme-then-donation request condition 2.2 times that of the donation-request-only control. That these results are consistent with the ones produced by Cialdini and his coworkers attests to the generality of the compliance induction mechanisms. However, the requests in this investigation as well as in the Cialdini et al. studies were altruistic ones. Thus, the effects have been shown to occur only under the somewhat limited set of conditions where the requests are prosocial in nature and are made in a no-delay situation. Evidence provided by Reingen and Kernan (1977b) suggests that the concession strategy may be ineffective in contexts where "selfish" rather than "socially desirable" requests are involved. A situation where selfish requests are involved would hardly resemble a bargaining interaction. Similarly, studies by Reingen and Kernan (1977a) and Snyder and Cunningham (1975) which employed time-delayed requests suggest that the concession approach may actually result in less compliance. These results are, of course, favorable to the concession viewpoint in that a requester's act of concession may not be as apparent when the requests are time-delayed.

Aside from these more practical aspects, the present findings have interesting conceptual implications as well. As far as the extreme initial request conditions are concerned, the findings provide support for a concession-based mediator of the compliance effects, but they as well as the ones obtained by Cialdini et al. in no way ultimately confirm the concession model. Other explanations may exist. For example, Cann, Sherman and Elkes (1975) suggest an alternative explanation based on dissonance theory. When a subject in an extreme initial

request condition refuses to comply with an initial request for help in a social cause, he probably feels some conflict about this which he can easily resolve by complying with the immediately-following second request. Another possibility is a perceptual contrast effect. By initially asking an extreme request, the second request may be perceived as smaller than it would have been if it alone had been presented. Interestingly enough, the major surprise of this study, which was the ineffectiveness of the extreme initial request conditions to produce a greater compliance with a request for subsequent help (i.e., volunteering as a fund raiser), can be easily explained by these two alternative interpretations but not by the concession model. From a dissonance viewpoint, the second request may have given ample opportunity for dissonance reduction. As far as the perceptual contrast explanation is concerned, the (third) request for subsequent help may have been perceived as large as the extreme (first) request, as is indicated by the very low compliance rate in the volunteer-request-only control group.

A second surprising aspect of the present data was the ineffectiveness of the extreme-then-donation request, even-a-penny condition to produce a greater compliance to donate money than the even-a-penny condition. Since the only difference between the two conditions was that the former involved a concession and the latter did not, no significant gain resulted from the concession approach. It appears that the addendum to the standard request, "Even a penny will help," is sufficient enough by itself to make it difficult for a target person to refuse to donate money.

SELLING A CITY: AN EXPERIMENTAL STUDY OF THE
COMMUNICATION EFFECTS OF MESSAGE TONE

Richard F. Yalch, University of Washington
Margaret C. Dempsey (student), University of Washington

Abstract

Residents and nonresidents of Seattle were exposed to persuasive appeals varying in message tone but all urging them to live within the city limits. The results support the use of positively and neutrally worded messages, but suggest that negatively worded appeals be used only under limited circumstances.

Introduction

Despite widespread praise because of its many favorable attributes, Seattle, as many other large cities, experienced a constant decline in its population and lost businesses to its suburbs during the past few years. Government officials attributed this partially to a negative image of urban living presented in news media accounts of urban problems and they sponsored a series of television commercials extolling the virtue of living within the city limits. The objective was to present "a number of really positive things going on around town the people never hear about" (Seattle Turns to Net TV, 1977). Concurrently, a county transportation agency tried to increase the demand for public transportation with an advertising campaign criticizing individuals who commute by automobile. The campaign was sufficiently negative toward automobile drivers (the slogan was "I'm no dummy, I take the bus") to motivate a public protest from the Executive Vice President of the Automobile Club of Washington which included his recommendation that the agency switch to a "positive" appeal (Dummies Who Drive, 1977). Although there may be a preference for a positive approach, the transportation agency's campaign and other critical messages seem justifiable if they are more effective in changing behavior than positive approaches.

The attitudinal and behavioral effects of these contrasting approaches to demand modification are usually unclear because of many environmental differences, and the controversy over the choice of wording seems best settled using controlled experimentation. Unfortunately, prior research on the relative effectiveness of positive and negative appeals has not yielded conclusive findings.¹ Although most studies favor the negative appeal (Evans, Rozelle, Lasater, Dembroski and Allen, 1970; McArdle, 1972; Powell and Miller, 1967; Wheatley and Oshikawa, 1970), several have found no differences (Leventhal and Perloe, 1970; Lucas and Benson, 1929) and one has found that positively worded appeals are more effective than negatively toned ones (Yalch and MacLachlan, in review).

¹The wording or tone of a message is determined by the proportion of the message content that is positive (i.e., discusses the benefits of acquiring some good, service, or idea), compared to that which is negative (i.e., mentions the disadvantages of not acquiring the product or acquiring a substitute). Thus, a positive appeal might stress how commuting by bus is relaxing while a negative message would emphasize the tension caused by rush hour traffic jams. This definition is consistent with Lucas and Benson's (1929) view that "avoidance is the basis of negative appeal in advertising, (p. 275), but is somewhat different from that offered by Wheatley and Oshikawa (1970).

Further, a review of this literature suggests that contributions to our understanding of the message tone effect can be made in at least four areas.

One problem is that many studies used a fear appeal as the negative message (cf., Evans et al., 1970; Powell and Miller, 1967; Wheatley and Oshikawa, 1970), and it is possible that its enhancement of persuasion was caused more by the greater anxiety experienced by the subjects during their exposure to this message than to the negative tone. The finding by Sigall and Helmreich (1969) that an anxiety-arousing situation enhances persuasion supports this suggestion. Thus, it would be desirable if all the messages in an experiment on message tone produced little anxiety or, at least, that the resultant anxiety levels were equivalent for all the messages.

A second limitation of the extant studies is that most used only two levels (one positive and one negative) of message tone (an exception is Powell and Miller, 1967). Many researchers have commented on the high probability that a message characteristic will have a nonlinear relationship with the audience's attitudinal response because of enhancing and attenuating effects on the intervening stages in the communications process. For example, Ray and Wilkie (1970) postulate that there is an inverted-u curve relationship between the level of anxiety aroused by a message and the amount of attitude change caused by it. Clearly, research designs incorporating more than two levels of message tone are needed to test for the possibility that neutrally worded messages are more effective than either positive or negative appeals.

A third concern is with the measures taken to assess the effects of exposure to messages varying in tone. In line with the previously stated possibility that the effects of tone have been confounded with anxiety arousal, it would seem useful to take a measure of the acute anxiety felt during the exposure to the message. Also, the effectiveness of the tonal manipulation should be demonstrated and carryover effects to perceptions of other message and source characteristics should be checked. Further, in consideration of wide support for McGuire's (1976) multimediational model of the communication process, the audience's comprehension of the arguments used in the message as well as the attitudinal effects should be assessed. Assessment of these mediating factors is critical in formulating explanations for why one message is more persuasive than another and in developing recommendations for actual message construction.

The fourth area requiring additional research is to evaluate the moderating effects of individual personality factors on the effects of positive and negative appeals. Wheatley and Oshikawa (1970) found that a positive appeal was more effective when the audience had a high chronic anxiety level, but that a negative, anxiety-arousing appeal was more persuasive with a low chronic anxiety audience. Subsequent reanalysis of their data, however, revealed that product ownership was a more critical factor than initial anxiety in determining the effectiveness of the negative message (Wheatley, 1971). It would seem worthwhile to explore this point further using a different experimental setting as the theoretical and empirical support for the moderating effect of chronic anxiety is quite substantial (see Wheatley and Oshikawa, 1970).

These four research questions were explored in an experimental study of the effect of message tone on an audience's comprehension and acceptance of a series of arguments favoring one's living within the city limits of Seattle. The confounding effect of anxiety-arousing cues within a negative appeal was minimized by the topic selected and pilot testing of the messages. Nevertheless, a postexposure measure of felt anxiety was administered to verify that this was not an important factor. A neutral message (neither positive nor negative) was included in the design to test for curvilinear relationships, and aided recall as well as attitude questions were asked to evaluate the messages' effects. Finally, in consideration of prior theorizing about the importance of individual characteristics as moderating variables, the participants' chronic anxiety and product ownership (as measured by place of residence) were included among the personal characteristic questions.

Method

Participants

Participants in the experiment were 184 adults contacted in public places such as bowling alleys, apartment buildings, government offices, and hospitals. A non-student sample was chosen in a nonlaboratory setting in order to enhance the external validity of the results. An effort was made to recruit an equal number of persons residing in the city and its suburbs to test whether the effects of the appeals varied with the initial opinion of the audience.

Procedure

Each participant was approached and asked if he or she would cooperate in a university research project. Those agreeing were given a booklet containing a questionnaire made up of several parts and one of the four written messages. Participants were randomly assigned to treatments by sorting the booklets using a random number table before the interviewers went into the field.

The initial part of the booklet consisted of a chronic anxiety scale to assess the participants' general anxiety level. This was followed by a description of the source of the message and the message itself, all on separate pages. After reading the message, the participants answered six pages of questions. These measured their feelings while reading the message (acute anxiety), their evaluations of the message and source (manipulation checks), their understanding of what the message said (reception), their agreement with a set of statements about living in Seattle and its suburbs (post-message attitudes), and their personal characteristics. Upon completion of the booklet, the participants were thanked for their assistance and debriefed on the purpose of the study and the need to expose them to a specially prepared message.

Independent Variable

The effects of message tone were studied using three experimental (positive-neutral-negative) and one control groups, each consisting of 46 participants. Prior to the final study, a sample of city and suburban residents ranked a list of reasons for selecting where to live (e.g., quality of schools and nearness to work). The reasons ranked as most important were converted into a set of statements about the advantages of living in the city and the disadvantages of living in the suburbs. Message tone was controlled by varying the proportion of city advantages and suburban disadvantages included in the appeal.

Positive appeal. The positive appeal argued entirely for the advantages of living in Seattle. The following is an excerpt from it:

When you buy a home in Seattle you get a lot of advantages...sewers, streets, utilities, and good schools are already available. Taxes in Seattle are lower than in the suburbs, which are still in the process of establishing these vital services.

The message's other arguments included the variety of housing available in the city, better public transportation, and time saved commuting to work. It began and concluded by praising those persons still living in the city.

Negative appeal. The negative appeal argued primarily against living in the suburbs in contrast to the positive appeal's arguing for living in the city. The following excerpt was constructed to correspond to that above for the positive message:

When you buy a lot or house in the suburbs, you have to help pay for the construction of sewers, utilities, and schools...things long established in Seattle and paid for years ago. In other words, taxes are higher in the suburbs than in the city.

In addition, the message began and concluded by criticizing those individuals who had recently moved from the city to the suburbs.

Neutral appeal. A third message was developed to be neutral in tone to test for possible curvilinear effects. It was composed of statements that were less negative and less positive than those used in the other appeals. The following excerpt corresponds to those previously given:

There are both advantages and disadvantages to living in the city rather than the suburbs. Taxes are lower in the city than the suburbs because vital services like sewers, streets, utilities, and schools are already established.

In this case, the message was moderated by deleting the references to buying a home and the necessity of establishing services in the suburbs. Further, there was no mention of approval for those remaining in the city or disapproval for those moving to the suburbs.

Control appeal. Because of the after-only design of the experiment, a nonpersuasive message was developed for presentation to a no-treatment control group in order to assess the absolute persuasiveness of the three experimental messages. It contained none of the arguments used in the other messages. The following illustrates the content:

Business in Seattle has recently been clicking along at a fast pace. The products turned out in Seattle are diverse...jet aircraft, space hardware, medicine, and more recently, professional sports team. The new King County Domes Stadium is the home of the Seattle Seahawk professional football team and will soon become the home of the Seattle Mariners professional baseball team. The "Dome" has brought great excitement to the residents of Western Washington.

Although the topics discussed were related to Seattle, they were more representative of the metropolitan area than the city itself and were neutral with regard to whether it was better to live within the city limits or the suburbs.

The positive and negative messages were pilot tested on a sample of city and suburban residents to verify that they were perceived as significantly different in message tone but not on any other major message characteristic. The neutral and control messages were developed after the pilot test.

Questionnaire

Chronic anxiety. A measure of the subjects' chronic or general anxiety was taken before they were exposed to the message. Although chronic anxiety should be insensitive to situational factors, it is desirable to assess it before exposure to potentially anxiety arousing information. Initial pilot testing revealed that the 47 question, Sarason Lack of Protection scale (Adams and Sarason, 1963, p. 245) used by Wheatley and Oshikawa (1970) was overly long for a field study. Therefore, the Taylor Manifest Anxiety scale (Taylor, 1953) was used in the present study. It consists of 20 statements such as "I feel anxious about something almost all the time" and "I don't like to face a difficulty or make an important decision," each rated from definitely agree to definitely disagree using a five-point scale. The participants' responses were distributed uniformly throughout the scale with the actual range being from 24 to 99 compared to the scale's total range of 20 to 100. The reliability for the entire scale was excellent (Cronbach's alpha = .92).

Acute anxiety. After responding to the chronic anxiety test and reading one of the messages, the participants reported their acute or temporary anxiety while reading the message. This section consisted of five semantic differential items (anxious-not anxious, confident-not confident, calm-tense, threatened-unthreatened, and nervous-relaxed). The responses were summed to form the acute anxiety scale (Cronbach's alpha = .89), and used to determine if the effort to equalize the anxiety-arousing aspects of the message was successful.

Message and source evaluations. In order to verify that the message tone manipulation had been successful and to determine if tonal changes would alter the audience's perceptions of the attributed source of the message, the participants were asked to respond to two sets of semantic differential items. The first set consisted of ten bipolar adjectives describing a message. These included three on message tone (positive-negative, optimistic-pessimistic, and threatening-not threatening), two on message clarity (confusing-understandable and clear-unclear), and five on other message characteristics (strong-weak, irrelevant-relevant, exaggerated-understated, interesting-uninteresting, and constructive-destructive).

The attributed source of the message (Mr. Jim Wilson, a recognized authority in the area of urban planning and development) was evaluated in the second set of adjectives on three credibility dimensions. These were expertise (knowledgeable-unknowledgeable, competent-incompetent, experienced-inexperienced, and expert-inexpert), trustworthiness (trustworthy-untrustworthy, subjective-objective, unjust-just, and biased-unbiased), and attractiveness (not likeable-likeable, pleasant-unpleasant, similar to you-dissimilar to you, and offensive-not offensive). The three summed responses were used to determine if differences in response to variations in message tone might be attributed to changes in source credibility, and, if so, which particular attributes were affected.

Reception. It has been postulated that differences in the effectiveness of persuasive appeals might be attributed to the mediating stages in the communications process. The possibility that messages differing in tone might vary in attention maintenance or ease of comprehension was tested by having participants report the

message's position on a series of statements. For example, participants were asked whether the statement, "Taxes are lower in the suburbs than in the city," was definitely true, partly true, undecided, partly false, or definitely false according to what they thought the message said. As the correct response was always definitely true or definitely false, it was possible to score the participants by how well their recollection matched this and to sum these into an overall measure of their understanding of the message (Cronbach's alpha = .61).

Postexposure attitudes. The participants were asked to report their level of agreement (five-point scale labeled strongly agree and strongly disagree at the ends), with ten statements about the advantages and disadvantages of living in the city or the suburbs. For example, "I would recommend living in the city to a newcomer to the Northwest," was one of the statements. Several statements were not relevant to the message and served as filler items. Therefore, only six of the ten statements were summed to form the overall attitude toward living in the city (Cronbach's alpha = .82).

Personal characteristics. The final section of the questionnaire consisted of five demographic questions about the participant's age group, education level attained, place of residence, male or female, and total annual family income. These responses were used to test the success of the randomization procedure and to determine whether product ownership as determined by place of residence moderated the effects of the message tone manipulation.

Results

The results of the experimental manipulation of message tone were analyzed in terms of the effects of exposure to the message on the participants' acute anxiety, reception of the arguments, and attitudes toward living in the city.

Randomization

The randomization of the participants to treatment groups was tested using the responses to the chronic anxiety scale which was administered before any were exposed to a message and to the personal characteristics questions. An analysis of variance of the anxiety scores and chi square analysis of the personal characteristics across treatment and control groups revealed that the groups were mostly homogeneous ($p > .10$). The only variation from homogeneity was for education. As the slightly lower educational level of the neutral and control groups relative to the positive and negative message groups was not thought to be theoretically important, the assumption that the groups were randomly selected was accepted as valid.

Acute Anxiety

The possibility that the messages differed in anxiety arousal as well as tone was tested by comparing the participants' reported feelings during their exposure to it. Unexpectedly, there was a significant difference ($F = 9.4$, $df = 2,122$, $p < .001$), with the neutral message being significantly less anxiety arousing ($M = 6.4$, $n = 44$) than the positive ($M = 9.0$, $n = 40$) and negative message ($M = 9.8$, $n = 40$) according to a studentized Newman-Keuls posterior comparison of the individual cells. However, because the negative message was not perceived as more anxiety arousing than the positive message, it was felt that comparisons of the postexposure differences in these groups would be a valid test of the effect of message tone independent of anxiety arousal differences.

Message and Source Evaluation

The participants' perceptions of the message are reported in Table 1. Substantial differences were found for the tonal attributions and these were all in the predicted direction. The positive and negative message did not differ on clarity or any other characteristic. However, the neutral appeal was thought to be significantly less clear, less understandable, and less interesting than the positive and negative appeals. This may reflect the participants' difficulty in reading a message that frequently changed message tone. Because of this difference, one must be cautious in interpreting the effectiveness of the neutral message used in this study.

TABLE 1

Message Evaluations by Message Tone

Measures	Message Tone			ANOVA	
	Posi- tive	Neu- tral	Nega- tive	df	F
Tone					
Positive- Negative	4.3 ^a (44)	3.0 ^b (46)	1.7 ^c (45)	2,132	74.0***

Understated- Exaggerated	2.4 ^a (44)	2.5 ^a (46)	2.4 ^a (44)	2,131	.1

Note: The cell means indicate how much the message was perceived as possessing the trait described by the left-most adjective. Cell sizes are in parenthesis.

abc Means in a row with different superscripts are significantly different from one another ($p < .05$).

* $p < .05$
** $p < .002$
*** $p < .001$

The source evaluations are reported in Table 2. There were no significant differences in the expertise dimension, but the source associated with the negative appeal was viewed as less trustworthy and attractive than those giving the positive and neutral messages. The neutral message source was evaluated most favorably on all three dimensions, though significantly so only in attractiveness.

TABLE 2

Source Evaluations by Message Tone

Measures	Message Tone			ANOVA	
	Posi- tive	Neu- tral	Nega- tive	df	F
Expertise	15.7 ^a (41)	16.0 ^a (45)	15.1 ^a (45)	2,128	1.1

** $p < .001$

Reception and Attitude Measures

The participants' immediate recall of the message and postexposure attitudes toward living in the city are reported in the last columns of Table 3 and 4, respectively. The negative message was significantly less well recalled and also resulted in the least favorable attitude toward living in the city. In fact, in comparison with the control group, the negative appeal group gave evidence of a "boomerang" effect. That is, they shifted their attitudes in the direction opposite from the argued in the message. However, a t test of the attitudinal differences between the experimental and control groups revealed that none of the differences was significant.

Moderating Influences of Chronic Anxiety and Residence

Two audience characteristics, chronic anxiety and current place of residence, were included in the analyses of variance of the dependent measures to assess their affect on the tone-persuasion relationship. The chronic anxiety scale responses were used to divide the sample into three groups (high-moderate-low) and reported residency responses were used to determine who was or was not a resident of the city (resident-nonresident). Tables 3 and 4 report the cell means for this breakdown and Table 5 has the analyses of variance with the three messages, three levels of anxiety, and two levels of residency as the independent factors.

After considering the important influence of the participants' residency and initial anxiety, message tone had a marginally significant effect on reception and an insignificant effect on attitudes. Comparing the interaction terms showed that the moderating effect of anxiety substantially exceeded that of residency for the reception measure and slightly exceeded it for attitudes.

The prediction that a positive message would be more effective than a negative message for individuals with high anxiety was in the right direction for both reception ($M = 33.0$ vs. 27.4) and attitudes ($M = 19.7$ vs. 18.1) measures, but was statistically significant only only for the reception measure ($t = 3.53$, $df = 112$, $p < .001$).² The other prediction, that a negative

²The statistical test used is that for planned comparisons between cells (Tables 3 and 4) with the error term being estimated from the analyses of variance (Table 5). See Winer (1971, pp. 384-388).

message would be more effective than a positive message for individuals with low anxiety, was also in the predicted direction for reception ($M = 33.5$ vs. 28.1) and attitudes ($M = 19.1$ vs. 18.1), but again the difference was only significant for the reception measure ($t = 2.75$, $df = 112$, $p < .01$).

Discussion and Conclusions

The results of this study offer further evidence that in the absence of differences in anxiety-arousing content, negatively-worded appeals are not more effective than positive messages. In fact, the data favor the use of positive appeals over negative appeals. Four issues identified in reviewing prior research (confounding of anxiety arousal with negative wording, necessity of having three levels of message tone, using multiple measures of exposure effects, and reexamining the moderator role of audience characteristics such as chronic anxiety and product ownership), were investigated by exposing participants to persuasive appeals varying in message tone but all urging individuals to live within the city limits of Seattle.

The participants' message evaluations and reported feelings during their exposure demonstrated that the positive and negative messages were successfully constructed to differ in tone without differing in anxiety arousal. However, both were significantly more anxiety arousing than the neutral message, apparently because they contained some social approval and disapproval statements. Since the neutral message was also perceived as being somewhat more confusing than the other two message, it is not clear that all postmessage differences should be attributed to the tonal differences in the messages and therefore conclusions about curvilinear effects are tenuous. The only evidence supporting the use of neutrally-worded messages was a generally more favorable evaluation of the message source compared to the positive and negative source evaluations.

One of the two major differences between the positive and negative messages was a loss of credibility for the source giving the negative appeal. The loss of trustworthiness and attractiveness suggests that an audience more easily views a negative appeal than a positive message as a persuasive attempt. This loss of credibility could be a serious concern for advertisers though there may be ways to counteract it, such as by employing highly credible sources to deliver the message. For example, the practice of having government health and safety warnings include a reference to the agency responsible would seem to be a wise strategy for enlisting public cooperation.

The other important difference was that the audience exposed to the positive message comprehended and recalled the content better than those exposed to the negative message. The fact that this led to only slight differences in postmessage attitudes probably reflects the single exposure opportunity, the message topic, and the audience. As most individuals had committed themselves to living in or out of the city, it would seem unlikely that they would easily change their opinion. With a less firmly established attitude or with repeated exposures it is possible that a significant attitude change would have been observed.

The improved reception combined with the higher source credibility evaluation offer strong support for employing only positive and neutral appeals and avoiding negative messages. Two factors argue against rigorous adoption of this recommendation, however. First, the literature review revealed that negative messages are effective when combined with other message factors, particularly anxiety-arousing information. Similarly, if very strong negative arguments are available, it is possible that

their ability to impede counter-argumentation would more than compensate for the undesirable effects of negative message tone. Under these circumstances, an advertiser would benefit by sponsoring the negative campaign.

Secondly, the effects of message tone were not uniform across audiences. The positive message was most successful with audiences initially opposed to the position being argued (nonresidents in this study), and with high anxiety individuals. Both of these groups would probably feel most threatened by the negative appeal which would result perhaps in avoidance (evidenced by the low message reception), source derogation (indicated by the unfavorable source evaluations), and counterargumentation. However, for those initially agreeing with the message's position (city residents), and low anxiety individuals, the negative appeal was as effective as the positive appeal and only slightly less effective than the neutral message. To the extent that an audience possesses any of these characteristics, an advertiser would not suffer by using a negativistic approach.

It should be noted that a reexamination of the relative importance of chronic anxiety and product ownership did not support a previous finding. Contrary to Wheatley's (1971) conclusion, a measure of chronic anxiety was a more important moderator variable than was a measure of product ownership (place of residence). There are several methodological differences between the two studies that could account for this. The present study used low anxiety-arousing appeals (all three messages yielded reported anxiety levels of less than 10 on a scale with a range from 5 to 25). The negative appeal in the original Wheatley and Oshikawa (1970) experiment, which served as the data source for Wheatley's (1971) conclusion, was designed specifically to be anxiety arousing. If all the participants are experiencing high acute anxiety because of their exposure to a threatening message than some of the communication effect attributable to individual differences in chronic anxiety could be obscured. Also, this study employed a different anxiety scale and used nonstudents in a field setting as participants which appeared to have increased the range of responses to the anxiety questions compared to the student subjects tested in a classroom in the previous study. An increase in the range of scores of an independent factor would tend to increase the likelihood that it would account for more of the variance in a dependent variable. Further, Wheatley's findings were based on attitude change scores rather than postmessage attitudes. It is possible that ownership is related to the reliability of attitudinal responses which would confound any attempt to assess the effect of the persuasive appeals. Additional research is needed to determine which of these differences account for the inconsistency in the conclusions of the two studies.

THE RELATIVE EFFECTIVENESS OF ONE-SIDED AND TWO-SIDED COMMUNICATION
FOR MASS TRANSIT ADVERTISING

Linda L. Golden, The University of Texas at Austin
Mark I. Alpert, The University of Texas at Austin

Abstract

This research investigates the relative impact of one-sided and two-sided communication on ridership intentions, attitudes toward transit features, and advertisement specific variables. The influence of varying numbers of claims is also studied. Two-sided communication was more effective than one-sided communication in increasing copy believeability.

Introduction

For several years now the advertising prohibition against saying something negative about the advertised brand has not been strictly adhered to. Some advertisers have been "disclaiming" certain trivial characteristics of their products in conjunction with positive claims. Volkswagen, for example, used this technique to poke fun at itself while it was actually making positive claims with regard to the product.

In a disclaiming situation, an advertiser makes positive statements about characteristics that are determinants of product use, but does not claim that the product performs well on certain characteristics that are not determinants of product use. Previous research indicates that disclaiming may tend to increase the credibility of an advertisement (Settle and Golden, 1974). This may then result in a more effective advertisement.

Disclaiming in an advertisement may be viewed as providing the audience (consumers) with a two-sided argument with respect to the advertised product. For years communication research has investigated the attitudinal impact of two-sided arguments; however, the research area has not been developed in an advertising context. The focus on this research is to investigate the relative effectiveness of one and two-sided messages for mass transit advertising according to hypotheses derived from the communication research.

One-sided and Two-sided Communication Research

Communication researchers offer slightly different definitions of two-sided arguments (McGuire, 1954; Hovland, 1954; Hovland, Lumsdaine and Sheffield, 1949; Jones and Girard, 1967). Unlike other authors' definitions, Hovland's (1954) definition of two-sided arguments explicitly states that the communicator takes into account both sides of an issue, but he is himself in favor of one side. This has been described by Klapper (1949) as partial impartiality. Even though the advertiser may say something unfavorable about his brand or something favorable about the competitor, overall the advertiser will present his product as the one the consumer should buy. The advertiser is, indeed, in favor of one side. Thus, for purposes of this research Hovland's (1954) definitions are used. A one-sided argument is an argument confined to one side of an issue (Hovland, 1954).

The earliest studies in this area were designed primarily to investigate the effects of two-sided presentations. In these studies, the communicator impartially presented both sides of an argument without favoring either side. The general conclusion derived from these studies is that when one is successively

exposed to first one side and then the other of a controversial subject, the typical result is that the individual is left at approximately his/her initial position (Sims, 1938; Schanck and Goodman, 1939).

The earliest experimentation explicitly directed to the investigation of the comparative effects of one-sided and two-sided communications was conducted during World War II by Hovland, Lumsdaine and Sheffield (1949). No main effect of direct attitude change was found in this study, but there were interactions with initial favorability such that one-sided communications were more effective for those initially in favor of the conclusion and two-sided communications were more effective for those initially opposed to the conclusion. There was also a significant interaction with education such that two-sided communications were more effective for high school graduates and one-sided communications were more effective with subjects who had not graduated from high school. Later studies by Janis, Lumsdaine and Gladstone (1961), Lumsdaine and Janis (1953), and Paulson (1954) also indicated that one-sided and two-sided arguments were about equally effective over-all in producing direct attitude change.

Thistlethwaite and Kamenetsky (1955) and Thistlethwaite, Kamenetsky and Schmidt (1956) investigated the attitudinal effects of refutation of opposing arguments rather than simple mention of opposing arguments. For some groups tested, there were no significant differences between the speeches with refutation and those without. For others, the refutation speeches had more influence. The authors concluded that the speeches with mention and refutation of opposing arguments had the effect of strengthening opposing attitudes. They suggest that listeners apparently discounted the speeches with refutation as "phony" attempts to seem impartial.

All of these studies seem to suggest that mention of opposing arguments should be handled with caution. The only groups that seem more positively affected by two-sided messages were those initially opposed to the conclusion and those of higher educational levels. Even these groups did not make large changes in attitudes. Two-sided messages, however, do have a specific place in the communicator's organizational framework. They can serve to "immunize" receivers against contradictory information in later situations (Lumsdaine and Janis, 1953; McGuire, 1961; McGuire, 1962; McGuire and Papa-georgis, 1961).

Development of Hypotheses

Direct generalizations from communication research to advertising are restricted. The topics of the persuasive communications presented in the communication research were of a controversial nature. It is doubtful that the topic of many messages featured in an advertisement for consumer package goods could be considered controversial. However, advertisements for some non-traditional products or services such as birth control, welfare, and possible mass transit have topics which may be considered controversial. Further, the dependent variable in the communication literature is attitude change. The objective of advertising is to

influence, in the long-run, not only attitudes but ultimately behavior. However, given the relatively high level of educational attainment of persons likely to switch from a car to the use of mass transit (Alpert and Davies, 1975) and the relative degree of controversy surrounding mass transit compared to consumer package goods, two-sided communication is a realistic promotional tool for mass transit to explore.

The purpose of this research is to investigate the relative impact of one and two-sided communications upon ridership intentions and attitudes toward mass transportation for individuals in a sample whose demographic characteristics approximate those of "potential switchers" to mass transit identified in previous research (Alpert and Davies, 1975). Because of the relatively high level of educational attainment by persons in this sample the following hypothesis was developed:

- H₁: Two-sided messages will be more effective than one-sided messages in producing changes in attitudes toward mass transit and ridership intentions.

Since the number of positive claims included in the message may influence the effectiveness of the disclaimers, the effects of number of attributes in the copy were also tested. One hypothesis was generated to test this proposition:

- H₂: The changes produced in ridership intentions and attitudes toward mass transit by one and two-sided messages will be influenced by the number of positive attributes included in the message.

Methodology

Presentation of both one and two-sided experimental manipulations requires selection of both determinant and non-determinant attributes for mass transportation. In the two-sided manipulations, the product does not claim to possess the non-determinant attributes, but does claim to possess the determinant attributes. For transportation, determinant attributes are those attributes of a product which determine the consumer's modal choice.

Previous research in the city studied had identified determinant attributes for potential switchers. The five most determinant attributes for which the bus was rated superior to a private car were selected for use in this research. These were: economy, freedom from parking problems, freedom from repairs, low energy use per passenger, and low pollution per passenger. Given a bus's perceived superiority on these features, it is likely that advertising which asserts these as advantages might be at least believable. The selection of the non-determinant attributes required additional testing, since it was necessary that the non-determinant attributes be believable both as positive claims (one-sided) and disclaimers (two-sided). The non-determinant attributes from previous research (e.g., "ability to read," "fun to drive") could not realistically be used for both positive and negative claims, because the image of one mode was perceptually superior.

The determinancy of fifteen potentially non-determinant attributes was tested on a sample of one-hundred university students who possessed characteristics closely approximating those of potential switchers. The results indicated that the attributes colorful interior and long windows would be suitable as non-determinant attributes for both the one-sided and two-sided manipulations. These attributes were rated as relatively unimportant

transportation features for which cars and buses do not differ.

Attitudes toward both the bus and the car on these determinant and non-determinant variables (freedom from repairs, freedom from parking problems, low energy use per passenger, low pollution per passenger, economical, colorful interior, and long windows) constituted one set of dependent measures. Another set of dependent measures investigated respondents' affect toward driving a car and riding a bus. A third set of dependent measures investigated ridership intentions for specific trip purposes: to work or school and for shopping or personal business. The final set of dependent measures was designed to investigate attitudes toward the copy itself: likelihood of reading all the copy, believability, perceived quantity of information, usefulness of information, and general affect.

A pilot study was administered to a sample of 110 subjects whose characteristics closely approximated those of potential switchers, to test alternative ways of presenting the one-sided and two-sided communication formats and placement of dependent variables. A subject received one of several experimental manipulations followed by the dependent variables tentatively selected for use in the final instrument. The order of presentation was either: (1) experimental manipulation, dependent variables, media questions, or (2) experimental manipulation, media questions, dependent variables. The message formats (experimental manipulations) tested varied in their presentation of the attributes of the bus. The attributes were listed in a column below several sentences of copy, and the bus was described in one of three ways on each of the attributes. In one treatment, the bus was given a rating of either "superior" or "inferior" on the attributes. The one-sided treatment identified the bus' performance on all of the attributes as "superior." The two-sided treatment identified the bus performance on the determinant attributes as "superior" and as "inferior" on the non-determinant attributes. A second treatment followed the same general format, but replaced the adjective "superior" with "good" and "inferior" with "fair." The third treatment used check marks (✓) beside the attributes under columns labeled either "bus gives you" or "bus doesn't give you." The one-sided treatment did not contain the column "bus doesn't give you" and checked each attribute under the column labeled "bus gives you." The two-sided treatment varied in that it checked non-determinant attributes under "bus doesn't give you." The results of the pilot indicated that the use of check marks provided a slightly stronger manipulation than any of the other two treatments tested. There were no significant differences for the alternative placements of the dependent measures.

The Final Instrument

The final instrument used an after-only design with control and contained five sections. The first section presented the respondent with one of ten different experimental manipulations. The respondent could receive either a one- or a two-sided communication containing either three, four, five, six, or seven attributes. The attributes were always presented in the same order, even though the number of attributes could vary. The non-determinant attributes were always the second and third attributes presented to the respondent. The experimental manipulation was printed on heavy glossy paper on a separate page in order to simulate an advertisement as closely as possible. A cover page told the respondent that the following page contained part of an advertisement and to please read it carefully. Figure 1 exhibits a two-sided experimental manipulation with seven attributes.

FIGURE 1
Experimental Manipulation for Two-sided Message
With Seven Attributes

A lot of people are switching to the Austin city bus these days. Whether you're going to work, shopping, or just visiting, the bus will take you there. Although we're not perfect, we have many advantages. Let us tell you what the bus can and can't offer.

	Bus Gives You	Bus Doesn't Give You
Economy	✓	
Colorful interior		✓
Long windows		✓
Freedom from parking problems	✓	
Freedom from repairs	✓	
Low energy use per passenger	✓	
Low pollution per passenger	✓	

Find out for yourself what the bus can give you!

The second section of the instrument contained five questions concerning the subject's reactions to the copy. These questions were designed to ascertain the subject's likelihood of reading the copy in a magazine, the credibility of the copy, the information provided, the usefulness of the information, and the general attitude toward the copy. Responses were elicited according to a seven-point horizontal scale with one indicating the negative extreme.

The third section of the instrument obtained information regarding the subject's media habits. Information concerning the extent and nature of the subject's use of newspapers, radio, and television was elicited.

In the fourth section of the instrument, subjects were asked to indicate how likely they would be to purchase the product described in the experimental manipulation. In addition, information concerning the extent to which the subject felt the product possessed each of the seven attributes which could appear in the experimental manipulations was obtained. Subjects indicated their responses according to a seven-point horizontal scale with one representing "not at all" and seven representing "very much."

The final section of the instrument obtained demographic and personal information. Information regarding age, marital status, sex, employment status, household size, income, education, race, living situation, and number of automobiles owned was collected. On the last page of the instrument, the subject had the opportunity to request a summary of the survey results.

The final instrument was pre-tested for clarity of presentation on a sample of twenty subjects whose characteristics approximated those of potential switchers. Minor wording changes were made in the instrument as a result of the pre-test. The control group instrument was identical to that containing the experimental manipulation, except that the five questions directly regarding the advertisement (which was absent) were deleted.

Sample Selection and Administration

The criterion for the selection of subjects for the instrument was the possession of characteristics approximating those for potential switchers. In the survey area, potential switchers to mass transit had been found to be relatively younger, have smaller households, are more likely to be full-time or part-time students (although most are non-students), and they are more likely to shop and work in the downtown area than are those less likely to switch to mass transit (Alpert and Davies, 1975).

Distinct areas of a medium-sized southwestern city were identified which contained a relatively high proportion of individuals possessing the characteristics of potential switchers. An enumeration of households in these areas was obtained from Cole's Directory. In order to obtain a sample of 1,500 individuals, computer-generated random numbers were used to identify every n th person to be included in the sample frame. Only residents, not businesses, were counted when identifying potential subjects. Further, the sample was restricted to households within one-quarter mile of a current bus route, so that intention to ride the bus could be realistically measured.

Having identified the potential respondents, interviewers then began contacting by telephone. Interviewers were to ask specifically for the person whose name appeared on their calling list. Upon contact, the interviewer first gave his or her name and then requested their assistance in a consumer attitude survey being conducted by members of the Department of Marketing. When an individual agreed to participate in the study, he or she was told that they would receive the survey within a week. The respondent was instructed to please fill out the survey completely and return it at the earliest convenient time in the enclosed return envelope. Subjects were randomly assigned to treatments at the time of mailing. A letter of appreciation was included with the survey which contained the telephone number of the Department of Marketing so that the subject would have a contact point for any questions.

Statistical Analysis

The final sample consisted of 292 usable surveys returned from respondents. There were no less than 20 respondents in each cell with a maximum of 44 in the control groups.

Descriptive statistics (Veldman, 1967) confirmed that the demographic composition of the sample was highly similar to the characteristics of "potential switchers" to mass transportation derived from previous research. A second preliminary analysis performed on the data was a discriminant analysis (Veldman, 1967) to determine if respondents assigned to alternative treatments differed significantly on demographic dimensions. Three separate analyses were run: (1) comparison of respondents assigned to one-sided or two-sided treatments, (2) comparison of respondents assigned to three, four, five, six, or seven claims, and (3) comparison of respondents in each of the eleven treatment levels (including control groups). In each of these analyses, the ten demographic questions constituted the independent variables. There were no significant differences between respondents according to demographic variables for any of the above three analyses. Thus, respondents appear to have been randomly assigned to treatments on this dimension.

A final preliminary analysis was a descriptive analysis (Veldman, 1967) of the sample's ridership of the bus. Ninety-nine percent of the respondents used their car for trips to shopping or personal business. Sixty-four percent of the respondents used their car for trips to work or school; however, twenty-two percent of the respondents did not respond to this question since they did not work or go to school. Only four percent of the sample used the bus at all in the last four weeks. Thus, the sample is composed of individuals who use their car as their primary mode of transportation.

In order to compare the effectiveness of each of the experimental manipulations (advertisement treatments) against a control group, individual t-tests were performed on each of the twenty dependent variables for the respondents receiving a bus treatment. In addition, the data were submitted to two-way analysis of variance

(Veldman, 1967) for the effects of communication type (one-sided versus two-sided) and the number of claims (three, four, five, six, seven). These results are reported in Tables 1 and 2 respectively, which appear in the next section. The data from the five advertisement specific dependent variables were submitted to two-way analysis of variance (Veldman, 1967) for each dependent variable separately in order to investigate the relative effects of communication type and number of claims. These results are presented in Table 3 of the next section.

Results

Table 1 presents the results of the t-tests between the control means and the experimental manipulation means. The four most important dependent variables that can be used to evaluate the bus advertising treatments are the first four variables listed in Table 1. These measure the behavioral intentions toward the use of buses for trips to work or school (commuting) and for shopping or personal business, both over the short-run (How likely are you to ride the bus in the next month?) and "for most of your trips." As can be seen in Table 1, neither the one-sided nor the two-sided advertisement style was able to achieve any strong pattern of impact on people's behavioral intentions, which remained near the low end of the seven-point scale.

As can be seen from the cells in Table 1, there are 200 possible comparisons between the dependent measure ratings given by persons exposed to varying treatments and those in the control group. However, out of 200 possible comparisons one would expect 10 "significant" differences due to error or sampling fluctuations, using the .05 level for type-I error and two-tailed tests. There were 14 experimental rating means which were significantly different from the control mean, and of these 14, nine experimental treatment means did better than the control mean. This is hardly a strong overall pattern of change in attitudes or ridership intentions toward mass transit. Further, all the significant treatment-control comparisons for the one-sided messages were greater than the control, while only two of the

seven significant comparisons for the two-sided were greater than control. However, five of the seven significant one-sided comparisons were for non-determinant attributes (not previously salient to buses).

Table 2 indicates the significant effects obtained in the two-way analysis of variance performed on the bus variables. For four of the twenty dependent variables, communication type was shown to have a significant main effect. In all of these, one-sided communication produced a more favorable evaluation of the bus than did two-sided communication. Two of the significant dependent variables, colorful interior and long windows, were disclaimed in the two-sided treatment, so it is logical that the one-sided treatment would have more impact. The theory had hypothesized that since these features were not determinant attributes of modal choice, it would be better to "give up" some perceptions in these attributes in return for higher evaluations in terms of the determinant attributes that would be claimed. Only one attribute mentioned in the copy, low pollution per passenger, showed a significant main effect of communication type. However, the results are counter-theoretical as the one-sided was more effective than the two-sided communication. The one-sided message was also more effective for liking the bus as an alternative to the car.

The results for colorful interior and long windows probably simply indicate that respondents believed the experimental manipulation, but beyond these two variables only two dependent variables showed a significant main effect of communication type. This is one more than would be expected by chance ($\alpha = .05$), but the results indicate a stronger impact of the one-sided message. On the basis of these results, the first hypothesis which states that two-sided communication will be more effective than one-sided communication is rejected.

As further noted in Table 2, the impact of the number of claims produced significant between group variation for three of the twenty variables, which is more than would be expected by chance. A significant main effect for number of attributes was produced by: likely to ride

TABLE 1
Significant^a Mean Comparisons for Bus and Control Treatments

Dependent Variable	One-sided Number of Attributes					Control Mean	Two-sided Number of Attributes				
	3	4	5	6	7		3	4	5	6	7
Likely to ride (shopping/personal business)			1.64			1.05			1.44

the bus for shopping or personal business within the next month, enjoy driving car, and the perceived economy of the car. No distinct pattern emerges with regard to the optimum number of attributes. It is interesting to note that the number of attributes mentioned in the advertisement about the bus influenced the perceptions of the perceived economy of the car.

There was no significant interaction between number of claims and communication type, indicating that the number of claims had no significant impact on the dependent variables -- no matter which format (one-sided vs. two-sided) was used -- given the range of claims used (three to seven). Thus, the second hypothesis, which states that the number of claims will influence the effectiveness of the communication type used, was also rejected.

In order to obtain further information on the appropriateness of particular strategies, it may be useful to consider respondents' reactions to the advertisements themselves. It may be that one reason why attitudes toward the bus were not significantly influenced by the treatments is that the advertisements themselves were at fault. Table 3 depicts the results of the two-way analysis of variance for the ratings of advertisement variables.

There were five advertisement specific dependent variables: likelihood of reading all the copy if the advertisement appeared in a magazine, perceived believability, perceived quantity of information, perceived usefulness of information, and the extent to which the respondent liked the copy. There was a significant main effect of communication type for one of the dependent variables: believability. The results tend to indicate that two-sided communication was more believable than was one-sided communication.

There was a significant main effect for the number of attributes for three of the five dependent variables: believability, quantity of information and like copy. Six attributes produced the highest mean ratings for all three dependent variables. There was also a significant interaction effect for communication type and number of attributes for the dependent variable likeability of the copy. The highest mean rating appears for the

two-sided communication with six attributes. For some numbers of claims, the one-sided communication appears to be more effective, and for other numbers of claims the two-sided communication was more effective.

Conclusions and Implications

The experimental manipulation used in this study was a piece of advertising copy administered at one point in time via a static after-only with control experimental design. This one-time exposure to a portion of an advertisement may help to account for the lack of extensive significant impacts of ridership intentions or attitudes toward the bus. However, the manipulations were strong enough to produce significantly different effects for the advertisement specific variables. In the context of the limitations of the experimental design and the product under consideration, several conclusions can be drawn from the results of this study.

Two-sided communications were no more effective in producing changes in ridership intentions or attitudes toward attributes of the bus than were one-sided communications. In fact, there was not only a lack of overall pattern of positive attitude changes, but there appears to have been a greater proportion of negative effects on specific bus features advertised for two-sided communication. It may be reasonable to speculate that the effect of advertising public transportation in a two-sided communication format to those who have the option of private transit and feel generally negative toward buses is to evoke less positive evaluations of bus features than are normally the case. It is also possible that people may be reacting against a possible attempt to influence them to use this transportation mode by rating it less positively than when they are asked (without any exposure to advertising copy) to indicate a behavioral commitment to using it. In general, attitudes toward the bus may be so negative (even for potential switchers) that even the mildest of disclaimers only serves to reinforce opposing attitudes toward the bus.

Communication research has shown that two-sided communication is likely to be more effective for higher

^ap < .05

educated persons and those initially opposed to the conclusion. Although the sample was relatively higher educated and did not tend to ride the bus, neither one- nor two-sided communication produced significant attitude or ridership intention change. It may be argued that it is unfair to expect much change in overall attitude toward the bus, given only one exposure to a partial advertisement. This is particularly a problem given the major perceived disadvantages of buses in terms of convenience, flexibility, safety from dangerous people, and other determinant attributes found in prior research in this area, and not covered in this advertisement. It may be that the key to changes in ridership intentions and attitudes toward the bus lies in changes in the system and not in the nature of the promotional message used for this product. Attitudes may be so negative that a product change may be required to shift them, because the product may not offer significant advantages (possibly it offers significant disadvantages) over the most popular mode of transportation: the car.

Two-sided communication does appear to produce more believable copy than does one-sided communication. However, the believability is such that it does not make attitudes more positive and may in fact cause attitudes to move in a negative direction toward the attributes for which positive claims are made.

The number of attributes described in the copy tended to be more critical to the effectiveness of the advertisement for this research than did the communication format employed. For attitudinal variables toward the bus, there was no clear pattern of the optimum number of attributes. However, this research indicated that incorporating six attributes in the copy produced the highest ratings on advertisement related variables. Consumers tended to believe the advertisement more, perceived more information and liked the copy better when it contained six attributes. In addition, liking the copy may be a function of both the number of attributes and the communication type. Clearly, the operational

relevance of this information depends upon the objectives to be achieved by the advertisement.

In order to more completely investigate the relative impact of one- and two-sided advertising, this research needs to be extended to more products, more independent and dependent variables, and to potentially stronger but realistic manipulations, over time. From the results of this research it appears that two-sided communication may be less effective than one-sided communication in producing positive attitude change toward product features. However, two-sided messages appear no more or less effective in influencing ridership intentions. Further testing is required with a myriad of situations and variables before any definitive relative effectiveness information can be discerned. What is likely to be most effective for mass transit is changes in the system along critical determinant attributes.

COLA PREFERENCES: DISGUISED TASTE VS. BRAND EVALUATIONS

Thomas J. Stanley,¹ Georgia State University

Abstract

This study was designed to determine if preferences for colas based on taste evaluations could explain overall cola brand preferences. In 25 of 60 cases studied, subjects' taste preferences were significantly related to their brand preferences. Thus, evidence supports the contention that taste is an important evaluative criterion that underlies consumer cola brand preferences.

Introduction

Recent studies (Lane, Zychowski, and Lelli, 1975; Thumin, 1962) have indicated that subjects can distinguish between popular brands of colas; however, these studies have not determined if the taste of colas is an important factor in explaining overall cola preferences. Several scholars (Posner, 1974; and Warne, 1962) suggest that the physical differences of products such as colas are usually unimportant factors in explaining consumer preferences. Social critics conclude that differentiation of cola brands via promotion of taste are nothing more than "foolish puffing." Governmental agencies also frown on what is called puffing ads, which promote in their words "pseudo-differences" (Backman, 1968; Posner, 1974; and Warne, 1962). In actuality, the cola industry has steered away from promoting direct taste comparisons, even though consumers disagree with the idea that product differences between competing brands of most products are insignificant and unimportant to them (Barksdale and Darden, 1972). Historically, the majority of cola advertisements have not emphasized taste (Block, 1975), but have attempted to develop strong brand images for their products by associating them with emotionally loaded themes such as brotherhood, nostalgia, and reference groups. Critics of advertising argue against the use of these conditioning methods.

Cola producers would have a strong argument as well as motivation for the use of advertising which emphasizes taste differences if they could demonstrate that taste is an important factor in explaining cola preferences. The success of future product as well as promotional developments in this context may hinge upon whether or not taste is an important factor in explaining overall brand preferences for colas (Block, 1975). This paper attempts to determine if taste preference evaluations can explain overall brand preferences for colas.

Method

Subjects

Sixty students from a state university participated in this study. There were 41 male and 19 female subjects who ranged in age from 19 to 27 years. Eleven of the original 71 volunteers did not participate in the study; five subjects indicated that they were not familiar enough with colas to evaluate them; and the other six

withdrew before completing their evaluations.

Procedure

The stimuli used in this study were seven cola drinks including: (1) Adirondack Cola; (2) Canada Dry Cola; (3) Coca-Cola; (4) Cott Cola; (5) Pepsi Cola; (6) Shasta Cola; and (7) Tab. Adirondack and Cott are regional soft drinks while the others are well known nationally. Shasta and Tab were the only diet colas used in the experiment.

Each subject evaluated two separate sets of stimuli. Subjects were first asked to indicate their preferences for the colas, in a blind, paired comparison taste test. Each subject rated all 21 pairs and indicated a preferred cola in each pair. No information about the identity of the cola was given the subjects prior to or during this part of the experiment. Approximately four ounces of each cola was given to each subject in opaque plastic cups. The colas were stored at approximately 5°C prior to their distribution. Salt free flour crackers were also distributed and subjects were instructed to consume a bit of the crackers after tasting each cola pair. The position of the colas in every pair as well as the order that pairs were presented in was randomized.

Following the completion of the taste evaluations each subject made preference evaluations on a set of 21 randomly ordered pairs of the names of seven cola brands. The brand names were those of colas tasted in the first step of the experiment. The responses to cola names (tastes) were used to construct a brand (taste) preference scale.

The Model

Both the taste and brand preference data were separately analyzed by the MD-PREF scaling algorithm. This program transforms subjects' paired comparison preference data matrices into rank orders or first score matrices. The Eckart-Young factor analytic procedure then decomposes the ranked data and generates a group stimulus space or matrix and termini of subject vectors (ideal points) that best agree in a least squares sense with the matrices of subjects' scaled preference values. In other words, MD-PREF determines the stimulus coordinate values and termini of subject preference vectors from the set of preference judgments that will most closely agree with the preference scale values for each subject (Green and Rao, 1972; and Green and Wind, 1973).

The output from MD-PREF includes the stimuli which are represented as points and subjects as vectors in the same space. A subject's rank preference ordering is depicted as a vector drawn through the origin of the stimulus space to the subject's ideal point. The correlation between the vector and a particular coordinate axis indicates how well a subject's preference ordering can be explained by the positions of the stimuli along that axis. The farther the subject's ideal point is from the origin the better the stimulus configuration can explain a subject's preference ordering (Carroll, 1972).

Rationale

Today, the average cola consumer must decide what cola

¹The author is indebted to Dr. Ralph L. Day, Professor of Business, Indiana University, for his helpful suggestions.

to purchase from a large set of offerings. From the results of previous cola taste experiments (Thumin, 1962; Lane, Zychowski, and Lelli, 1975) it is unclear if taste plays a role in explaining cola preferences. In this study subjects were asked to evaluate seven colas given in 21 pairs. This number (seven) may approximate the typical number of cola brands generally offered in the market area where the study was conducted. However, the possibility exists that subjects who tasted 21 successive pairs of colas encountered taste adaptation. Some amount of perceived adaptation may typify the actual market conditions under which consumers must make such decisions. Also adaptation would make it more difficult to reject the null hypothesis that no relation exists between cola preferences based on taste evaluations and those based on brand preference evaluations. Rejection of the null hypothesis under such conditions would provide a stronger argument that taste preferences are generally important in explaining brand preferences.

Both the taste and brand preference data were separately analyzed by the MD-PREF multidimensional scaling algorithm. The resulting preference orderings (taste preference and brand preference scales) for each individual were correlated to determine the extent to which taste evaluations could explain evaluations based on brand names. The multidimensional scaling method was used instead of more traditional scaling methods for several reasons. An important aspect of multidimensional scaling methods lies in their ability to accurately reproduce, in the form of a multiple dimension geometric space, preference as well as perceptual configurations (Dubois, 1973; Green and Carmone, 1970; and Stanley, 1976, a, b).

Results

Tables 1 and 2 illustrate the stimulus spaces from the MD-PREF analyses of taste and brand preference evaluations. Two factors explained 70 percent of the subjects' taste judgments and 78 percent of the preference evaluations based on brands. Factor one explained slightly more than 50 percent in both cases. In both cases the third factor added little to the explanation of preference judgments and was therefore excluded from further analysis.

Tables 1 and 2 demonstrate that in regard to factor one high negative scores are associated with the diet colas, namely Shasta and Tab, while high positive scores are noted for Pepsi and Coca-Cola. The direction of subjects' ideal points suggest that positive values are indicative of more preferred colas than those with negative values.

TABLE 1
Stimulus Matrix Generated
From Cola Taste Evaluations

Stimulus	Factor	
	I	II
Adirondack Cola	.0600	.2623
Canada Dry Cola	.1722	-.3947
Coca Cola	.2998	.0552
Cott Cola	.2700	.5126
Pepsi Cola	.3595	-.3706
Shasta Diet Cola	-.5890	.3979
Tab	-.5725	-.4626

TABLE 2
Stimulus Matrix Generated
From Cola Brand Evaluations

Stimulus	Factor	
	I	II
Adirondack Cola	-.3875	-.4339
Canada Dry Cola	.1221	.0400
Coca Cola	.5191	.1699
Cott Cola	-.0203	-.2856
Pepsi Cola	.5140	.0408
Shasta Diet Cola	-.2697	-.3078
Tab	-.4777	.7767

Factor one in both preference spaces indicates that subjects consistently evaluated Coke and Pepsi as distinctly more preferred over the diet colas. Therefore, the evaluations of Coke and Pepsi and the diet colas would make a substantial contribution to high positive correlations that may be found between taste and brand preferences. Without the assistance of other measures such as perceptual and corresponding property scales, no attempt to label the factors generated from an internal preference analysis should be made.

Subject Correlations

Two rank orders (individual taste and brand preferences) of the stimuli were computed from the two factor MD-PREF outputs for each of the 60 subjects along their preference vectors. In turn, 60 Spearman rank correlations were computed between the ranks assigned by each subject to colas on the basis of taste and brand evaluations (see Table 3).

Twenty-five of the 60 correlations were positive and significantly greater than zero, at the $p < .05$ level. The chance expectation at the $p < .05$ level is that only three of the 60 subjects will have a significant rank order correlation. As determined by the Poisson approximation to the binomial distribution, the probability of finding 25 or more of the 60 significant correlations where no actual relationship exists between taste and brand preference for any of the subjects is less than .001, where $n = 60$, $p = .05$, and $M = np = 3.0$.

Discussion

The results of this study indicate that a significant relationship exists between cola preferences based on taste evaluations and brand preferences. Therefore, a possibility exists that cola brand preferences could be predicted from taste evaluations. Thus, cola producers may wish to consider placing more emphasis on promoting and developing unique flavor characteristics for their products. By demonstrating that variations in brand preference can be explained by taste evaluations cola producers can counter social critics and government agencies who condemn the use of product differentiation themes in cola promotions.

Multidimensional scaling techniques appear to be a useful tool in measuring consumer taste as well as brand preferences. Future studies should investigate the perceptual properties that explain taste and corresponding brand preferences. By being able to understand the variations in the saliences consumers attached to the dimension of taste, cola producers will be in an excellent

position to develop products which are more closely tailored to the needs of various market segments.

NONMETRIC UNIDIMENSIONAL SCALING OF CONSUMER
PREFERENCES FOR PROPOSED PRODUCT DESIGNS¹

Murphy A. Sewall, State University of New York at Albany

Abstract

Multidimensional scaling is an increasingly popular device for analyzing consumer preferences. However, in some instances a one dimensional scale may provide an adequate basis for decision-making. This paper describes a procedure for unidimensional scaling of rating data and presents empirical confirmation of validity based upon an independent data set.

Introduction

Recent years have seen the development and application of increasingly sophisticated multidimensional scaling techniques for examining consumer perceptions and preferences (Green and Rao, 1972). The need to examine two or more components, or dimensions, may be necessary to understanding the mental process underlying relative perceptions and preferences in some cases. However, two arguments can be made favoring consideration of the alternative of unidimensional scaling.

From the point of view of the decision-maker, the relevant question is usually: "Which alternative(s) among a set of proposals is most preferred by potential customers?" Such a question is clearly a request for a ranking at minimum, and a ranking that indicates the relative differences between closely ranked proposals if possible. If a scale of only one dimension can fairly represent consumer preferences, such a scale is clearly consistent with the needs of the user (and sponsor) of the research.

Also, a simple explanation is preferable to a complicated one that offers little additional information. Multidimensional solutions are often difficult to interpret, difficult to explain, and hard to understand. Their implications for decision-making may be so difficult to determine that their practical value may be much less than their elegance. While much of the "real world" may be inherently too complex for anything less than a multidimensional solution, it could be a serious mistake to assume, without examination, that more than one dimension is needed to describe or explain a phenomenon.

This paper represents results of a survey of consumer reactions to 36 proposed bed linen designs. The analysis indicates that a nonmetric unidimensional scaling procedure does provide an adequate representation of relative group preference for this particular problem. The scale predicts the relative preferences of an independent ("holdout") sample of consumers with a high degree of accuracy.

The Problem

The 36 proposed designs evaluated in this study were supplied by a major seller of bed coverings (and a variety of other consumer products). The competition for the 650-700 million dollar market for bed linens has

grown increasingly intense. Over thirty name fashion designers are currently producing patterns for competing marketers of these products. In spite of the proliferation of designs, generic demand for some items in the line is actually declining, for example, approximately three quarters of sheets are sold at sale prices (Reif, 1977).

Selecting which patterns to introduce from among those proposed by designers has been an important problem for product managers ever since the advent of "designer" bed linen a decade ago. The increasing intensity in today's market places an even greater premium on preference information obtained from pre-tests of proposed designs on consumers.

The number of new patterns proposed for each selling season is typically twenty or more. Management would like to evaluate as many choices as possible since the number of potentially strong entries identified is believed to increase with the number of ideas examined. A researcher would prefer to keep the number of alternatives small in order to keep the survey task manageable. Requesting too many responses from individual consumers is likely to increase the frequencies of refusals to participate, refusals to provide complete responses, and rote responses which do not reflect the true preferences of the subjects.

Survey Design

Most preference scaling techniques are based on expressions of subjects' preferences for one of each possible pairing of all alternatives. Unfortunately, the number of pairs to be evaluated expands geometrically as the number of alternatives increase.

It is unreasonable to expect consumers to respond to the large number of paired comparisons that would be required to evaluate the number of bed linen designs that management wishes to consider. Hence, it is necessary to utilize a data collection technique which requires far fewer responses from each subject. A rating scale approach was selected because only one response per pattern is required, and rating also presents respondents with a readily comprehensible evaluation task.

The thirty-six patterns were photographed on a bed, without head board or foot board, against a plain white background and arranged on five display boards, each of which represented a designer "collection." Subjects were first asked to examine each collection as a whole. After they studied all five collections and were given an opportunity to consider their preferences over the entire set of patterns, respondents were asked to rate each pattern on a five point scale:

If this pattern were offered for sale -

1. I would definitely buy.
2. I probably would buy.
3. I might or might not buy.
4. I probably would not buy.

¹This project was supported by a Fortune 500 firm as part of a SUNY Albany MBA field project. The sponsor wishes to remain anonymous for proprietary reasons.

5. I definitely would not buy.

The survey also included a list of demographic questions (age, income of household, and so forth), questions about the number of bedrooms in the subject's home and the style(s) of furniture in each, and other questions about whether various attributes of the linen or the marketing firm were important to their purchase decisions.

Data were obtained by shopper intercept interviews at shopping centers in eight metropolitan areas (two in the Northeast, one in the Southeast, three in the Midwest, and two on the West Coast). A total of 399 interviews were completed (approximately 50 in each city).

Data Analysis Procedure

The use of rating scales in marketing research is quite common, and has been for some time. However, quantitative analysis of this type of data often involves statistical calculations which are used to draw inferences which are conceptually inappropriate (Adams, Fargot, and Robinson, 1965). The usual errors are the implicit assumptions that:

1. Adjacent response categories are equidistant (that is the data are interval scaled).
2. These intervals are constant across subjects.

Rating Scale Analysis

The most common approach to analyzing five-point intention to purchase ratings consists of ranking the stimuli in order of the fraction assigning one of the first two (would buy) ratings (Taylor, Houlahan and Gabriel, 1975). This procedure is subject to several criticisms. The calculations discard information by reducing the five-point ratings to a two-point scale. There is an implicit assumption that all subjects mean the same thing by "probably would buy." And, the analysis does not provide a statistical basis for determining how much more desirable a highly rated pattern is over one with a lower rank.

One paper that explicitly recognized the problem of assuming too much about rating data (Harris, 1964) is subject to similar criticism for using an arbitrary rule for determining which values should be counted (the top three categories in a 21 point scale which actually produced a forced ranking of the alternatives). The analysis in the study also assumes homogeneity across subjects in their interpretation of the range covered by the scale. Attempts to validate the scaling against a "sales index" for two types of patterns produced widely divergent results. While the explanation that is given for the disparity appears plausible, it is qualitative. The possibility that the one high correlation between the scale and the sales index was due to chance cannot be eliminated.

A procedure has existed for over 25 years for scaling rating data without assuming equal distances between categories (Edwards, 1952). The method of successive intervals does assume that subjects make the same evaluation of each response category (subject to some error in making individual judgments about the assignments of stimuli to categories). That is, scaling by this method assumes, for example, that all responses of "I probably would buy" represent the same probability of purchase for all subjects.

The method proposed in this paper is less restrictive in its assumptions about the original data than the method of successive intervals. It is also easy to use the scale reported below to verify goodness-of-fit to the original data or to predict responses of subjects from a

different sample, although it is possible to perform these calculations with the method of successive intervals.

Plans were made to scale the data for this study by the method of successive intervals for comparative purposes. Unfortunately, a limitation of the successive intervals approach aborted these plans. The frequency distributions for four of the thirty-six designs were found to be badly skewed. More than half of the subjects stated that they definitely would not buy these four designs. The method of successive intervals fails if the median occurs in an end point of the rating scale for any stimulus.

The skew in some of the frequency distributions for the pattern ratings is hardly surprising. The patterns are, after all, new product ideas, and the high consumer rejections rate for new product ideas is well known. The fact that skewed rating data is to be expected in this type of consumer research is an obvious indication that metric data analyses techniques are inappropriate.

Derived Paired Comparisons

The approach taken in this study is, in concept, one of restructuring the data into a form that has previously been solved. Specifically, each subject's ratings were converted into a set of pairwise preferences. The notion of a "derived paired comparison matrix" has been considered before. Neidell (1972) recommends derived measures for large stimulus sets. Green and Rao (1972, p 25) propose derived paired comparisons from multi-attribute rating profiles. Five-point intention to purchase ratings may be viewed as sorting n stimuli into k classes (Rao, 1971).

As proposed here, derived paired comparisons for each subject are obtained by comparing the two ratings for each possible pair and assuming the subject prefers the design toward which he has expressed the more favorable purchase intention (Reynolds, 1966). Tied ratings are treated as missing data. That is, subsequent calculations of the fraction of respondents expressing a preference for one pattern over another are based only on that portion of the sample that gave a clearly more favorable rating to one pattern. The alternative approach would be to treat ties as a value of one-half for each pattern in a pair (Benson, 1962). Computations were made for both assumptions about ties. Results were equivalent to two decimal places. The missing data approach is favored by the sponsoring management since subjects who expressed a greater degree of distinction between the patterns produce fewer tied comparisons and are, therefore, given greater weight in the resulting group scale. It is assumed that subjects who gave many patterns the same rating are relatively indifferent to which designs are marketed. There is a more sophisticated, but computationally complex, method for treating tied (no preference) data (Draper, Hunter and Tierney, 1969). Application of this procedure was not deemed appropriate, from a cost-benefit point of view, for this stage of the analysis.

Only two assumptions need to be made about the data in order to justify this formulation of derived paired comparison matrices theoretically:

1. Each subject applied a consistent underlying scale to his evaluations of all patterns presented.
2. This underlying scale is at least ordinal.

The first assumption implies that the subject is consistent with himself (but not necessarily with other subjects). The second assumes that his ratings are consistent with the stated rating categories. Since

the subjects studied all the patterns and responded to opinion questions about groupings of them (the five "collections") before rating the patterns individually, the likelihood that they formulated personal scales which remained nearly fixed over the 36 ratings requested is plausible.

Unidimensional Scaling

The derived paired comparison preference matrices are summarized (fraction of subjects preferring the column stimulus to the row stimulus for all columns and rows) and subjected to Thurstone scaling (Case V). The theory and method of this procedure was originally published fifty years ago (Thurstone, 1927) and has subsequently been treated in a wide variety of papers and texts (Mosteller, 1951a and 1951b, among many others). Thus, Thurstone V scaling is taken as "previously solved" insofar as mechanics and conceptual justification are concerned.

The scaling of stated intention to purchase data by this procedure may be viewed as an unusual application by some. A consumer's evaluation of his purchase intention is likely to involve a considerable number of considerations. Hence, one might think that purchase intention is far too complex a concept for Thurstone's procedure. However, at the outset, Thurstone noted that:

"It is not necessary to limit psychological analysis to stimuli which have intensity or magnitude as their principal attributes. For example, a series of handwriting specimens may be arranged in a continuum on the basis of general excellence (Thurstone, 1927, p. 369)."

A judgment about which of two handwriting specimens is "more excellent" does not seem to be altogether different from an evaluation of which of two bed linen designs is more desirable.

Fortunately, a statistical text exists (Mosteller, 1951b) for the adequacy of applying Thurstone V assumptions to a particular set of data. Numerically, the statistic involves a chi-square calculation based on arc sine transforms of the square roots of the predicted and observed percentages of subjects preferring one of each possible pair of stimuli. Thus, an empirical basis for arguing that an application of Thurstone V scaling does not violate the procedure's assumptions is available. This statistical test, and some others, may also be applied to predictions of the fraction of respondents preferring one pattern over another from a sample of subjects other than those used to develop the scale.

Results

Ratings for the 399 respondents to the survey were randomly sorted into two groups. These groups are labeled 'A' (195 subjects) and 'B' (204 subjects) in the discussion and tables below.

Goodness-of-Fit

Derived paired comparison matrices, and subsequently Thurstone scales, were formulated for each group. The scales were then used to predict the fraction of respondents preferring one of each of the 630 possible pairings of patterns (in matrix form, the fraction preferring the column designs over the row designs for the upper half matrix with missing diagonal).

Tables 1 to 3 each contain four statistical results. Since the data are randomly divided into two subsamples, it is possible to use each as a "holdout sample" to test the predictive power of a scale derived from the other.

The same statistics also may be calculated in the usual manner - using the subsample which produced a scale as the observed data (a less rigorous goodness-of-fit test than one based on an independent sample).

Table 1 contains statistics for Mosteller's (1951b) goodness-of-fit. The very low chi-square values indicate a close correspondence between scale predictions and observed proportions.

TABLE 1
Mosteller's Goodness-of-Fit Test

Scale From Sample	Observations From Sample	χ^2 d.f. 595	Tail Probability
A (n = 195)	A	.204	.983
A	B	.664	.972
B (n = 204)	B	.202	.983
B	A	.671	.972

Table 2 represents an alternative (and perhaps more familiar) perspective of the goodness-of-fit. This table contains correlation statistics between predicted and observed fractions of subjects preferring one of each pair of designs (630 predictions). The values are surprisingly high. The null hypothesis that the true correlations are zero is rejected at any reasonable significance level. It does not appear that multidimensional scaling would be likely to provide additional insight into the samples' aggregate preferences for bed linen designs.

TABLE 2
Product Moment Correlations

Scale From Sample	Observations From Sample	Correlation
A (n = 195)	A	.978
A	B	.920
B (n = 204)	B	.975
B	A	.921

Desirable Patterns

Table 3 contains statistics for means, standard deviations, and mean absolute deviations of the 630 prediction errors. The ninety-five percent confidence interval (based upon across sample error deviations) is approximately twelve percent. That is, if pattern 'A' is predicted to be preferred over 'B' by 62 percent or greater, then the likelihood that 'B' is actually preferred to 'A' is five percent or less.

TABLE 3
Prediction Errors

Scale From Sample	Observations From Sample	Mean Error	Mean Absolute Deviation	Standard Deviation
A (n = 195)	A	-.002	.025	.034
A	B	.006	.049	.061
B (n = 204)	B	-.003	.024	.033
B	A	-.010	.050	.063

Since management seeks above average designs, a decision-rule to classify a pattern as desirable if it has a predicted preference of 62 percent or greater compared to an "average pattern" (the mean preference scale value for all 36 patterns) was recommended. Seven of the 36 patterns in this study were identified as satisfying this decision-rule.

Conclusion

After the fact, it does not seem surprising that a scale of one dimension provides an excellent fit to the preferences derived from consumer intention to purchase ratings. A recent article discussing applications of conjoint analysis (Hupfer, 1977) points out that attempts to break down preferences for product choices into component attributes and benefits are probably inappropriate when relatively little conscious thought is given to the purchase. It seems plausible that consumers' analyses of cost-benefit trade-offs occur in choosing whether or not to buy new bed linen, and if so, in what fabric (muslin or percale) and style (flat or fitted) and for what purpose (beds, walls, windows, or furniture) (Reif, 1977). The choice of pattern from among the many competing within chosen fabric and price groups may indeed be made with little conscious analysis.

It is likely that nonmetric unidimensional scaling will prove appropriate for similar applications in other product areas. Certainly, in instances where brand competition is characterized by proliferation of "fashion designs," results similar to those obtained in this study may be expected.

Unidimensional scaling also appears to have merit as a preliminary to multidimensional scaling. When direct paired comparison data is obtained, Thurstone V scaling is straight-forward. It seems surprising that applications of Thurstone scaling rarely appear in recent marketing literature.

It also seems puzzling that scaling by the method of successive intervals (Edwards, 1952) has received virtually no attention from marketers. The method is computationally simple (particularly when programmed for a computer). One would expect that this method would be appropriate for the data collected in many studies (Reynolds, 19-6, for example). The nonmetric unidimensional scaling procedure described here may prove to be more general, and equivalent to successive intervals when both methods are appropriate, but this assertion remains to be verified.

UNDERSTANDING UNIVERSITY CHOICE:
A MULTI-ATTRIBUTE APPROACH

Ronald Vaughn, Bradley University
Joseph Pitlik, Bradley University
Behram Hansotia, Bradley University¹

Abstract

This article presents a detailed analysis of the components of a university's image. University choice criteria are studied as to their relative determinance (using a new modified determinant attribute approach). The underlying cognitive structure of university choice is also investigated via factor analysis.

Introduction

The need for the application of marketing theory to college admissions work has become apparent in recent years as the market has changed from the sellers market of the 60's to a buyers market for the 70's. Available information at present seems to indicate that the market for prospective college students will remain a buyers market into the 1990's and perhaps beyond.

Several factors external to the university system have contributed to this shift. The pool of applicants available from high school classes has peaked with the graduation class of 1970 and is expected to decline steadily through 1983. Furthermore, the abolishment of the draft and the ratio of college graduates to job openings in most academic majors appear to be vital forces in the prospective students initial decision as to whether to attend college. In the present competitive environment the four year institution now faces several factors that were almost nonexistent in the 1950's. The early 60's were characterized by the rapid development of community colleges, and closely followed by the development of technical programs offered at two year institutions. These two factors taken together have further reduced the pool of applicants or market potential available. The private university has yet another environmental threat. The large state university, long dormant in aggressively recruiting students, has awakened in recent years and appears to becoming active in its search for students to meet enrollment objectives.

The implication is clear. To successfully compete in the educational marketplace of the present and future, universities, especially private universities, must begin refining their marketing strategies. These refinements will often be in the form of tactical shifts in the promotion and product areas, and a sound base of research is almost a prerequisite to guide these strategies and tactical changes.

Some Problems

Image research has had wide use in marketing generally, e.g., company and brand studies, and in numerous store

imagery studies. In fact, since 1960, more than forty image-related articles have appeared in the marketing literature, more than half of these in the last five years. Further, several environmental trends seem to dictate that this type of research will intensify in the future due to the increasing sophistication of the shopper (including the educational shopper), increased shopper mobility, product proliferation, and other competitive pressures. Just as retailers are facing an intensification of inter-type competition which is causing retailers to combat retail sectors whose merchandise had never before competed with theirs, so to higher education's already declining market is being impinged upon by proprietary and industrial schools. Not only does IBM, General Electric and other corporations now offer bachelor's degrees, but there is increased competitive pressures from community colleges and other more traditional colleges. An article by Kotler and Levy (1969) point out that marketing is a pervasive societal activity and that student recruitment by colleges is even a marketing activity.

Despite the apparent need for imagery research on non-profit educational institutions and despite the wealth of imagery research on the profit-oriented business sector there has been a paucity of research dealing with the marketing problems of a university and hardly any research specifically investigating the image of a university. Although Kotler and Levy (1969) noted much earlier than nonprofit organizations have been typically ignored by the student of marketing, most of the university-oriented marketing literature to-date has been quite general and largely conceptual (e.g., Kotler 1976, O'Brian 1973, Berry and George 1975, etc.), except for a very limited study by MacLachian and Leister (1975) which used multidimensional scaling to develop perceptual maps of the institutional image and a more extensive study of a graduate school's image by Naidu (1969).

This paper attempts to provide insight on the image of a university. Specifically, evidence will be contributed on some of these issues. Can a university's image be measured along salient image dimensions? If so, which attributes are most important? Do determinant attributes exist? How is the information about a center structurally organized, i.e., rather than just describing a university as very good or bad, how is information about a university coded and grouped into cognitive categories? Studying these relatively new issues to educational choice behavior should provide insight as to how educational institutions are evaluated with respect to each other. Finally, understanding imagery development and the choice process in a university setting should serve as a prerequisite for developing better diagnostic and predictive models. While this paper has not been intended as a dissertation on the usage and development of multi-attribute models, a number of reviews have been done which would be quite helpful in later attempts to model the educational choice process, e.g., Cohen (1972), Hansen (1976), and Pessemier and Wilkie (1972). The conceptual article by Kotler (1976) would also be quite helpful in developing more explicit models of educational choice. Towards this objective, a variety of issues and directions for future research are provided in the final section of this paper.

¹Ronald Vaughn, Joseph Pitlik and Behram Hansotia are, respectively: Associate Professor in the Department of Marketing; Instructor in the Department of Marketing; and Associate Professor in the Department of Business Management and Administration. All three professors are at Bradley University.

Methodology

To determine an initial set of criteria that represents the salient components of university preference a preliminary study was conducted. Freshman College of Business Administration students at Bradley University were asked to give the five most important criteria they used in evaluating a university. This questioning process produced an extensive list of criteria that was further modified through discussions with the admissions director and associated admissions personnel plus a review of the literature. A final set of 16 criteria, shown in Table 1 was utilized for further study. While not

ed sample, the results presented are somewhat tentative and additional research is needed.

Results

One of the most complex processes the student and his parents go through is in making the final choice among colleges that have accepted him or her. In this final choice process the student is believed to rate each college's characteristics on the criteria they hold to be most important. Thus, basic to developing proper college marketing procedure is an understanding of the uni-

TABLE 1

*These three variables tied for the second rank.

**These two variables tied for the ninth rank.

exhaustive, these criteria are thought to represent those criteria most commonly used by prospective students and their parents. A questionnaire was then designed to determine the relative importance of these criteria, to both parents and students. Respondents were asked to rate in importance each criteria on a seven point scale where a "7" was extremely important. Respondents were also asked to identify and then evaluate each of their top three choices along the same criteria on a scale from 1-7 where a "1" was a poor evaluation and a "7" was a good evaluation.

In January of 1975 402 questionnaires were mailed to all students and parents of students who were admitted to the College of Business Administration for the Fall of 1974. The 30% response rate is primarily attributed to the rather low (16%) response rate in the category of "Parents of Students Admitted, but not Enrolled." However, the factors of a lengthy questionnaire and no monetary incentive provided for the respondent also probably influenced the low response rate. Due to the limit-

versity choice process, which, in turn, must be grounded in a thorough analysis of what attributes of a college are evaluated. We will attempt to provide insight to the university evaluation process by several analysis stages. The first stage of analysis will determine the relative importance of sixteen university choice criteria. Second, the evaluation of several alternative universities on each attribute will be compared. Third, selection criteria will be evaluated for relative determinancy, and fourth, the underlying cognitive structure of university choice will be explored using factor analysis.

Relative Importance of University Selection Criteria

Sixteen choice variables were selected for importance analysis. Table 1 shows that the variable means ranged from a low of 4.060 for the influence of friends who are attending the school, to a high of 6.449 for the quality of education received. Furthermore, the typical respondent put a premium on the quality of faculty, repu-

tation of the business programs, academic reputation of the university, amount of individual assistance that could be provided by the faculty, number and variety of courses offered, the number of students per class and so on. These findings appear somewhat consistent with those of Holland (1958 and 1959) in his studies of what aspects of a college made it "best." Using a sample of parents of National Merit Scholars they found the key aspects to be quality of faculty, scholastic standards, curriculum, reputation and facilities. However, in the actual choice of college "practical" and "financial" factors were of substantial influence with academic factors playing a moderate, secondary role. Knowledge as to which attributes are most important undoubtedly suggests that certain educational attributes must be particularly considered for attribute development, maintenance and promotional activities.

Institutional Evaluation

The marketing task of a college is to articulate a mission and purpose for the college that makes sense in view of its history, resources, opportunities, competition and other situational variables (Kotler, 1976). Further, a coordinated marketing effort must assist in developing a distinct posture for the university, i.e., an institutional position that will meet the educational needs and desires of its particular market segment as a means to satisfying institutional goals. With this in mind, one of the first steps in developing an institutional position is to measure and evaluate the university's current perceived position in the market in relation to competitors. While knowledge of which attributes are most important provides some direction for faculty and administrative efforts at developing and maintaining its position, periodic assessment of the university's current perceived position provides additional insight to institutional strengths and weaknesses and suggests areas of the educational product where improvement or change might be necessary. As Gould (1971) points out, constructive change by a college must be preceded by proper introspection: "higher education must be more truthful in its own evaluation of its current weaknesses in order to portray itself effectively to its many constituencies."

Stage two of the analysis was to evaluate Bradley University's image on each of sixteen criteria and compare it to the perceived image of several competing colleges (grouped into an other private and a state school classification). While it was expected due to the nature of the sample (people who had applied and been admitted to Bradley University), Bradley had a more positive evaluation than its competitors on most of the attributes. It should be noted that other publics of the university if sampled might have provided different average evaluations. Table 1 shows some attributes on which Bradley seems to be viewed as quite distinct while on others there seems to be an insignificant perceived difference. Bradley seems to be viewed as relatively different from its competitors (in a positive sense) on size of the student population, class size, college displayed a personal interest, the amount of individual assistance provided by the faculty, campus size, housing facilities and reputation of the business program. Bradley was viewed as quite different from its competitors in a negative sense on only the basic cost of attending. Only a slight variation among the evaluation seemed to exist on the influence of friends attending, academic reputation of the university, quality of the faculty, quality of the education received and availability of financial aid.

While this study of perceived evaluations by attributes is helpful in pinpointing relative strengths and weaknesses, additional information is needed. Although a university is perceived as quite different in a positive

sense from its competitors (on a given attribute), a relative strength does not necessarily exist unless that attribute happens to be of considerable importance to the educational consumer. Likewise, the fact that a university is viewed more poorly is not necessarily cause for alarm unless the criterion happens to be of crucial importance. Thus, this analysis suggests that a university should first, discover the relative importance of the various university selection criteria; second, investigate the image of themselves and their competitors on these same criteria; and, third, analyze the importance and evaluation scores in combination. The analysis of determinant attributes presented in the next section illustrates a way of analyzing attribute importance and evaluation together.

Determinant Attributes

The third stage of the analysis was to assess the principal university decision variables and their relative determinance in university selection decisions. Determinant attribute analysis should help to understand those features which move the educational consumer to action, i.e., to make him prefer a particular university, actually attend there and/or recommend it to friends. Because of their crucial relationship to preference, a university's perceived position with respect to these determinant attributes must be closely investigated to check for strengths, weaknesses, opportunities, etc.

Attribute determinance was estimated by evaluating (1) the importance associated with a particular university selection criterion and (2) the degree to which competing universities were perceived to differ in terms of that selection criterion (Myers and Alpert, 1978). While these two aspects of a determinant criterion are part of the original definition of "determinance," the operationalization of this concept represents a new approach. Using Hansen's (1977) "modified determinant attribute analysis" each individual's response on a given attribute was cross-tabulated based on their response to each of the two questions (i.e., importance and perceived variation). Table 2 presents a sample of such a cross-classification for a product attribute, where the table cell values are reported as percentages. Hansen (1977) presents a critical evaluation of this new operationalization compared to the more traditional operationalization of attribute determinance. Using the Myers and Alpert definition of determinance, the attribute having the highest proportion of respondents classified in cell 9 of Table 2 where both importance and variation are high, would be the currently most determinant analysis was based on the present or current perceptions of the product. Cell 7 of Table 2 is also of interest as it presents the proportion of the respondents who indicated the attribute was high in importance, but low in perceived inter-university variation. This cell 7 is referred to as "potential" determinance because if one of the competing universities could produce an educational product that is perceived or evaluated much higher than its competitors, then that university would have a distinct advantage. This is because the current high importance-low variation attributes may offer the greatest potential for improvement since an increase in a university's evaluation on that dimension would lead to a distinct perceived difference on a "potentially" crucial or determinant choice criteria. The other cell values in Table 2, e.g., 6, 5, etc. have similar implications in that strategies may be suggested to increase the university's evaluation, or to increase the perceived importance of an attribute, or both. The remainder of the analysis, however, concentrates on cell 7 and cell 9.

The results of the determinant attribute analysis are shown in Table 3. Several attributes stand out as

TABLE 2
SAMPLE CROSS-CLASSIFICATION
(Cell numbers are only for identification)

		Perceived Variation of Attribute		
		Low (0-1.000) ^d	Medium (1.001-2.000) ^e	High (2.001-or greater) ^f
Importance of Attribute	Low (1-4) ^a	1	2	3
	Medium (5) ^b	4	5	6
	High (6-7) ^c	7	8	9

^a"Low" importance represents a 1-4 scale value (extremely unimportant, somewhat unimportant and neither important or unimportant).

^b"Medium" importance represents a 5 scale value (somewhat important).

^c"High" importance represents a 6 or 7 scale value (very important or extremely important)

^d"Low" variation represents a standard deviation across alternative universities of one or less scale value standard deviations.

^e"Medium" variation represents a standard deviation across alternative universities of 1.001 to 2.000 scale value standard deviations.

^f"High" variation represents a standard deviation across alternative universities of greater than two scale value standard deviations.

currently relatively determinant: college displayed a personal interest (22.81%); size in terms of the college's student population (20.86%); campus size (19.83%); and, amount of individual assistance that could be provided by the faculty (19.30%). The potentially determinant university choice criteria include: academic reputation of the university (63.94%); quality of the faculty (63.82%); reputation of the business programs (55.46%); and, the number and variety of courses offered (46.22%). It must be noted, however, that the variables that came out as currently or potentially determinant in this sample are quite possibly not determinant or crucial to the selection process of other universities. Remember that the sample being studied in this case was students who had applied to and were admitted to the College of Business Administration at Bradley University (and the majority of these students actually enrolled). Thus, the nature of the sample suggests that the currently determinant criteria are more likely to be those variables that were crucial to the decision to attend Bradley. The fact that Bradley is evaluated much higher than its competitors in Table 1 lends additional credibility to this interpretation. On the other hand, the potential determinant criteria suggest attributes that could contribute more to Bradley being chosen if the perceived evaluation of Bradley could be improved to the point where it was viewed as quite different from its competitors. Table 1 also lends credibility to this interpretation as the evaluations of Bradley University on the potentially determinant criteria show relatively little difference from the evaluations of its competitors.

TABLE 3
RESULTS OF CROSS-TABULATION
CALCULATION OF ATTRIBUTE DETERMINANCE

Attribute	Proportion in High Importance High Variation Cell	Proportion in High Importance Low Variation Cell
Personal Interest	22.81%	26.27%
Size of College's Student Population	20.86%	21.01%
Campus Size	19.83%	15.25%
Amount of Individual Assistance by Faculty	19.30%	36.97%
Location	16.10%	24.37%
Number of Students per Class	15.65%	32.20%
Reputation of Business Programs Job Placement Service	13.91%	22.03%
Housing Facilities	11.01%	23.53%
Quality of Education Received	10.62%	23.73%
Academic Reputation of University	8.85%	63.94%
Quality of Faculty	8.77%	63.82%
Basic Cost of Attending	8.54%	33.05%
Number and Variety of Courses	6.96%	46.22%
Availability of Financial Aid	6.78%	26.27%
Influence of Friends Attending	4.27%	9.40%
Cognitive Structure of the University		

In stage four of the analysis a factoring procedure was used to determine the underlying constructs or dimensions which the respondents considered when selecting a university. The same 16 selection criteria listed in Table 1 were the subject of the factor analysis. PA2, the iterative procedure for determining communalities, was used from the SPSS package. In 23 iterations, five factors with eigenvalues greater than one were extracted. The fifth factor explained only 6.4% of the total variance and since after the varimax rotation the fifth factor had no significantly high factor loadings on it, we decided to drop the fifth factor. An "L" test as described in Van de Geer (1971) also confirmed our dropping the fifth factor, which had an eigenvalue of only 1.016.

The first four factors explained 56.3% of the total variance. Reported below is the matrix of factor loadings after the varimax rotation. The asterisks (*) adjacent to the higher factor loadings are placed to help identify the important attributes of each salient university selection dimension. Factor 1, for example, is loaded heavily on variables 2, 5, 3, 4, and 1, which are: quality of faculty, amount of individual assistance provided by faculty, reputation of the College of Business Program, academic reputation of the

TABLE 4
MATRIX OF FACTOR LOADINGS

Attributes	Factor 1	Factor 2	Factor 3	Factor 4
X ₁	0.652*	0.176	0.029	0.040
X ₂	0.654*	0.137	0.069	-0.158
X ₃	0.677*	-0.012	0.174	0.163
X ₄	0.604*	0.048	0.138	0.226
X ₅	0.562*	0.168	0.179	-0.146
X ₆	0.490	0.015	0.220	0.325
X ₇	0.235	0.547*	0.101	-0.168
X ₈	0.025	0.695*	1.019	0.190
X ₁₀	0.016	0.255	0.878*	-0.039
X ₁₁	1.107	0.164	-0.016	0.622*
X ₁₂	0.252	-0.133	0.337	0.010
X ₁₃	-0.071	0.847*	0.010	0.220
X ₁₄	0.108	0.442	0.092	0.004
X ₁₅	0.166	0.026	0.587*	0.098
X ₁₆	0.145	0.270	0.266	-0.016

university, and quality of education received. Apparently the first dimension is "university and College of Business Program quality." Interestingly, the respondents do not seem to look at only the quality of the Business program but also at the quality of the entire university. Furthermore, they seem to relate the amount of individual assistance to quality.

The second factor is loaded heaviest on variables 8, 13, and 7; which are size in terms of the college's student population, campus size, and size in terms of the number of students per class. Obviously, this is a "size" dimension.

The third factor is loaded on variables 10 and 15, which are basic cost of attending and availability of financial aid. This seems quite clearly to be a "total university cost" dimension. Thus, the respondents do not seem to look at just the cost of attending a university, but at the total cost obtained by offsetting tuition and housing costs by availability of financial aid.

The fourth and last factor has a high loading on only the eleventh variable, namely location. Hence, it can be labeled a "location" dimension. Note that of the 16 variables originally selected for the analysis (see Table 4), 5 did not have appreciably high loadings on any of the four factors. They are variables 6, 9, 12, 14, and 16. Of these, variables 12 and 16, namely job placement service after graduation and influence of friends who are attending, are least correlated to any of the four factors discussed above. Variables 6, 14 and 9 on the other hand do have modest correlations with factors 1, 2 and 3 respectively. Implying that variable 6 which is number and variety of courses offered is moderately correlated with the "quality" dimension. Variable 14, which is housing facilities, is moderately correlated with the "size" dimension and variable 9, college displayed a personal interest, is correlated with the "total cost" dimension.

Table 5 summarizes our findings in this section.

Research Implications

To continue to improve our understanding of the university choice process, research is needed on many issues, including the following:

1. How do university choice criteria differ between the parent (an important decision influencer) and the student? Are there differences in attribute saliency or determinancy between the student and the parent? Further, are there such differences for students who apply and do not enroll versus those who do enroll, i.e., users versus nonusers.

TABLE 5
SUMMARY OF FACTOR ANALYSIS

Four factors accounted for 56.3% of the total variance:

1. "University and Business Program Quality" Index, described by:
 - a. quality of faculty
 - b. amount of individual assistance
 - c. reputation of the Business program
 - d. academic reputation of the university
 - e. quality of education received
2. "Size" Index, described by:
 - a. size in terms of student population
 - b. campus size
 - c. size in terms of the number of students per class
3. "Total University Cost" Index, described by:
 - a. basic cost of attending
 - b. availability of financial aid
4. "Location" Index, described by location

Also, are there differences in saliency or determinancy for students of differing quality, i.e., for students with very promising academic potential versus average academic potential (Naidu suggested in 1969 that due to a greater number of alternatives, financial aid is more important to attracting students of high quality)?

2. What image does the university have among its other important publics, e.g., alumni, donors, high school and junior college counselors, and the community at large? As Shapiro (1972) suggests an institution such as a college is concerned with two primary sets of transactions or exchanges, one is with donors and the other is with clients and for a college highly dependent on external funding sources the donor group may be at least as important as the client group (students) to study and understand.
3. Do university selection criteria change (i.e., are there new criteria) after the prospective student enrolls and attends the college for some time? Perhaps more subtly do criteria saliences or evaluations change through time? A study by Naidu (1969) suggests that the "attractiveness" of graduate education varies from level to level, e.g., he notes that financial aid and faculty reputation are considered to be more important by the student at graduate levels, but at the undergraduate levels location of the campus and general reputation of the university seemed more important in evaluating the educational product. It may be particularly important to understand the differential needs of seniors so that they will graduate as satisfied customers. Also, a more thorough analysis of the needs or disconfirmed expectancies of sophomores and juniors may help reduce the problem of retaining students for four years.
4. Are the perceptions of university faculty, administrators and managers consistent with the perceptions of their publics? As the images held by collegiate personnel help to determine the university's projected image to other publics, this aspect of image may also be of real concern.
5. What are the key information sources which students and other publics use, and which are the basis for attitude formulation?

6. Can the educational market be meaningfully segmented? Just as in other businesses, a school needs to profile its perhaps rather small potential market as a guide to effective and efficient allocation of resources.
7. Once a university has assessed its current perceived position, what strategies and tactics should it consider? Kotler (1976) suggests that such strategies and tactics go beyond just the work performed by the admissions office, but should include such activities as institutional positioning, portfolio planning, applicant development work, applicant evaluation and notification work, recruitment effort evaluation, college improvement planning, and alumni loyalty work. Little empirical work has been done to determine the effectiveness of different strategies or ways of implementing them. Likewise, the differential sensitivity of different market segments to certain marketing strategies or tactics has had little focus by marketing people.

In summary, while there has been a considerable amount of research focused on nonprofit organizations by marketing people in the past 10 years (as illustrated by Rothschild's (1976) 43-page bibliography of works relating to marketing for public sector and nonprofit organizations), there has been a lack of focus on the educational sector, which is one of the largest and most important service industries in the U.S. It is hoped that the reported research study and suggestions, along with consideration of the benefits that may accrue directly to academicians, will prompt a more active interest in this area by marketing researchers.

AN EXPLORATORY STUDY OF THE INFLUENCES OF USAGE
SITUATION ON PERCEPTIONS OF PRODUCT-MARKETS

Rajendra K. Srivastava (student), University of Pittsburgh
Allan D. Shocker, University of Pittsburgh
George S. Day, University of Toronto

Abstract

Recent research has illustrated the importance of environmental influences in determining consumer behavior. A typology of relevant "objective" usage-situations is developed, and subsequently, the composition of competitive product markets determined based on the similarity of the usage patterns. Results appear to show the feasibility of creating meaningful product specific situational taxonomies.

Introduction

Consumer research in marketing, heavily influenced by a psychological tradition, has typically followed a paradigm where consumer choice in the market has been examined largely as a function of personal characteristics and preferences. In recent years, both the psychological tradition (e.g., Fredriksen (1972), Wicker (1972), Bowers (1973), and Endler and Magnusson (1976)) and consumer behavior research, (Belk (1975), Lutz and Kakkar (1975), Bearden and Woodside (1976), and Hansen (1976)) have examined the evidence for situational effects moderating consumer behavior and have proposed conceptual models of these effects. This work has generally supported the hypothesis of important situational effects but raised problems of measurement and classification.

Theoretical development in the area of situational influence on consumer behavior is still in an early stage. Although there appears little doubt that environmental factors affect behavior (see reviews by Lutz and Kakkar (1975), Belk (1975), and Endler and Magnusson (1976)), there exist differing viewpoints as to the line of inquiry which would best illustrate the interaction between individual characteristics and situations. Perhaps one of the more limiting drawbacks at the current stage of development is the lack of consensus on a classification schema or typology for situations within which consumer behavior may be systematically studied (Wicker (1972), Fredriksen (1972), Belk (1975), Russell and Mehrabian (1976)). Without such a comprehensive typology, systematic analysis of the influence of situations on choice behavior cannot be achieved. The two primary approaches to the development of such typologies have not been totally satisfactory. The first has sought to analyze objective situations (those meaningful to respondents) to find situational factors which appear to affect behavior (e.g., Belk (1975) proposed five groups of objective characteristics-- physical surroundings, social surroundings, temporal perspective, task definition, and antecedent states). The second has sought to classify situations by the nature of the psychological processes to which they give rise (e.g., Lutz and Kakkar (1975) attempted to classify situations in terms of Mehrabian and Russell's dimensions of pleasure, arousal, and dominance). Allen (1965), Barker (1975) and Wicker (1975), among others, have discussed variants of these approaches.

Typologies which retain an objective character have the advantage of greater meaningfulness (i.e., they provide some usable explanations for situational effects on behavior). Its major disadvantage is that the potentially large number of dimensions may lead to a correspondingly large number of distinct situational types.

The psychological situation in turn offers parsimony at the possible expense of relevance. However, for most managerial marketing purposes, one might expect that the psychological situation would prove less usable (Lutz, personal communication).

The focus of this paper is on the usage or application situation; that is, the objective circumstances for which the product or service is purchased. Specifically, the objective is to develop a situational typology that can account for a comprehensive array of usage situations. In other words, we are seeking a method for extracting the minimum number of underlying dimensions which account for the variability in the effects of a large number of usage situations. Not only is such a typology useful in clarifying the general concept of usage situation, it can also be used to suggest additional situations to incorporate in the analysis.

In discussing alternative criteria for the development of a classification of situations (centered upon various taxonomic procedures such as cluster and factor analysis), Fredriksen (1972) suggested that one could be based upon elicited behavior. The consideration of products or brands for use under various situational contexts would appear to be a worthwhile organizing criterion for such a classification. In this study the setting is consumer perceptions of competitive product-markets.

The composition of competitive product-markets is of considerable practical relevance for a number of managerial and public policy questions (Day and Shocker (1976)). Several researchers have argued for definitions of markets based on consumer behavior or judgment (e.g., Jain and Etgar (1975); Bourgeois, Haines and Sommers (1975)). By and large, these procedures are based upon measures of overall perceived product similarity and have not explicitly considered the effect of usage situations. Since competitive products are more or less appropriate for the same usage situations, a refinement of the approach to include situational effects would be desirable. Thus a corollary purpose of this paper is to develop methodology to implement this concept.

Though this is an exploratory study, there is some precedent for this general line of thought in the work of Steffire (1971) who found analysis of product-usage associations beneficial in operationally defining product-markets for the purpose of new product development. His purpose was not to create a situational typology but rather to find groupings of products which were similar in terms of their associations with a common set of uses. Nonetheless, his efforts would appear to provide some legitimization for our present efforts which can be considered a refinement and extension of his. As justification for further research lies in the validity of our findings, care has been taken at various stages to assess this. Of course, validation efforts need replication over a broader array of product-market contexts and over more diverse market segments.

Methodology

The Methodology progressed through two stages: (1) Determination of varieties of possibly related products and usage-situations and development of a products-by-usage situations matrix (such that each cell (ij) of the matrix provides a measure of the degree of appropriateness of product i for situation j). Subsequently, taxonomic procedures are used to examine the similarities between pairs of situations (in terms of products judged appropriate), to produce an initial situational taxonomy (and definitions of the competitive product-markets). (2) Refinement of the above taxonomy by development of morphological situational descriptions, testing whether these descriptions were interpreted by a new set of respondents in a manner similar to the researchers' conceptualization, and finally replicating the procedure in the previous step with the more complete morphological usage-situational descriptions.

The "breath freshener" market was chosen for the purpose of this exploratory study because: it (1) showed promise in its ability to show variability in product choice across usage situations, and (2) would be a product class familiar to a convenience sample of socially-conscious graduate students in business administration. The latter consideration is especially relevant as familiarity/experience with the product class would be important in the development of meaningful, realistic usage-situations and for minimizing "guesswork" on the part of respondents in indicating appropriateness of products for specific usage-situations (thus reducing the error component of individual differences between subjects).

Stage 1

A procedure adapted from Stefflre (1971) was used to determine the initial set of products and usage situations. Ten graduate students in administration at a major Eastern university were asked by questionnaire to go through an iterative procedure: from this starting point of a "core" of several breath freshening products and examples of usage situations, they were asked to identify additional situations where use of the products would be relevant and other products appropriate to the expanded set of situations, etc. This led not only to lists of commercial products/brands, but also numbers of home remedies (e.g., rinsing mouth with saltwater, sucking a lemon). An alternative data generation method involved group interviews with an additional 8-10 students which, while leading to additional products and situational descriptions, also explored the choice criteria used in determining appropriateness. Generally, the interviews provided a richer data source than had the questionnaires.

Our own judgments supplemented the insights gained from the interview and questionnaire. Duplications and redundancies in products and situations were eliminated. Additional products were added by surveying the product racks of supermarkets and drug stores. In identifying products, an attempt was made to consider all distinctions between brands that might prove relevant (e.g., breath sprays were distinguished from drops, brands such as Close-up--a brand with the flavor and clarity of a mouthwash--were explicitly identified, different flavors were distinguished). Further, a few "extra" products were included in the list to provide some validation for subsequent procedures (the expectation being that such products would be judged inappropriate). This process yielded a set of 18 situations and 46 products.

EXHIBIT 1

Examples of Products .

"Seven-Up" ("extra" product)	"Listerine" mouthwash
Fruit flavored chewing gums	"Dynamints"
"Roloids" (extra" product)	"Close-Up" toothpaste
"Ultrabrite" toothpaste	"Water-Pik"
"Binaca" breath spray	Mint flavored chewing gums

EXHIBIT 2

Examples of Situations, Stage 1

- To clean mouth upon arising in the morning.
- Before an important business meeting late in the afternoon.
- Before going to a formal party.
- When you have a sore throat.
- To get rid of a stale taste - anytime.
- For use during a social event - may have to offer to acquaintances.
- Before an unexpected business meeting with a client.

An additional sample of 46 graduate student respondents was then asked for each of the 18 usage situations to indicate whether each product was (a) appropriate, (b) inappropriate, or (c) no opinion. Given the large number of judgments required (18 x 46 = 828) and to relieve tedium, this was accomplished by presenting respondents with 46 cards (with product names and identification numbers). After shuffling the cards (once for each situation) and sorting them (products) into the above categories, this information was coded on a questionnaire form.

A Measure of Appropriateness of Product i for Situation j. By aggregating responses across subjects, it was possible to obtain a products-by-usages matrix such that within each product-situational cell we would have counts for the number of respondents judging (1) appropriate (A_{ij}), (2) inappropriate (I_{ij}), and (3) no opinion (N_{ij}). Define:

$$a_{ij} = \frac{A_{ij}}{A_{ij} + I_{ij}}$$

as a measure of the degree of appropriateness of product i for situation j. This measure excludes the "no opinion" responses (which were very infrequent) and merely reflects the proportion of people who considered a product appropriate for a particular situation.

The Test for Perceptual Homogeneity. If there were complete agreement among the subjects, virtually all (or none) would rate the product as a appropriate. Let:

$$v_{ij} = |a_{ij} - 0.5| \quad \begin{matrix} (= 0 \text{ if complete disagreement}) \\ (= 0.5 \text{ if complete agreement}) \end{matrix}$$

be a measure of the level of agreement between respondents for cell ij of the product-use matrix. By estimating the mean and variance of this measure (across all cells), one can compute whether the level of agreement (homogeneity) is "adequate" (for example, significantly different from 80% or 90%, *i.e.*, $v_{ij} = 0.40$ or 0.45 respectively). For Stage 1, v_{ij} has a mean of 0.31 and a variance of 0.0208 . This allows us to reject at the $\alpha = .01$ level the hypothesis that the entries in each cell occur purely by chance. At the same time, we cannot reject the hypothesis of nearly complete agreement (say, $v_{ij} = 0.45$).

Taxonomic Approach. In order to develop a taxonomy of usage-situational influences, we analyse the similarity between the situations (in terms of the products/brands associated with them). One such measure of similarity would be the correlation between columns (situations) in the products-by-usages matrix. This correlation matrix could be used as input into a variety of dimension reducing (taxonomic) techniques. Principal components analysis was the method adopted for the following reasons:

- (1) it was felt that since the input measures (degree of appropriateness) were ratio-scaled, a metric scaling technique was applicable.
- (2) it allowed us to examine the interrelationships between situations and products in the same reduced space (see below).
- (3) because some correlations between situations were very high, the use of a technique such as nonmetric multidimensional scaling would be problematic due to the associated problem of degeneracy.
- (4) further, scaling techniques are primary informative about large distance similarities (each point in a scaling configuration is located by reference to all other points, so that large distance similarities dominate) while clustering techniques are more informative about small distance relationships (Kruksal (1972)).

Since for the purpose of this exploratory study, we are more interested in the interrelationships between generic product types and the association between a set of usage situations, it would be more beneficial to use principal components analysis (metric scaling) to examine the large distance similarities. Subsequently, situational clusters could be formed (based on patterns of factor loadings) and product clusters generated (based on the pattern of factor scores). In addition to the development of a taxonomy of the objective usage-situational influences, these situational clusters would serve as a reasonable basis for product-market definition *i.e.*, product clusters closely associated with the same situational cluster being viewed as competitive and constituting a relevant market.

Analysis (Stage 1). Principal components analysis was conducted with the (18) usage situations as variables and the (46) products as cases using the BMD08M algorithm. The raw data were the appropriateness scores (a_{ij} 's of products for situations). Varimax rotation was performed to yield a rotated factor matrix that approximated simple structure, and unstandardized factor scores obtained for each of the 46 products. This analysis suggested two or three factors (accounting for 52%, 35%, and 6% of the variance, respectively, in the unrotated factor structure). Interpretation of the rotated factor was as follows:

Component 1 - Social versus Personal Concern (*i.e.*, did the situation involve others or just self-e.g., stale taste in mouth)

Component 2 - Away versus at home (implying privacy and availability of alternatives)

Only one situation ("when you have a sore throat") had high factor loadings on the third component. Since this situation had very low loadings on the first two dimensions it seemed to have little in common with the other situations. Examination of the product-use matrix revealed that products that were generally inappropriate for the other situations (e.g., cough syrups, sodas, and the "extra" products) had comparatively higher measures of appropriateness for this situation. It thus seems that this situation was picking up the variance for the products that were in general considered inappropriate for breath freshening. Accordingly, only two factors were retained.

The unstandardized factor scores for these 46 products were plotted. While not shown here, the results were highly intuitive with toothpastes and mouthwashes having high scores on component 2 (home) and low scores on component 1 (personal concerns). Similarly, candies, mints and gums loaded low on component 2 (away from home) and high on component 1 (social concerns). The "extra" products were not strongly associated with any of the situations thereby indicating their general inappropriateness as breath fresheners.

Discussion. The results of principal components analysis were to a large extent congruent with prior expectations. Commercial products as opposed to "home remedies" were generally associated with breath freshening. Toothpastes and mouthwashes were closely related in terms of their general association with virtually all situations. Breath sprays and drops appeared to be a distinct category. However, there were some things that were not anticipated. An interesting finding was that for several situations (generally centering around social occasions) mint-flavored gum and candy products were seen as more appropriate breath fresheners than fruit-flavored gums and candies. Flavor appeared to be a better indication of product-market differentiation than the nominal product types (candies or gums).

The purpose of this initial stage was to develop a crude taxonomy of situations (and products). The ad hoc elicited situations had been of varying levels of specificity (*e.g.*, to get rid of stale taste in the mouth - anytime) and completeness, and some more clearly called for breath freshening than others. For example, the situation "when you have a sore throat" was not associated to an appreciable extent with breath freshening products. In addition, four situations resulted in possible confusion regarding their interpretation (as indicated by a low level of agreement (v_{ij}) across respondents). In view of these shortcomings, it appeared useful to create a morphological set of usage situations of more uniform levels of specificity and completeness, and then to replicate the procedures described above.

Stage 2

A debriefing session was held with the 46 respondents who had participated at stage 1. They confirmed the ambiguity of several of the troublesome situations, suggested that current descriptions of situations were deficient in not disclosing the amount of time available to freshen breath, and indicated some lack of identification with certain situations. These comments called for changes in the procedures.

Interpretation of the two-factor solution at Stage 1 provided the major guidance for the development of a situational taxonomy. The comments of the students at the debriefing together with our own judgment suggested

two additional situational dimensions. Four dimensions were posited:

1. Personal vs. Social Concerns: "Self" - the primary concern is with the subjects' personal reactions to either their own mouth freshness or to the freshness of others' breath; "Other" - the subjects' primary concern is with others' reaction to their (the subjects') breath freshness. (2 levels)
2. Privacy of Use and Access to Alternatives: "Home" - usage of a breath freshener will be in a location affording considerable privacy of use and ability to use a wide variety of breath freshening alternatives; "Away" - usage of a breath freshener will be in a location affording less privacy of use and more limited ability to use a variety of alternatives. (2 levels)
3. Risk of Being Noticed: "High Noticeability" - a high expectation that the subjects' state of breath will be noticed by others or by self; "Lower Noticeability" - a lower expectation that the subjects' state of breath freshness will be noticed by others. (2 levels)
4. Amount of Time to Prepare: "Time to Prepare" - the subject has adequate time to freshen breath; "Limited Time to Prepare" - the subject has limited time to freshen breath. (2 levels)

The first two dimensions of the typology were obtained from the interpretation of the Stage 1 factor structure. The third and fourth were added because of their apparent plausibility.

New situational descriptions were generated to correspond to all possible (morphological) combinations of the levels of the four characteristics. 27 such descriptions were developed providing duplication for several of the possible (2x2x2x2=16) cases. In order to determine whether these descriptions validly represented their respective cells, successive groups of six to eight students were given each description together with the typology above and asked to code each description back into the typology. After each iteration an attempt was made to understand those instances where there was substantial disagreement among the subjects. Some situational descriptions needed to be rewritten. Two iterations of this process produced substantial convergence. All but three situational descriptions produced a high level of consensus and these three were dropped from further analysis. Unfortunately, some of the changes resulted in increased representation for several cells of the typology and no representation in a few others. In all further analysis, situational descriptions are assigned to the cells of the typology using this "back coding" of the judges. Exhibit 3 shows examples of situations in stage 2.

38 respondents in the Graduate School of Management at a major West Coast University completed the task of indicating appropriateness (appropriate/inappropriate/undecided/product unfamiliar) for the 48 products¹ for 14-15 randomly assigned (from the list of 24) situations. In addition data were collected on the overall effectiveness of each product as a breath freshener and the importance, frequency of occurrence, and "realism" of the situation.

¹Two products were added to the set of products at the first stage.

EXHIBIT 3

Examples of Situations, Stage 2

It is morning and you are preparing to go to work. You expect to be tied up in routine meetings most of the day.

You are preparing to go to a formal dinner at the home of an important client.

You are preparing to go to work knowing you have an appointment with your family dentist later that morning.

You are getting ready to go out on a blind date where you expect intimacy.

You are at home waiting for that important person in your life to arrive for some intimate pleasure.

You are at home preparing to go out to a casual social function with friends.

Measure of Appropriateness. A measure of the degree of appropriateness similar to the one in Stage 1 was designed to account for the inclusion of the undecided category. If A_{ij} = count for appropriate, I_{ij} = count for inappropriate, and U_{ij} = count for undecided, for each cell ij , then:

$$a_{ij} = \left(\frac{A_{ij} + 0.5 U_{ij}}{A_{ij} + I_{ij} + U_{ij}} \right)$$

The counts for U_{ij} (undecided) for each cell were very low compared to A_{ij} (appropriate).

Test for Perceptual Homogeneity. v_{ij} , the measure of the level of agreement, was again calculated. It had a mean of 0.258 and a variance of 0.019. This allowed us again to reject (at the $\alpha = 0.05$ level) the hypothesis that the entries in each cell were due purely to chance. The average level of agreement is lower in this stage. However we must keep in mind that each of the 38 respondents indicated product appropriateness for only 14-15 randomly selected (from the list of 24) situations. Thus on an average, the appropriateness measure (a_{ij}) and consequently the level of agreement (v_{ij}) were calculated on the basis of 25 responses. Consequently, a somewhat lower level of agreement may be expected as each "aberrant" response will have a larger effect on the measure of appropriateness.

Analysis. Again principal component analysis using the situations as variables was conducted. The first three unrotated components accounted for 57%, 30%, and 6% of the variance, respectively. Varimax rotation was again performed to improve interpretability. Examination of the rotated factor structure led to an interpretation of the first two factors as at Stage 1. (The third factor was more ambiguous with only two situations loading greater than 0.4 on it and one of those loaded quite heavily on factor 1). From this we conclude that the two additional dimensions in the typology added little. It appears in retrospect that dimension 4 (time for planning) would be closely related to dimension 2 (home vs. away) in that time needed would logically depend on whether a breath freshener needed to be first acquired or not.

EXHIBIT 4

SITUATIONS BY FACTOR LOADINGS
AND
PRODUCTS BY UNSTANDARDIZED FACTOR SCORES

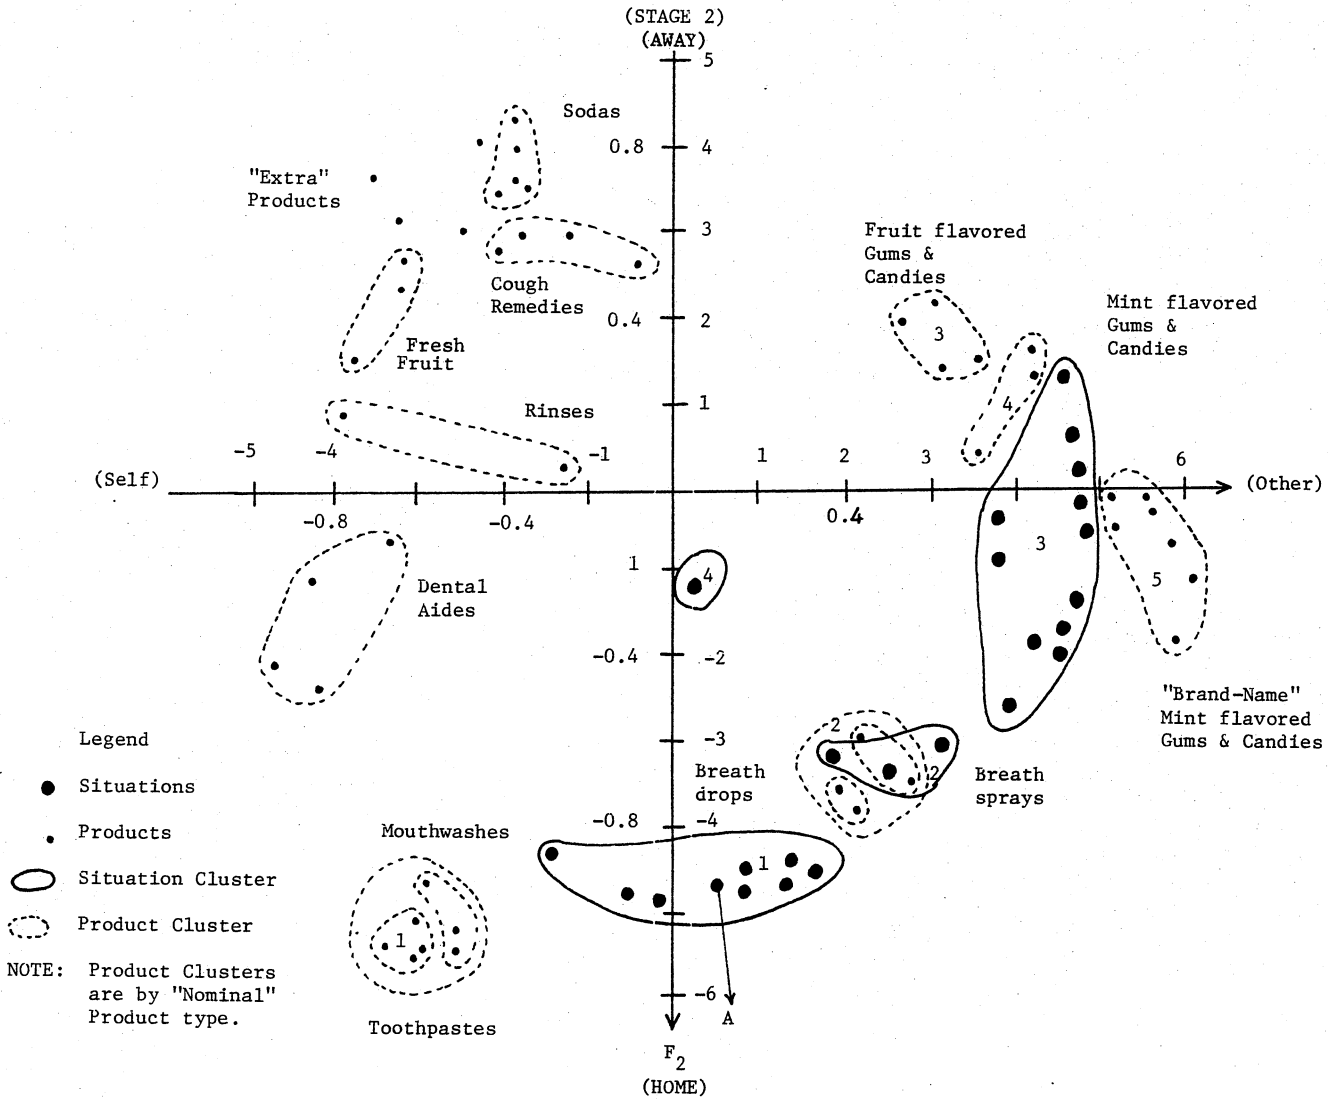

Exhibit 4 shows the 24 usage situations and 48 products of the second stage plotted in the space of the first two components. Points denoting the usage situations are merely plots of corresponding factor loadings (correlation coefficients with the principal components) which have directional properties only. The points denoting products are unstandardized factor scores, which have properties of both magnitude and direction.

Usage situation and product clusters were derived on the bases of patterns of factor loadings and factor scores, respectively, by visual clustering. In order to determine the relative appropriateness of product clusters for the situational clusters two methods could be used: (1) the projection of points representing products on the directional vector from the origin to the location of the centroid of each cluster of usage situations in reduced space would provide a measure of the relative appropriateness. The greater the projection along this directional vector, the more appropriate the product for the situational cluster. Thus in Exhibit 4, for situation "A", toothpastes and mouthwashes are considered more appropriate than breath

sprays and drops. This procedure may be repeated for each cluster of products and usage situations, (2) Alternatively, the original products-by-use matrix provides an explicit measure of appropriateness.

Situational clusters may be formed comprising situations that have similar product (cluster) appropriateness patterns and may be viewed as constituting a single market/submarket. This analysis revealed four submarkets (corresponding to the situational clusters shown in Exhibit 4).

For submarkets 2 and 4, product cluster 1 (mouthwashes and toothpastes) appears to compete with product group 5 (gums and candies). The extent of such competition, however, is an issue requiring further research.

Finally in order to assess the usefulness of the typology, average correlations were computed between pairs of situations coded in terms of the typology. These pairs had either zero to four typological dimensions in common (e.g., suppose situation A was coded 1, 0, 1, 1 (in terms of levels 1 or 2 of the four

typological dimensions) and situation B was coded 1, 0, 0, 1; then the two situations would have three dimensions in agreement). Correlations were across the original product appropriateness measures a_{ij} . The results are shown in Exhibit 5. As expected, as the number of typological elements in common increases, the extent to which pairs of situations have appropriate products in common also increases.

EXHIBIT 5

CONSISTENCY OF STAGE 2 USAGE SITUATIONS WITH TYPOLOGY

NUMBER OF DIMENSIONS in AGREEMENT	NO. OF PAIRS	AVERAGE CORRELATION	STANDARD DEVIATION
0	14	.25	.33
1	63	.36	.33
2	95	.47	.29
3	70	.72	.22
4	34	.84	.17

Discussion

Space did not permit the graphical representation results for Stage 1 (comparable to that reported for Stage 2 (see Exhibit 4)). If it had, the similarity of results between stages 1 and 2 would have been striking—this despite the several differences in stimuli (number of products, substantially different situational descriptions), the samples (eastern and western MBA candidates), and methods of data collection (card sorting versus partially overlapping questionnaires). All this is some testimony to the robustness of the procedures discussed.

As can be noted in Exhibit 4, brands within each generic product type (e.g., toothpastes, mouthwashes, breath sprays, cough drops) are generally close together in the space, indicating that subjects perceived fewer distinctions between brands than between product types and that such brands were generally perceived similarly in terms of their appropriateness to most usage situations (geometrically, the compactness of a cluster should connote a higher level of perceived substitutability with respect to all usage situations). It was particularly interesting to note, however, that flavor served to define the generic product rather than candies or gums. Cough drops were perceived differently from other candies (at least for breath freshening).

One particularly noteworthy consequence of our findings is the fact that just two principal components accounted for approximately 87 percent of the variation in association (93 percent for 3 components). This indicates that it may be possible to generate a parsimonious, yet meaningful situational typology for product types. Also, we observed that the first two factors in the two stages were quite similar. This may imply that "natural" situational descriptions serve about as well as morphologically-created ones for purposes of explaining systematic product-situation associations.

The relatively high measures of agreement among respondents would argue strongly against the presence of significant demand effects in the research. If respondents felt they should respond differently to each situation simply because of the task, it is unlikely that a_{ij} would be so high.

In stage 1, the appropriateness measure for each cell of the product-use matrix was based on 46 entries (respondents). On average, the number of entries of each cell was only 25 for stage 2. Yet, the results were strikingly similar. Again, this indicates the stability of the procedure for low ($n = 20$ to 40) sample sizes. A study by Rosenberg et al (1968) also reports stability of similarity matrices (based on concurrence/association measures) for small sample sizes ($n = 37$).

Conclusions

The results of the study are consistent with the following conclusions:

- (1) situational influences appear to affect the choice of products/brands in a systematic manner.
- (2) a parsimonious typology of objectively meaningful situations can be constructed based on behavioral criteria (the brands considered appropriate by consumers).
- (3) "ad hoc" (stage 1) descriptions of usage-situations serve about as well as descriptions based on a morphology (stage 2) in determining the composition of product-markets. In fact, the results of the two stages are strikingly similar.
- (4) product-market composition based on perceived consumer behavior across usage-situations would appear to stretch across generic product types (although the bases for defining a product-type may not always be apparent).
- (5) small sample sizes (30-40), using the procedure adopted, produced stable results.

Though we cannot claim to have developed a general situational taxonomy (although there is some similarity between our two dimensions and those of Belk (1975)), the procedures used here at least appear useful for a variety of scientific and managerial purposes. Further research is necessary with more significant sample sizes representing a broader cross-section of consumers and across a wider range of product-markets before generalizations can be claimed. But we have at least suggested that with product familiarity and usage situation controlled for, people's perceptions of the nature and composition of competitive markets are relatively stable. Individual differences in market behavior (e.g., in preferences and choice), which have become an important topic in consumer research, can more productively be explored within such a context.

ASSESSING THE EFFECTS OF VISIBLE
CONSUMPTION ON IMPRESSION FORMATION

Russell W. Belk, University of Illinois, Urbana-Champaign

Abstract

This paper reports a series of exploratory experiments measuring the impact of visible consumption of products and services on the impressions which others form about the consumers of these items. A method labeled "the detective study" is illustrated for measuring these impressions, and comparisons of effects are made between different types of consumption items and between male and female perceivers.

The belief that a person's possession and expenditures reveal something about the person may be one of the strongest cultural universals affecting consumer behavior. In virtually all cultures, visible products and services are the bases for inferences about the status, personality, and disposition of the owner or consumer of these goods. Relevant cues may be noted not only in the number and type of goods consumed, but also in such features as their style, color, uniqueness, condition and brand name. Where other information about a person is known, this information is integrated with visible consumption information in developing an overall impression of another. There are also many instances in which visible consumption cues dominate the overall impression, either because the cues are highly distinctive or because little additional personal information is available due to observing strangers or newly established or casual acquaintances. Nevertheless, while consumer behavior research has examined the messages about self or ideal self concept which consumers seemingly intend to display through their selections of products and services,¹ we have devoted little attention to the messages which consumption selections actually do convey to others. The broad intent of this research, therefore, was to initiate a program examining the influences which configurations of visible consumption items have on impression formation.

Prior Research

There has been little systematic research into the effects of visible consumption on impression formation, but there have been occasional studies examining isolated consumption factors affecting person perception. Perhaps the classic study was Haire's investigation of the image of Nescafé Instant Coffee, using subject descriptions of the presumed owner of a grocery shopping list including either instant or regular coffee (Haire, 1950). As indicated by subsequent replications, consumer images based on even these small differences in consumption patterns are significant and reliable as long as the product images remain constant (Westfall, Boyd, and Campbell, 1957), but may change as the images of the products change (Webster and Von Pechmann, 1970). A somewhat more visible item of consumption which has

received some attention in studies of person perception is clothing. Several researchers have found through unobtrusive experimental designs that those in higher status clothing (e.g., a suit and tie rather than casual clothes) seem to gain more compliance with their requests (e.g., signing a petition²) and also serve as models whose behavior is more imitated (e.g., crossing a street against a traffic light³). Holman (1976) has conducted an experimental study using photographs of a woman dressed in several different clothing ensembles, and found a number of differences in the inferred traits of the woman. While somewhat less conspicuous than clothing, cosmetics have also been found to affect person perception. In a study of the 1950's, McKeachie (1952) found that women wearing lipstick were judged by a sample of college men to be more frivolous, introspective, anxious, conscientious, and interested in the opposite sex than women not wearing lipstick. And Calder and Burnkrant (1977) recently found that a woman described as buying Revlon mascara was judged by college females to be more popular and competent than a woman described as buying Walgreens' mascara. Automobile ownership is another highly visible consumption characteristic which has been found to be related to person perception and related behaviors. Doob and Gross (1968) found that a more expensive and newer automobile which faked being stalled at a stoplight, received fewer horn-honking responses than a less expensive and older automobile. And Grubb and Hupp (1968) found that owners of Volkswagens and Pontiac GTOs were able to draw distinct and reasonably accurate profiles of the other group of owners' self concepts, knowing only the automobile which they owned.

In each of these studies, however, the investigated consumption items were examined in isolation from other consumption characteristics which might typically be apparent. It seems reasonable that people normally make judgments of others based on such broader configurations of visible consumption items. For instance, it is possible that a person who is wearing a suit and a tie with white stockings might be judged to be attempting to enact a role with which he is uncomfortable. In order to allow for such inferences, the present study sought a method which could systematically manipulate a composite of visible consumption items.

The "Detective Study"

The method chosen for the present research was to present each subject with a consumption profile representing a single cell from a factorial design. The experiment was presented in the guise of a "detective study" being done to help the New York City Police Department to more effectively locate the owners of unidentified property which was lost or stolen and later recovered by or turned in to the police. There are several

¹E.g., Grubb and Grathwohl (1967); Birdwell (1968); Grubb and Hupp (1968); Dolich (1969); Mason and Mayer (1970); Hamm and Cundiff (1969); Ross (1971); Grubb and Stern (1971); Greeno, Sommers, and Kernan (1973); and Landon (1974).

²Suedfeld, Bochner, and Metas (1971); Darley and Cooper (1972).

³Lefkowitz, Blake, and Mouton (1955).

advantages to this method. One desirable feature of the cover story is that it allows the presentation of a large number of consumption items without appearing forced. For instance, by including a wallet or purse in a particular group of items, their contents can also be manipulated. This allows the use of business cards, membership cards, credit cards, and specialty merchandise such as pocket calendars and matchbooks, all of which can manipulate the stimulus person's use of various moderately visible services. In addition, the use of this cover story removes any elements of social desirability which might otherwise inhibit the expression of consumption-related stereotypes. Subjects were told that the groups of items they would be shown in the descriptive form of "property tags" were ultimately returned to their owners, and that the characteristics of these owners were known. Thus, the stated purpose of the study was to compare perceptions of owners to the actual characteristics of the owners in order to see how much accuracy was possible from the items alone. This rationale also allowed the presentation of more than one group of unrelated items, amounting to participation in more than one experiment by the same subject.

Treatment Variables

All subjects were part of five different 2^5 factorial designs. There were ten subjects per cell for a total of 320 subjects participating in these experiments. Half of the subjects in each cell were males and all were undergraduate students at the University of Illinois. The five experiments differed in the visibility of consumption items included, in the sex of the stimulus person, and in whether or not the locational context where the items were reportedly found was manipulated. The two experiments which will be reported here both involved moderately visible consumption items for which locational context was not varied, but one involved a female stimulus person and the other involved a male stimulus person. The treatment levels for these two experiments are shown in Tables 1 and 2.

All treatment levels which a particular subject was to receive were simultaneously presented on 3 inch by 5 inch cards with the first two treatments presented on the same card and the order of the cards randomized. While it is not possible to claim that the two experiments were identical except for the sex of the stimulus person, both had a wallet or purse, a sports event, a restaurant, a personal care item, and either a travel mode or a travel abode. This rough equivalence allows comparisons between males judging either male or female stimulus persons, and females judging either male or female stimulus persons.

It was hypothesized that perceivers of the same sex as the stimulus person would be able to make more complete and consistent judgments about the person based on these visible consumption items (i.e., lower error variance) than could those of the opposite sex. The underlying assumption is that a person of the same sex will be able to bring more self-knowledge about use of the consumption items to bear on inferences about the stimulus person. For two of the consumption items (wallet/purse and haircare/lipstick) there may also be a greater familiarity with the nature of the consumption items themselves by a same sex observer. There has been a large amount of research on the effects of observer sex on person perception in studies not involving consumption stimuli,⁴ but the findings are inconsistent. The choice of the college subject pool, if it had an effect, probably biased results away from the hypotheses, since

⁴E.g., Taft (1955); Levy and Schlosberg (1960); Warr and Knapper (1968); and Tagiuri (1969).

at this prime age for dating, the students may be particularly alert to cues indicating the character of members of the opposite sex.

Descriptor Variables and Covariates

Based on pretests involving open-end responses describing the owners of many of the stimulus item configurations, the demographic and adjectival scales shown in Table 3 were selected as dependent variables ("descriptors"). These same variables, with the exception of the last two items, were used to obtain a self-description of the subject following participation in the five experiments. Because of the college subject pool, residence, family income, occupational class, and years of education were measured referring to subjects' parents.

The subject descriptions will serve as covariates in future analyses, but at present it is of interest to compare the intercorrelations of these covariates, the intercorrelations of the descriptor variables, and the cross correlations between covariates and descriptor variables, in order to consider whether several types of response styles may have affected judgments. This information is summarized in Figure 1 for the moderately visible male consumption items experiment using data from the 160 male subjects.⁵ An examination of the three matrices in Figure 1 allows several types of potential insights into subject responses. If the configurations of the covariate intercorrelations and the descriptor intercorrelations were equivalent, this could be taken as evidence of inherent clusters of traits, and factor or cluster analysis might be used to reduce the dependent measures prior to further analysis. Although there is some similarity between these two matrices, the differences in the number of significant correlations forces rejection of this conclusion and course of action. If on the other hand, the covariate intercorrelations were stronger than the descriptor intercorrelations, then one possibility would be that "halo effects" exist in self ratings and stimulus persons are viewed more discriminately. Another possible interpretation of such a pattern would be that while certain traits naturally occur together in the subjects (e.g., educated/successful), the consumption items presented are unnatural combinations which cause normal trait associations to fall apart. Since this pattern did not emerge, neither of these interpretations need concern us. A third possible pattern, and the one which is found in the data in Figure 1, is that the covariate intercorrelations will be weaker than the descriptor intercorrelations. The explanation in this case is clearer. The tendency to judge others using bundles of related attribute judgments has been referred to as "cojudgment" in person perception studies not involving consumption items (Warr and Sims, 1965). This phenomenon appears to be due to a reliance on implicit theories of personality types when judging others. That is, when judging others we tend to rely upon our knowledge or impressions of people in general to go beyond surface traits in deciding what characteristics people are likely to possess. This tendency leads to the use of groups of normally related personality characteristics. An overlapping but less plausible explanation for this pattern is that consumption characteristics reveal patterns of personality characteristic relationships which would not normally be found together. For instance, possession of a Rolls Royce automobile

⁵The absolute magnitudes and patterns of correlations differed somewhat by subject sex and stimulus person sex, but the relative strengths of the covariate intercorrelations versus the "projection diagonal" correlations versus the descriptor intercorrelations remained the same ordering over the four combinations of subject and stimulus person genders.

might lead to judgments that the owner is of high income and also ostentacious, even though the two characteristics are not normally correlated. However, if we assume that an observer tries to not only interpret the characteristics of a stimulus person, but also to form a familiar interpretation which will allow further predictions of that person's demeanor and behavior, then the cojudgment interpretation of descriptor intercorrelations is the most plausible.

One further possible basis for judgments of stimulus persons is examined in the "projection diagonal" of Figure 1. These are the correlations between the corresponding covariate and descriptor items. High positive correlations here would indicate that the subjects tend to project their own perceived traits onto the stimulus person. As the weak correlations indicate, this projection does not appear to have occurred. Instead it seems that while there may be some basis for expecting inherent trait clusters, cojudgment occurs in judging others to a greater extent than it does in self-descriptions. From the point of view of data analysis, this indicates that data reduction in the set of dependent measures should not be expected to yield a set of underlying variates which represent general person traits common to stimulus persons as well as subjects of both sexes. Avoiding data reduction also eliminates the potential problem of averaging the differences in relationships which may occur across cells of the experimental design.

Results

Because of the strong likelihood that multivariate analyses of variance would form different linear composites of the dependent variables across the two experiments and two subject groups of interest, MANOVA procedures were rejected for the present comparisons. While it would be possible to include subject sex as a sixth

independent variable in univariate analysis of variance, the complicated potential interactions between sex and the treatment variables would prove difficult to interpret. Therefore, the method of analysis chosen was to run separate ANOVAs for each dependent variable in each of the four combinations: (1) male subjects, male stimulus person experiment; (2) male subjects, female stimulus person experiment; (3) female subjects, male stimulus person experiment; and (4) female subjects, female stimulus person experiment. A sample ANOVA for the dependent variable "unattractiveness" with the data from combination 1, is presented in Table 4.

It may be seen from Table 4 that three main effects and three interactions are significant. The way in which these variables affect attractiveness judgments will be described shortly. For the moment, it is more important to note that these effects were able to account for 62 percent of the variance in attractiveness ratings, based on variance components estimates.⁶ This is the measure which is to be used for testing the hypothesis that subjects will be able to judge those of the same sex more completely and consistently based on consumption items. Table 5 shows a summary of proportions of variance accounted for in each dependent variable for the four subject/stimulus person combinations.

Looking only at the average proportions of variance accounted for over all dependent measures, it appears that females are clearly better judges of both male and female consumers than are males. Female judgments were more consistent across judges, leading to higher levels of explained variance. Male and female stimulus persons, on the other hand, appear to be equally easy to judge. This is true whether the perceiver is male

⁶See Dwyer (1974).

or female. Examining the proportions of variance accounted for in each separate independent measure, it appears that females are consistently the best judges of income, seriousness, weight, friendliness, and interestingness, while males more readily assess responsibility. Judges of the same sex as the stimulus person seem to do somewhat better at estimating age, life cycle stage, residence, occupation, and attractiveness, while judges of the opposite sex as the stimulus person were able to more consistently estimate generosity, happiness, likeableness, emotionality, successfulness, aggressiveness, and amount of money missing, using consumption characteristics. Generally, however, it must

be concluded that these patterns of differences fail to conform to an easily identifiable sensitivity stereotype such as one sex being more able to agree on affective judgments while the other sex focuses on more objective or cognitive characteristics.

Although the hypothesized ability of perceivers to judge those of the same sex more completely based on their consumption patterns was not supported in total variance explained, it is still possible that such effects are reflected in male and female differences in their interpretations of a particular consumption characteristic. In order to assess this possibility,

Tables 6 and 7 provide a summary of the direction of main effects found to be significant ($\alpha \leq .05$) in the two experiments, broken down by sex of the perceiver. Although space precludes presenting interactions, a substantial portion of the variance in these two experiments was accounted for by these main effects. In Table 6 and to an even greater degree in Table 7 it may be seen that the implications of these consumption item clues differs between male and female subjects. For the wallet and hand or shoulder bag items it does

appear that the subjects presumed to be personally most familiar with these items were able to provide more consistent descriptions of their owners. While this lends support to the hypothesized bases for sex effects in impressions formed from visible consumption, the same pattern does not emerge for the lipstick and haircare items.

TABLE 6

Summary of Main Effects for Moderately Visible Male Consumption Items Experiment

Treatment 1: Those whose wallets were found in an air terminal rather than a bus terminal were perceived...

<u>By Males Only As:</u>	<u>By Both Males and Females As:</u>	<u>By Females Only As:</u>
	Higher Income	Older
	Higher Occupational Class	More Generous
	More Highly Educated	More Responsible
	More Likeable	Friendlier
	More Successful	More Attractive

Discussion

For the two experiments for which results were presented, given the confidence level used in testing, nineteen main effects could be expected to occur by chance over the two subject groups. In fact, more than five times this many main effects were found to be significant. Even moderately visible and sometimes subtle consumption differences were found to produce consistent differences in the impressions formed of the consumers of these products and services. Of course, the particular effects obtained in these experiments can be expected to change with different groups of perceivers and over time. It is also likely that effects may differ somewhat with different presentation contexts. For instance, if consumption items are presented via photographs or videotapes, the cue that these items were lost or stolen disappears, the physical features of the stimulus person are introduced, and selective perception is likely to be more operative. Nevertheless, the detective study methodology presents an efficient way to examine the combined effects of a number of visible consumption items on impression

formation.

An examination of the effects summarized in Tables 6 and 7 reveals one disturbing but expected result. For example, consider the effect of the air/bus treatment in Table 6 on females. Not only was the air traveler judged by relatively objective wealth-related criteria as being higher income, higher occupational status, more highly educated, and missing more money than the bus traveler, but he was judged by criteria objectively unrelated to wealth to be more likeable, successful, interesting, generous, responsible, attractive, and aggressive! In part, this halo effect may be due to the business student subjects' identification with the socially distant reference group of executive/air travelers,⁷ but it also seems apparent that the more objective judgment of wealth creates a bias toward an array

⁷ See Cocanougher and Bruce (1971).

of other positive characteristics which bear no logical relationships to income. Whether estimates of income are in fact focal inferences which bring with them a number of collateral judgments in forming impressions based on visible consumption is a question which must await more detailed examinations of information processing and integration of such cues. Two somewhat parallel processes which may shed some light on this question are investigations of the integration of brand attribute information into an overall brand attitude, and the integration of information about the products and brands carried by a retailer into the overall impressions of the retailer.

We need to know much more about the role of visible consumption in impression formation. As Figure 2 illustrates, impression formation is an interactive process involving images of products and services as well as images of people consuming these items. Inferences about a product user are determined in part by the products he or she is seen to use or consume, provided that some prior image of these products exists for the perceiver. Similarly, inferences about the image of a product are partially determined by those seen to use or consume the product, provided that some prior image of these users exists for the perceiver. In addition to previously received external information about the person or product, inferences may be aided by information about the consumption situation in which a product is being used (e.g., an outfit being worn in a church rather than on a tennis court), and information about the role being enacted by the consumer (e.g., wearing an outfit as a salesperson in a particular store rather than as a customer in this store). The effects of product image on inferences about product user image are likely to be strongest where little prior information about the person exists, but Bem (1967) argues that some such inferences may take place even when the perceiver is the stimulus person. Whether or not such self-perception is normally a part of impression formation via visible consumption, however, it is clear that in order to know more about the role and function of product images, we need to know more about how the use of visible products and services influences our impressions of people.

EVOKED SET SIZE AS A FUNCTION OF NUMBER OF CHOICE CRITERIA AND INFORMATION VARIABILITY

Joseph A. Belonax, Jr., Bowling Green State University
Robert A. Mittelstaedt, University of Nebraska - Lincoln

Abstract

If consumers construct an evoked set by a sorting process, applying more choice criteria to information which contains more variability should increase the likelihood of achieving a smaller evoked set. A 2 X 3 factorial experiment to test these hypotheses is reported. Results support both hypotheses.

Problem

Conceptualizing the consumer as an information processor and decision maker, Chaffee and McLeod (1973) present a generalized model which defines the area of consumer information processing. The consumer is seen as making a buying decision according to some rule which combines information from an attribute-by-brand matrix. Within the context of this broad model, studies of information processing may be classified as structural or functional in their orientations.

Structural issues which have been investigated include the nature and number of product attributes used in making product evaluations and/or choices (a number of such studies are cited and discussed in Myers and Alpert, 1977). Other studies have examined the nature of the "evoked set," i.e., the number of brands actually considered by consumers when making a choice (Campbell, 1969; Gronhaug, 1973/74; Jarvis and Wilcox, 1973; May and Homans, 1977; Narayana and Markin, 1975; Ostlund, 1973).

Research on functional aspects of information processing has taken many forms (summarized in Bettman, 1977) but often involves fitting one or more decisions rule models to brand evaluations made by persons who have been exposed to an attribute-by-brand matrix of information. As Bettman (1977) has pointed out, some of these models (affect referral, linear compensatory, disjunctive and conjunctive) assume that persons process information by brand while others (lexicographic, elimination by aspects, semi-order lexicographic and additive difference) assume processing by attribute. The somewhat mixed results of studies attempting to fit various models may reflect situational differences in those studies. Further, as Bettman notes, modes of information presentation may bias results in favor of one model or another.

However, coming from a different perspective, it may be suggested that the attempts to fit a single model to a total decision process, especially when the buying situation has one or more relatively unfamiliar aspects, may be overlooking an important intermediate stage. The concept of evoked set suggests that choices are made only after the consumer has constructed a set of "acceptable" brands (Howard and Sheth, 1969). The implied two-process model, with information first used to form an evoked set, is consistent with the results reported by Pras and Summers (1975). They found the conjunctive model to be the best predictor of preference rank order when all alternatives were considered, but the linear compensatory model to predict best when only acceptable alternatives were considered.

This suggests that the construction of an evoked set may be an important phenomenon and this study is addressed to that issue. While no decision rule models will be fit to preference orderings, the number of alternatives

considered acceptable (evoked set size) will be examined with respect to two variables -- the number of choice criteria employed and the nature of the information presented -- according to hypotheses which follow from a "sorting view" of evoked set construction.

Hypotheses

Although all consumers may be exposed to the same set of alternative brands in an experimental setting or in the market place, the concept of evoked set implies that not everyone makes a choice from the same set of brands. Indeed, there appear to be substantial inter-individual differences in evoked set size for particular products (Campbell, 1969; Gronhaug, 1973/74; Narayana and Markin, 1975). Confronted with an array of information about a fairly large number of brands, it seems reasonable to suppose that a person would try to simplify the situation. While this could be done by reducing the number of brands or reducing the number of choice criteria, it seems more likely that a person would try to reduce the number of brands actively considered for at least two reasons. First, it would reduce the number of comparisons which would ultimately have to be made. Second, and assuming we are talking about attributes of importance, to simplify by eliminating choice criteria would force the consumer to, in effect, forego some of the consumption goals which he or she is trying to accomplish through the purchase of the product.

The consumer's task, then, is to eliminate brands from active consideration based on information about attributes of importance. Since the purpose of evoked set construction is to simplify the ultimate choice process, it seems likely that a person would use an "elimination rule" and proceed by "knocking out" brands which failed to meet some acceptable minimum level on one or more evaluative criteria. It would follow that, as the consumer applied a larger number of evaluative criteria to the awareness set, the likelihood of finding a reason for eliminating brands would increase. Further, the nature of available information should play a role. If the information about attributes consists of some sort of ratings of alternative brands, as the variability of those ratings increased and/or the general level of their desirability decreased, the likelihood of finding a reason to eliminate brands should also increase. Therefore, specifically hypothesized in this study are the following:

Hypothesis 1: The size of the evoked set is inversely related to the number of choice criteria used in the evaluation task.

Hypothesis 2: The size of the evoked set is inversely related to the variability and directly related to the mean level of the attribute ratings presented in the evaluation task.

Method

To test these hypotheses, a 2 x 3 factorial experiment was designed with "number of evaluative criteria used" and "variability and mean levels of presented attribute information" as independent variables and the reported size of the evoked set as the dependent variable. Before discussing the operationalization of the variables,

four preliminary design considerations will be discussed.

First, the product for which brand information was to be supplied had to be sufficiently complex to allow the use of several evaluative criteria. Further, as will be argued later, it was desirable to select a product about which participants would be relatively uninformed and, yet, one in which they would be somewhat interested. A product which appeared to meet these criteria, micro-wave ovens, was selected.

Second, since the number of attributes was an independent variable, it was necessary to attempt to insure that brand rating information was presented for attributes of importance. Forty-eight knowledgeable respondents (senior home-economics majors enrolled in a course which had previously discussed micro-wave ovens) rated the importance of and perceived interbrand differences for 16 attributes. Using the "direct dual questioning technique" described by Alpert (1971), 6 attributes with average importance and difference ratings significantly ($p < .01$) greater than the grand mean were selected as "salient." The six included browning uniformity, cooking precision, cooking uniformity, cooking versatility, oven capacity and warranty protection. When presented to participants in the experiment, the nature of each attribute was described in a short paragraph. Participants began the evaluation task by reading those descriptions which were then briefly discussed by the experimenter.

Third, since the size of the evoked set appears to be related to the size of the awareness set (Jarvis and Wilcox, 1973), it was necessary to hold constant the number of brands about which information was provided. To manipulate the variability of the attribute ratings "standard squares" were used (for reasons described below.) Since there were six salient attributes, information was presented on six "brands" to each participant.

Fourth, because other studies have suggested a relationship between product and/or brand familiarity and the size of the evoked set (Gronhaug, 1973/74; Jarvis and Wilcox, 1973; Ostlund, 1973), it was necessary to try to control for product familiarity. To this end, participants for the study were 300 students in an introductory nutrition course which had not discussed micro-wave ovens in class. Random assignment of participants to the several treatment levels should have reduced the effects of prior product experience. Finally, the "brands" were presented as "real, but disguised" and designated by the letters "A" through "F."

One independent variable, the variability and mean level of attribute ratings, was manipulated by systematically changing the ratings of the 6 previously determined "salient" attributes for each of the six "brands." Within each treatment level, the mean and variability were held constant by the use of "standard squares" (Kirk, 1968). However, between treatment levels, both the mean level and variability were systematically changed from the "low variability" condition ($X = 8.0$; $s^2 = 5.9$), through the "intermediate variability" condition ($X = 7.0$; $s^2 = 8.4$) to the "high variability" condition ($X = 6.0$; $s^2 = 14.0$). It will be noted that, to provide information which could be used for "sorting," the mean levels were decreased as the variability was increased.

While it is possible to hold the means constant and manipulate the variability, such a design would necessitate choosing a rather "middling" value for the mean and would result, in the lower variability conditions, in fewer (if any) "high" ratings on individual attributes. Since some persons are likely to focus on those attributes with high ratings, manipulating variability

without the simultaneous adjustment of mean values runs a serious risk of having a "self cancelling" effect.

The other independent variable was a stratification according to the number of choice criteria used. After examining the brand ratings and making an overall evaluation of each brand, participants were asked to indicate: (a) the importance of each attribute to the evaluation decision, (b) the minimum rating on each attribute which an oven would have to receive to be evaluated as "acceptable" and (c) the number (and designating letters) of brands considered to be acceptable for purchase. (The answer to this last question is the dependent variable, the evoked set size.) Answers from questions (a) and (b) were combined and a mean calculated for each attribute. Any participant's combined answer on any attribute which exceeded the mean for that attribute was designated an "employed choice criterion" and the number of such was determined for each participant. Previously it had been determined to consider those using 1, 2 or 3 criteria as the "few choice criteria" group and those using 4, 5 or 6 as the "many" choice criteria group. Splitting in this way resulted in reasonably equal numbers in each condition, with 164 in the "few" group and 136 in the "many" category.

Since the other independent variable was randomized across the entire group of participants, the two variables are "crossed" and the design factorial. Data were analyzed using the ANOVA subroutine of MULTIVARIATE (Finn, 1972). Although there were some differences in cell size (Table 1), reordering the variables for unequal cells did not affect significance.

Results

Table 1 shows the mean evoked set size for the various conditions of the study. An examination of the means

TABLE 1
Mean Evoked Set Size For All Conditions

Choice Criteria	Attribute Rating Variability			
	Low	Intermediate	High	Total
Many	2.55 (58)*	2.36 (39)	1.79 (39)	2.28 (136)
Few	3.09 (44)	2.76 (59)	2.18 (61)	2.63 (164)
All	2.78 (102)	2.60 (98)	2.03 (100)	2.45 (300)

* ("n" in parentheses)

shows that, as predicted in Hypothesis 1, those employing "few" choice criteria constructed larger evoked sets than those employing "many" choice criteria. Hypothesis 2 predicted that the evoked set would be smaller as the variability of the presented attribute ratings increased while their mean levels decreased. The means are in the predicted order for both the "many" and the "few" choice criteria groups and, therefore, in total. Table 2 presents the results of the two-way univariate analysis of variance. Both main effects are significant while the interaction is not. The results confirm both hypotheses.

TABLE 2
Univariate Analysis of Variance

Source of Variation	d. f.	Mean Square	F
Choice Criteria	1	9.356	10.002 (p<.01)
Rating Variability	2	18.038	19.284 (p<.01)
Interaction	2	.173	.185 (NS)
Error	294	.936	

Discussion

The results confirm the view that, even though relatively few brands were presented for evaluation, participants did not consider all of them to be acceptable. The "grand mean" is an evoked set size of only 2.45 brands. That the size of the evoked set seems to depend on the number of choice criteria used and the nature of the available information is consistent with the expectation that participants would engage in a simplification strategy to construct an evoked set. The evoked set is largest when relatively few choice criteria are applied to information which indicates that the brands are of fairly uniform "high" quality. When many choice criteria are applied to information which represents brands to be of relatively lower quality (but very good on some attributes and very poor on others), the participants responded by shrinking their evoked set size. This suggests at least two observations.

First, that people appear to construct an evoked set of a size dependent on the conditions of the study implies that greater attention should be paid to this phenomenon in information processing studies. Since there appears to be no way to directly manipulate the size of an evoked set, it can operate as an uncontrolled and possible confounding variable in information processing experiments. Although there does not appear to be any evidence bearing on the issue, it seems reasonable to assume that "overall" ratings (or rankings) of brands which are not included in the evoked set (i.e., are in the "inept" or "inert" sets) would be less reliable and/or less valid than those of brands included in the evoked set. Studies which attempt to fit models to "overall evaluation" ratings (or rankings) for all brands in the awareness set (or about which information is provided in an experimental setting) should probably closely consider the saliency of the attributes presented and the variability and mean levels of the information to which participants are exposed.

Second, it has been argued that, for persons using more choice criteria, decisions are more complex (Park, 1976). This seems reasonable as long as decision makers are combining attribute information in a manner simulated by one of the compensatory models. Indeed, the finding that persons using more choice criteria constructed smaller evoked sets may be explained by arguing that they anticipated the large number of comparisons which would have to be made and, thus, felt strongly impelled to reduce their evoked set size. However, as noted by Reilly and Holman (1977), using the "number of choice criteria" as a stratifying variable creates self-selected treatment groups and causal inferences become impossible. On the other hand, because there are substantial inter-individual differences in the number and saliency of choice criteria, manipulation of this variable is, if not impossible, so difficult as to rule out a straight-forward test of the relationship between the number of criteria used and complexity. In the present

study, since the evoked set shrank as the variability of attribute information increased (while the mean levels decreased), it appears more parsimonious to infer that the use of more choice criteria increased the likelihood of "knocking brands out" by finding some attribute which failed to achieve a minimum acceptance level. To the extent that persons "sort" brands to construct an evoked set, it appears that the use of more choice criteria does not increase complexity but, rather, facilitates simplification.

CONSUMER-ORIENTED VERSUS ADVERTISER-ORIENTED
LANGUAGE: COMPREHENSIBILITY AND SALIENCE OF THE
ADVERTISING MESSAGE

Martin R. Lautman, Associates for Research in Behavior, Inc.
Larry Percy, Gardner Advertising, Co.

Abstract

While the effectiveness of advertising is directly related to a receiver's ability to comprehend its message, too frequently advertising utilizes language which is neither salient nor understandable to the receiver. This paper addresses this problem of advertiser-consumer language compatibility in advertising, and illustrates a method, based upon a qualitative-quantitative research progression, for insuring understandable and meaningful copy in one's advertising.

Consumer-oriented Versus Advertiser-oriented Language:
Comprehensibility and Salience of the
Advertising Message

The effectiveness of an advertisement is directly related to the ability of a target audience to comprehend its message. This comprehension is a function of the message being presented in a manner highly compatible in both linguistic structure and semantic content with that commonly experienced and expected by the target audience (Lautman, 1974). In the broadest sense, to the extent the audience must make a series of simplifying "transformations" of the message to understand it, comprehension can be expected to suffer. Various studies have been directed toward these issues. For example, it has been shown that certain sentence structures (Wright, 1969; Olson and Filby, 1972) and various technical wordings (Lautman, Siegel, and Burkett, 1973; Siegel, Lautman, and Burkett, 1974) tend to affect the comprehensibility of a prose message.

The results of these and other psycholinguistic studies directly relate to the issue of advertising comprehensibility. Frequently, an advertiser is concerned that detailed or technical attributes of his product be clearly communicated to consumers. He is apt to select some specific technological superiority and use that "benefit" as the basis for differentiating his product. Or, more commonly, he may wish to include all of the features he perceives to be important, regardless of their inherent meaningfulness or salience to the consumer.

In attempting to execute copy describing these technical features, a copywriter often finds that descriptions and terminology must be included which may have little meaning to the consumer. More often than not, there is a strong tendency to use the advertiser's technical terminology rather than the consumer's language in composing these product descriptions.

A somewhat different scenario with similar results occurs when the advertiser uses terminology which over time has acquired alternative meanings. In the pharmaceutical area, for example, usage of the term "broader spectrum" for an antibiotic can mean either effective against more strains of a single type of bacteria or effective against more types of bacteria. Once again, in order to accurately advertise his product and make clear its advantages the advertiser is faced with understanding how his target audience perceives this frequently used technical term.

It is with these concerns in mind that this study is directed towards the problem of advertiser-consumer language compatibility and illustrates a method for insuring understandable and meaningful copy in one's advertising.

Key to this approach is a research strategy based on a qualitative-quantitative progression. Qualitative exploratory work alone, while generally able to develop a consumer language and identify salient attributes, may fail to answer for the advertiser both how best to use the consumer's language in his advertising, as well as how the consumer comprehends and perceives the salience of competitive messages. Exploratory quantitative work, while generally able to deal with these latter two questions effectively, without the benefit of the earlier qualitative exploration runs the dual risk of not identifying the most salient areas to the consumer and not developing an advertising language meaningful to him.

It should be pointed out that this qualitative-quantitative progression should not be viewed in the usual "hypotheses generating-validating" mode frequently assigned the step-wise use of focus groups and subsequent survey work. Rather, each contributes in its own right, with the initial qualitative work generating the parameters of consumer language and the subsequent quantitative exploration comparing those parameters with existing advertiser language.

This distinction is in part discussed by Calder (1976) in describing approaches for evaluating qualitative research goals. His "exploratory" approach follows the typical pattern of using focus groups to generate or select hypotheses which one plans to verify by fielding a large sample survey. A second approach, referred to as "clinical," belies the need for quantitative follow-up and relies on the "clinical" judgment of a specially trained analyst--frequently a psychologist--to reveal the underlying causes of behavior. His third approach closely follows the role of qualitative research as it is considered here within the qualitative-quantitative progression as applied to consumer vs. advertiser language. This Calder terms the "phenomenological" approach.

The phenomenological approach to qualitative research offers a description of how consumers perceive reality in their own terms. Calder points out that the goals of what he calls the phenomenological approach to qualitative marketing research is identical to that of phenomenological sociology as derived from Schutz (1967). For this reason, the phenomenological approach is ideal for describing the role qualitative research must play in the progression being suggested here for the study of consumer-advertiser language compatibility.

The advertiser for the most part, belongs to a social grouping whose perceptions are generally not the same as their target market. Reality to the advertiser is frequently divorced from that of the consumer. This appears to be especially true when the advertised products tend to be more "technologically" oriented (for example, electronics equipment) or when common usage of technical terms among a group of specialists (such

as physicians) tends to vary from traditional definitions. Using qualitative research to understand how consumers perceive a product, in their own terms, helps to bridge this social distance between the advertiser and consumer.

Quantitative research, still in an exploratory mode, is then able to juxtapose the consumer developed language from the focus groups with that used by the advertiser in an effort to sort out commonalities and misinterpretations, and provide guidance for those message points, again based upon consumer language, important to a positive buyer response to the advertising.

Study Design

In an effort to develop a consumer-relevant language for an electronics product, and assess the degree of congruence between the consumer-relevant language and that used by various advertisers in the category in describing product benefits, a two-part research study following the qualitative-quantitative progression outlined above was conducted. A general outline of the study design is shown in Figure 1.

FIGURE 1
QUALITATIVE/QUANTITATIVE PROGRESSION

Focus group discussions using a phenomenological approach to determine the parameters of consumer language and the salient attributes.

Exploratory quantitative research using personal interviews to evaluate (1) the comprehension of existing advertiser language by consumers, and (2) belief congruence and preferences within and between advertiser appeals and consumer desired attributes.

Method

Six focus groups were conducted among men and women owners, and those expressing an interest in owning an electronic product. Three groups were conducted in St. Louis and three in Philadelphia. In addition to the global concern of generating the parameters of consumer language, information was sought concerning awareness of brands in the category, specific evaluations of different product features, situational effects, etc. as they related to consumer conceptualizations of the entire product area.

Follow-up exploratory quantitative work was conducted among 120 male and female respondents in three cities: Pittsburgh, Tampa, and Phoenix. Personal interviews were conducted with a sample selected on an area-wide cluster basis, stratified to insure representation along a broad demographic base. Two basic exercises were conducted: 1) pairwise similarity data and a preference ordering in terms of intention to buy were gathered among selected advertising claims; 2) perceived pairwise belief congruence strength was measured among consumer suggested features along with a preference ordering in terms of importance of the features in a brand.

In the first exercise each subject was asked to provide pairwise similarity data on eight brand appeals currently in use by major category manufacturers by sorting a set of 28 cards, where each card contained one of the $n(n-1)/2$ pairs of appeals. Subjects were asked to look through all of the cards, placing those cards they felt contained similar appeals into one pile and all those cards they felt contained appeals which were not similar into a second. They were then asked to rank the first pile from the card containing the two most

similar appeals, and to rank the cards in the second pile from those containing the two most dissimilar appeals. The order of the second pile was then inverted and added to the first, providing a ranking or all 28 pairs from most to least alike. Following this sort, each subject ranked the appeals in ascending order according to their likelihood of buying a product if all they knew about that particular brand was that it was advertised in the way described on each card.

Next, pairwise belief congruence ratings were collected for each of 28 pairs of salient attributes described in consumer-relevant terms, as identified by consumers in the initial qualitative focus groups (each pair representing one of the $n(n-1)/2$ pairs of eight attributes). Using a five-point Likert-type belief scale, each respondent was asked whether they thought a typical brand in this category that contained one attribute feature would also contain another.

TABLE 1
ADVERTISER APPEALS AND CONSUMER-DERIVED ATTRIBUTES

Advertiser-Appeals	Consumer-Derived Attributes
1. Dependability	1. Solid guarantee
2. Nurturant I	2. Powerful
3. Personification	3. Rugged
4. Nurturant II	4. Easily repaired
5. Power	5. Moderately priced
6. Adventure	6. Solid state
7. Strength	7. Portable
8. Rugged	8. Foreign made

Finally, considering each attribute individually, they were asked to rank the features from most to least important in terms of their brand choice decision. The eight advertiser-derived appeals and eight consumer-derived attributes are shown in Table 1.

Analytic Design

The data collected in the pairwise similarity rankings of the eight current advertiser-derived appeals were submitted to Kruskal's (1969) M-D-SCAL 5M program for non-metric multidimensional scaling. Solutions were sought in three, two and one dimensions. The rank-order "likelihood-to-buy" data were then imbedded into the solution space via Carroll and Chang's (1967) PREFMAP. Solutions were explored for both Phases III and IV. This joint solution provides a geometric interpretation of the perceived cognitive similarity among existing product appeals as expressed in advertiser language, along with "ideal points" reflecting those appeals most likely to attract consumer interest.

The second exercise provided mean ratings on a five-point Likert-type belief scale for each pair of eight consumer-derived attributes. Rank ordering these means provided a belief proximity measure which was introduced into Kruskal's (1969) M-D-SCAL 5M program, solving for three, two, and one dimensional solutions. The rank order preference data for the eight attributes were then imbedded into the solution space via PREFMAP giving a geometrical representation of the belief congruence associated with the consumer-derived attributes and the salience of those attributes with respect to product preference.

Results

The first step in our qualitative-quantitative progression was to generate an understanding of how consumers talk about specific consumer electronics products. The results of the focus group discussions revealed a set of eight specific product attributes, described in the consumer's own language. In addition, probing of spe-

cific technical terms indicated little consumer understanding of what a manufacturer meant when using those terms. These findings provided the necessary consumer input for the exploratory quantitative follow-up, along with a strong indication that the advertiser's language in this category was generally not understood by the consumer.

The next step was to utilize these results, along with a set of advertiser-derived appeals, in an effort to determine the impact of each on general consumer understanding and preference. Utilizing Kruskal's M-D-SCAL 5M to analyze the $n(n-1)/2$ pairwise similarities rankings of the eight current advertiser-derived appeals considered provided a usable solution configuration in two dimensions. The results shown in Figure 2 demonstrate a significant amount of perceived discrimination among the various advertiser-derived appeals. It would appear that the executions of the Dependability, Rugged, and Strength appeals, which one might reasonably expect to be quite similar, are in fact perceived as highly dissimilar. While it should be cautioned that other executions of these same appeals could produce different results, it is nonetheless significant that the appeals of these three advertisers, as expressed in their language, were not perceived to have much in common by the consumer.

FIGURE 2
NON-METRIC MULTIDIMENSIONAL SCALING CONFIGURATION
FOR EIGHT ADVERTISER-DERIVED APPEALS FROM
M-D-SCAL 5M

Pairwise Similarity
Rugged Appeal

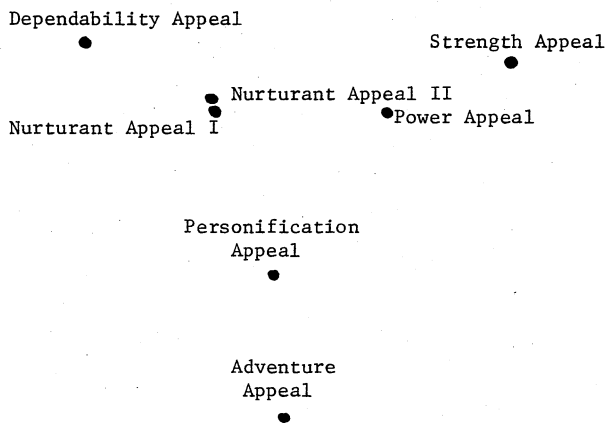

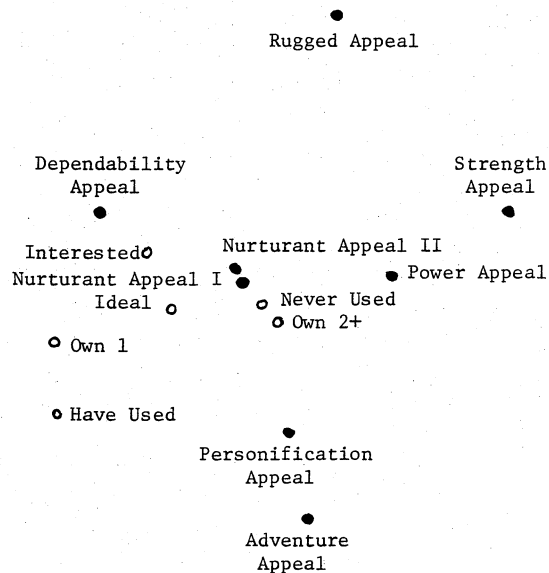

Figure 3 shows the results of a PREFMAP Phase III solution based on the likelihood to purchase given the advertiser-derived appeals. Those appeals most likely to stimulate consumer interest tend to be the Dependability appeal and the two Nurturant appeals.

FIGURE 3
TWO-DIMENSIONAL JOINT PLOT OF ADVERTISER-DERIVED
APPEALS WITH PREFERRED APPEAL FROM PREFMAP
PHASE III ANALYSIS

In an attempt to judge the extent of belief congruence among the consumer-derived attributes, the beliefs for each of the $n(n-1)/2$ pairs of attributes were analyzed via Kruskal's M-D-SCAL 5M. The resulting configuration shown in Figure 4 suggests that while consumers believed a product may be rugged, solid state, and have a solid guarantee, a product with these attributes had little in common with a product described by any of the other attributes. A powerful product, for example, was unlikely to be believed easily repaired or foreign made.

FIGURE 4
NON-METRIC MULTIDIMENSIONAL SCALING CONFIGURATION
FOR EIGHT CONSUMER-DERIVED ATTRIBUTE BELIEFS
FROM M-D-SCAL 5M

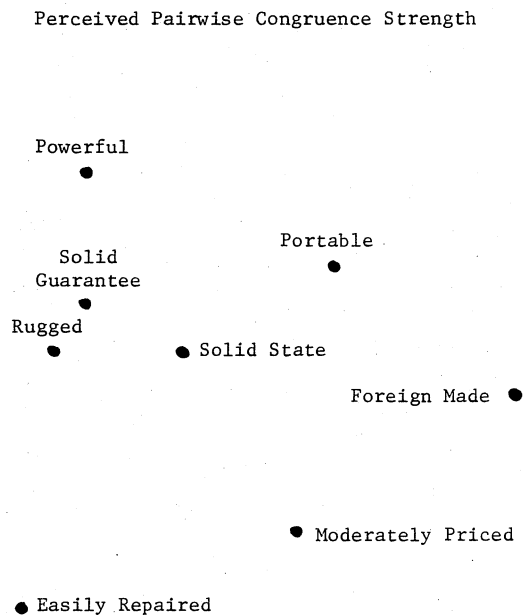

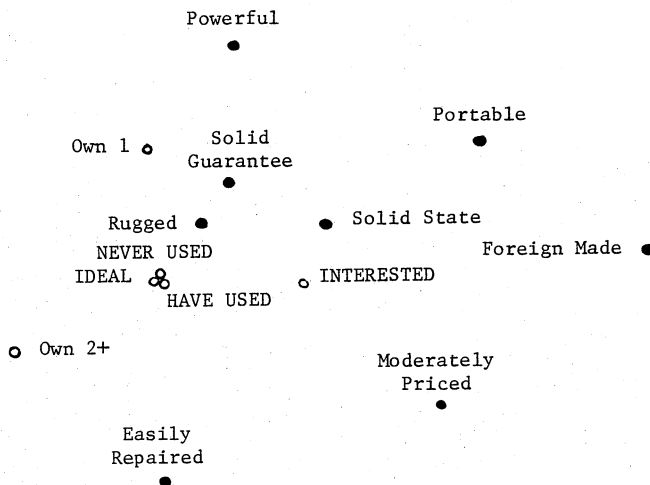

Figure 5 shows the results of a PREFMAP Phase III analysis of preference within the belief congruence solution configuration. It shows that while the rugged-solid guarantee features tended to be most preferred among non-owners, single product owners skewed towards powerful, and owners of two or more towards easily repaired.

Perhaps the most interesting overall finding was the extent to which little compatibility seemed to exist between the advertiser-derived appeals and the consumer-derived attributes. Advertisers were not generally addressing consumer wants with consumer language. Only the Dependability appeal appeared to be compatible with the "rugged - solid guarantee - solid state" cluster of consumer-described attributes. The advertiser's version of Rugged and Strength were not perceived as such by the consumer; and the advertiser's interest in Nurturant appeals (and miscellaneous others) did not seem to be reflected in desired consumer attributes.

FIGURE 5
TWO-DIMENSIONAL JOINT PLOT OF CONSUMER-DERIVED
ATTRIBUTE BELIEFS WITH PREFERRED ATTRIBUTE
ASSOCIATIONS FROM PREFMAP PHASE III ANALYSIS

The technical approach outlined here did not include a direct joint comparison of advertiser appeals and consumer-derived attributes. Two separate analyses were conducted and the results were compared. A more direct approach, and one which is advocated, is to have respondents compare the appeals in terms of the attributes. For example, the appeals might be rank ordered or rated in terms of their perceived offering of each salient attribute. An unfolding analysis might then show how much each attribute is associated with each appeal. Appeals viewed as best in terms of offering positively salient attributes might then be selected. When the observed incompatibilities are not as great as they were here, this direct approach will be a more sensitive test.

Discussion and Conclusion

While much research has been directed towards pinpointing consumer needs and preferences (for example, Haley, 1968; Sweitzer, 1975) and selecting advertising themes and executions which reflect them (for example, Percy, Lautman, and Kordish, 1976; Smith and Lusch, 1976) little, if any, research has been channeled towards directly studying the advertiser's use of language in the copy

of the ads themselves. This study has shown that for at least one technical product marketed to a mass audience, serious communication problems may exist. It was demonstrated that consumers (1) often do not understand the advertiser's use of technical language in promoting the product and (2) do not necessarily interpret advertising appeals designed to promote a particular product benefit or benefits, as was intended, finding the advertiser's language incompatible with their own consumer-oriented needs. The qualitative-quantitative research progression outlined and demonstrated here provides a methodology for identifying and bridging language gaps between the advertiser and consumer, and helping to assure comprehensible advertising appeals describing positively salient product benefits.

It is important to recognize that the results of this study should not be interpreted as suggesting that all technical wording be removed from advertising. Obviously, in the pharmaceutical, industrial and other areas advertising must be technical. What is being recommended, however, is that the advertiser test his use of technical terminology so as to insure that his target market both understands it and views it in the context of his appeal as directed towards promoting positively salient attributes.

Compatibility problems between advertiser and consumer-oriented appeals emanating from language can have various sources. First, particular words may not be generally understood. Second, particular words while generally understood may have multiple meanings and the context in which they are presented may not clearly identify which one is appropriate. Third, certain syntactic structures are more difficult to process and comprehend. Finally, the theme of the advertising may be misinterpreted or missed entirely through problems such as poor copy organization, inappropriate use of examples, unexpected or unusual presentations of the copy, etc. This study dealt only with the first, second, and, to a certain extent, the last of these sources of problems. Research on the third problem, the comprehensibility of various sentence structures, while studied extensively by psycholinguists (see Wright, 1972; Garrod and Trabasso, 1973; Kanouse, 1972; Abelson and Kanouse, 1966), has not often been directly investigated by consumer researchers in terms of identifying prose structures most suitable for advertising communication. The authors have found in an as yet unreported study that variations in sentence structure can have a significant effect on advertising headline believability, suggesting more inquiry into this area by researchers interested in consumer response to communications.

Perhaps the most important conclusion which can be drawn from this study is that advertisers cannot take for granted that a target audience will comprehend and interpret their appeals/language in the manner intended by the agency (Lautman, Percy, and Kordish, in press). In the process of translating advertising objectives into copy, care must be taken that the creative approach should not overwhelm or distort the intended communication. Even when technical terminology is not involved, usage of a consumer-oriented language can be expected to lead to easier comprehensibility of the advertiser's message. Testing that the advertiser's intended message is, in fact, the one being communicated to the target audience is a necessary step in assessing the effectiveness of any advertising copy.

Abstract

This paper uses a model of consumer buying behavior to identify household characteristics that should affect deal proneness. The model assumes that the household makes purchasing and inventory decisions much like a firm. In other words, the household's purchasing decisions are based on factors such as transaction costs, holding costs, and stockout costs in addition to product price. Household characteristics are then related to these cost parameters to predict which households are likely to be deal prone. The predictions are tested empirically using panel data on five frequently-purchased products. The empirical results indicate that it is possible to identify the deal prone household and that the key variables that affect deal proneness are household resource variables such as home ownership and automobile ownership.

Introduction

Marketing managers have always been interested in identifying the deal-prone household on the basis of available demographic data. If such households can be identified precisely, specific marketing strategies designed to appeal to such households are likely to be more effective. For example, demographic information is available by zip codes or census tracts. If certain demographic groups are more deal prone, coupon distribution could be restricted to those areas where households with higher deal proneness reside. This would reduce couponing costs with a less than proportionate reduction in response. Similarly, more accurate identification of deal prone households would increase the marketer's ability to match deal prone households and media audience characteristics, thus increasing the efficiency of media distribution of coupons and other promotional items.

Several studies have tried to identify the deal prone household. Webster (1965) and Montgomery (1971) have published two of the better known studies. The results of these and other studies are summarized by Frank, Massy, and Wind (1972, p. 124) who state:

The results of cross-sectional studies, almost without exception, indicate that there is, at best, only a modest degree of association between demographic, socioeconomic, and/or personality characteristics, and selected aspects of household purchasing behavior, such as total consumption, brand loyalty, and deal proneness.

One reason for this "modest degree of association" may lie in the methodological approach usually taken in these studies. Typically, a large number of potential explanatory variables are regressed against the proportion of purchases made on deal in a search for statistical significance. For example, Webster (1965) ran 200 regressions with different combinations of 45 explanatory variables. This approach is open to serious question because one cannot always determine if "signi-

ficant" relationships reflect a valid relationship or a spurious one which has arisen by chance alone. Without a theory to indicate which variables should affect deal proneness, there is a greater danger of accepting spurious results.

A related deficiency of prior studies of deal proneness arising from the absence of a clearly stated theory has been improper specification of explanatory variables. For example, Montgomery (1971) included "presence of children" as an independent variable in a model but was unable to predict a priori whether the presence of children should or should not increase deal proneness. However, if one hypothesizes that it is the age of the children that affects deal proneness (rather than their presence per se), it is possible to predict a priori the impact of "age of children" upon deal proneness. If the children are below the age of six (and are consequently not yet in school), they require more of their parents' time, thus reducing the time available for shopping. Having less time to shop leads to fewer shopping trips and fewer opportunities to take advantage of deals, thereby reducing the household's deal proneness. Montgomery's results led him to conclude that presence of children was not related to deal proneness. However, by considering the presence of children without determining how their presence should affect deal proneness, Montgomery may have arrived at an incorrect conclusion about a variable which, if properly specified, could well be related to deal proneness.

Like the studies cited above, this paper also attempts to identify the deal prone household. However, the approach used here is quite different from that used in most of the earlier work. We begin by formulating a model of household purchasing behavior. The model is then used to predict how certain demographic variables should affect deal proneness. Finally, an empirical evaluation of the predictions is made. The empirical results show that it is possible to identify the deal prone household using demographic variables and that the effect of these variables is substantial.

The Model of Household Purchasing Behavior

Model Assumptions

A household inventory model is developed in this section which is based on the assumption that the household is the same as any producing unit which needs to stock inventory and meet demand. This assumption follows from the notion of the household as a production unit which Becker (1965) and others have used to model consumer behavior in the economics literature. This modeling approach is used because it has proved to be very fruitful in several applied studies in economics (Michael and Becker, 1973) and also because it appears to be a potentially promising approach in marketing (Kunreuther, 1973). The inventory model proposed here also corresponds closely to models developed by management scientists to make better inventory decisions in more traditional production environments (Hillier and Lieberman, 1974, pp. 472-527).

¹This research has been funded, in part, by National Science Foundation Grant SOC73-05547.

The initial assumption in the model is that households make long-run decisions about whether to use a given product at all and the average number of units of the product to use per period. Decisions about product use and the average usage rate are determined exogenously by factors such as family size, family income, etc. It is also assumed that ratios of prices of the product in question and prices of substitutes and complements are constant during the period considered so that households need not evaluate their usage rate decision because of changes in relative price. The latter assumption is made in order to obtain a tractable model and because it permits us to concentrate on the purchase timing decision which is the basic focus of this paper.

Cost Structure of the Household

Four categories of cost affect household inventory decisions: (1) transaction cost, (2) storage cost, (3) stockout cost, and (4) the actual price of the item. Transaction cost is the opportunity cost of the time required to purchase an item once the consumer is actually in a store plus the opportunity cost of travel time required to get to and from the store where the purchase takes place. Transaction cost will vary across stores. And if a consumer has a "regular" or preferred store, one would expect the transaction cost of an item purchased there to be less than if a special trip is made to purchase the item at some other store. Storage cost represents interest on the capital required to maintain a given level of inventory plus the cost of the required space. Stockout cost reflects the foregone utility of not consuming an item which is not in stock at the time it is demanded. If the household can easily substitute other items in the event of stockout, or if it derives little utility from consuming the item, stockout cost should be low. Observed price per unit is the final component of cost. For purposes of the analysis, it is assumed that the observed price in a store is constant within any given period, e.g., a week. Prices may vary across stores and may change from period to period.

Mathematical Formulation of the Model

The household's purchase decision process is represented mathematically in Exhibit 1. The model shown requires the consumer to minimize expected costs over a finite time horizon which includes present as well as future periods. Thus, expectations about future prices and future demand affect the present period's decision. Note that though the household's average demand per period is known, the exact quantity demanded in each period is unknown at the start of the period. Thus, this quantity, \tilde{d}_t , is represented as a random variable in the model. Future price expectations are generated by probability distributions of the time between deals and the length of time a given deal is in effect. These distributions would be based on actual household experience with deal duration and time between deals in each store.

For the model shown in Exhibit 1, it is assumed implicitly that all brands in the product class yield the same utility to the consumer. Therefore, the consumer's objective is simply to minimize the "total cost" of buying the product. Again, this assumption is made only to obtain a tractable model. In order to consider the case where different brands offer different utilities, a framework which jointly considers utility maximization and purchase timing would have to be developed.

EXHIBIT 1 MATHEMATICAL FORMULATION OF THE MODEL OF HOUSEHOLD PURCHASING BEHAVIOR

$$\min_{X_{i,t}} E \left\{ \sum_t \sum_i f_{i,t} [X_{i,t}] + h_t \tilde{I}_{t-1} + u_t \tilde{S}_t \right\}$$

subject to:

$$f_{i,t} [X_{i,t}] = \begin{cases} T_{i,t} + P_{i,t} X_{i,t} & \text{if } X_{i,t} > 0 \text{ for } i=1, \dots, K \\ 0 & \text{if } X_{i,t} = 0 \end{cases}$$

$$\tilde{I}_t = \begin{cases} I_{t-1} + \sum_i X_{i,t} - \tilde{d}_t & \text{if } \tilde{d}_t < I_{t-1} + \sum_i X_{i,t} \\ 0 & \text{if } \tilde{d}_t \geq I_{t-1} + \sum_i X_{i,t} \end{cases}$$

$$\tilde{S}_t = \begin{cases} \tilde{d}_t - \tilde{I}_{t-1} - \sum_i X_{i,t} & \text{if } \tilde{d}_t > I_{t-1} + \sum_i X_{i,t} \\ 0 & \text{if } \tilde{d}_t \leq I_{t-1} + \sum_i X_{i,t} \end{cases}$$

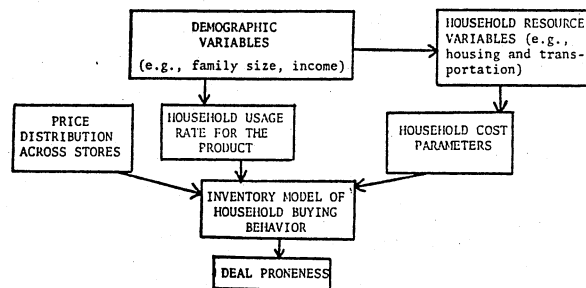

where:

- $T_{i,t}$ = transaction cost at store i at time t ,
- $P_{i,t}$ = price per unit of product at store i at time t ,
- $X_{i,t}$ = quantity purchased at store i at time t ,
- I_t = inventory on hand at beginning of time t ,
- \tilde{d}_t = quantity demanded at time t ,
- h_t = unit holding cost at time t ,
- \tilde{S}_t = amount of stockout at time t ,
- u_t = unit stockout cost at time t ,
- K = the number of stores.

Value of the Inventory Model

The inventory model described above provides a theoretical basis to identify demographic and household resource variables which should lead to deal proneness. To see this, consider Exhibit 2 which provides a diagrammatic representation of the manner in which the inventory model links demographic and resource variables with household deal proneness. Exhibit 2 indicates that the

EXHIBIT 2 DEAL PRONENESS AND HOUSEHOLD DEMOGRAPHIC AND RESOURCE VARIABLES

three inputs to the inventory model are: (1) the price distribution of the product across the stores, (2) the household usage rate for the product (which, in turn, is influenced by demographic variables such as family size) and (3) household cost parameters.

Deal Proneness and Household Cost Parameters

The first link of interest is the one that connects household cost parameters with deal proneness through

the inventory model. What does this link represent? Essentially, it indicates how the cost structure facing a household determines whether or not the household will be deal prone. For example, if storage costs were low, one would expect households to stock up on a commodity when a deal is on. Alternatively, if the transaction cost of traveling to a non-preferred store were sufficiently high, one would not anticipate a consumer to buy on a deal offered by the non-preferred store.

Cost Parameters and Household Demographics and Resources

But what factors determine the household's cost structure? To answer this question, consider the link in Exhibit 2 which connects Demographic Variables (like income) to Household Cost Parameters through Household Resource Variables (such as housing and transportation). Note first that income is an important determinant of household resources, i.e., households with higher income are more likely to own homes (as opposed to being renters) and are also more likely to own one or more cars. These household resources, in turn, affect the cost parameters of the model. For example, home owners typically have more storage space available compared to apartment dwellers and hence should incur lower storage costs. Similarly, car ownership makes transportation easier, thereby reducing the household's transaction costs.

It was noted earlier that low storage costs and low transaction costs both lead to deal proneness. Since low storage costs are associated with home ownership and low transaction costs with car ownership, it is possible to make specific predictions such as the following: home owners and car owners will tend to be more deal prone than apartment dwellers and households without cars.

One can see, therefore, that the inventory model's links with deal proneness and with household cost parameters makes it possible to (1) identify the relevant variables that should affect deal proneness and (2) predict the direction of their effect. The model is also useful in providing a quantitative evaluation of the relative impact of the various cost parameters on deal proneness (see Blattberg, et. al., 1977).

The Effect of Demographics and Household Resource Variables on Deal Proneness

In this section, we state formally our predictions of how some specific household resource and demographic variables lead to deal proneness. Because of the length constraints on this paper, only two types of explanatory variables will be studied: (1) the household resource variables mentioned earlier, i.e., car ownership and home ownership, and (2) income. Note that the data for these variables are available by zip codes or census tracts. Therefore, if these variables do affect deal proneness, the marketing manager can implement the results easily. This is in contrast to some of the variables found by Webster (1965) and Montgomery (1971) to affect deal proneness. For example, both found that brand loyalty was negatively associated with deal proneness. However, one must first identify who the less brand loyal consumers are before one can use such a finding.

Household Resource Variables and Deal Proneness

A key component of the transaction cost of shopping is transportation cost. Households that do not have cars available are forced to shop at stores that are nearby. They are also more likely to shop at a single store (see Kunreuther, 1973, p. 376). Since the ability to take advantage of deals depends upon the freedom to shop often and at many stores, households without cars should be less deal prone.

The second household resource variable is home ownership. This variable should be related to holding costs. Apartment dwellers usually have less storage space available than homeowners simply because apartments are smaller. Therefore, holding costs should be higher for apartment dwellers. Since lower holding costs should lead to greater deal proneness, homeowners should be more deal prone than apartment dwellers.

The Effect of Income on Deal Proneness

The usual argument given in support of a negative relationship between deal proneness and income is that low income households have lower time costs resulting in lower search and transaction costs. Furthermore, economic theory suggests that lower income households should be more price sensitive. Empirical research in marketing has rarely shown that income affects deal proneness (see Webster, 1965, for example). If an effect is found at all, higher income seems to lead to greater deal proneness rather than less.

The problem with studying the effects of income is that income effects are confounded by the effects of household resource variables. The influence of these other variables must be removed before the effect of income can be clearly evaluated. It was stated above that car and home ownership should increase deal proneness. Higher income households are more likely to buy capital goods such as cars and homes, thus increasing their deal proneness. The resulting interaction between income and household resources may result in the anomalous finding that high income households are more deal prone than low income households. If resources available were held constant, however, one should observe the opposite outcome.

Empirical Results

The data used to analyze deal proneness were the Chicago Tribune Panel purchase data and associated demographic variables. Consumers classified into three segments defined by Blattberg and Sen (1976): the National Brand Loyal Deal, the National Brand Switcher Deal, and Deal-Oriented, are defined here as being deal-oriented. All consumers classified into one of the other stable pattern categories (i.e., not including the Changing Pattern or Last Purchase Loyal patterns) constituted the non-deal prone population.¹ Five product categories were studied: aluminum foil, waxed paper, headache remedies, liquid detergent and facial tissue. The data were from 1958 to 1966, depending on the category.² The household variables studied are those described in the previous section.

Blattberg and Sen (1976) classified each household's purchase patterns into segments. Deal proneness was based on membership in one of the above three segments and was a dichotomous variable: deal prone or not deal prone. Given that the effect of the independent variables on deal proneness may be nonlinear, it was decided to use cross-classification analysis instead of regression (see Frank, Massy and Wind, 1972, pp. 126-129). A major problem in doing cross-classification analysis

¹The nonstable buying patterns contain some deal prone households who for certain periods of the data were deal prone and for other periods were not. They have been excluded because they were difficult to categorize. The size of this group is never more than 20% of the total consumers and is usually much smaller.

²Aluminum Foil (1962-66), Waxed Paper (1963-66), Liquid Detergent (1959-61), Facial Tissue (1958-61), and Headache Remedies (1959-61).

is that sample sizes may become small for certain cells when two or three sets of independent variables are simultaneously analyzed along with the dependent variable. This is a particularly vexing problem here because most demographic and household resource variables are inter-correlated. For example, high income households who rented and did not own a car were a very small percentage of all high income households. Initially, the data were analyzed individually for each explanatory variable. Then certain combinations of variables were considered together. In future studies, if larger samples are available, interrelationships between more sets of explanatory variables should be studied.

Household Resource Variables

The first two variables analyzed were home ownership and car ownership. Tables 1 and 2 give the results for each of the five product categories. The table entries are the percentage deal prone. For example, in the case of waxed paper, 29.5% of the households who owned a home were deal prone and 12.5% of the households who did not own a home were deal prone.

TABLE 1
HOME OWNERSHIP

Home Ownership	Product Category				
	Aluminum Foil	Waxed Paper	Headache Remedies	Liquid Detergent	Facial Tissue
Rent	30.9% ^a (81) ^b	12.5% (88)	22.7% (97)	29.6% (98)	23.4% (137)
Own	37.5% (120)	29.5% (152)	29.8% (151)	38.9% (229)	28.7% (230)

^aThe table entry is the percentage of aluminum foil buyers who rent a home and are deal prone.

^bNumbers in parentheses are total within-cell sample sizes on which each percentage is based.

TABLE 2
CAR OWNERSHIP

Car Ownership	Product Category				
	Aluminum Foil	Waxed Paper	Headache Remedies	Liquid Detergent	Facial Tissue
No Car	24.0% ^a (50) ^b	17.1% (70)	19.4% (67)	26.9% (67)	25.0% (88)
Car	38.4% (151)	25.3% (112)	30.0% (180)	38.8% (258)	27.3% (278)

^aSee Table 1, footnote a.

^bSee Table 1, footnote b.

Looking at the results in Tables 1-2, it appears that owning a car or a home makes a household much more deal prone. For every product category this result holds. These results are consistent with the predictions made in the previous section which indicated that home ownership and car ownership should lead to greater deal proneness.

One problem with analyzing the variables separately is that if one owns a car, one is also more likely to own a home. Thus, the observed effect may be due to one of the two variables and not the other. Table 3 studies the effect of the two variables jointly. The results show that except for facial tissue, owning both a home and a car results in the highest probability of being deal prone. The percentage deal prone is always higher when a household owned a car and a home than when it owned a car and rented. It is higher for 4 of the 5 products than when the household owned a home, but not a car. Thus, the effect is not due to only one of the two variables.

TABLE 3
CAR AND HOME OWNERSHIP

Home Ownership and Car Ownership	Product Category				
	Aluminum Foil	Waxed Paper	Headache Remedies	Liquid Detergent	Facial Tissue
No Car and Rents	21.2% ^a (33) ^b	14.0% (43)	22.9% (48)	28.6% (35)	18.3% (60)
No Car and Owns Home	29.4% (17)	22.2% (27)	10.5% (19)	25.0% (32)	39.3% (28)
Owns Car and Rents	37.5% (48)	11.1% (45)	22.4% (49)	30.2% (63)	27.3% (77)
Owns Car and Home	38.8% (103)	31.4% (105)	32.8% (131)	41.5% (195)	27.4% (201)

^aSee Table 1, footnote a.

^bSee Table 1, footnote b.

To get some idea of the magnitude of the effect that owning both a car and a home had on deal proneness, the following model was estimated:

$$D_{ij} = \alpha \beta_i \gamma_j \epsilon_{ij} \quad \begin{matrix} i=1, \dots, 4 \\ j=1, \dots, 5 \end{matrix} \quad (1)$$

where:

D_{ij} = percentage of deal-oriented consumers for product category j and consumer characteristic i .

α = average deal-orientation.

β_i = the effect of consumer characteristic i on deal-orientation.

γ_j = the effect of product category j on deal orientation.

ϵ_{ij} = the disturbance term.

Because product categories with very low deal proneness may have a lower absolute difference in deal proneness for a given household characteristic than product categories with high deal proneness, a multiplicative model was used. If one takes logarithms of both sides of equation (1), the effects (β_i and γ_j) can be measured using estimates calculated from standard analysis of variance formulas. The constraints are that

$$\sum_i \ln(\beta_i) = \sum_j \ln(\gamma_j) = 0. \quad (3)$$

The model is similar to the log-linear models described by Green et. al. (1977) and Bishop et. al. (1975). The exact estimates used are given in Hogg and Craig (1970, pp. 327-334).

Estimates of the model's β_i parameters are presented in Table 4. The results show that owning a car and a home had a 1.366 response, compared to not owning a car and renting, which had a .821 response. If we average across all the products so that the grand mean represents average deal responsiveness, we see that owning a car and a home increased deal responsiveness from 20.5% to 34.4%, a 67.9% increase. Owning either a car or a home, but not the other, increased deal responsiveness from 20.5% to 26.2%. It is clear, therefore, that owning both a car and a home greatly increases deal responsiveness, compared to not owning either or owning only a car or only a home.

³This constraint is the same as requiring $\prod_i \beta_i = \prod_j \gamma_j = 1$.

TABLE 4
CAR AND HOME OWNERSHIP

Grand Mean = 24.9%

Category	Response
No Car and Rents	.821
No Car and Owns Home	.932
Owns Car and Rents	.957
Owns Car and Home	1.366

Income

On theoretical grounds, household income level should be negatively correlated with deal proneness. Empirically, the opposite relationship may be observed because of the effects of confounding variables. Table 5 gives the results of income for three income levels -- low (\$0-5999) medium (\$6000-8999) and upper (\$9000 or more). The income categories are based on roughly 33% groupings. The results indicate that contrary to theoretical predictions, upper income households are more deal prone than low income households. For every product category except facial tissue, a higher percentage of upper income households are deal prone compared to low income households. The effect is not large in most categories, but it is persistent.

TABLE 5
INCOME

Income Level	Product Category				
	Aluminum Foil	Waxed Paper	Headache Remedies	Liquid Detergent	Facial Tissue
0-5,999	31.0% ^a (84) ^b	19.6% (97)	28.0% (100)	28.1% (114)	31.4% (137)
6,000-8,999	39.1% (64)	23.9% (71)	23.0% (87)	36.8% (114)	19.2% (125)
> 9,000	35.8% (53)	26.9% (52)	31.1% (61)	44.4% (99)	29.5% (105)

^aSee Table 1, footnote a.

^bSee Table 1, footnote b.

To isolate the effects of confounding variables, income was analyzed adjusting first for home ownership and then for car ownership. (Because cell sizes became very small, it was impossible to analyze income simultaneously with both home and car ownership). Tables 6-7 present the results. They indicate that if one adjusts for resources available, the income effect no longer persists (except for liquid detergent).

TABLE 6
HOME OWNERSHIP AND INCOME

Income Level and Home Ownership ^c	Product Category				
	Aluminum Foil	Waxed Paper	Headache Remedies	Liquid Detergent	Facial Tissue
0-5,999 and Owns Home	37.1% ^a (35) ^b	28.9% (58)	40.9% (44)	31.8% (66)	35.0% (62)
0-5,999 and Rents	26.5% (49)	13.6% (59)	17.9% (56)	22.9% (48)	29.3% (75)
6,000-8,999 and Owns Home	45.0% (40)	30.2% (53)	22.0% (59)	36.1% (85)	25.5% (85)
6,000-8,999 and Rents	29.2% (24)	5.6% (18)	25.0% (28)	35.7% (31)	10.0% (40)
9,000 or More and Owns Home	31.1% (45)	29.3% (41)	29.2% (48)	47.5% (80)	30.1% (83)

^aSee Table 1, footnote a.

^bSee Table 1, footnote b.

^cCertain categories were omitted because the sample sizes were too small.

TABLE 7
CAR OWNERSHIP AND INCOME

Income Level and Car Ownership ^c	Product Category				
	Aluminum Foil	Waxed Paper	Headache Remedies	Liquid Detergent	Facial Tissue
0-5,999 and No Car	21.6% ^a (37) ^b	17.6% (51)	20.0% (45)	21.1% (38)	25.9% (58)
0-5,999 and Owns Car	38.3% (47)	21.7% (36)	35.2% (54)	32.0% (75)	35.4% (79)
6,000-8,999 and Owns Car	37.5% (56)	23.3% (60)	25.0% (72)	37.5% (96)	19.0% (105)
9,000 or More and Owns Car	39.6% (48)	27.3% (44)	31.5% (54)	46.0% (87)	29.8% (94)

^aSee Table 1, footnote a.

^bSee Table 1, footnote b.

^cSee Table 6, footnote c.

To see this more clearly, Tables 8-9 present the β_1 parameter estimates for the model in equation (1). First, for income and home ownership, the highest deal-oriented category is low income households that own a home. The difference between rents and owns for all three income groups is dramatic. The income effect seems to disappear when rent or own is taken into account. Similarly for car ownership, the income effect is small compared to whether a car is owned.

6,000-8,999 and Owns Car	.974
9,000 or More and Owns Car	1.213

^aSee the footnote to Table 8

Thus, higher income does not lead to deal proneness as would be concluded if the income effect were not adjusted for car and home ownership. If the effects of car and home ownership could be simultaneously partialled out, we would expect to find even stronger evidence that lower income households are more deal prone than higher income households.

CONCLUSIONS

This paper has used a specific model of buyer behavior to identify household variables which should affect deal proneness. The model assumed that households make inventory decisions the same way that firms do. The variables that affect the buying decision are holding costs, stockout costs, transaction costs, purchase price and usage rates. Household characteristics were linked to these cost variables, and predictions were made about which types of households should be deal prone. The predictions were then tested empirically.

The empirical results showed that household resource variables: car and home ownership, were strong predictors of deal proneness. 34.4 percent of the households that owned a car and home were deal prone. Only 20.5 percent of the households that did not own either a car or a home were deal prone. The effects of income were also analyzed and the results showed that upper income households were more deal prone. However, when income was adjusted for household resources, this effect became negligible.

COMPARATIVE ADVERTISING: ISSUES AND PROBLEMS

Michael Etgar, State University of New York at Buffalo
 Stephen A. Goodwin, State University of New York at Buffalo

Abstract

The recent growth in use of comparative advertising has led to increased efforts to measure its effectiveness. Empirical efforts in this area should address seven important research issues. This paper identifies and expounds upon these issues and evaluates recent empirical studies of comparative advertising, particularly with respect to the way they have addressed these issues.

Introduction

The general research issue involving the communications-effectiveness of comparative advertising as compared to alternative message-presentation styles cannot be resolved until a large number of research questions have been tackled and answered. It is possible that the effectiveness of comparative advertising messages will depend substantially on the specific conditions under which the ad is communicated. In particular, interaction effects need to be identified and measured, and the nature of the advertisement, the message, the promoted product, the compared-to-product(s) and the respondents must be carefully and explicitly specified.

This paper deals specifically with issues that should be addressed when studying and researching the effectiveness of comparative communications vis-a-vis other types of message appeals. In order to accomplish this, we review seven studies which empirically addressed the effectiveness of comparative advertising, our focus being placed upon elicitation of major issues and the extent to which these studies come to grip with such.

All seven studies to be reviewed used an experimental design of one form or another. In these experiments, a group of subjects were exposed to comparative ads while other groups were exposed to some form of a non-comparative communication. The effectiveness of each type of message style was generally measured along a vector of effectiveness variables (typically linked to some part, or all, of a hierarchy-of-effects model) computed from respondents' paper and pencil responses.

In order to facilitate presentation, the issues and research findings from the above-mentioned seven studies are summarized below in Table 1. In this Table, the issues are listed horizontally while the seven studies are listed vertically in approximately chronological order. Cell entries reflect positions taken on an issue and/or whether or not the specific issue was addressed.

VII. Testing & Methodology							
1. Independent variables	Type of message appeal (C - NC)	C - NC ads, Advertising competitive position, Claim substantiation, Copy theme	Type of message appeal (unsubstantiated, subjective C)	BX vs C	Media (audio & print), Type of message appeal (BX or C), Type of sponsor (supermarket or fast food chain), Market position of sponsor (leader or follower)	Type of message appeal (C or NC), Message-sidedness (1 or 2), Market position of sponsor (leader or follower)	Type of message (C vs BX), Substantiation (substantiated vs unsubstantiated)
2. Dependent variables	Believability, Confusion perception of important differences in brands advertised, Unaided brand identification, Persuasiveness of ad (pre- & post-exposure brand choice differences)	Purchase intentions, Relative importance of product attributes mentioned in ad	Ad informativeness, Believability, Offensiveness, Interestness; Product quality, Trustworthiness of sponsor	Unaided brand recall, Perceived credibility of claim, Perception of sponsor's competitive position, Message recall one week after exposure (& claim recall but aided)	Unaided recall, Aided recall, Over-all brand attitude measures, Dynamism, authoritativeness & character of message	Attitude & belief scale, Unaided & aided recall, Free response protocols, Dynamism & character of message	Measures of reliability & helpfulness
3. Pre-tests/manipulation checks	None	None	None	None	None	None	None
4. Covariates/block variables	Considered only product class users for analysis	Brand loyalty (toward advertised & compared-to-brand)	Considered only product classes which were familiar & used by subject population	Prior preference of compared-to-brand established, Kelman & Cohler's test for cognitive clarity	None	None	Users and non-users
5. Analytical technique	Difficult to determine	Analysis of covariance, Analysis of variance	Analysis of variance (split plot design), Scheffe multiple comparison test	Goodman's contingency table analysis, Mann-Whitney U test, Chi-square analysis	Analysis of variance, Multiple comparison tests	Analysis of variance, T-tests	Regression

Discussion of the matrix is row-wise, reflecting our primary interest in the issues involved. In each instance, we discuss the research topic involved and then the approaches taken (if any) by specific authors. A critical review of these approaches is presented and in some cases suggestions for improvement are offered.

The issues explored pertain to five major dimensions: the characteristics of the brands which appear in the ad, the audience toward whom the ad is directed, the message design utilized, other factors relating to the ad (media utilized, multiple exposures, etc.), and the methodology used for testing and evaluating ad effectiveness.

Product Class/Brand Characteristics

It is generally accepted among marketing scholars that (regardless of the type of message-style utilized) an advertisement should develop and/or reinforce audience cognitions, attitudes, and intentions which will ultimately lead to trial and (hopefully) repeat purchase of the advertised brand. Whatever the reference point, it would seem obvious that certain characteristics of the brands presented in a communication can have crucial implications for message design. In evaluating the effectiveness of one type of message design versus another, such characteristics should be analyzed.

While in non-comparative (typically referred to as supportive) ads, designers have to be concerned only with the characteristics of the promoted brand, in comparative communications they have to consider also those of the compared-to-brands as well as the dimensions of comparison (e.g., product attributes) to be used in the ad.

Characteristics of the Advertised Brand

Product Typology. A major rationale advanced in favor of comparative advertising is that naming names of specific brands to which the advertised brand is compared, provides the consumer with more factual information and consequently aids him in making more rational brand choices (c.f., Wilkie and Farris, 1975). Consequently, comparative advertising is primarily applicable to messages which compare specific measurable product attributes such as weight, price, speed, etc., and therefore may be especially applicable for products which are primarily bought because of their functional attributes; namely, their performance along measurable dimensions, or their capacity to perform specific measurable tasks.

A large number of products, however, are bought not because of their task-related capacities, but because of the psychological or social benefits which they promise. The ability of an ad to compare and contrast performance of different brands in providing elusive benefits is more restricted. While one can establish or claim with a reasonable degree of credibility (of course, the Substantiation Doctrine of 1972 would apply in this instance; FTC Report, 1972) that one automobile brand, for example, has a better gas mileage performance than another brand, it is difficult to extend the argument and claim that one auto confers more status to its user than another brand.

The effectiveness of comparative advertising may therefore depend on whether the advertised product provides primarily functional, utilitarian benefits or social/psychological ones. However, none of the seven studies summarized in Table 1 have explicitly considered this issue by integrating it into the experimental designs, or comparing comparative advertising effectiveness for different product classes (differing along a functional-social continuum).

Product Life Cycle Stage. While some researchers used existing brands in their experiments, others relied on new (typically fictitious) brands as the advertised stimulus. The use of existing and well-known brands in an experiment raises the issue of subjects' prior experience with and current attitudes toward such brands. It is important to recognize that such predispositional information should be controlled for. In many cases, consumers have well established perceptions and opinions about specific brands which may have required prolonged promotional effort involving the encoding of numerous messages over substantial periods of time. Not controlling for such "contamination" would tend to complicate inferences drawn from an experimental study.

Additionally, it is reasonable to expect that "one exposure" experiments (which was the case for all seven published studies) could create insignificant marginal changes in respondents' attitudes and perceptions of well-known brands (in at least a "maturity" stage of the product life cycle), regardless of the message design utilized.

Thus, unless subject predispositional variables are taken into account (e.g., through analysis of covariance or use of a treatment-by-levels type design; Lindquist, 1956), it is preferable to develop messages for new fictitious brands.

Characteristics of The Compared-to-Brands

Naming of Compared-to-Brands. As defined by Wilkie and

Farris (1975) a comparative advertisement must either specifically name the compared-to-brand(s) or refer to them in such a way as to leave no doubt regarding what they are. Additionally, the comparison must involve specific attributes of the brands.

If we utilize Wilkie and Farris' definition as a reference point, then any indirect comparison should be general so as to preclude consumer recognition of a specific comparison (e.g., Brand A lasts longer than other leading brands, as opposed to Brand A lasts longer than the leading seller).

The so-called "supportive" or non-comparative ad may also be viewed, at the most general level, as a comparative ad. Even where there is absolutely no allusion to a competitive offering, where the message communicates only information about the promoted brand, is it not fair to say that the consumer is likely to mentally make a comparison with available and known alternatives? Thus, we have a continuum of message approaches which include truly comparative communications, Brand X ads, and supportive ads. In operationalizing communication styles, care must be taken to ensure that the experimental ads truly reflect the underlying conceptual structure. For example, in the Prasad (1976) study, it is extremely likely that a number of subjects knew which brand was the "leading brand" of movie cameras. If this assumption is tenable, then Prasad has not, in fact, manipulated comparative versus Brand X ads. In effect both conditions presented comparative communications (particularly for knowledgeable respondents).

In reviewing the seven studies, we see that there is some doubt as to the existence of isomorphic relationships between concept and variable; and this is particularly the case for the so-called Brand X advertisement.

Market Position of Compared-to-Brand(s). The market position(s) of the compared-to-brand(s) are important to consider because such position(s) may affect the consumer's frame of reference as it relates to the evaluation of the brand promoted. One strategy commonly found is to compare the promoted brand to the leading brand in the pertinent generic product class though its superiority is far from established. One assumed advantage of using a leading brand for comparison is that it can potentially reduce misidentification of the promoted brand and misunderstanding of the corresponding message as well as attract the attention of current users of the leading brand and thus, at a minimum, lead to increased likelihood of greater awareness for the advertised brand.

Other researchers disagree. Kershaw and Tannenbaum (1976) argue that where both the promoted and the compared-to-brands are relatively unknown to the audience, the viewers may confuse the brands, possibly leading to the paradoxical situation whereby a comparative ad improves consumer attitude toward (and ultimately sales of) the compared-to-brand.

Still other opinions reflect the belief that use of market leaders for comparison may be a futile exercise in increasing awareness. While a greater number of consumers might be attracted to the ad, these people may be much less prone to change their attitudes and purchase behavior patterns due to their brand loyalty; further, such brand loyal consumers may be more likely to disbelieve the message claims made by the "new" (or small, in terms of market share) brand. Perhaps, then, anchor brands should be other than the market leader.

So far, none of these arguments has been validated by actual research. Even though Golden (1976) and Mazis (1976) have manipulated the market position of the sponsored brand, to date, none of the published studies have manipulated the market position of the compared-to-brands. Clearly this area may be very important

vis-a-vis practical marketing strategy implementation.

Similarity of Brands. In many generic product classes, subgroupings exist. For example, even though economy, luxury and sports cars belong to the same general product class of automobiles, consumers may use different evaluative criteria and hold different evoked sets in each group.

Comparison claims between brands from different subgroups may be tenuous. There are two points to be made in this context; first, consumer perceptual/attitudinal evaluation of ads which make "dissimilar comparisons" may be more negative than for comparisons involving brands likely to be included in the typical evoked set; second, the legal ramifications of such a strategy are not clear. While the claims made may be literally true (e.g., VW has more trunk space than Cadillac Coupe de Ville, better gas mileage than Mercedes 220 SL, etc.) the impression made may be false. Thus, the advertiser considering a comparative message appeal between dissimilar items runs the risk of FTC involvement on the basis of advertising deception. None of the published studies have dealt with this issue. It merits empirical inquiry.

Number of Brands Compared. Some comparative ads include only one compared-to-brand; others use several. On an a priori basis, there is little behavioral evidence to indicate which approach should be more effective, if any. However, it may be reasonable to expect that a substantial increase in the number of brands compared can add to communication noise (e.g., information overload), while a modest comparison set may improve the credibility of the message. The bulk of the reported studies utilize only one brand for comparison. The exception is McDougall (1976) who used two. Experimental manipulation of this variable has not, in any case, been operationalized.

Product Attributes on Which Brands Are Compared

Number of Attributes Presented

Comparative ads found currently in the media reflect a diversity of approaches. While some restrict discussion to one product characteristic, many make comparisons on multiple dimensions, believing that more information lends additional credibility concerning the claim (or in order to be consistent perhaps with a particular positioning strategy which management wishes to invoke). The issue of course is to find out, other things being equal, the differential effects (if any) due to presentation of differing amounts of attribute information.

Perhaps the "information overload" (Jacoby, et al., 1974) framework which suggests that consumer evaluation of ad and brand advertised conforms to some kind of inverted u-shaped function of amount of information provided in the communication is useful here.

If this argument is tenable, a comparative ad which uses one or a small number of attributes as comparison points may have more "positive" effects than similar appeals making a greater number of attribute comparisons; or, perhaps an intermediate amount of brand characteristic information would be "best". Most of the studies in Table 1 have used one or two product attributes for comparison: two (Prasad, 1976; and McDougall, 1976) have used four characteristics. None of these studies, however, have operationalized an "amount of attribute information" variable and attempted to compare the impact of change in this variable on communicative effectiveness.

Saliency of Brand Attributes

The effectiveness of a comparison between two or more brands on a specific attribute dimension in terms of

consumer evaluative response may depend very much on the relative importance (perception of saliency) of the attributes for the targeted audience. If the discussed characteristics provide important benefits to the consumer, then the comparison may be interesting and informative, and likely to make a positive impact. Consumers who are only marginally interested in the brand attribute(s) discussed may not be influenced at all (or even negatively influenced).

Consequently, pretesting the saliency of brand attributes should be a basic initial step in any research design for testing effectiveness of comparative communications. Yet none of the published studies reported in Table 1 have selected product attributes according to such a pretest; therefore, it may be that, for the subject population studied, marginal or non-salient attributes were used for comparison. Golden (1976) did measure product attribute importance in her study, but apparently only after selection for the experiment. She found that selected attributes were rated as important; but she had no way of knowing if others, not included, were relatively more important.

Respondents

Type of Respondents

Researchers studying effectiveness of comparative advertising have employed two distinct groups of subjects: students and female heads of households (housewives). Use of adult housewives has generally been lauded due to the ostensible increase in external validity of the study results. Furthermore, it may be likely that housewives are more concerned with product classes which have been utilized in the various studies, and consequently are more involved in the task presented them regarding assessment of ad and brand advertised. Still, use of students as subjects may be entirely acceptable and consistent with improved external validity if product classes advertised are salient to them (i.e., they purchase and consume brands from such product classes). Two of the studies in Table 1 (Ogilvy and Mether, 1975; and McDougall, 1976) have used female heads of households as subjects; the others have used students. Only Wilson (1976) and Prasad (1976) explicitly measured product/brand relevance explicitly.

Knowledge of the Product Class/Brands

In order to derive evaluative conclusions from a message presented by a comparative communication (or any type of appeal, for that matter), the consumer will draw upon knowledge gained about the compared-to-brands. Certainly, lack of such knowledge will have some impact on the evaluation process; at the extreme, evaluations of the comparison claims may be meaningless to a particular viewer heretofore unknowledgeable about the product class and/or brands promoted and compared. Of the studies reviewed, only Wilson's checked for degree of prior consumer knowledge.

Usage Rates. A useful surrogate for product knowledge, perhaps, is usage rate which details the extent to which the consumer has been buying or using various brands from the pertinent product class(es). Usage rates were not incorporated in any of the studies in Table 1.

Brand Loyalty. Related to usage is the notion of brand loyalty. Consumers who exhibit substantial brand loyalty to compared-to-brand(s) in comparative communications may be likely to resent the comparative claim(s), perhaps in response to cognitive dissonance. Whether or not, in principle, this cognitive response is general, the point remains that respondents should be measured on this basis to permit an examination of such effects. As with the above suggested measures, brand loyalty measurements

permit increased control of error variation, and can be utilized in experimental designs via covariance analysis or directly in the form of a leveling variable.

Brand loyalty was incorporated in two studies: Golden (1976) and McDougall (1976). Golden measured brand loyalty by subjects' reported relative frequency of purchase of the advertised and compared brands, and used it as a covariate in an analysis of variance design. McDougall measured brand loyalty by assessing subjects' degree of agreement with a semantic differential statement with endpoints "loyal to the (specific) brand" and "different brands are purchased", or "don't buy". He then compared the means of responses regarding subjects' opinions as to the reliability and helpfulness of the ads between loyal and non-loyal subjects, by using a simple t-test.

It should be mentioned, too, that Prasad (1976) measured his subjects regarding the number who already (prior to the test) preferred the compared-to-brand (in this instance, Kodak XL movie camera); he found, via nonparametric tests, that there was no evidence of "selective recall" between Kodak-preferred and non-Kodak-preferred groups.

Personality Traits

While we do not advocate use of general personality inventories (Kassarjian, 1971), we do feel that certain carefully selected measures may shed additional light on consumer response to comparative vis-a-vis non-comparative communications. In particular, those traits which pertain to the ability and motivation of the consumer's processing of information varying in terms of uncertainty, ambiguity, etc., are of some interest. While none of the six authors incorporated personality trait measures in the external designs a couple can be mentioned here. The Mehrabian-Russell Arousal-Seeking Tendency Scale (Mehrabian and Russell, 1974) which measures the general tendency or proneness of curiosity-seeking/variety-seeking behavior is one example. Consistent with a point mentioned by Wilkie and Farris (1975) that comparative ads are likely to be perceived as more novel than "ordinary" supportive message appeals, we should find that consumers high on arousal-seeking tendency would evaluate comparative ads more positively than those consumers "low" on arousal-seeking tendency. A second example is Kelman and Cohler's (1967) test for "cognitive style". This test identifies two major styles regarding consumer's characteristic mode of resolving cognitive uncertainty: clarifiers (people who react "positively" to uncertainty by seeking clarification, additional information, etc.) and simplifiers (people who simplify their environments by keeping out obtrusive cognitions, and tend to avoid uncertainty at "all costs"). Assuming that the information encoded in comparative communications may arouse the cognition of uncertainty or ambiguity (at least as compared to a more traditional supportive communication), it may be reasonable to suppose that clarifiers will explore comparative communications more thoroughly, and generally evaluate them more favorably (perhaps be affected more by them), than would be the case for simplifiers.

Other Design Considerations

Medium

The studies presented in Table 1 cover a good range of media-vehicles. Several experiments invoked mock print advertisements, others used radio and/or television (video-taped) ads. McDougall (1976) suggests that for comparative advertising, print media may have substantial advantages over audio-visual media because comparative advertising includes relatively more information (data not only about the promoted brand but also about additional brands) and correspondingly more complex messages, and thus may be communicated more effectively via

the print medium where the consumer can spend more time with the message, and do so at his/her own pace. Audio-visual approaches automatically restrict message-consumer interaction time.

Two of the summarized studies (Mazis, 1976; and Ogilvy and Mather, 1975) have operationalized their communications via audio-visual or only audio vehicles. The remaining studies used print medium only. Mazis also compared print versus radio media. In this study he found insignificant differences on major response variables between message modalities, shedding some light on the previously mentioned opinion that comparative advertising is likely to be more "effective" in print rather than audio-visual media. The issue is still open, however, for future study.

Number of Ads Presented

Some of the researchers exposed their subjects to only one advertisement and compared the results between conditions using essentially factorial experimental designs. Others exposed subjects to several ads, all of which were studied (Wilson, 1976) or only the one which was tested (e.g., Prasad, 1976; here the rationale of using a portfolio approach was to create a more "natural" format and simulate a "real life" exposure situation).

It is possible that the portfolio approach inadvertently creates unnecessary demand characteristics; subjects' attention is spread out, a memory set is likely to be aroused, etc. It is important to come to grips with the potential trade-off between "real-life" simulation and confounding demand characteristics. (We recognize that if the primary response domain pertains to memory, a portfolio approach is virtually mandatory: more on this in the last major section of the paper.)

Frequency/Intensity of Exposure

Cognitive response to advertising may be affected by the frequency of message exposure. Repetition effects (Sawyer, 1973; Ray and Sawyer, 1971) deserve careful study, but to date the experiments published have invariably been single-exposure. It is difficult to assess those studies that have focused upon recall (aided or unaided) measures in evaluating comparative versus non-comparative ads when only one single exposure has taken place. Replication designs ought to be considered by future researchers; furthermore, recall/memory measures should be taken at realistically spaced time intervals rather than immediately (or shortly) after advertisement exposure. All of the studies measuring recall suffer from this potential problem, although Prasad (1976) readministered his measures to subjects one week after his single-exposure.

Other Message Characteristics

Message characteristics which may affect cognitive, affective, or behavioral responses to communications include the issues of substantiation (factual or subjective claims), sidedness of the message, and the relative position of the comparative claims within the advertisement.

Substantiation

Several critics of comparative advertising (Kershaw, 1976; Chevins, 1975) have suggested that when the comparisons include generalized, non-substantiated statements, the consumer may become misinformed as well as confused. Claims of superiority, for example, which are not supported by independent (or company) tests may reduce the credibility of the message. McDougall (1976) tested for the relative effectiveness of use or non-use of substantiated claims across various message appeals. Using separate regressions for comparative substantiated, noncomparative

substantiated, comparative unsubstantiated, and non-comparative unsubstantiated messages, with measures of ad reliability and helpfulness as dependent variables, McDougall found that, overall, substantiated claims receive greater acceptance in terms of reliability and helpfulness; non-comparative substantiated claims were found to be superior to all of the others. Golden (1976) also manipulated claim substantiation. She found no differences in message-appeal effect.

Wilson's study (1976) also bears on this issue in that all of his ad manipulations involved subjective (unsubstantiated) claims. He found that unsubstantiated comparative ads were significantly perceived as more confusing and less believable than their unsubstantiated non-comparative counterparts.

One-Sided versus Two-Sided Appeals

In his working paper, Mazis (1976) provides an interesting perspective regarding sidedness of message appeals. Drawing upon work done by Hovland, et al., (1949), and integrating McGuire's Inoculation Theory (1961), Mazis presents a conceptual framework for assessing message sidedness with respect to comparative or non-comparative advertising. Specifically, Mazis points out that comparative communications can be constructed along conventional lines by mentioning only positive comparisons in the advertised products favor (one-sided comparative ad), or alternatively by mentioning both positive and negative facts about the promoted brand (two-sided comparative ad).

From the managerial perspective, it may be the case that such communications are not only more believable, but that the overall image of the brand (and perhaps the company sponsoring it) is enhanced due to the "refreshing" glimpse at honesty. It is plausible to assume that most consumers would applaud an attempt at "telling it like it really is" rather than only mentioning positive benefits accruing to brand consumption. From the public policy point of view, such two-sided comparative ads may provide even more objective information upon which the consumer may make a brand choice. This is entirely consistent with the stance taken by the FTC.

Operationally, of course, there is always the chance that such a communication problem may win an ad agency an Effie, but lose the company precious sales and market share. It deserves careful study. Mazis initiates such a study in his second experiment reported in the above-mentioned working paper. The results are clouded, unfortunately, by an unrealistic operationalization of the negative appeal in the two-sided communication; nonetheless, he has made an important first step in studying the interesting, and potentially useful (managerially and public policy-wise) message-appeal strategy.

Relative Positioning of the Claim(s)

In rounding out this section, we mention that effectiveness of comparative advertising communications may depend, in part, on the positioning of the comparative claims (e.g., at the beginning, the middle or end of the ad). None of the seven studies explored this issue, although admittedly it is a minor point in contrast to some of those previously discussed. Also related to this "recency-primacy" issue is the question of whether the compared-to-brand(s) might be mentioned first or last in the message.

General Issues Pertaining to Testing and Methodology

Independent Variables

Manipulations of message appeals require close attention to proper operationalizations. Accordingly, scrutiny of the isomorphism between concept and variable is

imperative. Where correspondence is considerably less than 1 to 1, the researcher is not in a position to make conclusive inferences with respect to the response effects. Thus, it is important that the researcher fully understands what is meant by "comparative advertisement", "Brand X" ad, and "supportive" communication so that reasonable working definitions can be operationalized. The same is true whatever independent variable is selected for study.

We have seen, for example, that there is some doubt as to whether or not Prasad's (1976) "Brand X" ad was, in fact, truly perceived as a Brand X ad or rather a standard comparative ad (at least for some of the subjects in his study). As a general rule, it is advisable to thoroughly pretest these manipulations, utilizing different subjects from the same population. Such pretesting is the exception rather than the rule in published studies.

Dependent Variables

Without getting into the debate as to what constitutes reasonable measures of advertising effectiveness, we can say that perhaps the majority of advertising academics and certainly practitioners are comfortable with some sort of hierarchy of effects model (e.g., Lavidge and Steiner, 1961).

In such models the consumer is viewed as responding to advertising stimuli according to a hierarchy such as "awareness", "comprehension", "interest", "liking", "intention", and "behavior". As pointed out by Lavidge and Steiner (1961), such a portrayal of response to stimuli covers three stages: cognitive - affective - and conative (behavioral). The advertising researcher, over the years, has developed a variety of measures which more or less tap dimensions of each of these three stages. Depending upon the purpose of the ad, whether copy pretesting or market post-testing is the primary focus, combinations of these measures are gathered.

The seven studies summarized have utilized all or part of such hierarchical responses. Some (Prasad, 1976; Mazis, 1976; Ogilvy and Mather, 1975) stressed memory or recall ability occasioned by the various manipulated advertisements. Such measures reflect the researcher's concern for assessing the cognitive dimension. Others utilized a battery of questions designed to shed light on the entire spectrum, with the exception of memory measures (Wilson, 1976).

However, both evaluations of the ad itself and the brand advertised should be measured. Some of the studies looked at one or the other (e.g., Golden, 1976; McDougall, 1976), but not both.

Pretests and Manipulation Checks

It is extremely important that the researcher verify that his/her manipulations are in fact being perceived in a manner which is consistent with his/her objectives. This is true of independent variable operationalizations as well as dependent measures (scales) administered and gathered.

Thus, pre-tests/manipulation checks are crucial to ensure internal validity. While such checks can be made after the experiment is completed by using the same subjects, it may be more advisable to perform them before the experiment by using different subjects drawn randomly from the same population from which the experimental respondents will be selected. Such a pre-test strategy mitigates against likely demand characteristics operating (Sawyer, 1975). Thus, use of scale which is not discriminating will yield statistically insignificant results when, in fact, such results may exist. Golden's study suffers in this respect. All her subjects regardless of experimental condition appeared to generally use

the same small range on her intention scale. Perhaps the scale was not explained adequately; perhaps an 11-point subjective probability scale should have been utilized instead of the 7-point scale which was used; perhaps the independent variables were operationalized poorly.

Another related point concerns the nature of the measurement level of the scales used to tap dependent responses. Unless such scales are thoroughly examined and pre-tested so as to permit an assumption that they are interval-scaled, it is difficult to argue in favor of parametric analytical techniques. And, since parametric techniques (e.g., analysis of variance, regression) permit assessment of interaction effects (whereas assessment of such by use of non-parametric techniques is not clear cut), it behooves the researcher to strive for development of dependent measures which can be assumed to be at least interval scaled. This requires the discovery that subjects perceive distances between each number in a given scale as reflective of approximate equal psychological distances.

Covariates

When a researcher does not collect predispositional measures which presumably relate to informational processing of advertising stimuli, error variance may be unnecessarily large, resulting in non-significant differences.

To reduce error variation (or adjust for extraneous sources of error), the researcher might design experiments which include important predispositional variables (e.g., treatment-by-levels designs (also referred to as randomized block designs); see Lindquist, 1956; or Winer, 1971) as one (or more) of the factors. Alternatively, he might consider the use of such predispositional variables as covariates, where any contaminating influences may be statistically adjusted for. The Golden study is illustrative of this approach: she gathered a measure of brand loyalty which she used to statistically adjust responses to treatment combinations. Clearly, assessment of main and interaction effects (as well as the various multiple comparisons which may be of interest) can be clouded by failure to reduce reasonable sources of confounding error variation (e.g., product class usage experience, brand loyalties, evoked sets, related personality traits).

Summary and Conclusions

The purpose of this paper has been to explore the various issues involved in assessing the communications effectiveness of comparative advertising. Using seven recent studies as reference points, we have endeavored to point out the complexities of comparative advertising research. No matter what the scope of an individual study, there are several crucial considerations necessary. These involve the advertised product class (brand) characteristics (e.g., product class, salience, life cycle stage), the characteristics of the compared-to-brand(s) (e.g., market position(s), number of brands compared), product class (brand) attributes on which comparisons are made (e.g., number of attributes and their salience), the subjects (e.g., type, usage rates, brand loyalty, personality traits), the advertisement design (e.g., media-vehicle utilized, frequency/intensity of ad exposure), other message characteristics (e.g., use of substantiation, sidedness of appeals), and methodology used (e.g., experimental designs, manipulation checks, covariates).

The seven studies addressed only some of the research questions identified in this paper. Notably, there is an important gap in that the bulk of the studies failed to experimentally manipulate (or control error variation via covariance analysis) major product-, subject-, and situational-related variables. While it is true that exploration of all research questions raised in this

paper are beyond the scope of any individual study, we suggest that future research should address the specific issues presented.

Careful attention to the identified issue areas should contribute to the development of body of knowledge which could then provide answers as to when, if, and how comparative advertising can be used.

MEDIATING EFFECTS OF COGNITIVE RESPONSES TO ADVERTISING ON COGNITIVE STRUCTURE¹

Abstract

This paper reports results of an initial study of the mediating effects of cognitive responses to advertisements on selected elements of cognitive structure. To create variation in cognitive response, consumers were shown one of several new product ads that varied in terms of product price and the presence or absence of information regarding additional (non-price) attributes of the advertised product. Type of cognitive response was sensitive to both aspects of ad content. As expected, counterargument and support argument responses were both strongly related to several cognitive structure elements.

Introduction

The measurement and explanation of persuasive communications impact has occupied the attention of a wide variety of academic, industry, and public policy researchers. In literally hundreds of studies attempts have been made to model the effects of the persuasive communication process and its subsequent influence on consumer behavior. The importance of this issue for marketing and public policy is evidenced by the more than \$28 billion spent in the United States on advertising in 1976.

The lack of a clear understanding of the communication process may be attributed to several factors, the broadest and most critical of which may be the absence of a vigorous, process-oriented, empirical research tradition. The dominant research paradigm for communication research involves the measurement of some dependent variable (attitudes, opinions, sales) following exposure to a persuasive communication. The independent variables typically manipulated in these studies are usually concerned with characteristics of the source or channel of the message, the message itself, or the receiver of the message (Mitchell & Olson, 1977). The purpose of such studies is to identify generalizable relationships between the presumed goal of the persuasive communication (e.g., attitude change) and the communication variable of interest. For the most part, these simplistic attempts have not been successful (cf. Fishbein & Ajzen, 1975).

In contrast to this generally atheoretical approach to studying communication effects are two streams of research based upon attitudinal and information processing perspectives. Both focus on the cognitive states and/or processes that intervene between or mediate exposure to persuasive communications and changes in attitude, behavioral intention, or overt behavior. These two approaches, broadly termed the cognitive structure and cognitive response models, provide the theoretical foundations for this study.

The Cognitive Structure Model

The cognitive structure model has its theoretical roots in learning theory and emphasizes beliefs as the fundamental cognitive element (see Lutz & Swasy, 1977; Olson & Mitchell, 1975). For example, Fishbein proposed expectancy-value models that depict the causal relationships between beliefs and attitudes, intentions, and eventually behavior (cf. Fishbein & Ajzen, 1975). Specifically, attitudes are thought to be based on beliefs

(Fishbein, 1967):

$$A = \sum_{i=1}^n b_i e_i \quad (1)$$

where:

A = attitude toward (evaluation of) an object, action or event.

b_i = strength of belief about the "ith" attribute or consequence.

e_i = evaluation of the "ith" attribute or consequence.

n = number of salient beliefs.

By this model, Fishbein proposed that attitudes are a function of belief strength and the evaluative aspects of beliefs combined in an additive, compensatory manner. An extension of this attitude model (see Fishbein & Ajzen, 1975) relates the attitude concept to behavioral intentions (BI) which, in turn, are causally related to behavior (B) itself, as indicated by arrows in the following simplified schema:

$$\sum b_i e_i \rightarrow A \rightarrow BI \rightarrow B \quad (2)$$

Fishbein's model of attitude formation implies that a persuasive communication will affect attitudes indirectly via the processing of information contained in the communication which first creates b_i and e_i cognitive elements (see Fishbein & Ajzen, 1975). This approach to monitoring communication effects represents a step beyond the traditional research paradigm by actually measuring the cognitive variables (beliefs) that presumably mediate and determine attitude change and is becoming increasingly evident in the consumer behavior literature (cf. Kuehl & Dyer, 1977; Lutz, 1975; Mazis & Adkinson, 1976; Olson & Dover, 1976, in press). Beliefs formed by processing the information contained in the persuasive communication presumably are integrated into a pre-existing belief framework. According to Fishbein and Ajzen (1975), the resulting change in overall belief structure due to the integration of previous beliefs and beliefs derived from the communication information is the fundamental basis for attitude change and behavior modification.

Cognitive Response Models

An alternative conceptual view of communication impact is provided by cognitive response models which were developed explicitly for monitoring communication effects. The basic premise of these models is that the spontaneous unstructured cognitive responses (thoughts) elicited by a communication message act as mediators of attitude formation or change. In this view, a precise understanding of prediction of communication impact is not possible without attention to the cognitive thought responses emitted by the receiver upon exposure to the

²Associate Professor, Assistant Professor and Assistant Professor, respectively. This research was conducted while the second and third authors were doctoral students in Marketing at the Pennsylvania State University.

communication.

The measurement paradigm for a cognitive response study typically includes the following procedures (see Wright, 1974, for a more complete discussion). First, the subject is asked to either write down or verbalize all of his/her thoughts either during or immediately after exposure to a persuasive communication. These protocols are assumed to indicate the internal subvocal cognitive responses which occurred during and after exposure to the communication. Then, the cognitive responses are categorized according to various criteria, either by the subject or by the experimenter. Possible criteria include whether there is a "critical" or "favorable" orientation to the message, the perceived origin of the thought, and whether or not the response meets the prescribed definition for a class of cognitive responses. Examples of cognitive response categories include counterargument, source derogation, support arguments, and curiosity statements (see Wright, 1973, 1974). The third step is to compute cognitive response indices or scores based upon the categorization. These scores may represent either a simple addition of the number of counterarguments, source derogations, or support arguments, or more elaborately, use of a model in which each cognitive response type is weighted by subjective indications of importance (e.g., Wright, 1973). In both cases the scores represent an operationalization of the cognitive response mediators and are typically used to predict some criterion, usually attitude or intention.

The application of direct thought monitoring in communication research is in its infancy. Only a few studies, mostly in the social psychology literature, have used this conceptual and methodological orientation. In these investigations, the research emphasis has centered on the study of distraction effects (Osterhouse and Brock, 1970; Keating and Brock, 1974; Insko, Turnbull, and Yandell, 1974; Petty, 1977; Petty, Wells, and Brock, 1976), attitude change/persuasive impact (Cook, 1969, Wright, 1973, Petty, 1977), product versus task involvement (Krugman, 1967; Wright, 1973) repetition and media modality effects (Ray, Sawyer, and Strong, 1971; Wright, 1973; Ray, Ward, and Reed, 1976; Ray and Webb, 1976), source credibility (Cook, 1969) and fear arousing messages (Janis and Terwillinger, 1962). Wright (in press) has reviewed the current literature on cognitive response models. The potential of the cognitive response/thought monitoring approach to advertising research, although largely unexplored, appears strong and warrants the attention of consumer behaviorists.

A Combined Cognitive Structure/Cognitive Response Model

Both of the previously mentioned research orientations possess advantages and disadvantages as a modeling perspective for studying the impact of persuasive communications. However, if the two approaches are combined, it may be shown that each complements the other's weak points. Whereas the cognitive structure model focuses on the structural aspects of stored knowledge in the form of beliefs, the cognitive response model is more concerned with cognitive processing activity. Together, the two models can provide a relatively comprehensive model of communication impact. That is, cognitive responses (subvocal thoughts) can be seen as directly mediating the formation of new beliefs or changes in pre-existing beliefs. The belief structure so created would, in turn, mediate attitude formation and change. The advantages of, and potential for, this joint model approach were independently recognized and clearly presented in a particularly thorough paper by Lutz and Swasy (1977).

The present paper represents an initial attempt to examine the conceptual and predictive utility of the cognitive response perspective as a mediating process occurring between exposure to a communication and the formation of or change in cognitive structure variables such

as beliefs, attitudes and intentions. Due to space limitations, emphasis is on the more general and heuristic effects of cognitive responses on cognitive structure, as a function of exposure to advertising communications. Our long-range goal is to encourage and contribute to the development of a more precise and complete theory of communication effectiveness, at an individual level.

Methods

Research Design

To more clearly identify the mediating effects of cognitive responses, it was necessary to experimentally create alternative communications (in the form of simple, poster-like advertisements) that should lead to variations in magnitude and type of cognitive response. These differences, in turn, would be expected to have a variable impact on cognitive structure variables. Two factors were selected for manipulation, a product attribute and an ad content variable. Ads were created which communicated one of five arbitrary price levels for the ball point pen product--29¢, 49¢, 79¢, \$1.49, and \$3.95. Additionally, information regarding other salient (non-price) attributes of the pen was either present or absent. Thus the design was a 5 x 2, between-groups factorial involving 5 levels of price and the presence or absence of additional, non-price information about the product (see Table 1).

TABLE 1
Experimental Design

Information Contained in the Ad	Price Level				
	29¢	49¢	79¢	\$1.49	\$3.95
Price, only	n=15	n=17	n=17	n=16	n=17
Price & Additional Attribute Information	n=15	n=17	n=17	n=17	n=17

Basically, consumer subjects were exposed to one of the 10 advertisements (treatment combinations). Then their cognitive responses (thoughts) to the ad were recorded, followed by an extensive measurement of cognitive structure elements.

Although highly specific hypotheses were not considered possible given the current state of theory, we intuitively anticipated greater counterargument for higher prices. However, it was not clear a priori whether additional non-price information would lead to greater or less counterargument compared to price-only conditions. Moreover, we generally expected counterargument and support argument to mediate the formation of less positive and more positive cognitive elements, respectively.

Product and Subjects

Several factors influenced the choice of ball point ink as the focal product in this research. First, pilot interviews indicated a relatively simple cognitive structure for ball point pens in terms of salient product attributes. Thus, measurement complexity was kept within reasonable limits. Second, a relatively new, inexpensive pen possessing several unusual features had been recently introduced in the local market and was still unfamiliar to nearly all subjects. The actual brand name of this pen was used throughout the study, but is omitted in this paper.

Because ball point pens have a high usage rate among college students, a student population was considered appropriate for this research. Subjects were 165 undergraduate students from introductory business courses who were paid \$2.00 for their voluntary one-hour participation.

Advertisements

In all, ten separate ads were professionally created to correspond to the ten treatment combinations in the research design (see Table 1). Centered at the top of each in large type was the brand name followed by the headline, "Introducing the New ----- Ball Point Pen." In the center of each ad was a black and white drawing of the pen.

The experimental manipulations of price level and other information were accomplished by varying the remaining information in the ads. The price level was presented in the lower right corner of each ad -- e.g., "only 29¢," or "only \$3.95."³ In the price only conditions, no information other than price was given. In the "additional information" conditions, four other product features were listed in the lower right corner and very briefly described. These included (a) the physical construction of the ball point tip, (b) the tungsten carbide ball and thin, free flowing ink, (c) the attractive design, and (d) the comfortableness of using the pen.

Procedures

Subjects were run in groups corresponding to each treatment combination. The procedure by which subjects signed up to participate at a particular time was considered to be essentially equivalent to a formal randomization procedure.

Upon entering the research room, subjects were told in general terms that the study concerned their reactions to a new ball point pen and some promotional material for the product. Then, to meet University regulations, they signed an informed consent form certifying their voluntary decision to participate. Following this, subjects completed a two-page questionnaire regarding general knowledge of and purchase behavior towards ball point pens and the perceived importance of several pen attributes.

Next, subjects were told that a rough mock-up of a forthcoming ad for the new ball point pen had been obtained. This ad was described as one that might be used as a point-of-purchase poster, perhaps on a store counter-top. Each subject was then given a black and white copy of the ad to examine. After two minutes, subjects were instructed to turn the ad face down on the table and to write (on a blank sheet of paper before them) "all the things that came to mind as you read the ad." They were given exactly two minutes to record their cognitive responses. Following, subjects turned to the next page and began responding to the post-exposure questionnaire. To separate somewhat the measurement of cognitive response and cognitive structure, the first page of the questionnaire contained six structured and two open-ended questions regarding subjects' general reactions to the ad itself. Following this were questions measuring b_i , e_i , A_0 , A_{act} and BI elements of cognitive structure regarding the pen.

After completion of the questionnaire, the study continued with an actual trial experience with the pen and subsequent re-measurement of the cognitive structure variables (this post-trial data is not relevant for the present paper). At the conclusion of the study, subjects were debriefed (the deceptions used were thoroughly explained and justifications were given) and were paid and dismissed.

Dependent Variables

The elements of cognitive structure measured in this paper are those identified most closely with structural models of attitudes (cf. Fishbein and Ajzen, 1975) and

are represented in terms of their general causal relationships in (2).

The measurements of the belief strength (b_i) and evaluative aspects (e_i) were based on the vector model and methodological procedures proposed by Ahtola (1975). A major contribution of Ahtola's modification of the familiar Fishbein expectancy-value model (1) is the emphasis on a more specific and precise identification of the belief concepts. In the Ahtola view, a product attribute is conceptualized as a dimension containing several discriminable levels or amounts of the attribute. In perceiving or encoding information about a product attribute, a consumer essentially assigns the product to one or more of the discriminable categories along that attribute dimension. For example, a wine could be classified as sweet, slightly sweet, medium dry, dry, or very dry along the sweet-dry attribute dimension. From this perspective, each category or level represents a discriminable belief. If, for example, one is positively certain that a particular wine is medium dry, then the belief strength (b_i) for that category should be maximal and the b_i 's for the other categories should be zero. This basic notion suggests that people learn these categories (cf. Wyer, 1974) and thus cognitive structure research should focus on identifying the discriminable categories used by subjects to encode the meaning of a particular stimulus such as a brand.

Through pilot interviews with several undergraduate students, seven modally salient attributes for ball point pens were identified: price, ink flow consistency, comfort, appearance, ease of writing, writing quality, and value for the money. Discriminable categories (levels or amounts) for each attribute were developed based partially on experimenter intuition. For the categories along each attribute (e.g., very good, good, average, poor, and very poor value for the money), subjects indicated their belief strength by assigning 10 points to the several levels or categories such that the number of points indicated the strength of belief that the pen possessed each attribute level. Subjects also rated their evaluation of each attribute level.

An index of the overall evaluation associated with each attribute can be obtained by summing the $b_i e_i$ products over the category levels to yield a vector score of evaluation ($\sum b_i e_i$). An index of overall evaluation associated with the entire cognitive structure is represented by summing the separate vector/attribute scores ($\sum \sum b_i e_i$). Attributes toward the pen (A_0) and the act of buying the pen (A_{act}) were each measured by averaging the scores on the three 5-point scales following Fishbein's recommendations (1967). Intention to purchase for one's own personal use on the next shopping trip (BI) was measured on a 5-point scale (not likely--very likely to buy, 1-5, respectively).

Classifying the Cognitive Response Measures

The measures of subjects' cognitive responses to the various ads were classified by following closely the criteria proposed by Wright (1973). The two cognitive responses of major interest were counterargument and support argument. Briefly, counterargument is indicated by statements that are directed against (disagree or clash with) the product in general, its use, or a specific claim or idea contained in the ad. Support arguments are indicated by thoughts in favor of (agree with) the product, its use, or a specific claim or idea in the ad. Several other types of cognitive response were also identified, including: (a) curiosity statements -- general thoughts evidencing curiosity regarding product characteristics, (b) positive ad-related statements -- thoughts about positive aspects of the ad itself, and (c) negative ad-related statements.

³The actual price of the pen was 79¢ in most stores.

Treatment Effects on Cognitive Responses

Although this paper is primarily concerned with support and counterarguments, Table 2 presents, for the reader's interest, a summary of all the types of cognitive responses elicited by the two types of advertised information (collapsed across all price level conditions) and for the entire design. The overall average of 2.94 cognitive responses per subject is somewhat lower than that typically obtained in other studies (e.g., 3.8 to 10 or more). However, most of these other studies used much more complex communications with rather extensive copy thus providing more material to cognitively respond to. Moreover, most of these studies did not place an explicit time limit on the thought monitoring task and subjects may have generated items in the course of thought recording (cf. Wright, 1977a, 1977b, for excellent reviews and analyses of the methodology used in this research).

TABLE 2
Summary of All Cognitive Response Types

Type of Cognitive Response	Type or Information		Grand Total
	Price only	Price & Attributes	
Counterargument	53 (.65)	73 (.88)	126 (.76)
Support argument	38 (.46)	62 (.75)	100 (.61)
Curiosity statement	68 (.83)	32 (.39)	100 (.61)
Neutral statement	36 (.44)	31 (.37)	67 (.41)
Positive ad-related	7 (.09)	8 (.10)	15 (.09)
Negative ad-related	41 (.50)	36 (.43)	77 (.47)
Total	243(2.96)	242(2.92)	485(2.94)

Note: Mean number of responses are in parentheses

Note in Table 2 that curiosity thoughts dominate in the price-only ads where virtually no information other than price was available. In contrast, for the conditions involving information about price and other attributes, counter and support arguments were the most frequently occurring cognitive responses. Because these types of responses are thought to have the major mediating influence on cognitive structure, the remainder of the paper focuses only on support and counterargument effects.

Table 3 summarizes the effects of the experimental manipulations on the number of counterarguments and support arguments elicited by ad exposure. As expected, Price Level had a significant main effect on the number of both counterarguments and support arguments. Figure 1 illustrates this main effect -- i.e., the mean number of counterarguments as a function of Price. A Newman-Kuels analysis revealed that the 29¢ and \$3.95 prices produced significantly fewer and more counterarguments (p 's < .05) than the three intermediate prices, which did not differ from one another.

The experimental treatment effects on number of support arguments are less clear-cut. Although a main effect of Price Level was obtained (graphed in Figure 1), Type of Information was found to interact with Price. This two-way interaction is not readily interpretable and, therefore, is not illustrated. Finally, the significant main effect of Type of Information was such that more support arguments were elicited by price-plus-other-attribute information ($\bar{X} = .75$) than price-only information

($\bar{X} = .46, p < .05$).

TABLE 3
Effects of Price Level and Type of Advertised Information on Number of Counter and Support Arguments

Price Level	Number of Counterarguments		Number of Support Arguments	
	Price only	Price & Attributes	Price only	Price & Attributes
29¢	2 (.13)	7 (.47)	7 (.47)	19 (1.27)
49¢	10 (.59)	15 (.88)	8 (.47)	10 (.59)
79¢	8 (.47)	17 (1.00)	17 (1.00)	11 (.65)
\$1.49	13 (.81)	11 (.65)	5 (.31)	17 (1.00)
\$3.95	20 (1.18)	23 (1.35)	1 (.06)	5 (.29)

F-ratios from ANOVAs

Information Type (A)	F-ratio	F-ratio
Information Type (A)	2.59	5.20*

A x B	<1	2.76*

* $p < .05$; ** $p < .01$

Note: Means are given in parentheses

FIGURE 1: Main Effects of Price Level on Magnitude of Counter and Support Argument.

Given the above evidence that the experimental treatments did cause differences in type and level of cognitive response, our attention turns to the mediating effects of counter and support arguments on elements of cognitive structure. To keep this paper within its space limitations, it was necessary to examine only selected cognitive elements. In other papers, we will tackle the complex analyses involved in studying cognitive response effects on individual belief elements. In the present paper we will concentrate on the more global cognitive elements such as attitudes and intentions.

Cognitive Response Effects on Cognitive Structure

To determine the relationship between counter and support

arguments and these selected cognitive structure elements, two analyses were performed. The first involved collapsing the price level factor and computing correlations between number of counter and support arguments and selected cognitive variables for the two information type conditions. Table 4 summarizes the results of this analysis. As expected, counterargument was negatively related to cognitive structure variables, while support argument was positively related to cognitive structure elements.

TABLE 4
Correlations Between Number of Counter and Support Arguments and Selected Cognitive Elements

BI	-.33*	.32**

^aVector evaluation score for "value for money"

* p < .05

**p < .01

Both counterargument and support argument were significantly related to the belief vector regarding value for the money ($\Sigma b_i e_i$), the overall cognitive structure index ($\Sigma \Sigma b_i e_i$), and intentions to purchase. The relationships with attitude (A_o and Aact) were generally significant but somewhat weaker. Moreover, the relationships between cognitive response and structural variables are generally stronger and more consistent for the condition involving information about price and other attributes than for the price-only ads. When the information-type factor is collapsed, both counter and support argument responses are significantly related to all the more global elements of cognitive structure, although none of the relationships is particularly strong (r 's from .16 to .33, p 's < .05).

An alternative and perhaps more useful perspective on cognitive response influence is gained by examining the magnitude of the mediating effect on selected cognitive variables. This analysis was accomplished by collapsing the price level factor and dividing the subjects in each information type group into those making no counterarguments ($CA = 0$) vs. those with some ($CA \geq 1$) counterarguments ($X = 1.47$). In effect, this internal analysis created a 2 x 2 design composed of two levels of information type and two levels of counterargument magnitude (some and none). The cell means and ANOVA results for several cognitive variables are presented in Table 5. Scores for Aact are not shown because no effects were found for this variable. Note that Counterargument was consistently and significantly related to the value-for-the-money belief vector, and to belief structure, product attitude, and purchase intention. Information Type had generally weaker main effects. Only one (relatively weak) interaction was obtained. In all cases, the effect of counterargument was to lower the positiveness (increase the negativity) or weaken the cognitive variable.

The same internal analysis was conducted by splitting the sample based on those subjects who reported no support arguments (n=98) and those who reported one or more support arguments (n=67). When this blocking factor was combined with the information-type treatment conditions, a 2 x 2 internal analysis was again conducted on the selected cognitive variables of interest. The results are presented in Table 6. Support Argument was significantly related (main effects) to each of the cognitive elements, such that the variable was more positive or stronger when subjects engaged in support arguing. Information Type had some main effects on the belief and attitude variables. No interaction effects were obtained.

Conclusions and Implications

The results of this study provide support for the notion that cognitive responses to persuasive communications (ads in this case) mediate the effect of the message on elements of cognitive structure (Lutz and Swasy, 1977; Wright, 1973; 1974). Both counterarguments and support arguments were found to be related to a wide range of cognitive variables including beliefs, attitudes, and purchase intentions. Although strict cause and effect statements cannot be supported by this design, it seems logically reasonable to presume that cognitive responses precede and thus influence the formation of cognitive structure elements. The direction of influence of the types of cognitive responses was, of course, opposite, with counterarguments leading to less positive or weaker cognitive states and support arguments leading to more positive or stronger cognitive states. The broad consistency of these effects across different analyses and over a variety of cognitive measures, lends additional credence to the basic conceptual ideas about cognitive responses and to their construct and measurement validity. In sum, cognitive response theory appears to have considerable utility for improving our generally weak theories of the persuasive communications process, and therefore warrants specific attention in future advertising/communication research.

The relatively strong and consistent mediating effects of support and counterargument responses as evidenced in this study may be seen as even more robust when contrasted with earlier research. The bulk of the past research has used rather strong, overtly persuasive communications--ones quite likely to maximize cognitive responses, especially support and counterarguments (Wright, 1977a, 1977b, in press). In contrast, the present study examined ads which were primarily informational in "flavor" rather than distinctly persuasive. This was particularly true of the price-only ads. One point is that consumers may counterargue and/or support argue

with message content that does not directly attack established beliefs. Another is that such processes may occur and mediate impact on cognitive structure even for seemingly unimportant, low involvement products such as ink pens. A third and very important applied application of the present results is that specific aspects of ad content (such as the type of information conveyed) may have a fairly strong effect on the cognitive responses produced and, in turn, on subsequent effects on cognitive structure. This latter idea suggests that advertising research could focus on determining specific

ad content variables that would minimize counterarguments (or maximize support argument), thus "paving the way" for cognitive structure effects favorable to the firm.

In conclusion, it would seem that cognitive response theory and methodology warrant the attention of consumer researchers. When combined with other theoretical ideas regarding information processing, this approach may offer new insights into the communication process. Moreover, the entire research area holds promise of applicability to real world communication problems.

THE ORGANIZATION OF PRODUCT INFORMATION IN MEMORY IDENTIFIED BY RECALL TIMES¹

Eric J. Johnson (student), Carnegie-Mellon University²
J. Edward Russo, University of Chicago

Abstract

A chronometric technique is used to examine whether consumers' memory structure for product information reflects the input organization of that information, or whether people will reorganize into a preferred structure, either brand-based or attribute-based. The evidence clearly favors congruence between memory structure and input organization, although some reorganization did occur.

This report has two purposes: (1) to call attention to the role played by memory for product information in purchase decisions, and (2) to introduce a chronometric technique to the study of the structure of remembered product information. When consumers make purchases, they use product information from two sources. The external environment contains package labels, point-of-purchase displays, posted prices, etc., relevant to the purchase decision. However, most information needed for the purchase decision is retrieved from memory. Information like use experience, family preferences, word-of-mouth communications, and advertising (except point-of-purchase advertising) must all be mediated by memory. Further, if all brands are not available from a single vendor, then information about the missing ones must come solely from memory. The point is that product information retrieved from memory plays an essential role in almost all purchase decisions. Unfortunately, research into consumer decision making has largely ignored this role (Olson, 1977).

Role of Memory

A processing history of product information can be outlined as follows:

1. encoding of product information from external sources.
2. retention of product information in memory.
3. retrieval and use of product information in the purchase decision process.

The second stage, retention in memory, is the focus of this paper. It will be useful, however, to consider the interactions between retention and the other two stages.

The Effect of Retention on Decision Strategies

Does the nature of the stored information determine the type of decision process? For example, if product information is organized around brand names, as many researchers have suggested, will the decision rule have to be compatible with this information structure? Two studies suggest that the answer may be yes. Simon and Hayes (1976) used different cover stories for the same problem to induce different internal representations of the problem information. The subjects then selected problem solving strategies that were compatible with

¹The authors would like to thank John Herstein for introducing them to the problem, Patrick Langley for helpful discussions, and Jeff Godliss for running subjects.

²Order of authorship is alphabetical; the authors' contributions are equal.

their specific internal representations of the information. Different representations led to different strategies. If purchase decisions are seen as a type of problem, the Simon and Hayes result implies that different representations of this same product information may well lead to different decision strategies. Further, this implication should hold whether the representations are internal or external.

The last assertion has been explicitly confirmed by Bettman and Kakkar (1977), except that they relied entirely on externally available rather than remembered information. Each of their subjects was shown product information in one of three formats: a brand-organized display, in which information was available most easily by brand name; an attribute-organized display, in which the same information was available most easily by attribute; and a matrix display, which equated the availability of the information. Although consumers could process the available information however they wished, Bettman and Kakkar found that the decision rule was usually chosen to be compatible with the format of the product information. Thus, decision rules that required the information to be processed by brand were most frequent with the brand-organized format. This study provides direct evidence that consumer decision rules are flexible and will depend on the structure of the available product information.

The Effect of Encoding on Retention

Just as the structure of product information can influence the subsequent decision strategies, the process used in encoding the information can determine how the information is stored. For example, if product information is presented in a brand-organized fashion, will it be remembered in a brand-organized structure? Alternatively is there a preferred memory structure into which product information is always organized no matter what the original presentation and encoding format?

Unfortunately, the authors know of no studies that have investigated the relation between the encoding of product information and its organization in memory. The experiment presented in subsequent sections was designed to address this issue.

The Realworld versus the Laboratory

The existing research literature has largely ignored the role of memory in purchase decisions. Most laboratory studies attempt to bypass any memory stage. Instead, all product information is provided externally.

We believe that researchers in consumer behavior have not deliberately shunned memory issues *per se*. Rather, this omission follows naturally from the information acquisition paradigm, which dominates research on consumer choice behavior. Within this paradigm experiments are designed to rely as much as possible on externally provided information because the information acquisition sequence provides the necessary data base. Since acquisition from memory is unobservable, it can provide no insight into the purchase process.

This information acquisition paradigm is, of course, unrepresentative of realworld purchases. Most such purchases rely primarily on remembered information.

Thus, an unfortunate consequence of a generally successful research paradigm has been a systematic gap in our investigation of consumer behavior.

Representation of Knowledge

Two alternative structures have been proposed to represent a consumer's product knowledge. This knowledge can be stored by brand or by attribute (Bettman, 1978; Payne, 1976). Storage by brand assumes that a person's knowledge about a product class is organized around each brand. To take peanut butter as an example, a verbal statement of brand-organized knowledge might be: "Skippy tastes very good, contains preservatives and costs \$.99 for an 18 oz. jar." In contrast, attribute-organized knowledge could be verbalized as: "Price, let's see, Skippy costs \$.99, Jif costs \$.99, but Peter Pan costs only \$.95." Note that whether the product information is stored by brand or by attribute, the information itself is identical. The price of Skippy is stored as \$.99 in either structure. The concern is not with the content of memory but with its structure or organization.

This conceptualization of product knowledge should be distinguished from such theories as those underlying multidimensional scaling and semantic differential scales. The emphasis of the present research is not on the content of the stored information, but with the organization of the information itself. Although not everyone will share the same sets of brands and attributes, especially across different products, it is suggested that preferred organization is independent of content.

Representations in Cognitive Psychology

A major concern of cognitive psychology is the representation of knowledge. There are several highly related formalisms for representing the structure of long-term memory, including list structures (Simon and Newell, 1974) and semantic networks (Anderson, 1976). References to these and other readings in the representation of knowledge can be found in Norman (1976, pp.197-198). Because list structures can be most easily simplified, Figure 1 presents the previous example in a list structure format. Both the brand-organized and attribute-organized versions are shown.

FIGURE 1
List Structure Representations of Product Knowledge

	(Skippy	(Taste	Very Good)
		(Preservatives	Yes)
A		(Price	\$.99)
		(Size	18 oz.)
	(Jif	(Taste....	
	(Price	(Skippy	\$.99)
B		(Jif	\$.99)
		(Peter Pan	\$.95))
	(Taste	(Skippy....	

The top structure (A) is brand-organized, while below it (B) is an attribute-organized list structure.

The essence of the list structure representation is the use of the "next" relation to connect items. Thus, in Figure 1A Skippy is followed by a list of its attributes, whereas in Figure 1B, Skippy is followed by the other brands. The links created by the next relation can be traversed to get from any item in the complete list structure to any other item. Of course, the nature of the list structure can either facilitate or hinder such activity. In the brand-organized list

(Figure 1A), if one is at Skippy-Preservatives-Yes, it is easier to reach Skippy-Size 18 oz. than to reach Jif-Preservatives-Yes (not shown).

The Response Time Technique

The verification of structural representations such as those depicted in Figure 1 is often accomplished by using chronometric techniques. In essence, these techniques assume a direct relation between the amount of processing and the time taken to perform a task. If the task is recall, the time to recall is assumed to measure the "distance" in the memory structure between the recall cue and the target item.

It is important to realize that it is not just access time that makes up time to recall. The subject may, in fact, have the needed information in memory, but in a form different from that necessary for the correct response. Therefore, some time must be spent converting the internal representation to a more useful form. However, whether more cognitive processing is required by greater "distance" or by the conversion of "near" information, the longer recall time accurately indicates the greater effort needed to recall the given item.

Chronometric analysis has been developed into a sophisticated methodology. Although only the basic principles will be used in this report, it is worth noting two elaborations. In most tasks, it is possible to trade speed for accuracy. Such a trade-off threatens the validity of recall times in identifying cognitive structure. In practice, this trade-off is avoided by enforcing minimal error rates through instruction and training. However, more powerful techniques are available for situations with large or unstable error rates or when the retrieval dynamics must be known in detail (e.g., Doshier, 1976). A second elaboration is the partitioning of the total response time into segments that measure the durations of several, nonoverlapping stages of processing. This version of chronometric analysis was developed by Sternberg (1969), and many successful applications could be cited (see Chase, 1977).

The analysis of retrieval times is one of a surprisingly large number of techniques for investigating memory representations (for a review, see Bower and Tulving, 1974). A more common technique is to ask the subject to respond to a presented item as the "same" as or "different" from some member of the memorized set of items. Both techniques require the recall of a remembered item. However, the verification task seems more removed from most purchase situations. Occasionally a consumer may search memory to verify a manufacturer's claim, but usually the consumer is recalling the relevant product knowledge as rapidly as possible. Thus, the recall time technique not only enables the discrimination between brand-organized and attribute-organized memory structures, but also relies on behavior that is similar to the retrieval of information in real shopping situations.

Experimental Rationale

The focus of our experiment is the relation between the first two stages of the "processing" of product information, namely encoding and retention. Specifically, we inquire whether the encoding format, brand-based or attribute-based, determines the storage organization or whether there is a systematic tendency to reorganize into a preferred memory structure regardless of input format.

The basic design had subjects learning a booklet of product information. The total information set was a complete brand x attribute matrix with four brands and four attributes. Each page of the booklet consisted of a column of information headed by either a brand name or an attribute name. The column itself contained, respectively, either the four attributes and their values for that brand or the four brands and their values for that attribute. These two input organizations were called brand input and attribute input, respectively.

The information in a complete brand x attribute matrix is rarely available in the realworld. However, it was important to the success of this experiment to treat brands and attributes equally. That is, any preferences for brand-based or for attribute-based memory structures had to be separable from encoding factors that favored one over the other. For this reason a complete, symmetric brand x attribute matrix was used. Future studies can address the effects of encoding factors, especially as they occur in realworld sources of product information.

After learning a booklet, the subjects performed a cued speeded recall task. They were presented with one of the brands or attributes and asked to recall, as quickly as possible, all the information associated with that cue. For example, if the cue was Skippy, a subject had to report each of the four attributes followed by its value for Skippy.

The cued speeded recall task was the same whether the information had been learned by brand or by attribute. The response times, however, should be different. In the brand input condition, the links between attributes within a brand should permit relatively fast recall of information to a brand cue. In contrast, a cue like price is separated from the necessary information by a larger set of links. Thus, our experiment depends on this simple principle: if information is stored by brand, it can be recalled more quickly by brand than by attribute; if it is stored by attribute, it should be recalled faster by attribute than by brand.

Method

Materials

Two brand-attribute matrices were used, one for air conditioners and one for cooking oils. These products were selected to represent both an infrequently purchased major durable and a common nondurable with a high repurchase rate. For air conditioners the brands were Admiral, Carrier, Frigidaire and Westinghouse, and the attributes were average price, circulation, energy use, and indoor noise. All 16 values took on one of three levels, high, medium or low. This matrix was adapted from evaluations of air conditioners published in Consumer Reports (July, 1973; and July, 1975). For cooking oils the four brands were Crisco, Kroger, Planters, and Wesson, and the four attributes were fat count, flavor, smoke point, and unit price. All 16 values took on one of three levels, fair, good, or excellent. This matrix was adapted from an evaluation of cooking oils published by Consumer Reports (September, 1973). Accompanying the attributes for each product category was a description of the meaning of the attribute. Subjects began the learning of product information by studying these attribute descriptions until they felt comfortable in their understanding of all of them.

The selection of particular brands and the phrasing of attribute labels were designed to maintain equal syllable counts for all rows and columns of a product matrix. This insured that response time was a measure of re-

trieval difficulty and not the output (speaking) time. Preliminary tests of the time needed to read each row and column within a matrix confirmed the approximate equality of the time to speak the eight files in a matrix.

Design

There were three main factors: A, input organization (brand or attribute); B, product (air conditioners or cooking oil); and C, probe type or cue type (a brand name or an attribute name). A fourth factor (D) is the specific cue, e.g., a specific one of the four brand names of air conditioners. This factor is nested within combinations of B and C. Each of the factors was fixed.

The three main factors were fully crossed (i.e., factorial) with one critical exception. Subjects could not be expected to learn information about the same product (Factor B) twice, once in each of the two input organizations (Factor A). Instead, each subject memorized both booklets once, alternating input formats (with order counter-balanced). The design for Factors A and B was a 2 x 2 Latin square fractional factorial design (see Kirk, 1968, p. 407). The main import of this design is the loss of all information about the A x B and A x B x C interactions. The only possible alternative design required a single subject to memorize both booklets in the same input organization. This split-plot design, by confounding group and input format effects, made the main effect of input (Factor A) indeterminate, which was even less desirable than losing an interaction effect.

The 2 x 2 Latin square divided the subjects into two groups (with 10 subjects in each group). Because 8 recall times (4 attribute cues and 4 brand cues) were obtained from both products and from each of the 20 subjects, a total of 320 observations formed the data base.

Subjects

Twenty-four undergraduates at Carnegie-Mellon University participated in the experiment. They were either volunteers (2) or were fulfilling a course requirement for introductory psychology (22). Two subjects were eliminated because they made more than three errors on the sixteen possible trials. Additionally, two subjects took an excessive amount of time to learn the information booklet for the first product. They were not asked to finish the experiment and their data were discarded. Thus, a total of twenty subjects provided data for the experiment.

When the response time data were analyzed, the means of 19 subjects ranged between 8.8 sec and 16.4 sec. The remaining subject's mean was 33.4 sec. Because this subject's responses were so unique and because they would thoroughly disrupt any pattern of results that held over the other 19 subjects, he was dropped from the study. One of the two subjects who failed to pass the error criterion had participated in the same condition as the dropped subject. This former subject was returned to the sample to maintain ten subjects per group.

Procedure

Subjects were told that they were participating in a study examining consumers' knowledge of various products. They were then asked to learn the contents of the first booklet. Instructions emphasized that the material in the booklet had to be remembered accurately. Subjects were also asked not to switch between pages of the booklet but rather to look at the book one page

at a time. After they had informed the experimenter that they thought they had learned the booklet, subjects were administered a criterion test. Subjects were asked to name the value of four different product-attribute combinations. If a subject could not successfully name the four values, he was given the booklet and told to try again. Subjects who passed the criterion test went on to the cued speeded recall task. The total time until the subject passed the test was recorded.

In the recall task subjects were presented either an attribute or a brand name. If the probe was an attribute name, they were told to recall all of the appropriate brand names and their values. For a brand name probe, they recalled the various attributes and values for that brand. The recall time was measured (in msec) from the onset of the probe to the end of the list. For each booklet the subject received four attribute probes and four brand probes. Order was randomized across subjects.

After completion of the first recall test, subjects were given the second booklet, this time with the opposite organization. The procedure for criterion testing and cued speeded recall was repeated.

Finally, subjects were presented an empty matrix for the first product class. The four attributes and the four brands were given but the sixteen values were missing. The subjects were asked to recall these values, and to write them down, in whatever order they wished. The output order was recorded. This was done for the second product as well. Then the subjects were debriefed and released.

The written free recall measure is not necessarily an independent measure of memory structure. Inherent in the cued memory task is recall by both brand and attribute. This task demand could cause reorganization which could well affect subsequent free recall. Also the time between learning the information and recall varies and the structure as therefore measured may be different than that measured with the cued recall. High convergence between these two recall methods may well wait until they are tried under a different experimental procedure.

Results

Encoding Time and Error Rate

A preliminary analysis tested for differences in the time necessary to learn the product information. An analysis of variance showed that learning times did not differ between the types of input organization, the different products or the two groups of subjects. Also, no interactions among these factors were significant. This precludes the possibility that differences in recall time could be due to differences in how well the lists were initially learned.

In the same way, differences in recall time could be confounded with differences in error rates across conditions. If speed is traded off for accuracy, then a difference in recall time can be due to different error rates as well as to the effect of an independent variable. Error rate was defined as the proportion of cued recalls for which at least one of the four required values (belonging to a single brand or a single attribute) was incorrect. The overall error rate was 7.8% (25 of 320). Using individual χ^2 -tests for the equality of two proportions, no significant differences in error rate were found between levels of input organization, product category, or cue type.

Taken together, these analyses imply that differences in error rates or thoroughness of learning can be ruled out as explanations for observed differences in recall speed.

Recall Times

Differences in recall times were tested by an analysis of variance. An examination of the residuals of the appropriate model indicated that a log transformation was needed to stabilize the variance over different levels of recall time. The results of the analysis of variance on the transformed recall times are reported in Table 1. The total degrees of freedom, 294, reflect the removal of the 25 recall trials on which an error occurred. Note that there are no replications in the design. The error term was estimated from the Group x Probe and Subject x Probe interactions. If these terms include any systematic efforts, the resulting F tests will be conservative.

*** $p < .001$

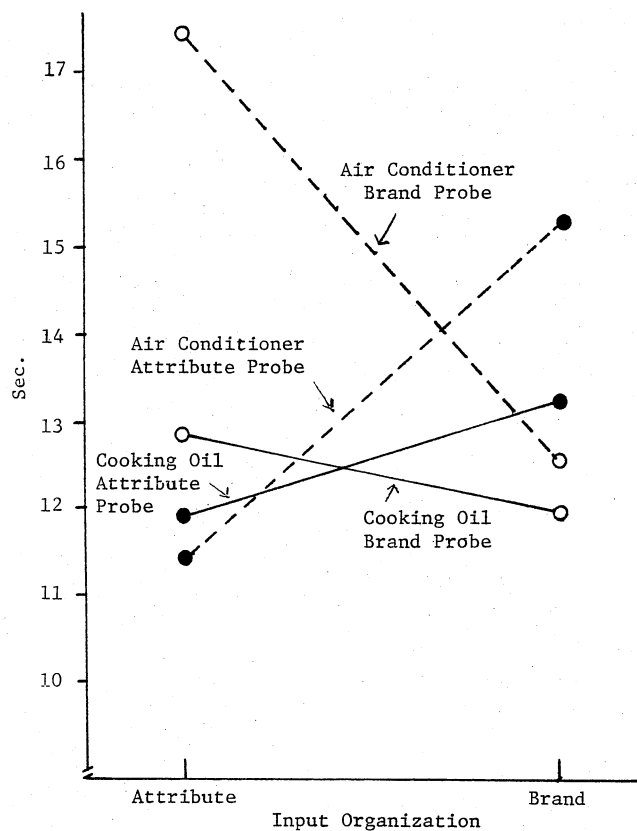

The critical prediction concerned the A x C interaction. This interaction captures the effect of storage organization (as induced from input organization) on the cued recall. It was predicted that recall would be faster when the probe type matched the structure stored in memory. Attribute probes would result in faster recall with attribute-organized information, and brand probes would be faster for brand-organized information. The "incompatible" probes would lead to slower recall.

As predicted, the A x C interaction is statistically significant and, furthermore, is the largest effect (in terms of mean squares) in the model. Before pursuing this and related effects, the subject and cue differences are noted. The presence of significant subject differences is typical in chronometric analysis. They are potentially attributable to many factors including motivation and strategy differences. There was no difference between groups, indicating that

subject differences were not systematically related to group. Note that in this design the A x B interaction is confounded with group. Therefore, the lack of a significant group effect validates the assumption of zero A x B interaction. The only other possibility is that both effects were of equal magnitude and opposite direction, thus cancelling each other out. Individual cue effects (Factor D) were also significant. This result was explored with a series of *a posteriori* contrasts. These tests revealed only one significant difference: for cooking oil the cue "cost" was faster than the cue "fat count." In general, the differences among cues exhibited no systematic relation, and they are of little intrinsic interest. The observed differences may be due to any articulation time or to irrelevant factors affecting memory, such as word frequency or concreteness.

To communicate the results involving the major independent variables, means over subjects and cues were computed. These values are plotted in Figure 2. The two pairs of crossing lines represent the A x C interaction, separately for the two product categories. Using *a priori* contrasts, both interactions were found to be significant. For air conditioners $F(1, 203) = 47.30, p < .001$; for cooking oils the interaction was less dramatic, $F(1, 203) = 5.93, p < .05$. Both the contrasts and an inspection of Figure 2 reveal that, though the predicted effect of compatibility between cue type and input organization is present for both product categories, the size of this effect differs across products.

FIGURE 2
Mean Recall Times

Returning to Table 1, it can be seen that both Factors B (product category) and C (cue type) show significant effects. As shown in Figure 2, cooking oil information was recalled faster than air conditioner information, holding all other factors constant. One possible explanation for this difference is articulation time. Though speaking times were approximately equalized across all brands and sizes within a product category, there were differences between categories. The total number of syllables over the eight brand or attribute names is 27 for air conditioners and 16 for cooking oil. Thus, the articulation time would be expected to be longer for air conditioners, as confirmed by the means in Figure 2. The other possibility is that cooking oil information is genuinely easier to recall. However, both products were learned as quickly and both yielded equal error rates during recall. These results suggest that the difference in recall times is not due to memory retrieval but rather to an output factor like articulation.

Differences between cue types are also apparent in Figure 2. The mean recall times were 12.97 sec for attribute probes and 13.70 sec for brand probes. This difference, though relatively small (2.7%), is intriguing. Although one can only speculate given the present data, this effect might be related to a more general preference for attribute information. Factor A, input organization, exhibited no significant effect. The equality of recall times over brand and attribute inputs is compatible with the absence of differences in learning time or error rate.

The B x C and G x C interactions are probably attributable to differences in large A x C interaction for each product combined with the nature of the design. As noted earlier, any A x B interaction is confounded with G. Thus, G x C is confounded with A x B x C, and the G x C interaction may well be explained by the product differences (Factor B) in the A x C interaction that are so apparent in Figure 2. In a similar way, the B x C interaction, which is smaller, seems to have no natural interpretation. It may be related to product differences or to the large A x C effect combined with the confounding of Factors A and B within groups. In sum, the G x C and the B x C interactions show that product category affects the strength and nature of the effect of display format on memory structure. However, these differences are small when compared to the main A x C interaction, accounting for less than a fourth of its variance.

Finally, the interactions with subjects (S x A, S x C and S x A x C) should be acknowledged as statistically significant. Since these effects are not large and reflect only individual differences, they are not particularly meaningful. For completeness, it is noted that the error term is composed of the G x D and S x D interactions.

In summary, the pattern of recall times indicates a strong effect of congruence between input organization and cue type. Attribute probes led to faster recall when the input organization was attribute-based, and similarly for brand cues with brand-organized information. This result confirms the main prediction of the study. In addition, marked product differences were found when the input x probe (A x C) interaction was examined separately for each product.

Results for Individual Subjects

Chronometric studies are usually based on data analyses that are complete within individual subjects. This requires the collection of many data points to enable reliable estimates of mean response time and statistical tests with adequate power. Collecting this large amount

of data becomes more costly as the task becomes more cognitively complex. In such cases, it is not unusual to find a subject participating for 20 or more hours in one experiment (e.g., Doshier, 1976). In the present study only 16 response times are available for each subject. Thus, although statistical tests of within-subject differences can be performed, some real differences may be obscured by variability.

The 16 recall times were classified by input organization and cue type (Factors A and C), creating four groups with four observations each. For each input organization, there are two mean response times, one for attribute cues and one for brand cues. The difference between the latter two means can be used to measure congruence between memory structure and input organization. This congruence will be termed input boundness. If the product information was learned in an attribute format, the mean for attribute probes is subtracted from the mean for brand probes. The larger this difference, the greater the input boundness. These then can be thought of as estimates of the degree to which a subject's internal representation is congruent with the external source. For each subject two such measures exist, one for attribute-organized input and one for brand-organized input. By summing these two measures, individual estimates of input boundness are obtained.

Using the estimate of MSE obtained from the analysis of variance, a t-test was performed for each subject. The significance level for this t-test (one-tailed) was set at .10 to favor the detection of differences in spite of the small number of data points. Using this criterion, 8 of 20 subjects exhibited significant input boundness. Thus, the main prediction and finding of this study, the congruence between input organization and memory structure, may be characteristic of less than half the subjects.

The reduced number of subjects showing an effect of input boundness could be due, in part, to the reduced statistical power of the individual tests. Additionally, the individual estimates of input boundness are confounded with product category. The observed differences across products may weaken comparability between mean response times for a single subject. Finally, it must be remembered that typical chronometric analyses of individual subjects require much larger sample sizes than available here.

Written Free Recall

After both sets of product information had been learned and probed via the cued speeded recall task, a written free recall was collected. For each product class, an empty 4 x 4 matrix was shown. The row and column labels were provided, and subjects were required to write in the 16 missing cell values. Each such output sequence consists of 15 intercell transitions.

Each of these transitions can occur within a column, within a row, or both to a different row and a different column. Since the booklets arranged information by column, a column transition was judged to be congruent with the original display. Row transitions could only occur if the memory structure is dissimilar to the original display. Therefore, each transition was coded as congruent (column) or incongruent (row or other) with the original input organization. At the end of a column or row, when all entries are filled, no more transitions within that file are possible. Thus, transitions from filled files could not be used to measure congruity with input, and they were excluded from the analysis. This left a data base of 12 transitions for each protocol.

The overall proportion of congruent transitions is .72 (344 of 480). This value indicates a strong tendency for the written free recall to be congruent with the input organization. This confirms the major finding from the recall time data, the significant tendency for memory structure to be determined by input organization.

The proportion of congruent transitions were partitioned by the two possible independent variables, input organization and probe type. These data are reported in Table 2. The striking aspect of the pattern of proportions is their uniformity except for the brand-cooking oil cell. The other three proportions are all quite high, indicating input boundness. But when cooking oil information had been learned in a brand-organized format, considerable reorganization occurred. That is, subjects tended to reorganize from a brand-based input to an attribute-based memory structure. Again, this result confirms the findings from the recall time data.

TABLE 2
Proportion of Free Recall Transition Congruent with Input Organization

Product	Input Organization	
	Attribute	Brand
Air Conditioner	.83 ^a	.78
Cooking Oil	.80	.45

^aEach proportion is based on 120 observations.

At this point it is worth recalling the problems associated with the written free recall data that were discussed in the method section. The problematical nature of this recall technique, as it was implemented in this experiment, implies that all findings must be tempered with qualification. It is comforting that the free recall data averaged over subjects agree with the results based on the cued speeded recall task. However, a stricter test of the convergent validity between these two recall techniques can be based on the data of individual subjects. The proportion of congruent transitions was computed for each subject and correlated with the Bound statistic that is based on recall times and discussed earlier. Both are measures of input boundness. The correlation over the 20 subjects was .33, a value significantly greater than zero ($p = .02$) but not very high. It should be concluded that the free recall transitions are not as reliable as they should be--or as they could be with a different experimental procedure. However, when averaged over subjects, they probably present a satisfactorily accurate picture of memory organization.

Discussion

Summary of Results

The main finding was the congruence between input organization and memory structure. Averaged over the twenty subjects, both cued recall times and the output order of the written free recall supported this conclusion. Individual subject analysis of recall times suggested that 10 of the 20 subjects were significantly input bound. Input boundness was sensitive to type of product, with air conditioners inducing relatively consistent input boundness and cooking oil exhibiting more reorganization of the memory structure.

An important question is whether people prefer attribute-based or brand-based memory structures. A

very preliminary result of the present study is that attribute structures were preferred. This result is as intriguing as it is tentative.

Generality

The findings of this study, although clearly supporting the view that memory structure is input bound, should be considered only in light of product differences. There was much greater reorganization (less input boundness) for cooking oil than for air conditioners. Possible factors that can influence the input boundness of a product class need to be isolated. It is interesting to note, for example, that both the brand names and the attribute names were more familiar for cooking oil. Also, at least one of its attributes (polyunsaturated) fat count is health-related and apt to be especially salient. Clearly, a wider range of products will have to be examined before any relation between reorganization potential and product type can be established.

Because the subjects in this experiment were undergraduates, the findings may not generalize to representative shoppers. Bettman and Kakkar (1977) argue that such shoppers would be more brand conscious than undergraduates. A shopper's experience within a particular product category may contribute to brand consciousness or, alternatively, to the ability to reorganize by attributes. Questions of this nature can only be answered by studies designed to test the generality of the present findings over a much wider sample of products and subjects.

The Chronometric Technique

One of the positive results of this study is the demonstration of the usefulness of chronometric analysis. This is especially true for the study of the representation of product information in memory. The present use of chronometric analysis to identify the memory structure of product information parallels the recent recognition of the importance of this topic (e.g., Olson, 1977 and Bettman, 1978). However, chronometric analysis can be applied to a wide range of other consumer research problems. See Gardner, Mitchell and Russo (1978) for a discussion of this point and an application of this technique to low involvement advertising. As a final methodological note, the reader should be reminded that the chronometric technique used here is among the least sophisticated. More powerful methods are available and, hopefully, will be brought into the study of consumer behavior. However, even the simple chronometric techniques may be adequate given the size of the effects observed here which are considerably larger than those reported in most chronometric studies.

Implications for Policy

Memory structure for product information, and its relation to input format on the one hand and decision rules on the other, has important policy implications. We give one example. To the extent consumers are input bound, their memory structures will reflect the organization of product information in the environment. As just pointed out, this organization is largely brand-based (advertising, etc.). This is all well and good if consumers make better purchase decisions using brand-based strategies. But if attribute-based strategies are superior, and a growing body of evidence suggests this (e.g., Russo and Doshier, 1976), then brand-organized storage contributes to less accurate and more effortful purchase decisions. We may then find a conflict between superior decision rules and the organization of currently available product information.

This suggests a potential need for public policy intervention. More importantly, it suggests that any policy of information provision may want to alter the current format of product information. If the ultimate policy goal is to improve consumer decisions through information disclosure, the format of the information should be designed for compatibility with the preferred decision rules.

Future Research

A major direction for future research is to examine this relation between memory structures and decision rules. Does the structure of stored product information determine the decision rule(s) that can be employed? Or, conversely, does a preferred decision rule lead to the reorganization of product information into a compatible memory structure? The relative strength of influence between memory structure and decision rules is an important question in consumer research.

A related issue concerns the conditions surrounding the acquisition of knowledge about products. Consumers may intentionally retain information with the conscious goal of making a purchase decision. Knowledge can also be retained, possibly incidentally, for more general, future use (Greeno, 1976).

A second topic for future research is the influence of different external organizations of product information on memory structure. What is the preferred memory organization if a complete brand x attribute array is available? Suppose the externally available information is very unstructured, possibly in a discursive format or only accessible in a random order. Will shoppers attempt to organize an unstructured external display into a consistently preferred internal structure? Finally, what if product information is available as it typically is in the market place: from several sources (advertising, use experience, word of mouth, published ratings, etc.) that are not naturally comparable and that may include inconsistencies? Further, most real-world product information is brand-centered. Does this imply that memory structures are usually brand-organized whether or not attribute-based structures are preferred?

In the realworld, memory of product information is the link between information acquisition and the purchase decision. This topic is a major understudied area of consumer behavior. There are many important research questions associated with it, only a few of which have been posed above. By actively studying memory of product information, it may be possible to close a major gap between current laboratory research and the realworld consumer setting.

LOW INVOLVEMENT VERSUS HIGH INVOLVEMENT COGNITIVE STRUCTURES¹

John L. Lastovicka, Temple University
David M. Gardner, University of Illinois

Abstract

Multidimensional scaling of compact car perceptions is used to examine differences in cognitive structure between those highly involved with compact cars and those who are not. The empirical results, in line with prior theory, suggest a less differentiated and integrative structure for the low involved.

Introduction

Krugman's (1965) low involvement learning model has recently received renewed attention by consumer behavior researchers (Maloney, 1977; Banks and Hart, 1977). Krugman contended that television advertising is a special low involvement communication situation in which receiver responses are akin to the passive learning of nonsense syllables. He further suggested that the repetition of advertising resulted in a replacement of old brand perceptions with a new set of beliefs. This new cognitive structure was said to guide brand choice behavior without changing attitude (affect) first.

Krugman's original research stimulated consumer behavior researchers to conceptualize the advertising process in a situation-specific "micro theoretical" manner. For example, Ray et al. (1973) present alternative hierarchies of effect for different levels of involvement. One hierarchy, the standard COGNITIVE→AFFECTIVE→CONATIVE order, is labeled the learning hierarchy, and is seen as most appropriate for high involvement decisions which typically deal with high priced, high risk products. Another hierarchy, a COGNITIVE→CONATIVE→AFFECTIVE order, is labeled the low involvement hierarchy, and is seen as being appropriate for much repetitive brand choice behavior of inexpensive, low risk products. Figure 1 presents the two hierarchies.

Figure 1
Alternative Hierarchies of Effect[†]

[†]Adapted from Ray et al. (1973). "Learn-Feel-Do" terminology from Raymond (1976).

Despite the extensive research on low involvement consumer behavior (Maloney, 1977; Banks and Hart, 1977; Bowen and Chafee, 1974; Chafee and McLeod, 1973; Hupfer and Gardner, 1971; Preston, 1970; Robertson, 1976; Rothschild and Ray, 1974; and Ward, 1975), very little is known about the details of the differences between the cognitive structures in the two alternative hierarchies of effects.

One general assumption in this literature is that a low involvement cognitive structure is much less complex than a high involvement cognitive structure. Based on this assumption, it has been suggested that those advertising low involvement products discuss fewer product attributes in their advertising copy (Rothschild, 1977; Lastovicka and Gardner, 1977). Yet this global hypothesis, of less complex cognitive structure in low involvement, has not been specifically put to empirical test. The intent of this paper is to test this global hypothesis.

Method and Hypotheses

One approach of demonstrating the effects of involvement on cognitive structure is to compare and contrast groups of respondents who differ in their level of involvement with a given product class. In this study subjects highly involved with compact cars were compared to subjects who had a low level of involvement with compact cars. Although a correlational approach necessarily creates ambiguous statements, such an approach provides an opportunity to richly demonstrate the powerful effects of involvement on cognitive complexity.

Schroder, Driver and Streufert (1967) discuss several aspects of cognitive complexity in information processing. Two important aspects are "differentiation" and "integration." Broadly defined, differentiation refers to dimensionality or the number of dimensions used by an individual in processing information; and integration refers to the extent dimensions are interrelated or used simultaneously. The influence of involvement on both differentiation and integration were tested with these hypotheses:

H₁: A unidimensional model of car model similarities will produce a better representation of car model perceptions for low involved consumers than for high involved consumers. More complex multi-dimensional representation of brand perceptions will be better models of the cognitive structure of the high involved, but not necessarily the low involved consumers.

H₂: For a given dimensionality, highly involved consumers will tend to be more integrative and rely simultaneously on several perceptual dimensions. Low involved consumers will rely primarily on a lesser number of perceptual dimensions.

¹Preparation of this paper was aided by University of Illinois participation in the General Motors Intercollegiate Marketing Competition. The authors acknowledge with thanks the assistance of graduate students Patrick Merrill, Bruce Newman, Gary Pope, and Kwok-Cheung Wong for use of their data.

Data

One hundred twenty-seven respondents from an introductory marketing course completed a questionnaire dealing with low price, medium price and luxury domestic compact cars. Responses were collected on:

1. Twenty-two lifestyle items. A 1-5 strongly disagree --strongly agree scale was used.
2. Forty-five paired comparison dissimilarity items for ten different compact cars. A 1-9 extremely similar --extremely dissimilar scale was used to measure perceptions of these ten compact car models:

Pontiac Ventura	AMC Pacer
Ford Maverick	AMC Hornet
Mercury Comet	Oldsmobile Omega
Buick Skylark	Ford Granada
Mercury Monarch	Chevrolet Nova

These ten cars include the "look-alike" parity models of Granada-Monarch, Nova-Omega-Skylark-Ventura, and Maverick-Comet.
3. In addition to the forty-five paired comparisons for the ten stimuli, a repeated set of ten paired comparison items were completed by each subject. Test-retest reliability on the paired comparison task could then be measured for each subject.
4. A battery of familiarity questions. Subjects were asked how familiar they were with each of the ten car models on a 1-7 not at all familiar--very familiar scale.
5. A battery of demographic questions including age, sex and perceived social class.
6. A battery of ten questions in which respondents were asked to sort each of the car models into different categories of acceptability. The question posed was:

"How acceptable to you are each of the following car models?"

	Definitely Not Acceptable			Neutral		Definitely Acceptable	
	1	2	3	4	5	6	7
Pontiac Ventura	1	2	3	4	5	6	7
AMC Hornet	1	2	3	4	5	6	7
.
.
.
Chevy Nova	1	2	3	4	5	6	7

This last battery of ten questions is based on the Sherif and Sherif (1967) Own Categories Procedure measurement of involvement. The Sherif method starts with a list of items relevant to an attitude. This may be objects, pictures, or verbal statements about some topic or issue. In the current research the items are ten brand names of compact cars.

In the Own Categories Procedure respondents are asked to sort items into categories of acceptability. Considerable research (Sherif and Howard, 1961; Sherif, Sherif and Nebergall, 1965) confirms that the items that an individual accepts, rejects and towards which he is neutral or noncommittal varies systematically with his personal involvement. Specifically the Sherifs found:

Proportional to his lack of involvement, the number of positions the individual accepts and rejects become approximately equal and his latitude of noncommitment increases. This means that highly involved persons have a much broader latitude of rejection than persons less concerned, and that they remain noncommittal toward fewer

positions, even when not required to evaluate all of them. (Sherif and Sherif, 1967, p. 191, italics added.)

Typically, an involvement index is created in which the ratio of the number of items rejected to the number of items accepted, adjusted by the number of neutral items, is computed. With the current data such a measure was undefinable for many respondents for whom the number of items accepted and/or rejected was zero.

However, an involvement index which relied on the number of items which subjects were neutral or noncommittal about was operable with the current data. Depending on their degree of noncommitment or neutrality, respondents were rated in involvement with the following index:

$$\text{Involvement Index for Individual}_i = \frac{10}{\sum_{j=1}^{10} |X_{ij} - 4|}, \quad (1)$$

where X_{ij} is the i th individual's response to the j th of the ten acceptability questions and 4 is the neutral point on the 1-7 scale. Following Sherif, a high involvement index number computed from (1) indicates a small degree of noncommittal and a high level of involvement. A low index number represents a large latitude of non-committal and a corresponding low level of involvement.

By recoding the responses to the acceptability questions for the ten makes and models of compact cars using (1), an involvement index with a range of 0-30 was computed for each respondent.

Analysis and Results

A pair of multidimensional scaling (MDS) models, Young's TORSCA (1968) and Carroll and Chang's INDSCAL (1970), were used to uncover the underlying dimensions used by the respondents in evaluating the similarities between the ten compact cars.

Information processing researchers Schroder, Driver and Streufert (1967) cite aggregate level MDS methods as a good measure of differentiation or the number of dimensions used by individuals in processing information. Individual differences MDS models such as INDSCAL, which indicate to what degree respondents use the underlying dimensions, offers direct measurement of integration or the degree to which the dimensions are used simultaneously and are interrelated. Also, MDS researchers Shepard, Romney and Nerlove (1972) show MDS useful in recovering degree of cognitive complexity. MDS, therefore, seems well suited for tapping cognitive complexity.

Preprocessing the Data

Since each respondent provided two sets of judgments for ten of the possible forty-five paired comparisons, a reliability index was computed for each respondent with Spearman's rank order correlation. Those 79 respondents of the 127 whose reliabilities were above the critical level of .54 were retained for both the TORSCA and INDSCAL analyses. The average Spearman correlation for this retained group of 79 was .77.

Once involvement indices were computed, the retained sample of 79 was divided into three, approximately equal sized, involvement groups: low, medium, and high. The low group consisted of thirty respondents whose involvement indices were 17 or less. Twenty respondents, with indices between 18 and 21, were the medium group; and another twenty-nine respondents, with indices of 22 and over, were the high group. The mean involvement indices

for the low, medium and high groups were 14.28, 19.90 and 24.70, respectively.

Hypothesis One

Average, standardized similarity matrices for the paired comparison data were computed for the high and low involvement groups. The result was two 10 x 10 average matrices of car model dissimilarities. The high and low involvement dissimilarity matrices were scaled at an aggregate level using the TORSCA algorithm. In each case, solutions were obtained in one through four dimensions. Figure 2 shows the relationship between the Kruskal's stress statistic (the goodness of fit between the original dissimilarities data and the n-dimensional MDS configuration) and the dimensionality of the solution. Examination of Figure 2 should be done in the same spirit as the "root staring" procedure in factor analysis in which eigenvalues are plotted versus their number. This comment is made because established statistical tests for comparing stress levels are not available. Just as in "root staring," then, subjective judgment must play a large role in the current analysis.

The stress measures for the high and low involvement scalings shown in Figure 2 are in support of the first hypothesis. A simple unidimensional model of dissimilarities is a much better representation of cognitive structures for the low involvement group than the high involvement group. This simplest scaling indicates that a more complex model is needed for the high involvement group. For the two and three dimensional scaling solutions, differences in stress are not great. Yet these two and three dimensional solutions offer slightly better fit for the high involvement group. Finally, for the four dimensional scalings, the most complex models built in this analysis, the results are as theory predicts. Such further complication does not provide a better representation of cognitive structure for the low involvement group, yet better fit is marginally obtained for the high involvement group.

Hypothesis Two

The INDESCAL model was used to examine cognitive complexity in terms of integration. This model assumes a common stimulus space, with differential weighting of the dimensions of this common space for each respondent. A respondent's position in the INDESCAL person space represents the salience he assigns to each of the dimensions in the common stimulus space. Thus, the weights can be used to estimate an individual stimulus space for each person. The individual stimulus configurations are based on the common stimulus space, but are differentially "stretched" in accord with the square roots of the respondent's own weights.

The two dimensional group stimulus space in Figure 3 was interpreted with the classic LUXURY and SPORTY dimension.

The person space, showing each of the 79 respondent's saliences for the two dimensions of the common stimulus space, is shown in Figure 4. Using visual clustering the respondents were grouped into three clusters representing three integrative styles. A "left" cluster of 29 respondents who made disproportionate use of the SPORTINESS dimension was identified. A "center" cluster of integrative respondents who made roughly equal use of both of the common stimulus space dimensions has 24 respondents. The third cluster, a "right" cluster of 26 respondents, contains those who made disproportionate use of the LUXURY dimension.

The next step of the analysis was to test the influence of involvement on integrative complexity. In a two group discriminant analysis, involvement along with life-

style, familiarity and demographic measures were used to predict membership in the integrative "center" cluster or the nonintegrative "left" and "right" cluster. Though the prime interest is in detecting the influence of involvement on integration, it was felt the predictive power of this variable should be compared with others. Examination of normalized discriminant function weights allows easy comparative assessment of the predictor variables.

Rather than use the entire battery of the 32 lifestyle and familiarity measures as predictors in the discriminant analyses, two independent principal axes factor analyses were used on these measures to create a set of six parsimonious underlying factors.

The first factor analysis conducted on the 22 lifestyle items revealed four common factors. After a varimax rotation the four factors were easily interpretable. The first factor, an automotive knowledge factor, had high positive loadings on items such as: "I know a lot about cars;" and "People often come to me for information." The second factor, a functional automotive preference factor, had high positive loadings on items like: "I like to drive a car that will hold up in an accident;" and high negative loadings on items such as: "You can tell a lot about a person from the model of car he drives." The third factor, an image preference factor, loaded highly on items like: "I think cars are a mark of status;" and "I like to have the best looking car on the road." The fourth lifestyle factor, an automotive thrill-seeking factor, loaded highly on items such as: "I like to drive fast;" and "I like to listen to music while driving." Factor scores were then estimated on these four lifestyle factors.

The second factor analysis was conducted on the familiarity ratings for the ten compact cars. Two factors were extracted in this analysis; the first was an overall familiarity factor and the second was familiarity with certain models of parity cars. Familiarity with the differences between the "look-alike" parity models of Omega, Nova, Skylark and Ventura, for example, was independent of overall familiarity. Factor scores were also estimated for these two familiarity factors.

Using lifestyle factor score estimates, familiarity factor score estimates, the involvement index, age, social class and a dummy variable for sex, a significant discriminant function was found to differentiate between the integrative and non-integrative groups. The obtained value of Rao's F-ratio approximation, $F_{10,68} = 1.96$, is just significant at the .05 level. Using the discriminant function weights shown in Table 1, 70.8 percent of the integrative group and 72.7 percent of the non-integrative group could be correctly classified. Predictive validity was further tested using U-method pseudo jack-knife classification (Crask and Darden, 1977). With the U-method a classification function was computed for each of the 79 cases with that case omitted from the computations. Since each of these functions was used to classify the left-out case, a less biased classification occurs.

Based on the U-method jack-knifed classification functions, 50 percent of the integrative group and 67.3 percent of the non-integrative group were correctly classified.

Examination of the relative size of each standardized discriminant weight in Table 1 gives an indication of the relative importance of the ten variables in differentiating between the two groups. As hypothesized, involvement is found to be a good explanatory variable for cognitive integration. The weight for the involvement index, .806, is almost twice the size of the next largest weight. Examination of the cluster means on the discriminant function shows that the "center" cluster,

Non-Integrative ("Left" and "Right" Clusters)	1.84

the integrative group which used both the INDSCAL stimulus space dimensions equally, has the highest score. It seems then that equal use of both dimensions occur primarily under high involvement. Low involvement cognitive structures seem less integrative and rely primarily on one dimension.

Discussion

The general findings of this study are in line with prior theory. Low involvement cognitive structures do seem to be simpler than high involvement structures in at least two ways. First, low involvement structures seem less differentiated as they can be represented adequately with fewer dimensions than high involvement structures. Second, low involvement structures tend to be less integrative. In the current data, a two space map of a low involved individual's compact car perceptions is typically most reliant on one dimension. The simultaneous, integrative approach is apparently not worth the effort on the part of the low involved consumer.

Despite the support for the global hypothesis, several points must be kept in mind.

First, the differences found in cognitive structure can only be said to be potentially due to involvement. Crucial differences besides involvement may be responsible for the observed phenomena. Further research in this area should include both use of experimentation and multiple measurement approaches to involvement.

Second, cognitive structure, the dependent measure, was measured only along two dimensions: differentiation and integration. Cognitive differences in terms of discrimination, for example, were not examined.

Third, differences have been examined between individuals for a given product. Though such an approach is useful for market segmentation, the real thrust of low involvement consumer behavior concerns differences between products.

In conclusion, this study should be seen as a very basic exploration into the nature of the differences between high and low involvement cognitive structures. The paper should help to underscore that there is a difference between the low involved consumer and the high involved consumer that most researchers have implicitly assumed.

A STUDY OF THE INTERFACE BETWEEN ATTITUDE STRUCTURE
AND INFORMATION ACQUISITION
USING A QUESTIONNAIRE-BASED INFORMATION-DISPLAY SHEET

Morris B. Holbrook, Columbia University¹
Karl A. Maier, Ketchum, MacLeod & Grove, Inc.

Abstract

A new technique for measuring information acquisition in a survey questionnaire is applied to a study of the relation between the selection of brand-attribute cues and the multiattribute model of attitude structure. A relationship is found between attribute importance and the acquisition and impact of product-related information.

Introduction

A growing body of consumer research has investigated the acquisition of information during the decision-making process. By far the most common technique for studying this search phenomenon uses information-display boards that array cues on m attributes of n brands in an $m \times n$ matrix (Bettman, 1976; Bettman and Jacoby, 1976; Chestnut, 1976; Jacoby, 1975, 1976; Jacoby, Chestnut, and Fisher, n.d.; Jacoby, Chestnut, Weigl, and Fisher, 1976; Jacoby, Szybillo, and Busato-Schach, 1977; Payne, 1976a, b). Typically, choice-simulating subjects select a brand-attribute combination of interest, remove a card from that cell of the matrix, read the information on the back of the card, and deposit it into a pile before choosing the next card. The resulting deck of used cards represents the extent and sequence of information sought about each brand on each attribute.

The potential relevance of such information-acquisition measures to the multiattribute models of attitude structure is obvious. Yet a comprehensive review of recent attitude research in marketing suggests that little effort has been made by consumer researchers (with or without the use of information-display boards) to study the interface between attitude structure and the informational inputs that presumably shape beliefs or other basic components of the multiattribute models (Holbrook, 1976).

Holbrook (1975, 1976, 1977) has argued that--according to Bayesian decision theory (Edwards, 1965; Green, 1964; Winter, 1975), Berlyne's (1960) theory of cognitive motivation, and the theory of perceived risk (Cox, 1967; Ross, 1975; Taylor, 1974)--information to aid consumer decision making should be sought primarily on those attributes that are subjectively perceived as most important. More broadly, it appears that the value of information should depend upon the importance, uncertainty, and confidence associated with the attributes to which it pertains. This conclusion is supported by the so-called Principle of Information-Processing Parsimony (Haines, 1974, p. 96), which suggests that limited cognitive capacity forces problem solvers to adopt heuristics restricting their attention to the minimum amount of data necessary for satisficing decisions (Bettman, 1974; Haines, 1974; Payne, 1976a; Wright, 1973, 1974). That principle is consistent with the lexicographic decision model's assumption that information on various attributes will

be sought in order of their perceived importance (Payne, 1976a, b; Wright, 1975), but apparently this hypothesized relation between subjective attribute importance and search priority has been tested only occasionally, rather unsystematically, and with mixed results (Jacoby et al., n.d., 1976; Bettman, 1974; Myers, 1976; Nakanishi and Bettman, 1974; Tigert, 1966; Winter, 1975). In further accord with the Principle of Parsimony, numerous studies have shown that a very simple model of attitude structure, summing only the belief scores on those attributes considered the few most important, predicts affect at least as well as more complex forms of the multiattribute model (Bass and Wilkie, 1973; Holbrook, 1976; Holbrook and Hulbert, 1975). All these perspectives on attribute importance suggest that its role at the interface between attitude structure and information acquisition may be fundamental to our understanding of preference formation and brand choice.

If such propositions are to be tested on reasonably large and representative consumer samples of the type recently called for by Ferber (1977), it will be useful to develop measures of information acquisition that can be mass administered through survey-questionnaire techniques. To this end, the authors have designed an information-display sheet that is analogous to the information-display board except that the respondent acquires cues by removing gummed stickers placed over the cells of interest in an $n \times m$ brand-attribute matrix. Self-administration of this instrument makes it suitable for use in field-survey research.

Accordingly, the study reported below had three major purposes: (1) to evaluate the feasibility of the questionnaire-based sticker-removal task as a measure of information acquisition; (2) to test the hypothesis that attribute importance, as an indicant of information value, is a key determinant of the extent and sequence of information seeking on that attribute; (3) to test the hypothesis that preference is adequately predicted by a simple model summing the evaluative beliefs on those attributes considered important enough to be the object of search.

Method

Subjects and Choice Task

One hundred students at Columbia University's Graduate School of Business participated in a questionnaire-based choice task in which each respondent sought information before selecting a phonograph record to receive as a raffle prize if he was one of five winners in the lottery for a \$5.00 gift certificate. In order to approximate the conditions typical of a mail survey, respondents completed the questionnaires at their leisure on a self-administered basis.

The records presented in the choice task were fictitious vocal albums that differed on six attributes described by the questionnaire as follows:

1. SINGER'S STYLE: traditional--a well known pop artist who has been around for a number of years; or contemporary--a relative newcomer setting trends in the current idiom

¹ Morris B. Holbrook gratefully acknowledges the support of Columbia University's Faculty Research Fund.

2. TYPE OF SONGS: standards--familiar tunes that most listeners have heard before; or originals and recent hits--new songs composed by the performer or recently made popular by someone else
3. TYPE OF PRODUCTION: studio--recorded in a fancy studio, usually with complex background arrangements; or live--recorded in front of a live audience, typically with a small back-up band
4. JACKET: informative--album cover contains extensive liner notes with biographical data on the artist and full credits for producers, arrangers, musicians, etc.; or visual--album cover features attractive photos or other graphic artwork suggesting the mood conveyed by the recording inside
5. LABEL: major--one of the big entertainment-industry conglomerates; or independent--a small, privately run record company
6. PRICE: \$5.59--a 20% discount from the list price of \$6.98; or \$4.19--a 40% discount from the list price of \$6.98

Attribute-Specific Measures

Immediately following these descriptions, the six attributes were rated on 7-point scales representing: (1) the importance of each attribute to the respondent's evaluation of a pop vocal album (from "not at all important" to "extremely important"); (2) the respondent's confidence in his ability to understand and interpret information concerning each attribute (from "not at all confident" to "extremely confident"); (3) the respondent's certainty that virtually any vocal recording on the market would be satisfactory with respect to each attribute (from "not at all certain of satisfaction" to "extremely certain of satisfaction"). In addition, the two characteristics cited in describing each attribute were rated for their desirability on the 7-point scales shown below:

	EXTREMELY UNDESIRABLE	EXTREMELY DESIRABLE
Traditional singer	_ : _ : _ : _ : _ : _	_ : _ : _ : _ : _ : _
Contemporary singer	_ : _ : _ : _ : _ : _	_ : _ : _ : _ : _ : _
Standard songs	_ : _ : _ : _ : _ : _	_ : _ : _ : _ : _ : _
Originals and recent hits	_ : _ : _ : _ : _ : _	_ : _ : _ : _ : _ : _
Studio recording	_ : _ : _ : _ : _ : _	_ : _ : _ : _ : _ : _
Live recording	_ : _ : _ : _ : _ : _	_ : _ : _ : _ : _ : _
Informative cover	_ : _ : _ : _ : _ : _	_ : _ : _ : _ : _ : _
Visual cover	_ : _ : _ : _ : _ : _	_ : _ : _ : _ : _ : _
Major label	_ : _ : _ : _ : _ : _	_ : _ : _ : _ : _ : _
Independent label	_ : _ : _ : _ : _ : _	_ : _ : _ : _ : _ : _
Price of \$5.59	_ : _ : _ : _ : _ : _	_ : _ : _ : _ : _ : _
Price of \$4.19	_ : _ : _ : _ : _ : _	_ : _ : _ : _ : _ : _

The importance and confidence ratings were scored from 1 to 7. By contrast, the certainty ratings were scored in the direction of increasing uncertainty, from 7 to 1. Finally, in acknowledgement of the debate surrounding the proper coding of evaluative scores (Ahtola, 1975; Fishbein, 1976; Glassman and Fitzhenry, 1976; Lutz, 1976), two alternative codings of the desirability ratings were investigated: -3 to +3 and 1 to 7.

Test Objects

The dichotomous characteristics for each attribute were used to specify eight records according to the kind of fractional factorial design described by Green (1974) as suitable for conjoint-measurement studies. The rows of the resulting 8x6 matrix were randomized and labelled from "A" to "H." The entire matrix of attribute-specific cues describing each record album appears in Table 1.

The Information-Display Sheet

After providing the attribute-specific ratings discussed above, the respondent turned to an information-display sheet consisting of the matrix shown in Table 1 with each cell covered by a gummed sticker appropriately labelled from A1 to H6. Written instructions asked the respondent to remove enough stickers to give him the information needed to choose the album he wished to receive as his raffle prize if he won the drawing for a \$5.00 gift certificate. The bottom of the page contained another matrix entitled "Order of Sticker Removal" with boxes labelled from "1st" to "48th." The respondent was instructed to place each sticker into the box designating its order of removal. He was told that he could obtain all the information needed to make his choice by peeling off as many stickers as he wanted, but that each piece of information acquired would result in the deduction of 5 cents from the \$5.00 value of his potential prize.

After completing this task and making his choice, the respondent was further instructed to continue removing stickers until he had collected enough information to permit him to rank all eight recordings in order of preference. He was told that no cost would be imposed for these additional stickers and that they should therefore be placed in a second set of boxes labelled "1st" to "48th" and entitled "Order of Removal of Additional Stickers." When he had completed this second process of cue selection, the respondent ranked all eight records in order of preference.

In sum, this procedure obtained measures of both choice and preference order with associated indices of costly and costless information acquisition. Not surprisingly, the 5-cent charge for cues in the choice task was somewhat discouraging to information acquisition. On the average, respondents acquired only 9.02 cues in this task, as compared with an average of 25.46 in both the choice and ranking tasks combined. Full analyses of both the single and combined information-acquisition measures produced virtually identical results. Accordingly, only the data for the combined total of cues selected are discussed in the present report.

Operational Definitions

Extent of information acquisition. The extent of information acquisition (EIA) on each of the six attributes was defined operationally as the number of cues acquired across all eight records:

$$EIA_j = \sum_{i=1}^8 ACQ_{ij} \quad (1)$$

where ACQ_{ij} is a zero-one dummy variable representing the removal of a sticker in either the choice or ranking task, i refers to the eight records ($i = 1, \dots, 8$), and j refers to the six attributes ($j = 1, \dots, 6$).

Sequence of information acquisition. The sequence of information acquisition (SIA) on each attribute was defined operationally as the average rank order of acquiring information on that dimension across the eight records:

$$SIA_j = \sum_{i=1}^8 RANKACQ_{ij} / 8 \quad (2)$$

where $RANKACQ_{ij}$ is either the rank order in which a cue was actually selected in the two tasks combined or the average rank order for those remaining cues not selected in either task.

TABLE 1

Matrix of Information Representing Record Albums
Specified According to a Fractional Factorial Design

	1. Singer's Style	2. Type of Songs	3. Type of Production	4. Jacket	5. Label	6. Price
Record A	contemporary	standard	live	visual	major	\$5.59
Record B	contemporary	recent	studio	informative	independent	\$5.59
Record C	contemporary	standard	live	informative	independent	\$4.19
Record D	traditional	standard	studio	informative	major	\$5.59
Record E	contemporary	recent	studio	visual	major	\$4.19
Record F	traditional	recent	live	visual	independent	\$5.59
Record G	traditional	recent	live	informative	major	\$4.19
Record H	traditional	standard	studio	visual	independent	\$4.19

Information value. Several alternative indices of information value were examined for their ability to predict the extent and sequence of information acquisition. In addition to the attribute-specific scores for importance (IMP_j), confidence (CON_j), and uncertainty (UNC_j), multiplicative information-value indices were defined as follows:

$$\text{importance-confidence index} = IMP_j \times CON_j \quad (3)$$

$$\text{importance-uncertainty index} = IMP_j \times UNC_j \quad (4)$$

Attitude structure. In accord with the multiplicity of available multiattribute models of attitude structure (Bass and Wilkie, 1973; Fishbein and Ajzen, 1975; Holbrook, 1976; Wilkie and Pessemier, 1973), several alternative attitude models were examined for their ability to predict preference order:

$$\text{Partial Additive Model} = \sum_{k=1}^6 B_k \cdot E_k \cdot ACQ_k \quad (5)$$

$$\text{Partial Averaging Model} = \left(\sum_{k=1}^6 B_k \cdot E_k \cdot ACQ_k \right) / \left(\sum_{k=1}^6 ACQ_k \right) \quad (6)$$

$$\text{Full Additive Model} = \sum_{k=1}^{12} B_k \cdot E_k \cdot ACQ_k \quad (7)$$

$$\text{Full Averaging Model} = \left(\sum_{k=1}^{12} B_k \cdot E_k \cdot ACQ_k \right) / \left(\sum_{k=1}^{12} ACQ_k \right) \quad (8)$$

where k refers to the twelve characteristics that a given record does ($k = 1, \dots, 6$) and does not ($k = 7, \dots, 12$) possess; $B_k = 1$ if the record possesses characteristic k or $B_k = -1$ if it does not; E_k represents a respondent's evaluation of the desirability of characteristic k (scored from -3 to $+3$ or from 1 to 7); and ACQ_k is a zero-one dummy variable representing the acquisition of information on characteristic k .

In addition to the attitude models listed above, importance-weighted versions were also investigated. These were identical to the above forms except that $B_k \cdot E_k \cdot ACQ_k$ was replaced by $B_k \cdot E_k \cdot IMP_k \cdot ACQ_k$. Note that, for all such models, the inclusion of the multiplicative ACQ_k term has the effect of setting belief scores equal to zero for those characteristics about which information was not acquired. Note also that the Partial Models assume that preference depends only upon the evaluations

of the characteristics known to be present in a record whereas the Full Models assume that preference may be enhanced (reduced) by the absence of undesirable (desirable) characteristics. The Full Models thus incorporate logic analogous to that underlying arguments for the bipolar coding of belief and evaluative-aspect scores in the Fishbein model (Fishbein, 1976; Fishbein and Ajzen, 1975).

Hypotheses

Given the operational measures defined above, two key hypotheses were tested:

H_1 . Information value predicts the extent and sequence of information acquisition

H_2 . Attitude-structure models based on the information acquired predict preference rank

There were no a priori hypotheses concerning the relative predictive efficacy of importance, confidence, uncertainty, the importance-confidence index, and the importance-uncertainty index as measures of information value or of the Partial and Full Additive and Averaging Models as representations of attitude structure. Rather, findings concerning the relative performance of these alternative indices and models were considered exploratory.

Statistical Procedures

Statistical routines were run separately for each respondent using (1) Pearson product-moment correlations across the six attributes to test hypothesis H_1 and (2) Spearman rank-order correlations across the eight records to test hypothesis H_2 . The use of intraindividual analysis is considered essential in such correlational tests to avoid utility comparisons between individuals and to minimize yea-saying bias (Bass and Wilkie, 1973).

Results

Few problems appeared to arise in the respondents' self-administration of the instrument described above. All but a handful of the questionnaires were returned in proper order (the exceptions were, of course, discarded), and where a sticker was occasionally damaged or defaced, respondents showed a reassuring tendency to write in the

^aN = 100.

missing identification number by hand or to use a piece of Scotch tape to stick it firmly in place.

Results for hypothesis H₁ are presented in Table 2. Attribute importance offered fairly good mean predictions of both extent and sequence of information acquisition ($\bar{r} = .587$, $Z_{\bar{r}} = 15.45$, $p < .0001$; $\bar{r} = -.633$, $Z_{\bar{r}} = -17.11$, $p < .0001$). Because the distributions of these correlations were skewed, the medians were substantially stronger than the means ($\bar{r} = .722$ vs. $.587$; $\bar{r} = -.752$ vs. $-.633$). The predictive performance of attribute importance was significantly better than that of either confidence or uncertainty: $\bar{r} = .587$ vs. $.186$ ($t_{99} = 8.33$, $p < .0001$); $\bar{r} = .587$ vs. $.055$ ($t_{99} = 7.38$, $p < .0001$); $\bar{r} = -.633$ vs. $-.161$ ($t_{99} = 9.25$, $p < .0001$); $\bar{r} = -.633$ vs. $-.052$ ($t_{99} = 8.18$, $p < .0001$). Finally, the multiplicative indices of information value (importance-confidence and importance-uncertainty) failed to improve upon the predictions obtained by importance considered alone: $\bar{r} = .587$ vs. $.543$ ($t_{99} = 2.87$, $p < .01$); $\bar{r} = .587$ vs. $.438$ ($t_{99} = 3.82$, $p < .001$); $\bar{r} = -.633$ vs. $-.577$ ($t_{99} = 3.11$, $p < .01$); $\bar{r} = -.633$ vs. $-.478$ ($t_{99} = 3.90$, $p < .001$). In sum, among those variables tested, attribute importance (with median correlations above $\bar{r} = .70$) was the simplest and best index of information value for predicting the extent and sequence of information seeking.

Table 3 presents the results for hypothesis H₂. In no case did the coding of desirability (E_k) from 1 to 7, instead of from -3 to +3, have any statistically significant impact on the performance of the Partial or Full Additive or Averaging Models in predicting preference. Nor did the inclusion of importance weights provide any significant improvement in the predictive performance of these models (probably because the models included only those belief scores considered important enough to have prompted information seeking in the first place). Table 3 therefore contains only the rank-order correlational results for the simple Partial and Full Additive and Averaging Models with desirability (E_k) coded in the theoretically appropriate manner,

TABLE 3

Mean and Median Spearman Rank-Order Correlations
Within Individuals Between Brand Preference
and Models of Attitude Structure

Model of Attitude Structure	Mean Rank-Order Correlation ^a	Standard Error ^a	Median Rank-Order Correlation ^a
Partial Additive Model ^b	-.568	.039	-.704
Partial Averaging Model ^b	-.542	.041	-.670
Full Additive Model ^b	-.558	.040	-.699
Full Averaging Model ^b	-.551	.040	-.683

^aN = 94 due to some cases with missing data.

^bIn all cases, results are reported for the models without importance weights and with desirability (E_k) coded from -3 to +3. These results did not differ significantly in any way from those obtained with importance-weighted models or with a 1-to-7 coding of E_k .

from -3 to +3. It is clear that all four versions of the model supported hypothesis H₂ by performing fairly well, with mean rank-order correlations ranging from $-.542$ to $-.568$ ($Z_{\bar{r}} = 13.22$, $p < .0001$). Again, the distributions of these correlations are skewed so that the medians are considerably stronger, ranging from $-.670$ to $-.704$. Since there is no statistically significant difference between the correlations obtained by any pair of

these four models, it might be argued that the "best" is therefore the simplest--namely, the Partial Additive Model, which simply sums the desirability scores of those characteristics known (after information seeking) to be possessed by a particular record. Although these results concerning the relative performance of the Additive and Averaging Models were considered exploratory in the present research, this finding may reinforce doubts about the often-claimed superiority of the averaging formulation (Lutz, 1976; cf. Fishbein, 1976; Fishbein and Ajzen, 1975). Further work comparing additive and averaging versions, using the sticker-removal task, is in progress.

Discussion

Limitations

The study reported above is subject to several important limitations. First, though an effort was made to select a product (phonograph records) of considerable relevance to the student population, it may be that, in acquiring information to evaluate records, students behave differently from housewives evaluating other consumer products (e.g., toothpaste), thus limiting the generalizability of the findings. Moreover, the records used were identified only by letter rather than by title and name of artist. This procedure helped guard against confounding effects, but represented a further departure from the real market place. It might also be objected that the self-administration of questionnaires passed out by hand differs in some nonobvious way from the completion of those received through the mail. Given the relative anonymity of the respondents, however, this potential problem does not appear to have been too damaging in the present situation.

Perhaps most seriously, the study's design may be subject to the impact of task structure on acquisition strategy recently demonstrated by Bettman and Kakkar (1977). For example, the first attribute (singer's style) was widely regarded as the most important, thus suggesting the alternative hypothesis that the relationship between importance and acquisition may have resulted, in part, from a tendency for respondents to begin at the left of the matrix and work their way to the right. This interpretation is at least partly ruled out by the fact that the last attribute (price), on the far right, was also generally regarded as highly important. Nevertheless, future work with the sticker-removal task will attempt to eliminate such potential order effects.

Conclusions

Apart from these limitations, the study seems to have achieved its purpose of using a new technique, suitable for administration by survey questionnaire, to test two key hypotheses concerning the relation of information acquisition to the multiattribute model. In general, the findings support the key role played by attribute importance at the interface between information acquisition and attitude structure. Specifically, in accord with hypothesis H_1 , attribute importance appears to guide search toward the most important attribute-related cues. Further, in accord with hypothesis H_2 , these most important cues appear to determine preference rank. This support for hypotheses H_1 and H_2 suggests a determinant role of perceived attribute importance in directing search toward information that, in turn, shapes the beliefs incorporated into attitude structure.

Finally, the study demonstrated the usefulness of the questionnaire-based sticker-removal task for investigating information acquisition. If consumer researchers are to heed Ferber's (1977) recent call for studies

using more representative samples, with a probable resultant loss in the feasibility of applying the techniques of laboratory experimentation, some such survey approach to studying information acquisition may well be necessary in the future.

ALTERNATIVE APPROACHES TO ASSESSING
THE QUALITY OF SELF REPORT DATA

Robert A. Hansen, The Ohio State University
Carol A. Scott, The Ohio State University

Abstract

Consumer behavior researchers place a great deal of emphasis on self-report or questionnaire data as input to decision making, but give little attention to assessing the quality of subjects' responses. A review of classical reliability theory indicates that available reliability measures are inappropriate in many consumer behavior data collection situations. This is particularly true in those cases where non-scaled or ad hoc measures are collected. Data quality requirements are discussed and some alternative methods of assessing data quality are presented.

Introduction

Consumer behavior researchers depend heavily on self-report data generated through mail survey questionnaires or interview schedules for information about consumer attitudes, preferences, and behavior. Self-report data is an integral part of laboratory and field experiments as well as survey research, and the recent explosion of articles on generating responses to self-report instruments attests to its importance (see Houston and Ford, 1976; Kanuk and Berenson, 1975). Pressley, 1976 for reviews). Much of this work, however, has been limited to a focus on the quantity of data collected primarily through mail questionnaires. Little attention has been devoted to the parallel issue of the quality of self-report data regardless of the collection method used.

This paper attempts to examine the topic of self-report data quality in some detail. Specifically, the objectives of this paper are to critically evaluate current methods of assessing data quality in those situations where traditional methods cannot be used. To provide an adequate context for this discussion, basic data quality requirements are first reviewed.

Data Quality Requirements

At least two broad criteria for data quality can be identified. First, responses must be meaningful. That is, they should reflect something other than a random checking of alternatives. This implies that responses reflect a true assessment of a particular behavior (e.g., frequency of purchase) or a true assessment of some personal characteristic (e.g., attitudes, brand loyalty, dogmatism), as opposed to unsystematic, situation-specific variation. The issue here is typically thought of as the degree of reliability of the responses.

Second, responses should be good indicators of the phenomenon of interest. That is, given that an adequate degree of reliability has been achieved, one must demonstrate that the scores are an adequate representation of the construct or quality under investigation. The issue in this case is one of validity (predictive, content, construct, etc.), which is examined by investigating the sources of the systematic variation observed.

This paper will focus primarily on the first of these criteria since reliability is necessary (but not sufficient) for validity. A second reason for this emphasis is that there are unique problems associated with the assessing the meaningfulness of responses to nonscaled measures which are frequently used by consumer behavior researchers and other applied scientists, and these

problems have received relatively little attention in the consumer behavior literature. Finally, the soundness of decisions (whether of managerial or public policy significance) based upon research data is profoundly affected by the degree of reliability associated with the data. As one prominent methodologist notes (Stanley, 1971, p. 58):

Unreliability places a question mark after the score (or response) and causes any judgment based on it to be tentative to some extent. The lower the reliability of the score, the more tentative the judgment or decision must be, until, in the extreme case, as reliability approaches zero, the score (or response) provides no basis at all for any judgment or decision...

Traditional Methods of Assessing Reliability

Appropriate methods of assessing the reliability of data depend upon the type of measurement instrument used. Consumer behavior researchers generally use two types of instruments: scaled measures and non-scaled, or ad hoc, measures. A scaled measure is defined here to be the result of pooling or combining a number of items selected from a larger pool to yield a score on the particular dimension of interest (e.g., androgeny, authoritarianism, attitudes toward government, etc.). Non-scaled or adhoc measures are those which are not designed to be combined for a summary score, but rather are of interest in and of themselves (e.g., frequency of purchase, preference for a given brand, etc.). Although specific methods for assessing reliability will differ depending upon the type of measurement instrument used, the logic should be similar. That is, one should gain some insight into the degree of systematic variation captured by the instrument. The discussion here is an evaluation of the appropriateness of currently available techniques for scaled and non-scaled data.

Scaled Measures

When the measurement instrument consists of a series of items which form a scale, assessing reliability can be accomplished by using one of several traditional methods. The mechanics of these techniques are outlined, and the relative merits of each are discussed, in several marketing research textbooks (e.g., Churchill, 1976; Tull and Albaum, 1973; Tull and Hawkins, 1976) and in several recently published articles (e.g., Lundstrom and Lamont, 1976; Pressley, 1976).

If two measurements are possible, a test-retest correlation can be calculated. This is perhaps not the best alternative, however. It is impractical in many consumer behavior research contexts to contact respondents twice for the necessary repetition of the measure. And, many constructs of interest to consumer researchers are variable over time. Since attitudes toward brands can change substantially even in the short run, for example, a low test-retest correlation would be difficult to interpret. It might be possible to administer parallel forms of the same instrument, but this may be possible only in those situations in which a researcher or his representative is present to provide an explanation for any apparent repetition, and where length of time

necessary to complete the parallel forms is not prohibitive.

Equivalence or internal consistency measures are also appropriate for a set of items which form a scale for which a summary score will be derived (Cronbach, 1951; Kuder and Richardson, 1937). This type of coefficient, unlike test-retest, is easily obtained, and should be calculated routinely for scaled instruments (Nunnally, 1967). A high reliability coefficient will provide some evidence that the responses reflect a systematic tendency, and will provide some rationale for combining the responses to form a scale score. Unlike test-retest procedures, equivalence coefficients should not pose any practical difficulties in terms of supervisory or time needs.

In summary, researchers should follow the standard procedures outlined in measurement texts in those instances where scaled measures are used. In some situations, a scaled measure does not exist, but could be constructed. That is, the concept is potentially scalable, but consumer researchers have not yet attempted to do the scale development work. It should be clear, however, that scales should be constructed whenever possible (Hughes, 1971; Lundstrom and Lamont, 1976).

Ad Hoc Measures

In some situations, the researcher cannot or perhaps would not want to construct a scaled measure, and a non-scaled or ad hoc measure is used instead. These non-scaled measures present some difficulty for quality assessment. The following section discusses ad hoc independent and dependent measures in greater detail.

Ad Hoc Independent Measures. In assessing the reliability of ad hoc independent or predictor measures, the use for which the data is intended must be considered since some procedures will be feasible for theory-testing research and others will be appropriate for applied or problem-solving research. An example using the multi-attribute product evaluation framework will illustrate this difference. If a researcher is interested in predicting product preference or purchase behavior, a strong case can be made for using the domain sampling model (Nunnally, 1967) and selecting multiple items which represent all aspects of the product evaluation process. Traditional methods such as Cronbach's coefficient alpha could then be used to assess reliability via internal consistency. An applied researcher, however, is frequently interested in evaluating a select group of the product's attributes. Further, he is most likely interested in the individual attributes themselves rather than in an overall summary score. Test-retest procedures are generally not acceptable for practical reasons, and internal consistency is not appropriate since a summary score is not desired. As yet, there are no widely accepted methods for assessing the reliability of this type of data.

Ad Hoc Dependent Measures. Criterion measures such as purchase behavior or product usage must also be examined from a reliability standpoint since reliable predictor variables applied to an unreliable criterion may produce misleading results. Many criterion variables are analogous to physical behavior and motor skills measures discussed by (Stanley, 1971). That is, an item pool does not exist because there are only a small number of ways in which certain questions can be asked. Since these variables are not scalable, traditional measures of reliability cannot be used as indicators of data quality, and therefore, other methods must be developed.

Alternative Approaches to Examining Data Quality

There are several techniques which the consumer behavior researcher can use to infer data quality when traditional

tools are not appropriate. These methods include analysis of the completeness of response, depth of response, and internal consistency of response patterns. These methods are admittedly non-traditional with only internal consistency of response patterns bearing a slight resemblance in title and operation to a psychometric interpretation of reliability. It must be remembered, however, that the data collection needs of the consumer behavior researcher are also quite often non-traditional in nature requiring the collection of ad hoc or non-scaled data. The results of these analyses can be used in two ways. First, the researcher who has collected data from a number of people can identify those individuals whose responses might be of questionable quality. These questionable respondents might then be discarded from the data base. Second, they may be used to assess the overall effectiveness of various methods used to collect data. Viewed in this manner, the measures could be used, for example, to evaluate the effects of alternative methods of stimulating mail survey response rates (Houston and Ford, 1976).

Completeness of Response

Completeness deals with the issue of item non-response. Of course the researcher's goal is to generate 100 percent response to all questions. Any deviation from total response to all questions raises a number of difficult problems. In many instances, methods used to handle missing values (e.g., drop those cases from the analysis, substitute a mean value, etc.) can have a serious effect in the representativeness of the results (Hansen and Scott, 1977).

Item-nonresponse can be expressed in a variety of ways. These include the mean number of missing values, the percentage of missing values, and complete versus incomplete response (Houston and Ford, 1976). However non-response is defined, any modification of the data collection process which yields a lower item non-response is desirable. Modification of a mail survey could mean the inclusion of an incentive to respond or the promise of anonymity. A second modification of the data collection process could involve the researcher allowing respondents to ask questions or by providing a don't know option for questions.

Depth of Response

Quality can also be viewed in terms of response to open-ended questions. The additional insight provided by an analyses of the depth of response is illustrated by the following example from a project currently being completed by one of the authors. In a mail survey, potential respondents were randomly assigned to one of three incentive groups: a monetary incentive group (i.e., 25¢ included with the survey), a non-monetary incentive group (i.e., a comparable value ball point pen included with the survey), and a no incentive group. The response rates for the three treatments (which indicate the quantity of data) were 38%, 22% and 14%, respectively. These results seem to indicate rather dramatically the effect of including inducements in the survey. However, when the returned questionnaires were analyzed for percent of missing values, the rates were significantly higher for both incentive groups. In addition, an independent panel of three judges rated the responses to a series of open-ended questions on the questionnaire and these ratings were subsequently analyzed. Results indicated that a significantly greater proportion of the responses in the non-incentive group were rated superior by the judges. In general the overall quality of response from the non-incentive control group was significantly better than that for the two incentive groups. Clearly in this case at least, the quality of data obtained issue causes us to re-evaluate the supposed superior performance of the inducements to respond to a mail survey.

There is another important aspect of assessing data quality which relates to those questionnaires where the respondent has in fact answered all or nearly all questions and where content analysis of responses is not possible. One would, of course, suspect the quality of responses from a person whose questionnaire contained a significant number of nonanswered questions. The equally important but more complex issue of evaluating the quality of a completed questionnaire is discussed below.

Internal Consistency

Internal consistency as used here is perhaps most closely associated with the concept of response bias. Response bias is frequently mentioned in connection with the self selection problem in mail surveys. In a number of these studies mathematical estimates of bias have been generated. (Kanuk and Berenson, 1975) discuss this interpretation of bias and the controversy surrounding its use. In addition response bias has been investigated by validating responses given in self-report sessions against other records of the same information (Kerin, 1974; Kerin and Peterson, 1977). In still other cases, bias has been defined as a difference in response pattern derived from a similar population using for example, different incentives to respond (Whitmore, 1976) or other attempts to stimulate response (Field, 1975; Wiseman, 1972). Bias it appears then has been used as a general umbrella to encompass a number of processes from true validity checks to simple checks of difference. In the former, it is assumed that one response is true (and deviations are errors), and in the latter it is just assumed that differences are bad. Bias, when operationalized using a known or accepted as true validating test, captures the essence of the data quality issue. Bias when defined in this manner focuses on the question of whether the responses are indicative of a true feeling as opposed to a random response or systematically altered response.

There are, however, two problems associated with using validated response bias as an overall indicator of data quality. First, there is the practical problem of collecting the validation information. This kind of information is only rarely available (Kerin, 1974; Kerin and Peterson, 1977) and if it has to be collected in addition to the data of interest it will increase project costs considerably.

A second drawback associated with using bias as a quality indicator is offered by Ferber (1948, p. 670): "The problem of response bias must be considered with specific reference to a particular question or characteristic. The presence of bias in one question does not mean a priori that the replies to other questions on the same questionnaire are also biased."

This suggests that question dependent response bias is not an acceptable indicator of overall response quality. What is needed is an assessment of quality derived from the entire self report data collection process. One possibility for assessing data quality which seems consistent with this goal could include bogus questions (Friedman and Goldstein, 1975), but could be expanded to include simple response inconsistencies. Additional questions may have to be added to the data collection instrument, but in many cases this will not be necessary. Careful attention to question wording can be used to generate logic checks. In this way the overall quality of respondent answers is inferred by the overall logic or consistency in response patterns. For example, if a respondent indicates that he/she has never heard of a particular product and then proceeds to evaluate that product, then one should be suspicious. Or, sequential sets of questions may be developed to allow for examination of the pattern of responses. If a respondent indicates that he/she never engages in a behavior and then in a later section answers a frequency question with a

response of greater than zero, one must be suspicious of the quality of the data.

Clearly, there are a number of safeguards which must be built into the analysis of such logic checks. First and foremost, all procedures must be pre-tested for clarity of instructions and ease of understanding. Second, one must examine the incidence of logic errors. One such error should not be taken as evidence of poor quality or response. Several errors of this type, however, would indicate problems with the quality of responses.

An example should help illustrate the usefulness of the process in detecting problems with data collected. A study was conducted by one of the authors in which a number of logic checks were built into a series of questions dealing with attitudes toward receiving direct mail, readership habits with regard to direct mail, and actions taken in response to direct mail (e.g., use of coupons, shop at store, sales, etc.). Results of the study indicated that approximately six percent of the returned questionnaires contained some logic errors. Only a small proportion of these poor quality respondents had a high proportion of missing values. If it is assumed that the incidence of logic checks indicates poor quality, then attempting to "clean-up" the data by setting some cut off point for an acceptable level of missing values would not accomplish the goal. Low data quality can be a problem even when item non-response is low.

Discussion and Conclusion

The quality of self-report data is of central importance to consumer behavior researchers. As shown in this paper, however, the applied researcher must develop his own indices of response quality in many instances. Where scaled measures exist or can be developed, standard measures of data quality exist and should be used. In those cases where these techniques are not applicable, data quality cannot be ignored. Several checks on the quality of responses have been suggested in this paper, and researchers can doubtlessly think of many others.

The procedures suggested are stop gap measures at best. Clearly, more work is needed in this area to develop standard techniques of assessing the quality of responses to non-scaled measures. Research is needed which has as its primary focus the quality of self-report data. This research should attempt to investigate definitions and measures of data quality and their relationship to standard definitions and measures of reliability and validity. Once these measures and definitions are developed, replication of their operationalization must be carried out across topics and populations.

A second area of research should focus on methods of increasing the quality of data. Instructions, for example, may be tested for their ability to provide better data. The inclusion of a "don't know" option should be tested to determine whether it will reduce item non-response and inconsistent patterns of data. Or, special questions may be included to screen out those respondents whose opinions and answers may be unreliable. For example, respondents could be asked to indicate how certain they are of their judgments. Respondents who are extremely uncertain of their answers may be dropped from further analyses. The efficacy of this approach could be tested by examining the correlation between certainty scores and test-retest reliability scores. Finally, one may conclude that special questionnaires must be developed for different populations of respondents who demonstrate difficulty with standard questionnaire formats.

In any case, it is not enough to suggest that researchers develop scales for every measurement situation and use

traditional reliability and validity techniques. There are too many instances in applied research settings where variables are not scalable, or where a score is not particularly useful to the researchers. A better tactic is to recognize the issue of data quality and to develop measures to fit the research context.

AN EVALUATION OF TELEPHONE SAMPLING DESIGNS

E. Laird Landon, Jr., University of Houston
Sharon K. Banks, University of Oregon

Introduction

The use of telephone interviewing in survey research has increased rapidly in the past decade. The increasing costs of personal interviewing, coupled with the higher crime rate in inner cities, have made personal interviewing less practical. On the other hand, the inherent biases and problems assumed to be created by the use of telephones in surveys appears to have been reduced. The percentage of households with telephones has reached an extremely high level. Improved telephone services, including WATS and pushbutton phones have increased efficiency. Sampling methods have been improved to better reflect the populations being sampled. These factors have contributed to the tendency of many researchers to substitute telephone interviewing for personal interviewing where appropriate. When considering the use of telephone interviewing, the adequacy of the sampling frame is of vital concern to the researcher.

Directory Sample Frame

Any research method which exclusively uses the telephone regardless of sample design may produce biased estimates because of the exclusion of non-telephone households. The extent of the bias depends upon how different households without telephones are, with respect to the issues under study. Studies conducted in 1968 and 1969 in Missouri showed that households without telephones tended to have lower incomes and live in rural areas more often than did households with telephones (Leuthold and Scheele, 1971). On the other hand, Klecka and Tuchfarber (1975b) state that, "... even personal interviewing techniques have difficulty locating the very people who are least likely to have phone service--namely, transients, the exceptionally disadvantaged and social dropouts." Also, the researcher may be less interested in the responses of non-telephone households. Because of the research objectives any bias may be unimportant.

Additionally, the percentage of households without telephones is apparently growing smaller. By 1976 over 90 percent of the households in the United States could be reached by telephone (Tuchfarber, et al., 1976). Sudman (1973) estimated that 98.5 percent of households in two Chicago suburbs had telephones.

Sample designs based only on telephone directories may suffer additional biases due to the many households with telephones which are not listed. Some households do not want to be in the directory so they are voluntarily unlisted--often paying a charge for the service. However, many households are not in the directory for reasons beyond their control; these households are involuntarily unlisted. Households may be involuntarily unlisted because they have recently moved into the community, they have moved within the community, for some other reason their number has been changed, or an error has occurred in producing the directory (Cooper, 1964). The total percentage of non-listed households has been estimated to be between 18-20 percent nationally (Cooper, 1964; Glasser and Metzger, 1975). However, unlisted percentages were estimated to be as high as 29 percent in some large metropolitan counties (Glasser and Metzger, 1975) and below 5 percent in some rural areas (Sudman, 1973).

The age of the directory is also a contributing factor to the percentage of unlisted households. A new direc-

tory may exclude only about 3 percent of all households involuntarily, while a year-old directory might exclude as many as 12 percent (Perry, 1968-69). The voluntarily unlisted percentage is probably fairly stable throughout the year--perhaps between 6 percent and 13 percent (Brunner and Brunner, 1971).

While the exact nature of bias created by not listing certain households depends on the population and the topic under investigation, some studies have discovered significant differences in unlisted households. In a 1967 study in Toledo, Ohio, Brunner and Brunner (1971) found that heads of voluntarily unlisted households tended to have less education, tended to be younger, and tended more often to be divorced than listed households heads (see also Leuthold and Scheele, 1971). Voluntarily unlisted households "... were less likely to own their homes, and relatively fewer of them resided in suburbia . . ." and fewer had lived at their present address for over two years. Glasser and Metzger (1972; 1975) found that unlisted households (including both voluntary and involuntary) "tend to have younger heads and fewer members 12 years of age or older . . ." and a higher proportion of 18 to 34 years-olds. Leuthold and Scheele (1971) found that unlisted households are much more likely to be black and be city dwellers than listed households in Missouri. Because unlisted households may represent up to 30 percent of all telephone households, the potential bias may be large.

Another problem with the directory as a sample frame is multiple telephone listings within a household. Households with more than one listing have a larger chance of being in the sample. Cooper (1964) found that about 3 percent of all Cincinnati households had more than one listing in the directory. Glasser and Metzger (1972) estimate that 2.2 percent of all households have more than one telephone number and 0.2 percent have three or more numbers.

Alternative Sample Frames

Because of the inadequacies involved in designs using the telephone directory as the sampling frame, researchers have developed alternative sampling methods (Chilton Research Services, 1976; Cooper, 1964; Glasser and Metzger, 1972; Hauck and Cox, 1974; Klecka and Tuchfarber, 1975a; Landon and Banks, 1977; Sudman, 1973). These designs have sought to overcome the problems of unlisted telephones. The alternatives utilize some form of random generation of telephone numbers. This article will evaluate several sampling methods which propose to eliminate the inadequacies of telephone sampling. Researchers must be aware of each sampling method's strengths and weaknesses, to choose the most appropriate one for the research study.

The methods may be divided into two basic classes--designs involving the directory and designs not involving the directory. Sample designs involving the directory begin with a sample of numbers from the directory and modify these numbers to allow the inclusion of unlisted telephone households. Other sample designs, not using the directory at all, combine random digits with some type of sample of existing telephone prefixes.

While both types of methods improve the quality of the sample compared with simple directory designs, they all tend to be less efficient. Because not all randomly

generated numbers are connected with households, the alternative designs develop samples that require more call attempts than the simple directory design. The classic trade-off in sampling between quality and cost is clearly present.

Evaluative Criteria

The sample designs will be evaluated on the following criteria:

1. Bias--the difference between the expected value of the sample statistic and the population statistic. An unbiased sample design is one for which the average of all possible sample statistics of size n would equal the population statistic.
2. Precision--the standard deviation of the sample statistics distribution. Precise sample designs will tend to be closer to the population statistic, for a given sample size.
3. Efficiency--the percentage of all telephone numbers in a sample which do connect with households. Random digit sample designs fabricate telephone numbers, some of which may not be connected with households (unassigned numbers and non-residential numbers). The more non-household numbers in a sample, the less efficient it is. Interview costs are inversely related to sample efficiency.

Of course, the completion rate in a sample of telephone numbers depends on more than the efficiency of the sample. The number and timing of callbacks--to numbers which do not answer or are busy--is critical to the completion rate. With no callbacks, the rate will be lower. Therefore, the efficiency of a sample depends on the sampling method, while the percentage of sample numbers contacted (completion rate) depends on callback procedures as well. The present definition of efficiency is restricted to factors relating only to sample design.

4. Feasibility/Ease of Drawing--sample designs differ on information needed about the population and the effort involved to draw the sample. If some required information is unattainable or the effort is larger than expected benefits, the sample design will not be practical.

Non-Directory Sample Designs

Non-directory random digit samples are basically of three kinds: simple two-stage, two-stage cluster, and stratified. A simple two-stage sample selects a working prefix, including its area code, at random, then adds a four-digit random number. The procedure is repeated until the sample is complete. A two-stage cluster design clusters telephone numbers by prefix (exchange, central office). A sample of prefixes is then selected by either a random or systematic procedure. Within these selected prefixes, four random digits are generated to create the sample of numbers. The stratified sample develops random digits for each working prefix, thereby stratifying the population by prefix. Stratified designs differ on the methods used to allocate the sample to the prefix strata.

While the two-stage designs are commonly used in national studies, the stratification designs have been used in local and regional studies. It is not feasible to stratify by prefix in national samples because there are more than 28,000 working prefixes (Chilton Research Services, 1976). All these sample designs can produce unbiased samples of telephone numbers, assuming that accurate prefix information is available.

Simple Two-Stage Samples

Klecka and Tuchfarber (1975a) and Glasser and Metzger (1972; 1975) have used the simple two-stage design. The only information needed is an enumeration of all working prefixes in the area to be sampled.

To reduce non-response bias researchers have developed methods to deal with not-at-homes and refusals. Klecka and Tuchfarber (1975a) made up to six callbacks of non-answering phones. These calls were made on different shifts to increase the likelihood of contacting a respondent. Glasser and Metzger (1972) made up to 20 callbacks. The great effort in making callbacks permitted the authors to accurately estimate the percentage of working numbers in the entire sample. Glasser and Metzger (1972) calculated that 21.3 percent of all sample numbers were connected with households in 1970. The efficiency of the simple two-stage sample--21 percent--is the lowest for all the sampling methods discussed. The primary cause of the low efficiency is that no allowance is made for non-working banks of numbers within working prefixes. (Each prefix consists of 10 banks of 1,000 numbers each. For example, the 1,000 numbers between 3000-3999 are a bank.) If one were to know which banks of numbers were non-working, the sample could exclude random digits which fall within these banks and efficiency would greatly increase. Unfortunately, information from telephone companies on active banks is not readily available. Some researchers have been able to obtain this information (Brunner and Brunner, 1971; Chilton Research Services, 1965; Cooper, 1964; Klecka and Tuchfarber, 1975a, 1975b) while others have ingeniously used directories to determine working banks (Sudman, 1973).

It is also desirable to reduce the refusal rate in the sample. Klecka and Tuchfarber (1975a) had different interviewers recontact initial refusals. If necessary a supervisor made another attempt to gain cooperation. The authors report that these attempts reduced the number of refusals by 30 percent, to 7.2 percent of eligible households. While these methods are successful in reducing non-response, they may be ethically questionable.

Two-Stage Cluster Samples

Chilton Research Services (1965; 1976) has developed (see also Eastlack and Assael, 1966) a national two-stage cluster sample which increases efficiency over simple cluster samples. A sample of 1,000 prefixes is drawn from a list of all working prefixes. The prefixes are listed according to size within regions of the country. Therefore, a systematic sampling of the 1,000 prefixes yields a regionally balanced sample. From each selected prefix a fixed number (e.g., 50) of four-digit random numbers are produced. Finally, numbers are eliminated which fall within non-working banks, which, contrary to most researchers, Chilton has been able to obtain through local business offices.

Chilton makes three callbacks on no-answer calls and has different interviewers recontact initial refusals. Chilton (1976) estimates that working prefixes are only 22 percent full, as a national average. This fullness is relatively close to the efficiency rating of the simple two-stage samples of 21.3 percent. However, when numbers falling within non-working banks are eliminated, Chilton estimates that 48 percent of their sample numbers connected with telephone households. The efficiency of this technique is about twice as efficient, because non-working banks are eliminated.

The relative precision of these two-stage sample designs is difficult to estimate. The two-stage cluster sample would have some loss of precision due to clustering. Because respondents within a prefix may be more alike

than respondents in different prefixes, the clustering of the sample may produce a larger standard error. However, the balancing of geographic regions and other factors may produce standard error gains over the simple two-stage design. While the Chilton design standard error could be reduced by spreading the sample over more clusters (say, 5,000 clusters of size 10), the gain would probably not offset the added effort of acquiring the non-working bank information.

Stratified Samples

Cooper (1964) and Landon and Banks (1977), using two slightly different approaches, have used stratified telephone samples where every prefix within the population is sampled. These approaches differ on the allocation methods to the prefixes. Both methods require information on working banks, and the second method uses information on the number of telephone households within each prefix. Cooper, after determining all working prefixes and working banks within these prefixes, allocates the sample equally to each prefix bank. Information on working banks might be obtained from the telephone company or could be estimated from the directory. Of course, new banks might be added after the directory is published.

From Cooper's data, the stratified sample using equal allocation to working banks has an efficiency of 41 percent, as measured by eligibles reached. While the efficiency is very close to the two-stage cluster efficiency two factors must be considered: callback procedures and working bank fullness. First, Cooper used no callbacks on no-answers, and one callback on busy signals. Thus, 27 percent of the numbers in the sample resulted in no contact (busy signals and no-answers). Many of these "no contacts" might have resulted in completions if callbacks had been made. Therefore, 41 percent is a conservative estimate of efficiency. Second, Cooper's study was conducted in the greater Cincinnati area. Efficiency scores are influenced by the relative fullness of the working banks. The efficiency of the equal allocation stratified method and the two-stage cluster method, using similar callback procedures, should be equivalent to the average prefix fullness of all working banks. Because Cooper's efficiency with no callbacks was equal to Chilton's, the fullness in Cincinnati was probably higher than the national average.

Landon and Banks (1977) allocated a sample to each prefix, proportional to the number of working phones. This allocation method placed more calls in fuller prefixes and fewer calls in less full prefixes. Therefore, efficiency was increased. However, this information is not always available to the researcher. The efficiency estimate of this allocation method in one study was 48 percent, 2 percent higher than the average fullness of all prefixes, indicating that allocation proportional to size is only slightly better than equal allocation.

The precision of the stratified methods should be better than the two-stage methods because every prefix is sampled. However, if respondents do not differ substantially between prefixes, gains will be small. It must also be pointed out that samples stratified by prefixes are virtually restricted to a local study. It would be difficult to stratify by prefix for a national study. Who wants to work with 28,000 strata?

Because completion probabilities differ between strata and the proportional allocation method unequally divides the sample, the strata means must be weighted to insure that the population estimate is unbiased. In the cited study, the weights did not significantly change the results, probably because the population is homogeneous between strata. However, weighting does slightly decrease precision and does add some work to the analysis. It appears as if proportional allocation, in this

example, gave little increase in efficiency and little loss in precision. The benefits of proportional allocation would be greatest where fullness differences between prefixes are large and differences between strata estimates are small. An illustration of these gains will be presented relative to the following sample design.

Directory Sample Designs

If the geographic area to be sampled is concomitant with the area covered by a telephone directory, then random digit directory sampling may be appropriate. A comparison of the feasibility and ease of drawing directory and non-directory samples will be presented in the next section.

Random digit directory sample designs begin by drawing a sample of numbers from the directory. This sample is often drawn using a systematic procedure. These numbers are then modified to allow all unlisted numbers a chance to be included.

With the systematic sample procedure, an interval is determined by dividing the total number of listings in the directory by the sample size. The interval is employed beginning with a random starting point between one and the interval.

Alternatively, by using the pages in the directory as clusters, and taking the same systematic sample on each page, one can use a hammer-and-nail method. The sample from any page is drawn and a nail is driven through the entire directory at the location of the chosen numbers. In this way, samples are simultaneously drawn from each page. However, the researcher must take care not to nail the directory to the desk (or nail through telephone numbers so they can't be read).

Inverse Sampling With Probabilities Proportional to Size

The inverse sampling method devised by Sudman (1973) systematically picks a set number of prefixes and working banks (his illustration uses 10) from the directory. This procedure gives each listed prefix/working bank combination a probability of inclusion proportional to the number of listed telephone numbers in the directory. The final three digits for each prefix-bank drawn are generated by a series of random numbers. Interviewers are instructed to continue dialing within the bank until a quota (his example was 5) of interviews is completed. Just as in two-stage block sampling all numbers have an equal chance of inclusion.

The efficiency of Sudman's method should be equal to the average fullness of the working banks. However, because numbers are clustered, it is possible to have a large share of the sample from relatively empty (or full) banks. While the theoretical efficiency is equal to average bank fullness, a particular sample using this method may have either a much higher or lower efficiency. Sudman presents an illustrative example reproduced in Table 1. The 10 selected banks required 108 calls to complete 50 interviews, largely because one bank had only 100 working numbers. In this bank alone, 58 calls were placed to complete the quota of five interviews. The expected completion rate was only 44.4 percent (48/108). If Cooper's method had been used, the 108 attempts would have been equally divided among the 10 banks. It can be shown that these calls would have yielded about 82.6 completed interviews for a completion rate of 76.5 percent. The improvement over Sudman's directory sample results from not allocating so many calls to the relatively empty bank. If the 108 calls were allocated proportional to the number of working lines within each bank, the 108 calls would have yielded about 90 interviews for a completion rate of 83.3

TABLE 1

COMPARISON OF SAMPLING METHODS ON NUMBER OF CALLS AND COMPLETION RATES BASED ON SELECTED BANKS

# of Banks	Bank Fullness	P(completion)	Sudman		Cooper		Landon	
			Calls Necessary	Calls* Completed	Calls Necessary	Calls Completed	Calls Necessary	Calls Completed
1	700	.7	6	4.2	10.8	7.56	9.9	6.93
2	800	.8	5	4	10.8	8.64	11.3	9.04
3	800	.8	5	4	10.8	8.64	11.3	9.04
4	850	.85	5	4.25	10.8	9.18	12	10.2
5	850	.85	5	4.25	10.8	9.18	12	10.2
6	850	.85	8	6.8	10.8	9.18	12	10.2
7	900	.9	5	4.5	10.8	9.72	12.7	11.43
8	900	.9	6	5.4	10.8	9.72	12.7	11.43
9	900	.9	5	4.5	10.8	9.72	12.7	11.43
10	100	.1	58	5.8	10.8	1.08	1.4	.14
	7.650		108	48	108	82.62	108	90.04
**Completion Rate				44.4%		76.5%		83.3%

* Calls Completed = P(completion) x Calls Necessary.

** Completion Rate = Calls Completed ÷ Calls Necessary.

percent. The gain is the result of allocating only 1.4 calls to the relatively empty bank and 12.7 calls to the fullest banks. While this illustration is rather extreme--bank fullness ranging from 10 percent to 90 percent--it shows the impact of sampling method and bank fullness on efficiency.

The inverse sampling method is advantageous in that no information is required other than a directory and a random number table. This advantage may make the method much more practical than the non-directory methods. While the inverse method makes no allowances for callbacks, it would not be difficult to include a systematic callback procedure.

Two Random Digits

A simpler procedure for sample selection is outlined by Hauck and Cox (1974). Once the sample of numbers is drawn from the directory, the final two digits are replaced with random digits. This simple design uses no quotas and requires no information from the telephone company. Of course, any new banks or sets of 100 numbers which have been added after the directory is printed cannot be included in the sample.

The efficiency will tend to be slightly higher than previously discussed designs because random digits are used for only the last two numbers. Therefore, non-working sets of 100 numbers are not included. These sets could be included in previous designs when the last three or four digits are randomized. Sample precision should be similar to the two-stage cluster method.

Plus-One Sample

Plus-one samples merely add one to the last digit of each number obtained from the directory. Plus-one has also been called add-a-digit, because researchers can create a new sample by adding another digit to a previously constructed sample.

Because only the last digit is modified, the plus-one method is likely to be most sensitive to omission of new sets of numbers being put in service after the directory is printed. Furthermore, all telephone numbers do not have an equal chance of inclusion. For a telephone number to be included the previous number (e.g., 442-5756 plus one = 442-5757) must appear in the

directory. Sample precision should again be similar to the two-stage cluster method.

To counter-balance potential bias problems, plus-one samples appear to be very effective in avoiding calls to non-working numbers. To test the higher efficiency expectations of plus-one as compared to random digit dialing, two projects conducted in separate communities began with equal numbers of telephone numbers selected either by plus-one or a stratified random digit method, utilizing proportional allocation (Landon and Banks, 1977). The efficiencies (as measured by eligibles reached) of the plus-one subsamples are 18 percent and 11 percent higher than the random digit subsamples. See Table 2. The plus-one design proved to be significantly ($p < .01$) more efficient than the random digit method because of the reduction in the inclusion of non-working numbers. The plus-one subsamples include 16 percent and 9 percent fewer non-working numbers than the random digit subsamples. Because only the last digit is changed the plus-one sample is restricted to working banks and working sets of 100 and even sets of 10 numbers.

TABLE 2

RESULTS FROM TWO DIFFERENT SAMPLING METHODS FOR TWO TELEPHONE SURVEYS

Category	Sterling		Boulder	
	Random Digit	Plus-One	Random Digit	Plus-One
Eligibles	47%	65%	38%	49%
Non-Working	26	10	38	29
Non-Residential	8	8	10	12
Not Connected				
(Busy, No-Answer)	19	17	14	10
	100%	100%	100%	100%
\bar{n}	367	362	454	456
Average Fullness of Banks:		59%		46%

While plus-one appears to be more efficient than random digit dialing, it may potentially be more biased. While

fewer non-working numbers are sampled, the design also may not give all working numbers a chance to be included.

Bias is introduced in plus-one samples to the extent that the response from numbers which have no opportunity to be in the sample would be different from those responses of numbers which could be in the sample. For example, if a group of high income residents began unlisted telephone service at the same time, and if the numbers were assigned sequentially, then all but the first resident would not have a chance of inclusion. If a study were conducted to measure income (or any correlate of income) the study would underestimate the population value. Plus-one may be more efficient than random digit designs. However, there may be idiosyncracies involved in the assignment of phones and the listing of phones which may cause some inherent bias. This bias might be avoided or certainly reduced if the researcher uses a random digit dialing sampling technique. Thus, researchers using plus-one must cautiously apply the design and compare the sample demographics with known population demographics as a check on bias.

Feasibility and Ease of Drawing Directory and Non-Directory Random Digit Samples

Directory and non-directory samples differ on how the sample is drawn and what information is needed to draw the sample. Non-directory samples, depending on type, need to have a list of all working prefixes covered, and to be efficient, a list of all non-working banks. Proportional allocation further requires knowing how many working household numbers are in each prefix. The more efficient the sample must be, the more information is needed. However, the only source of this information is the telephone company. Several researchers have commented on how difficult it is to get information (Cooper, 1964; Glasser and Metzger, 1972; Sudman, 1973). AT&T Long Lines does publish a Distance Dialing Reference Guide which lists all working prefixes in the country by area code. Even though most telephone business offices have the publication, it is only for internal use. The researcher needs special approval to use it. AT&T, Long Lines Division, does make a magnetic tape available with area code and working prefix information. The researcher must contact the local Long Lines Division for the \$43 tape. The request must be approved by the local office and the area vice president before the order is filled. The tapes are updated in January and June, but the researcher must buy each tape separately. Information on non-working banks within prefixes is very difficult to obtain. The only source for the information is the local business office controlling the prefix. Some offices consider the information to be confidential, while others need to seek approval from headquarters. On a local level it may be possible to establish contacts with telephone company officials. These contacts may provide the cooperation necessary to design more efficient samples.

Non-directory samples may be very easily drawn with the aid of computers. For national samples particularly, prefixes and random digits may be generated very quickly and cheaply. Research firms which conduct many studies may find the programming of sample selection to be very time saving. On the other hand, local studies which cannot take advantage of existing programs may find a directory sample quicker and easier to draw. Modified directory samples require no information from any outside source. If the directory is recent newly assigned sets of numbers will be included in the sample. However, because directories are required, national samples are difficult to draw.

It cannot be generally concluded whether directory samples are easier to draw than non-directory samples. The appropriateness of the design depends upon the

availability of necessary information, the scope of the study, and whether the researcher will draw many samples or only one.

Conclusion

Each sampling method described in this paper has the advantage of reducing potential bias compared with simple directory sampling. However, each method is also less efficient and more difficult or infeasible to draw than directory sampling. There tends to be an inverse relationship between efficiency and costs and the reduction of bias. Thus, the researcher must carefully weigh the objectives and budget of a study to determine the optimal balance. This paper has evaluated the relative merits and problems of available sampling methods, so that the researcher can balance the efficiency, costs, and potential bias.

WHETHER TO AGREE-DISAGREE OR DISAGREE-AGREE:
THE EFFECTS OF ANCHOR ORDER ON ITEM RESPONSE

David Sheluga (student), Jacob Jacoby, and Brenda Major (student)⁽¹⁾
Purdue University

Abstract

Research to date has generally focused on item content rather than item format as a source of questionnaire response bias. A laboratory experiment was conducted to assess the effects of different orderings of verbal and numerical anchors on responses. Results indicate that different rating scale formats differentially influence the degree of item endorsement. An "Agree (=1)---Disagree (=7)" format generates greater degrees of item endorsement than any other verbal and numerical anchor format.

Introduction

A commonly used approach in attitude assessment is to have respondents indicate the extent to which they agree or disagree with one or more attitude statements. Various types of biases may arise when employing such a measurement approach, particularly when a series of items is used and a cumulative score derived. A topic which has received considerable attention is the question of whether such scales are susceptible to response sets or styles, particularly acquiescence (e.g., Cloud and Vaughn, 1970; Elliott, 1961; Jackson, 1967) or "yea-saying" (Couch and Keniston, 1960) response bias.

While debate goes on regarding whether response styles are meaningful or even exist (e.g., Rorer, 1965; Jackson, 1967), those who have attempted to control or adjust for possible agreement response bias have focussed primarily on manipulating item stems through item content (e.g., Jackson, 1967; Elliott, 1961; Wrightsman, 1965; Cloud and Vaughn, 1970). One approach, the method of balanced keying (e.g., O'Neill, 1967; Terborg and Peters, 1974), presents even numbers of positively and negatively worded statements. In contrast to item content, the question of whether response format is sufficient to create, affect, or be used to control agreement response bias has received relatively little attention. As Cook and Campbell (1976, p. 242-3) remarked: "Attitude scales are often presented to respondents without apparent thought... to varying whether the positive end of the response scale appears on the right or on the left of the page."

Considerable evidence exists to show that order effects exist for checklist alternatives (e.g., Belson, 1966; Rugg and Cantrill, 1942). Thus, a reasonable concern is whether such order effects can cause agree or disagree response bias when present in rating scales. Given a seven-point rating scale, would responses differ if the scale ranged from seven (at the top or on the left) to one (at the bottom or on the right), rather than the more common one-to-seven? Similarly, would there be any differential effects if verbal end-point anchors appeared in positive-to-negative (e.g. "agree" to "disagree") rather than negative-to-positive order?

Given that both verbal and numerical anchors are used, another issue meriting consideration is the appropriate

combination of these anchors. To illustrate: is "strongly disagree" more reasonably associated with a "1" or a "7"? In some respects, the issue is analogous to the question of "fittingness" described by Kanungo (1968, 1969).

Accordingly, the present investigation examines the question of whether there are order effects for both verbal and numerical rating scale anchors. Specifically, two studies are described which address the following questions:

1. Do differential, perhaps biasing effects result from having horizontal seven-point graphic rating scales anchored in all four combinations of agree-disagree and 1-to-7?
2. What is the most natural or "fitting" combination of verbal and numerical end-point anchors?

Based upon research cited below, a seven-point scale anchored only at the endpoints was chosen for examination. Considerable literature (e.g., Bendig, 1954; Finn, 1972; Green and Rao, 1970; Guilford, 1954; Lehmann and Hulbert, 1972; Komorita and Graham, 1965; Matell and Jacoby, 1971, 1972; and Symonds, 1924) exists to suggest that 6-7 point scales are optimal for individual level analysis while 3-point scales are adequate for aggregate level analysis. Studies on verbal anchoring suggest that anchors at the end-points are preferred over anchors at every scale point or no anchors at all (Altemeyer, 1970; Bendig, 1953, 1955; Finn, 1972).

Method

Subjects

Subjects were 240 (167 male and 73 female) undergraduates enrolled in Introductory Psychology at Purdue University during the Spring 1976 semester who participated in order to fulfill a class requirement.

Procedure

Measures for the present studies were embedded in a larger set of questionnaires designed to investigate several fundamental issues in questionnaire construction. The combined battery, consisting of eight questionnaires, was administered during one 1-hour session. Each subject responded to all eight questionnaires, with the exception of one questionnaire which always appeared first (described below), the remaining questionnaires were presented in counterbalanced order and were randomly assigned to subjects.

Study 1

An eight-item questionnaire was developed to measure attitudes toward abortion. This topic was chosen based on pre-tests which had indicated that, relative to 12 other topics, abortion was a subject of moderate interest to comparable Purdue undergraduates. Although the eight item stems were identical for all subjects, four different response formats were constructed corresponding to a full crossing of verbal and numerical anchors. The response format for any one subject was the same for all eight items. Each response scale had seven-points. The end-points were labeled both

¹ The authors acknowledge with appreciation the contributions of Amy L. Lubitz and Peggy Whan in planning and executing this study, and Angelo DeNisi, Bernie Dugoni, and John Hollenbach for their statistical assistance.

numerically and verbally as indicated below, while the five intermediate points carried only the intervening numerical descriptors. Subjects were to respond by circling the one number along the scale which best represented their degree of agreement toward that particular attitude statement.

Form	Left Anchor	Right Anchor
1	1 = Agree	7 = Disagree
2	1 = Disagree	7 = Agree
3	7 = Agree	1 = Disagree
4	7 = Disagree	1 = Agree

Form 2 of the questionnaire is provided as Appendix A.

Study 2

This study was directed toward determining whether natural associative tendencies existed between the verbal anchors of Agree -- Disagree and numerical scale end-points of 1 and 7. The design corresponded to a 2 X 2 situation involving the following four scales:

FORM

1a	_____	1	2	3	4	5	6	7	_____
1b	_____	7	6	5	4	3	2	1	_____
2a	Agree	_____	_____	_____	_____	_____	_____	_____	Disagree
2b	Disagree	_____	_____	_____	_____	_____	_____	_____	Agree

This questionnaire was always the first one that each subject received.

Half the subjects received Form 1a while the other half received Form 1b. In both cases, subjects were instructed to write the words "Agree" ("Disagree") and "Disagree" ("Agree") on the lines at the end of the scale (the wording of the instructions was counter-balanced within and across conditions). Form 1b is provided here as Appendix B. Half the subjects in each of these groups then received Form 2a while the other half received Form 2b. Subjects were instructed to write-in scale points from 1 to 7 (or 7 to 1) along the line provided. Again, the wording of the instructions was counterbalanced. Form 2a is provided as Appendix C. Finally, half the subjects engaged in the "assign verbal anchors" task first, while the other half received the "assign numerical anchors" task first.

Results

Study 1

Responses to the eight-item abortion scale were re-coded so that all were aligned in a uniform direction, in terms of numerical and verbal anchors. Responses to the eight items were summed for each subject and a two-way analysis-of-variance for unequal n's was applied. Table 1 presents a summary of these data.

TABLE 1

Analysis of Variance Summary for effect of verbal and numerical anchor reversals on total scale scores.

Source	df.	Mean Square	F Ratio	P
Verbal anchors (V)	1	292.27	4.14	< .05
Numerical anchors (N)	1	516.759	7.35	< .01
V X N	1	54.857	.78	N.S.
Error	236	70.276		

Reversals of both the verbal and numerical anchors produced significant differences in the mean scores ($p < .05$ and $p < .01$, respectively), indicating that anchor order does indeed affect the nature of the response. There was no significant interaction effect. Figure 1 depicts these findings.

FIGURE 1

Summary of main effects by two-way ANOVA for reversals of verbal and numerical anchors.

The mean of Form 1 (30.6) differed significantly from the means of Forms 2, 3, and 4 ($\bar{X}_2 = 34.5$; $\bar{X}_3 = 33.7$; $\bar{X}_4 = 35.7$) using a Newman-Keuls range test (Winer, 1970, p. 193).

Data collected using the four formats were next examined to determine whether these formats differed in terms of degree of reliability. Despite the small number of items, a test of split-half reliability produced moderately respectable correlations ranging from .46 to .55 for the four formats. Using Fisher's r-to-z transformation, these differences were found to be insignificant, suggesting that the different forms were equivalently reliable.

Next, responses to each of the eight items were analyzed using separate one-way ANOVAS. Table 2 summarizes these results.

TABLE 2

Analysis of Variance summary for effects of verbal and numerical anchor reversals on item means.

Question	Form	Mean	S.D.	F	p=
#1	#1	3.30	2.01	3.95	.009
	#2	3.95	2.22		
	#3	4.30	1.94		
	#4	4.47	1.94		
#2	#1	6.19	1.34	1.97	.120
	#2	6.00	1.65		
	#3	5.66	1.73		
	#4	6.23	1.06		

TABLE 2 (Continued)

Question	Form	Mean	S.D.	F	p=
#3	#1	4.01	1.94	3.00	.030
	#2	4.69	2.03		
	#3	4.77	2.06		
	#4	5.07	1.95		
#4	#1	2.46	1.74	.69	.560
	#2	2.72	1.70		
	#3	2.27	1.61		
	#4	2.57	1.90		
#5	#1	4.59	2.08	2.08	.100
	#2	5.45	1.77		
	#3	5.03	1.87		
	#4	5.23	2.11		
#6	#1	4.02	2.09	2.93	.030
	#2	5.00	2.18		
	#3	4.64	2.05		
	#4	5.00	2.09		
#7	#1	2.74	1.82	3.09	.030
	#2	3.55	1.98		
	#3	3.66	1.91		
	#4	3.50	1.72		
#8	#1	3.26	2.01	.84	.476
	#2	3.10	1.88		
	#3	3.41	1.88		
	#4	3.65	2.05		

df = 3 in each case

Four of the eight items revealed significant ($p < .05$) differences in means across the four formats, and a fifth item revealed a marginally significant difference ($p = .10$). Examination of individual items revealed that these five statements were relatively "tight," short, and to the point. The three non-significant items, by comparison, had stems which were much longer in word length, and were somewhat more ambiguous.

Study 2

The results of this study are summarized in Table 3.

TABLE 3

Chi-square summary of responses: Study 2

Presented as:	Response Order		Chi Square	P
	AGR-DIS	DIS-AGR		
1-to-7	64	54	.85	N.S.
7-to-1	84	38	17.34	.0001
TOTAL	148	92	13.07	.0001
	1-to-7	7-to-1		
AGR - DIS	68	52	2.13	N.S.
DIS - AGR	84	36	19.20	.0001
TOTAL	152	88	17.07	.0001

Nearly 62% of the subjects felt the most natural response to Form 1 was completing the verbal endpoints in the order of Agree-Disagree ($p < .001$). One-sample Chi-Square analysis showed subjects did not significantly differ in their responses to Form 1a. Associating Disagree-Agree ($n = 54$) to a 1-to-7 scale was almost as frequent as associating Agree-Disagree ($n = 64$) to such a scale. However, responses to Form 1b were significantly different ($p < .001$). That is, responding Agree-Disagree ($n = 84$) to 7-to-1 scale was much more prevalent than responding Disagree-Agree ($n = 38$).

Subjects completed Form 2 by filling-in scale point anchors in the order of 1-7 63.3% of the time ($p < .001$). While responses to Form 2a were not significantly different ($n = 68$ for 1-to-7, and $n = 52$ for 7-to-1), responses to Form 2b (Disagree-Agree presentation format) were significant ($n = 84$ for 1-to-7 vs. $n = 36$ for 7-to-1; $p < .001$).

Discussion

The investigation focused on two related issues. Attention was first paid to the effects on subject responses caused by reversals of verbal and numerical endpoint anchors. Second, given that respondent motivation or willingness of report is a prime condition for successful data collection" (Cannell and Kahn, 1968, p. 537), subject preferences and response tendencies for various scale formats were also assessed. Parenthetically, using subject preference as a criterion may be viewed as reflecting a "consumer (qua respondent) orientation." Within the limitations imposed by the sample, questionnaire, etc., the findings may be summarized as follows:

1. Reversals of either numerical or verbal anchors are sufficient to cause significant differences in response to an Agree-Disagree attitude statement.
2. The Agree-Disagree order resulted in more agree endorsement than did the Disagree-Agree order. Likewise, the 1-to-7 order produced more agree endorsement than did the 7-to-1 order.
3. A rating scale employing an Agree (1) - Disagree (7) order produces significantly more agree endorsement than any other combination of numerical and verbal anchors.
4. Ambiguous or double-barrelled items appeared resistant to being affected by scale reversals.
5. Scale reversals exerted no significant effect on the split-half reliability of the total scale score.
6. Subjects seem to perceive a "natural" association between 1 and Agree, and between 7 and Disagree.
7. Directional tendencies for a scale combining verbal and numerical anchors results in the Agree (1)-to-Disagree (7) format being most frequently selected and considered most "natural."

Closer examination of the data reveals the strength of this preference for the Agree (1)-Disagree (7) format. When the numerical anchors were presented in 1-to-7 order, the subjects were evenly divided as to which verbal anchor order was most appropriate. In other words, the 1-7 order appeared so natural, that either verbal anchor order seemed appropriate when paired with it. This is in contrast to the responses obtained when the presentation format was in the 7-to-1 order. In this condition, subjects overwhelmingly preferred the Agree-Disagree verbal anchor order.

Similarly, when verbal anchors were presented as Agree-Disagree, subjects were evenly divided on the appropriate order for the numerical anchors. The two orders (i.e., either 1-7 or 7-1) seemed equally appealing. In contrast, when the presentation order was Disagree-Agree, the overwhelming choice for appropriate numerical anchor counterpart was the 1-7 order. It is noteworthy that these data are based on a dependent measure requiring more behavioral input from subjects (i.e., "fill-in the end-point as appropriate") than would be required by simple preference ratings of the four formats.

Pre-testing had indicated that, compared to twelve other questionnaire topics, the topic of abortion was of intermediate interest for this student population. This is not unlike topics used in actual survey research. Actual surveys often feature topics which may be of high interest to the sponsor, but are perceived to be bland by the respondents. Thus, the use of a moderate interest topic for this study was considered desirable.

Earlier findings (Elliott, 1961) suggest that there will be a high amount of agree endorsement for low interest topics. Given the predominantly male sample used in this particular study, the topic could be judged as having low personal relevance for these subjects. Again, actual surveys are not often greeted with equal degrees of interest by all respondents. Rather, survey topics are usually differentially relevant to the respondents and therefore vary in interest to the sampling audience.

Our findings indicate that Form 1 facilitates agree endorsement when interacting with a moderately interesting topic having low personal relevance for the subject sample. In part, this may be due to the fact that the ordering of Form 1 was the most "natural" response format, as judged by subjects in Study 2. This familiarity, coupled with moderate or low interest, seems to facilitate the generation of an agree endorsement response style. The findings also suggest that this endorsement can be counterbalanced by reversing either the numerical or verbal anchor order. Usage of either Form 2 or 3 is therefore recommended on this basis. However, both verbal and numerical anchors should not be reversed at the same time, since this seems to cause an inordinate amount of disagree endorsement, as in the case of Form 4.

Use of any of the four combinations does not seem to affect item reliability. This reflects Nunnally's (1970, p. 429) view that format changes will not affect the important psychometric (e.g., reliability) properties of test instruments.

The experimental findings pose a small dilemma. Because respondent frustration may cause response error or "uncooperative" behavior, care should be taken to provide a preferred response format; one with which the respondent feels comfortable. Therefore, Form 1 -- Agree (1)-to-Disagree (7) -- appears most advisable to use. However, caution should be used when employing this format, because it appears that a preferred or "natural feeling" format enhances agree endorsement. It seems advisable that format 1 be avoided when a relatively low interest topic is being investigated. In such instances, Forms 2 or 3 appear more appropriate. Additional research is necessary to more directly investigate the interaction between high and low content interest and the effects of scale reversals.

Appendix A

Attitudes Toward Abortion Survey

Instructions: Please respond to each of the following statements by CIRCLING the number along the line which best expresses your own opinion regarding that statement.

1. It should be left to the woman alone to decide whether or not to have an abortion.

Disagree | 1 | 2 | 3 | 4 | 5 | 6 | 7 | Agree

2. In general, it would solve many social problems if all unwed pregnant women were forced to have abortions.

Disagree | 1 | 2 | 3 | 4 | 5 | 6 | 7 | Agree

3. All states should enforce the Supreme Court decision legalizing abortions.

Disagree | 1 | 2 | 3 | 4 | 5 | 6 | 7 | Agree

4. Pregnant women should be required to obtain authorization from a medical doctor before being permitted to have an abortion.

Disagree | 1 | 2 | 3 | 4 | 5 | 6 | 7 | Agree

5. Abortions should only be legal in the case of a woman who wants an abortion because she was raped.

Disagree | 1 | 2 | 3 | 4 | 5 | 6 | 7 | Agree

6. Abortion is the equivalent of murder.

Disagree | 1 | 2 | 3 | 4 | 5 | 6 | 7 | Agree

7. No abortion should be performed on a fetus over 16 weeks old.

Disagree | 1 | 2 | 3 | 4 | 5 | 6 | 7 | Agree

8. Women on welfare should be able to obtain abortions free of charge through federally financed programs.

Disagree | 1 | 2 | 3 | 4 | 5 | 6 | 7 | Agree

Appendix B

Instructions: Please complete the scale below by writing the words "AGREE" and "DISAGREE" on the dotted line, assigning the words to either end so that the finished scale will be most meaningful and natural for you.

That is, should the number 1 be associated with "Agree" and number 7 with "Disagree"? Or should the number 1 be associated with "Disagree" and the number 7 with "Agree"?

----- . . . | 7 | 6 | 5 | 4 | 3 | 2 | 1 | . . . -----

Appendix C

Instructions: Please complete the scale below by writing the numbers 1 through 7 on the points along the scale, assigning the numbers in the order that will be most meaningful and natural for you.

That is, should the numbers run from 1 to 7, left to right? Or should the numbers run from 7 to 1, left to right?

Agree | | | | | | | Disagree

NEAREST NEIGHBOR ANALYSIS: INFERRING BEHAVIORAL
PROCESSES FROM SPATIAL PATTERNS

Sanford L. Crossbart, University of Nebraska
Robert A. Mittelstaedt, University of Nebraska
Gene W. Murdock, University of South Dakota

Abstract

This paper describes a statistic for analysis of spatial patterns generated by behavioral phenomena. Issues associated with use of the method, an application to Whyte's word of mouth study, and other suggested research applications are reviewed.

Problem

The researcher who studies the role of social influence in consumer behavior faces many difficult problems. This is especially true when researching the diffusion or "social contagion" aspect of the innovation adoption process. Using survey methods to isolate the influence of earlier adopters on those who adopt later raises many conceptual and methodological problems, not the least of which are the difficulties in identifying non-verbal influence ("demonstration effects" as Bass, 1969, called them) and the often reactive nature of the measures used (Coughenhour, 1965; Menzel, 1957). However, since the adoption process occurs over time within a social system, many have attempted to infer the presence (or absence) of social influence in observed temporal or spatial patterns of adoption.

It is generally held that an adoption pattern which, over time, conforms to the general shape of the Gompertz logistic function, is evidence of social influence in the adoption process. While the idea is not without its critics, and Midgley (1976) has proposed an alternative model, it is obvious that all studies of temporal patterns require longitudinal data. Some researchers have been able to track an innovation from the moment of its introduction into a social system and have used rather ingenious, nonobtrusive measures of adoption (Coleman, Katz and Menzel, 1957). However, more frequently, researchers have begun their studies only after the innovation has been partially diffused. When historical sales data which allow one to isolate first time purchasers (or assume away repeat purchasers) are available, a pattern can be reconstructed. However, when sales data are not available (as with an innovation which is not an economic good or, possibly, an economic service) or when they contain known but non-identifiable repeat sales (as with goods of relatively short re-purchase cycles) the only course of action is to attempt reconstruction of the process through survey methods.

Rather than examining temporal patterns, one might relate observed spatial patterns of adoption to expectations based on assumptions of social influence. If "contagion" is at work in an adoption process, one would expect to find adopters spatially clustered to some degree. Indeed, this was the argument made by Whyte (1954) in his classic study of air conditioner ownership in a North Philadelphia neighborhood: "As the location of conditioned homes was plotted on a map, a curious distribution pattern began to show up and it could only be explained by the presence of a vast and powerful network (Whyte, 1954, p. 141)".

However, before inferring the existence of social influence from the observation of clusters of adopters, it is necessary to specify the expected spatial distri-

bution in the absence of social influence. Presumably, with neither verbal nor non-verbal interaction among adopters, communications about the innovation would come from an impersonal source (i.e., mass media). Unless there is a predictable relationship between physical location of an adopter within a social system and his/her susceptibility to mass media influence, it would follow that the expected spatial adoption pattern would be that generated by a random process.

Unfortunately, random processes do not produce "uniform" spatial patterns (as Whyte seemed to suggest, p. 141) but would be expected to produce some clusters. Furthermore, as the saturation level of the innovation increased, the incidence of clustering, as a random phenomenon, would also increase. The argument is analogous to that presented by Witt and Bruce (1970) when discussing the use of inter-individual similarities of brand choice as a measure of group conformity. As they correctly argued, any measure of conformity "should reflect not only the degree of brand choice congruence but also the probability that such a group brand choice distribution could have occurred by chance given the market share of the brands involved (p. 533)." To infer social influence from spatial clusters of adopters, the degree of observed clustering should exceed that amount which would be expected by chance alone, at that stage of market saturation.

The purpose of this paper is to describe the nature of a test statistic suitable for this purpose. This statistic, known as "nearest neighbor," will be described in some detail and, by way of example, will be applied to Whyte's North Philadelphia air conditioning data. Rather than dwelling on nearest neighbor calculations or the derivation of associated probability density functions, the discussion will focus on the logic of the analysis and the conceptual and methodological problems which confront researchers who apply the technique. The paper concludes by suggesting some areas of research to which this test statistic might be usefully applied.

The Logic Of Nearest Neighbor Analysis

A nearest neighbor measure is the linear distance between pairs of designated neighboring locations. The analysis can be applied to behavioral phenomena which possess discrete spatial locations which may be mapped as points. Nearest neighbor analysis utilizes the fundamental concept of randomness. A distribution is random when each spatial unit in the area containing the points has an equal opportunity of receiving a point. A nonrandom point pattern is either more clustered than random or more uniform than random. Nearest neighbor analysis reduces the complexities of spatial distributions of observed points to a pattern description called random, more grouped than random, or more clustered than random. Relations between neighboring points are derived under the assumption that such points are randomly distributed in terms of the Poisson distribution. These relations are subsequently used to detect the presence of nonrandomness in given patterns. With the Poisson distribution employed as a standard of comparison, a chi-square comparison has also been employed (Thompson, 1956) but is not utilized in the present

discussion; attention focuses on divergence from randomness along the R scale. R is the ratio of observed average neighbor distance (\bar{F}_a) to expected random neighbor distance (\bar{F}_e) in a spatial distribution

$$R = \bar{F}_a / \bar{F}_e \quad (1)$$

R scale values range from 0 to 2.149. A value of 1.0 provides the standard of randomness, increasing R values are indicative of increasing dispersion leading to a limiting case of regularity, and decreasing R values provide evidence of increasing clustering (Clark and Evans, 1954; Dacey, 1960; Neft, 1966; Taylor, 1977).

Conceptual And Methodological Problems

The nearest neighbor statistic is a useful tool for dealing with certain spatial phenomena. Its successful application depends, of course, on an appreciation of its conceptual and technical limitations as well as the conditions under which its usefulness will be maximized. These considerations are summarized below.

Distinguishing Pattern From Processes

The R scale provides a pattern description. Patterns themselves are the product of underlying processes which develop over time and space. Since patterns provide only static evidence of spacing, they must be approached with notions derived from a rationalization of processes thought to evolve over space. In this sense patterns are no more than abstractions derived by artificially halting dynamic processes. Point patterns are therefore, a synthetic visual expression at a given point in time of processes which continuously operate over space. For this reason any observed point with a spatial distribution represents an event in time and space (Taylor, 1977). Alternative values of R do not necessarily justify the conclusion that either a random or a systematic process is operating. A distribution of observed points provides no direct information about the underlying processes giving rise to the observed distribution (Amedeo and Colledge, 1975). Inferences from patterns to processes can be defended only when processes are considered in forming hypotheses concerning changing R values which are observed over time (Getis, 1964; Pinder and Witherick, 1972; Dawson, 1975).

Limiting Values of the R Scale

As points in space tend to cluster interpoint distances, \bar{F}_a , and hence R, would tend toward zero. The opposite tendency to clustering is dispersion. Taken to the extreme, dispersion results in a limiting regular pattern based on a triangular lattice and an R of 2.149. These theoretical limits to the R scale are rarely observed in practice. The complex processes underlying spatial distributions tend to produce spatial distributions which are more complicated than those reflected by the theoretical limits of the R scale (Pinder and Witherick, 1972). Hence it has been observed (Taylor, 1977, p. 148) that the empirical values of R are likely to range between .33 and 1.67.

Processes Generating Nonrandom and Random Patterns

Extreme cases of clustering and regularity are deterministic in the sense that they have singular R values associated with unique average interpoint distance's which satisfy each extreme case. This determinism does not hold for a randomly produced distribution. A number of random patterns share an R value of 1. In fact, we may purposely use a random procedure to generate a pattern whose R value differs from 1 (Dawson, 1975). In such a case a known random process could be shown to produce a spatial pattern with a tendency toward clustering. This is evidence of a well known phenomena in

inferential statistics, namely that variation in random processes must be taken into account in interpreting stochastic events (Taylor, 1977). The R scale is not merely a descriptive tool which measures a pattern. Various subprocesses are capable of producing R values within the central range of the R scale, resulting in a large number of R values which exhibit small divergence from a random expectation. Attention to this range of random matching (Pinder and Witherick, 1972) forces the researcher to consider the standard error of \bar{F}_e as well as the difference between \bar{F}_a and \bar{F}_e when interpreting a spatial pattern (Clark and Evans, 1954). Still, statistical caution cannot replace an understanding of the dynamics of processes which produce patterns. A narrow view of the application of nearest neighbor analysis (Dacey, 1960) would state that the test is limited to a sensitivity to nonrandomness but cannot be employed to explore hypotheses regarding uniform or concentrated spatial patterns. This view may presuppose the existence of either random variables which produce random patterns or variables which simultaneously contribute to clear cases of regularity or clustering. A broader view (Pinder and Witherick, 1972) maintains that the concept of randomness is not satisfactory as datum. In the real world one might regard a given pattern as a deviation from either or both extremes of regularity and clustering. In the case of diffusion, for example, in certain settings residential sites may bear social meanings which reflect the social leadership character of residents (e.g., larger corner lots). Such a situation could contribute to a hierarchical regular adoption pattern over time. Simultaneously, social contagion would contribute to an observed clustering of adopters. Meanwhile, the psychological effects of mass media could be influencing randomly spaced individual families to make adoption decisions. When such factors operate the random point on a nearest neighbor R scale increases in meaning. The factors which influence the location of adopters are unlikely to operate in a random fashion, but they may distort extreme conditions of regularity or clustering so that the observed pattern is matched by a random distribution. This cannot be attributed to the operation of random forces, but instead might be seen as the significant complex interaction of location and other factors. The role of the researcher is to specify the nature of these factors and their relationships.

Higher Order Analysis

Considering the space or distance between all points and their first or closest neighbor can result in utilizing only a small portion of the information available in a spatial pattern. Imagine pairs of points which are evenly dispersed over space. The distance between any given point and its nearest neighbor would be small. Yet obviously we are not dealing with a clustered pattern as would be indicated by a low R value. Unless each point is considered in relation to all others, the character of the spatial distribution will be obscured by nearest neighbors (Getis, 1964; Neft, 1966; Charlton, 1976; Vincent, 1976). The solution is to identify and average the distance between each point and not only the original nearest neighbor but succeeding neighboring points (second, third . . . nth nearest neighbors). At any order of analysis (so named to refer to the number of succeeding neighbors considered) (Dacy, 1963) observed neighbor distances can be compared to expected distances randomly generated from Poisson distributions. Higher order analysis was made possible by Morrissa's (1954) and Thompson's (1956) derivations of expected distance to nth order neighbors based on calculation of high order probability density functions. In distributions lacking a pronounced spatial bias an order of analysis which is less than n can be employed. Similarly the absence of a pronounced spatial bias supports a direct selection of neighboring points while a bias may support the use of a sectoral decision rule. With this

algorithm the space around each point is divided into the number of sectors equal to the order of analysis and distance from the reference point to the nearest neighbor in each sector is determined (Dacey and Tung, 1963).

Properties of Observed and Expected Distances and the R Scale

The range and interpretation of the R scale depends on the type of analysis employed. The two principal types of more complex nearest neighbor analysis call for either a division of the space surrounding each observed point into k sectors (where $k > 1$) (Taylor, 1977) or measures of spacing between each observed point and its n nearest neighbors (where $n > 1$) (Clark and Evans, 1954; Dacey, 1963). The sectorial method is more sensitive to randomness in a pattern biased toward uniform spacing while raising the order of analysis provides more power efficiency when points are biased toward grouping or clustering (Dacey and Tung, 1962). These types of analysis can be combined, e.g., a space can be divided into k sectors and the distance to n neighbors in each sector can then be determined. For purposes of clarification we shall consider separately the effects of sectorial and n th order nearest neighbor analysis on expected average distances and R scale values. With first order nearest neighbor analysis in which both k and n equal 1, the R scale ranges from values of 0, indicative of maximum clustering through 1.0, indicative of the observed average distances equal to that expected under Poisson conditions ($\bar{F}_a = \bar{F}_e$), to a maximum of 2.149, which represents the case of maximum hexagonal regularity (Neft, 1966; Haworth and Vincent, 1976).

The interpretation of clustering is unaffected by altering the type of analysis in terms of either k or n . This follows from the fact that maximum clustering ($R = \bar{F}_e/\bar{F}_a = 0$) occurs when all points exist at one location and thus the value of observed average interpoint distance would be unaffected by increasing the number of sectors or increasing the number of neighboring distance measures.

By definition, an R value of 1.0 will define a situation in which the observed and expected (under random conditions) average distance are identical. This is obviously unchanged by altering the type of analysis. What will change, however, is the expected average neighbor distances under Poisson conditions. In this sense the distance standard by which the relative randomness of a spatial distribution is judged depends on the type of analysis performed (Morista, 1954; Thompson, 1956; Dacey and Tung, 1962; Dacey, 1963; Taylor, 1977). In a sectorial analysis this outcome is produced by the fact that increasing the number of sectors while holding the order (or n) constant has the effect of increasing the number of nearest neighbor observations. Once the analysis proceeds beyond a single sector ($k = 1$), the expected average distance under Poisson assumptions will naturally increase. Similarly when k is held constant and the n value or order of analysis increases the expected average distance will also increase. Thus while an R value of 1.0 continues to indicate the existence of a random pattern, it masks the important underlying changes in \bar{F}_e which are produced by changes in k and n .

A change in the meaning of R values will occur only in interpreting the regularity of an observed distribution. The R value 2.149 indicates maximized regularity for all values of $n > 1$, just as it does in the first order case where $n = 1$. However, as k or the number of sectors increase an even lattice of points will produce an R value equal to $2.149/k^2$. As k increases the limiting value of R will decrease and actually become less than 1.0. Thus, as the number of sectors around each point is increased the upper limiting case and value of the R scale corresponds, not to that of regularity but, to one

of random expectation under Poisson assumptions. This presents no difficulty if the researcher is aware of scale properties of R under these conditions. This decrease in the R value representing maximum regularity is caused by the fact that, given an even lattice of points, neighbor distances do not increase as k continues to increase and thus the average distance becomes less than that which would be expected under random conditions ($\bar{F}_a < \bar{F}_e$).

Boundary Definition

The parameters for limiting cases of R are based on the assumption of an infinite space or plane. Area is considered only in terms of density and area per point. In reality, of course the boundaries and their effects must be considered. No study area is infinite (Dacey, 1960; Ebdon, 1976).

One associated problem is that of a point whose nearest neighbor lies outside a defined boundary. Ignoring the point results in a pattern description which is biased toward dispersion. Including the point makes the definition of density subject to challenge, but produces a less biased pattern appraisal. For this reason the latter approach is usually taken (Dacey and Tang, 1962; Taylor, 1977). Often, however, the boundary definition is a conceptual rather than technical problem. Defining the area of analysis in terms which correspond to the conceptual nature of the problem being studied will often eliminate the need to consider outlying neighboring points. It is crucial that the spatial context which is under investigation be logically justifiable (Getis, 1964; Bartlett, 1971; Pinder and Witherick, 1972).

This is related to the matter of the size and shape of the study area. For example, an artificially created large study area defined around a small regular pattern of points will provide R values indicating a relatively clustered pattern (Sibley, 1976). In an opposite fashion, shaping the area by drawing boundaries which irregularly follow the observed points and enclosing them in a small space will produce R values indicating regularity. In certain cases, such as that involving linear distributions, special adaptations of nearest neighbor analysis are required (Pinder and Witherick, 1975). In short, the analysis should be modified to meet the peculiarities of the subject and spatial pattern under study. Boundaries must also be defined with attention to the phenomena being studied (Charlton, 1976). Care must be taken to consider how other researchers of similar phenomena have determined relevant boundaries before assertions can be made regarding the comparability of results.

An Application of Nearest Neighbor Analysis

Nature of Data

A classic study by William H. Whyte provides a vehicle to demonstrate an application of nearest neighbor analysis in consumer research. In his *Fortune* article Whyte (1954) described a "powerful communication network" between neighbors as the "web of word of mouth" responsible for the "clusterings" of window air conditioners in a homogeneous Philadelphia neighborhood. These results have been variously referenced in literature dealing with consumer behavior (Engel, Kollat and Blackwell, 1973, p. 404), marketing research (Cox and Enis, 1972, p. 244), diffusion (Rogers and Shoemaker, 1971, pp. 254-55), and marketing principles (Stanton, 1975, p. 105). The findings consist of identified residents of nearly identical \$12,000 row-house type homes, who had adopted window air conditioners. Whyte explains that the neighborhood was physically homogeneous and the occupants (white-collar couples between twenty-five and forty who

earned between \$5,000 and \$7,000) were also fairly homogeneous.

However, the data itself are not presented by Whyte. Results take the form of two aerial photographs of the neighborhood in which the air conditioned homes are marked with X's. One photograph appears in the original article and another photograph, apparently taken at a different time and angle, appears in a later reproduction of the article (Whyte, 1955). Because the data must be gleaned from careful examination of both photos, it has become somewhat altered in later references such as Cox and Enis' research text (1972) which condenses the block lengths, omits homes, and inverts the original distribution. The drawings of blocks used to supplement the photo in Whyte's article represent a purely hypothetical example rather than actual adoptions over time. For illustrative purposes the dominant portion of the neighborhood for which blocks run from left to right within the photographs is transformed in Figure 1 into a spatial distribution of adopters (indicated by darkened areas.) A reference system which defines spatial coordinates is included. The coordinate system was developed from Whyte's photographs by maintaining spacing in proportion to the aerial dimensions of the homes. The center of each air conditioned home provided the spatial coordinates which served as input for the analysis.

FIGURE 1
Whyte's Air Conditioner Ownership Data

Application of Nearest Neighbor Program to Data

A fourth-order nearest neighbor analysis was employed. Given the nature of most distributions, fourth order analysis is sufficient to extract all necessary information from a spatial pattern. To input Whyte's data required that homes be plotted with the streets and "alleys" removed. It was assumed that points would be located in the area within the minimum and maximum coordinates defining the boundaries of the study area, although a researcher has the alternative of specifying boundaries as input parameters. While homes of different adopters cannot possess the same coordinates, this deviation from an assumption regarding a random distribution presents no major problem since any tendency toward clustering or regularity would still be detectable.

Results

Thompson (1956) has shown that in fourth order nearest neighbor analysis the expected neighbor distance is:

$$\bar{r}_e = 1.0937/m^{1/2} \quad (2)$$

and the standard error of \bar{r}_e is:

$$S.E.\bar{r}_e = 0.2774/m^{1/2} \quad (3)$$

where m is the density of observed points, found by dividing N (the number of points) by A (the area in square coordinate units.)

The spatial distribution of air conditioner adopters shown in Figure has the following characteristics:

$N = 123$ points

$A = 2560$ square coordinate units

$m = .04805$ points/coordinate unit

Substituting these values in Equations (2) and (3):

$$\bar{r}_e = 1.0937/((.04805)^{1/2}) = 4.990$$

$$S.E.\bar{r}_e = 0.2774/((.04805)^{1/2}) = 1.265$$

Since the observed mean nearest neighbor distance (\bar{r}_a) is 4.252, the R scale value is computed from Equation (1):

$$R = 4.252/4.990 = 0.8521$$

indicating that the distribution is more clustered than random. To answer the question of whether this is significantly different from the random expectation, it is necessary to recall that the earlier discussion centered on the Poisson distribution as the standard of comparison with the distribution of nearest neighbor distances regarded as approximately normal. Utilizing this line of reasoning, the ninety-five percent limit for the expected mean of N observations would be represented by:

$$\bar{r}_e \pm 1.96 (S.E.\bar{r}_e)/N^{1/2} \quad (4)$$

or

$$\bar{r}_e \pm 1.96 (1.265)/(123)^{1/2}$$

With the limits of expected difference, 4.776 and 5.214, it can be seen that the observed mean nearest neighbor distance (\bar{r}_a) of 4.252 does not fall within the limits of expected distance. (For an alternative derivation of confidence limits under Chi-square assumptions, see Thompson (1956)). Hence it appears that the observed spatial distribution of air conditioner adopters shown in Figure 1 is significantly different from random and exhibits clustering tendencies.

This is not surprising. Our purpose was to apply the R scale to a well-known spatial distribution rather than to challenge Whyte's conclusions regarding the diffusion of air conditioners. In other circumstances involving more complex distributions, neither the spatial pattern nor the outcome would be so obvious.

Research Applications of Nearest Neighbor Analysis

Spatial dimensions of consumer behavior have received insufficient attention. Hopefully this paper will foster increased interest in the consequences of processes which evolve over time and manifest themselves in spatial distributions. It is not intended that the R scale be interpreted as the only or best analytic tool for spatial investigation. Certainly other statistics and theoretical distributions deserve the attention of consumer researchers. For the present the intent has been to highlight the useful nature of nearest neighbor analysis. In addition to applications involving diffusion patterns, the method may be able to shed light on a number of matters including:

- 1) the spatial nature of retail shopping patterns,
- 2) patterns of exploratory movement within retail stores and shopping centers,
- 3) features of cognitive maps representing customer images of the contents of large scale shopping areas,

- 4) the relationship between the perceived locations of retail facilities,
- 5) the distribution of sets of ideal store locations and
- 6) the nature of consumers' social interaction patterns.

These are but a few of the many behavioral phenomena with interesting research possibilities. Application of the nearest neighbor technique will increase our knowledge of its uses and limitations and, as a consequence, may enrich our understanding of consumer behavior.

DURABLE ACCUMULATION: AN EXAMINATION OF PRIORITY PATTERNS

Robert F. Lusch, University of Oklahoma
Edward F. Stafford, Jr., University of Oklahoma
Jack J. Kasulis, University of Oklahoma

Abstract

This paper examines the order of accumulation of discretionary durable goods by consumers. Guttman scalogram analysis was used to identify the underlying priority patterns. A multi-measure procedure was developed to evaluate the reliability and item homogeneity of the derived scale.

Introduction

Over a person's life cycle he or she consumes many goods. Some of these are nondurables, and therefore the consumer derives satisfaction from them over a relatively short span of time. In addition, since these goods are nondurable, the consumer must purchase them with relative frequency. On the other hand, satisfaction from durable goods is derived over an extended period of time and as a consequence these goods are not purchased as frequently.

Most consumers cannot purchase all the nondurable and durable goods they would desire at any given time. This is especially true of durables since they generally involve a larger financial commitment. Therefore consumers will need to decide the order in which they will acquire durable goods. The order of acquisition of durable goods has received little attention by the various parties studying consumer behavior. Instead, the focus has been on how a single good is acquired and on how a consumer selects a brand from among a field of competing brands. Although these two types of investigations have considerable value in the study of consumer behavior, they will not be addressed here. Rather, the purpose of this paper is to explore the order of accumulation of discretionary durable goods by consumers. The order of acquisition of discretionary durable goods is an important area of inquiry since knowledge of acquisition patterns can: (1) aid managers in forecasting sales for consumer durables, (2) provide managers with a framework for directing marketing efforts at consumers at various points in the acquisition process, and (3) provide a framework for more theoretical areas of inquiry such as the adoption of innovations.

Theoretical Background

There are at least three types of models that have been used to explain the acquisition of durable goods. These three models are: (1) growth models; (2) behavioral models; and (3) income consumption models.

Growth Models

Growth models attempt to predict the acquisition of new products by a population. The epidemic growth model which has been adopted from the biological sciences is one such example. This model, which was developed by biometricians to depict the spread of disease, basically postulates a logistics growth curve. When this model is adapted to the consumption of durable goods, the result is a model which can be used to predict the adoption of a new durable good by the population. Briefly, the model suggests that at first only a few people have contact or exposure to a new type of durable good. These few people interact with others and as a result the sales of the product spreads as does an infectious disease spreading

through a closed population. This type of model has been validated for use in predicting the demand for durable goods by Derksen and Rombouts (1937), Roos and Von Szeliski (1939), and DeWoolf (1938). In addition, Bass (1969) has developed a growth model which is a variant on the classic epidemiological model. The model produced fairly good forecasts for the eleven appliance innovations that Bass tested the model with. Several other growth models are discussed by Kotler (1971, pp. 519-560). All of these growth models attempt to depict how the population as a whole adopts new durable goods. Furthermore these growth models depict how a population acquires a single durable good over time. No attention is given to how populations prioritize their acquisition of a set of durables over time.

Behavioral Models

Many constructs and models have been borrowed from sociology and psychology to help understand and predict the purchase patterns of consumers. A large number of these constructs have been combined into comprehensive models of consumer behavior such as the Howard-Sheth model (1969) and the Engel, Kollat and Blackwell model (1968). The major constructs that these models include are: attitudes, motives, personality, perceptual processes, learning processes, and social influences. A complete review of the consumer behavior literature on each of these is obviously unnecessary here. However it is important to point out the lack of evidence on the performance of these models in their entirety. Even more disheartening is the fact that the majority of the available evidence on parts of the models deal with nondurable goods. Consumer behavioralists in general have examined how consumers purchase beer, cigarettes, catsup and cereal, and have deemphasized the study of how consumers purchase durable goods such as houses, air conditioners, and televisions. More important to the discussion at hand, no behavioral research has been directed at how consumers acquire a series of assets (i.e., what are the behavioral determinants of how consumers decide upon which asset to acquire first, second, third, and so forth).

Income Consumption Models

Perhaps the most formal and rigorous theory of consumer behavior available is the classical microeconomic theory of consumption behavior. This theory postulates that given a set of prices for a group of products, consumers will allocate their income to the purchase of these products so as to maximize utility. Importantly, microeconomic theory deals with perishable goods and does not address the problem of how individuals purchase durable goods, such as houses, in which utility is derived not only from consuming the product but from holding stocks of the product. Theil (1954) has suggested that classical economic theory could be reconstructed so that the individual consumer's utility function would depend both on the consumption during a period and stocks held at the end of it.

Derived from the classical economic theory of utility are income consumption curves which allow one to derive the income elasticity of demand. These curves, also frequently referred to as "Engel Curves," have led to the

development of macroeconomic models that quantify the relationship between increases in income and the consumption of goods (durables and nondurables). Predictably, the decision to purchase a durable depends on other factors such as consumer stocks and prices; nonetheless, over the long run there is generally a fairly strong relationship between income and the demand for durable goods. Some examples of the specific relationships for several commodity groups are given in Shubin (1961, pp. 423-441) and Spencer (1968, pp. 146-157). The available evidence suggests that income-consumption models perform better over longer periods of time than for short periods of time and generally do not do well during cyclical periods. In addition, they do a fair job at predicting industry demand for durables but are inadequate for predicting market share within the industry. They do not address the issue of how consumers prioritize their wants for durable goods over time as their income increases.

Order of Acquisition

Three types of models that could be used to explain the acquisition of durable goods have been briefly mentioned. Importantly none of these models has attempted to theorize how consumers go about developing a priority pattern for the acquisition of durable goods. Additionally none have attempted to investigate whether members of a population have similar priority patterns. Obviously, given limited income, consumers will not be able to acquire all the durables they desire at a given moment. Therefore it follows that an order of acquisition will need to exist which will by definition be a temporal concept.

Although classical economic theory does not deal with the consumption of durables, one could reasonably hypothesize that consumers acquire goods over time so as to maximize the present value of their utility function. Thus, given knowledge of future prices, consumer incomes and the utility function, one could theoretically determine the order of acquisition of consumer durables for an individual consumer. Assuming further that all consumers have similar utility structures, one could predict that all consumers would acquire goods in a stated order. For example if there were k durable goods then there would be $k!$ possible patterns of acquisition. Nonetheless, given the above scenario one could predict the order of acquisition; possibly it could be: $D_1, D_2, D_3, \dots, D_k$. Thus, first D_1 would be acquired, then D_2 and so on until D_k is acquired. Initially this assumes that not more than one of a given product could be acquired; but this need not be the case since additional units of a durable good could be treated as separate products. If we wanted to allow for the consumer to purchase up to four of any given durable then given k durables a consumer would have to prioritize $4k$ items.

This notion of the necessity for consumers to prioritize their acquisition of durable goods leads to the hypothesis that populations can be characterized as having a common order of acquisition for many types of consumer durable goods. This implies that consumers will have similar enough utility structures that in general they will acquire consumer durables in the same order.

Several researchers, using a variety of techniques, have examined whether consumers tend to have similar priority of acquisition patterns for sets of consumer durables (Paroush, 1965; McFall, 1969; Hebden and Pickering, 1974). Analysis techniques have included the Guttman coefficient of reproducibility (Paroush, 1965; McFall, 1969), the point correlation matrix (Paroush, 1965), and a matrix of conditional probabilities (Hebden and Pickering, 1974). Generally, it has been found that all three of these methods can be used to construct priority patterns for consumer durables. In addition priority

patterns have been generated for different segments of a market (McFall, 1969; Hebden and Pickering, 1974). The results from this type of analysis suggests that priority or acquisition patterns vary by market segment, however, some overlap tends to exist among the patterns. Finally, priority patterns have been generated based on both intentions to purchase and cross sectional ownership data (McFall, 1969). These two types of analysis tended to generate different patterns of acquisition or priority.

The study at hand will use Guttman scaling, however, importantly multiple measures of scale quality will be computed. Thus although the research reported here is not totally novel, it is unique in that it subjects the Guttman scale to more stringent statistical criteria.

Methodology

The empirical analysis of this paper focuses on the household's acquisition of major discretionary kitchen durables. Included for study are washing machines, dryers, dishwashers, freezers, and microwave ovens. Refrigerators and ranges are the only two major kitchen durables excluded from the analysis. These two kitchen appliances are excluded because they are viewed as necessities for modern household operation, with ownership being inordinately dependent on home ownership. It should further be noted that apartment dwellers may not own washing machines and dryers due to community washers and dryers being provided in the apartment complex. However apartment dwellers were included in the analysis since they were relatively few in number. Furthermore the inclusion of apartment dwellers could not possibly strengthen the scale quality since the presence of community washers and dryers in apartments would induce error into the scale. Thus our procedure is conservative (i.e., by excluding apartment dwellers our measures of scale quality would improve).

Subjects

The data for analysis was obtained from the DRP/OPUBCO Continuing Consumer Audit. The Distribution Research Program (DRP) at the University of Oklahoma and the Oklahoma Publishing Company (OPUBCO) collaborate in the collection of data on the purchasing behavior of individuals in the Oklahoma City SMSA.¹ Reported in this paper are some findings of the 1975 Audit which includes 1854 respondents from a stratified random sample. The sample is representative of the populations in geographic regions in the OKC SMSA which includes subjects from urban, suburban, and rural areas. It includes all types of dwelling units--houses, apartments, condominiums, trailers, etc. New samples are drawn each year with the distribution of the sample reflecting population changes in the strata.

Procedure

The Consumer Audit questionnaire is administered in a personal interview with both the male and female heads of the household responding. Each visit is a "cold" call with no pre-visit contact made with the potential respondent to request cooperation; i.e., the first contact is when the doorbell is rung. Not-at-home families are revisited at different hours of the day four times before a substitute respondent is designated for the interview. The data is collected continuously throughout the year by professional interviewers under close supervision. Each week completed questionnaires are returned

¹The authors wish to thank Phil Stout and Jim Williams of the Oklahoma Publishing Company for their continued cooperation in the collection and use of the Continuing Consumer Audit data base.

for processing. Telephone callbacks are made within three days of the return to verify the data collection. In addition, subjects may be telephoned again to obtain clarification of responses if need be.

Analysis

The stock of durables that a household possesses can be characterized by a multivariate distribution of 0's and 1's. A value of "one" would depict possession of the durable. A value of "zero" would represent non-ownership. If it is true, as hypothesized, that consumers have relatively similar utility structures for discretionary kitchen durables, the data on durable consumption behavior can be described in terms of a unidimensional "scaling" model.

The approach used in this paper is similar to that of Paroush (1965). In dealing with five household durables, a logically consistent conceptual model would be theoretically characterized by the pattern exhibited in Table 1. This indicates the order of acquisition to be D_1 , D_2 , D_3 , D_4 , D_5 . If it is observed that each consumer fits into any one of these patterns (rows), then we could transform the multivariate data into a unidimensional scale. Thus, by only knowing the last durable acquired, one can perfectly predict a consumer's total stock of durables. In other words, if the last durable added to one's stock of durables is D_4 , then we would know that this consumer also possesses D_1 , D_2 , D_3 and not D_5 .

Table 1
Theoretically Perfect Patterns of Durable Ownership

Subject	Durables				
	D_5	D_4	D_3	D_2	D_1
S_5	1	1	1	1	1
S_4	0	1	1	1	1
S_3	0	0	1	1	1
S_2	0	0	0	1	1
S_1	0	0	0	0	1
S_0	0	0	0	0	0

Now that the theoretically pure or ideal situation has been developed, it should be clear that not all consumers will acquire a set of durables in the same pattern. For whatever the reasons, the perfect durable acquisition scale will not be able to characterize all people since deviants will inevitably exist. The task is to determine whether divergence from the ideal model is a function of relatively unimportant aberrations or whether the divergence is sufficiently large for the perfect model to be considered unrealistic for the real world. Thus, some measure of scalability is needed to empirically test the appropriateness of the model.

Guttman (1971) developed a scaling model called scalogram analysis which may be applied to this task even though it was originally devised for a different purpose (attitude measurement). In the discussion of attitudinal dispositions, and the role of scalogram analysis, Guttman has stated that "...the universe is said to be scalable for the population if it is possible to rank the people from high to low in such a fashion that from a person's rank alone we can reproduce his response to each of the items in a simple fashion." (Guttman, 1971, p. 188).

From the Guttman perspective, an attitude scale should possess two properties: (1) unidimensionality and (2) cumulativity. A unidimensional scale is one in which

the component items measure movement toward or away from a single underlying object. A cumulative scale is one in which the components can be ordered by degree of difficulty; i.e., if a respondent replies positively to a more difficult component of the scale, then he would always respond positively to each of the less difficult scale components. For example, consider the following two simple attitudinal statements: (1) I would use Brand X coffee if it were given to me as a sample. (2) I would buy Brand X coffee in the supermarket if I could. A positive response to both statements would indicate a stronger disposition toward Brand X than a positive response to only one of the statements (unidimensionality). A positive response to Statement 2 should always result in a positive response to Statement 1, but not necessarily vice versa (cumulativity).

Guttman scaling has been traditionally used with cross sectional data in order to rank an individual's attitude toward an object. In the case at hand, it is desired to use Guttman scaling to model the temporal phenomenon of consumers acquiring discretionary durable goods. Although the data used in this study is cross sectional, it is possible to scale the underlying temporal phenomenon. Since the sample represents a true cross section of the entire population of the Oklahoma City SMSA, individuals at all stages in the order of acquisition process will be present in the sample. Thus, because this cross section of individuals is at various stages in the acquisition process, conclusions can be drawn about the order of acquisition over time.

From the above discussion, the appropriateness of scalogram analysis in examining our hypothesis is evident. The thesis of this paper is that the five discretionary kitchen durables mentioned earlier tend to be acquired in a designated priority pattern with the "more difficult" durables being acquired only after the "less difficult" appliances. In this context, a lesser degree of difficulty is synonymous with higher levels of expected utility derived from the ownership of the appliances. Among the various scaling techniques available, the Guttman approach is almost unique in its possession of this cumulative property (Nie, et al., p. 529).

The various techniques used to analyze the data collected for this study are detailed in the Appendix to this paper. These techniques include the original measures suggested by Guttman (1971); the Kuder-Richardson Equation 20 (Kuder and Richardson, 1937); the approach of Loevinger (1948); the extensions of the Kuder-Richardson and Loevinger works, suggested by Horst (1953); and the unique approach suggested by Green (1956). (A Technical Appendix, detailing the calculations performed using these techniques in order to derive the statistics reported in Table 3, is available on request from the authors.) The results of applying these techniques are presented in the next section of this paper.

Results and Analysis

As mentioned earlier, for the five discretionary kitchen durables, there are 32 ownership situations, yet only one pattern of acquisition represents the perfect scale. (There are $k+1=6$ ownership situations represented by this perfect scale.) To examine the extent of deviation from the perfect scale pattern, a variety of techniques (described in the Appendix) were used. A statistical summary of the data used to generate the Guttman scalogram, and to generate the scale reliability measures associated with these analytical techniques, is presented in Table 2.

A brief interpretation of Table 2 is in order. The scale rankings (row labels) are determined, for each respondent, according to the Guttman "perfect scale" technique. That is, a respondent receives a scale score equal to the

Table 2
 Statistics Summary of the Guttman Scale Analysis for Consumer
 Acquisitions of Discretionary Kitchen Durables^a

Scale Ranking	Durable Good										Totals

^aBasic Guttman analysis was obtained using SPSS(Nie, et al., 1975, pp. 528-539).

^bA 0 column gives the number of respondents not owning the durable;
 A 1 column gives the number of respondents owning the durable.

^cScale rankings are assigned according to the Guttman "perfect scale" technique.

^dOf the 1854 respondents surveyed, 61 failed to complete one or more questions related to the five items in this scale, and thus were discarded from the sample.

number of positive responses (1's) he gives to the items on the scale. For this study, a ranking of 3 indicates that the respondent possessed three of the five kitchen durables. Each column of Table 2 actually consists of two columns of numbers; the left-hand sub-column represents the number of respondents who did not possess the item represented by the overall column, for a given scale ranking, while the right-hand sub-column represents the number of respondents who did possess that item, for the given ranking. For example, of the 344 respondents who received a scale ranking of 4, two did not possess a dishwasher, while 342 did. Note that the sum of the sub-column entries, for any column, equals the total number of respondents in this study. Further, the sum of the sub-column elements for any row equals the number of respondents receiving that row's scale ranking.

The "easiest" items (most possessed) start at the right of Table 2, and progress to the "most difficult" items (least possessed) at the left of this table. Thus the "ideal" order of acquisition of kitchen durables would be: washer, dryer, dishwasher, freezer, and finally microwave oven. The values in the box of each sub-column of Table 2 represent the number of respondents that deviated from the perfect scale, for the item represented by the overall column. For example, of the 181 respondents scaled as a '1', 60 did not own the first item in the scale, a washer. Of these 60, five owned a dryer as their single durable; 18, a dishwasher, and 37, a freezer. These item errors occurred either by respondents possessing an item of greater difficulty than their scale value suggests, or by not possessing an item that would normally be owned, given their assigned scale value. The various row and column totals from Table 2 are used to generate the reliability measures, presented in Table 3, and discussed below.

Examination of the performance measure values presented in Table 3 provides strong support for the hypothesis of this paper that consumers tend to acquire discretionary kitchen durables in a pattern that can be detected through scalogram analysis. The Guttman measure of scale reproducibility exceeds 0.85, the minimum level suggested by Guttman for claiming a valid scale. Further, Green's

index of consistency substantially exceeds his suggested minimum value of 0.5; and the coefficient of scalability is well above 0.6. These results suggest that the proposed scale, based on the hypothesis stated earlier, is both reproducible and consistent.

Table 3
 Reliability Measures of the Discretionary
 Kitchen Durables Scale

Analytical Technique	Total Sample	Split Half I	Split Half II
Guttman			
Coefficient of Reproducibility	0.926	0.933	0.920
Minimum Marginal Reproducibility	0.734	0.737	0.731
Percent Improvement	0.193	0.196	0.189
Coefficient of Scalability	0.724	0.745	0.703
Loevinger			
Index of Homogeneity	0.659	0.675	0.644
Kuder-Richardson			
Standard KR ₂₀	0.688	0.689	0.688
Corrected KR ₂₀	0.850	0.854	0.840
Green-B			
Index of Reproducibility	0.963	0.966	0.960
Expected Coefficient of Reproducibility	0.895	0.898	0.893
Index of Consistency	0.646	0.668	0.624
Sample Size	1793	893	900

Drawing conclusions from the Loevinger Index, the Green Index, or the corrected Kuder-Richardson Equation 20 measure is considerably more difficult. To date no suggestions of reasonable minimum levels for any of these performance measures has been found anywhere in the literature. Despite this apparent lack of historical/theoretical guidance, the procedure described below for combining the Guttman, Green, Loevinger, and Horst measures for assessing the validity and reliability of scales developed from a set of dichotomous variables has been chosen. Future research efforts need to identify reasonable bounds of the Loevinger, Green, and Horst

measures.

First since both the Guttman and the Green Reproducibility Coefficients measure the same phenomenon, both should approach, if not exceed 0.85. Second, the Coefficient of Scalability should exceed 0.6, and/or Green's Index of Consistency should exceed 0.5. Further because the Loevinger measure and the Green Index of Consistency both attempt to evaluate the homogeneity of a scale, the Loevinger Index should also exceed 0.5 as a minimum. The value of the Horst measure, then, will also exceed 0.5 because it is always a multiple (≥ 1.0) of Loevinger's Index. If all of these conditions are met, it is concluded that a valid, reliable scale has been identified.

For this current study, all sample values of the various reliability and homogeneity measures exceeded the stated minimums. Hence it was concluded that a reliable and valid scale has been identified for the acquisition of discretionary kitchen durables.

To further test the internal validity of the scaling procedures reported above, the sample of 1854 respondents was split into two halves. The respondents were split according to the odd or even last digit of their sequential identification number to provide two subsamples. Since the completed questionnaires, gathered over many months of 1975, were numbered as they were collected from the interviewers, neither split-half sample was biased by seasonal factors. The reliability statistics calculated for each split-half are reported in Table 3. Inspection of these statistics strongly suggests that the sampling procedures used in this study were indeed random, unbiased and internally valid.

For the present, Paroush's notion of examining an item correlation matrix for simplex structure has been excluded from this scale evaluation procedure. This was done because it is not clear just which of the many available procedures for calculating correlations should be used. The method used by Paroush provides a significantly different matrix than the Yule's procedure employed in SPSS; nonetheless, each method produced a matrix that had a nearly perfect simplex structure. The Paroush version of the point-correlation matrix for the items examined in this study is presented in Table 4. The only flaws in this matrix are both associated with the item "freezer." This same phenomenon also appears in the data shown in Table 1.

Table 4
Point-Correlation Matrix for the Discretionary
Kitchen Durables Scale Items

Item	Washer	Dryer	Dishwasher	Freezer	Microwave Oven
Washer	1.000	.750	.389	.271	.090
Dryer		1.000	.459	.260	.118
Dishwasher			1.000	.291	.146
Freezer				1.000	.057
Microwave Oven					1.000

Discussion and Conclusions

This paper expanded earlier work on an intuitively appealing application of Guttman scaling. Is the application of any value; and if this application has value, is its value theoretical, managerial or both? We believe that the ability to characterize the population's multivariate acquisition of goods by a single scale offers both immediate managerial and theoretical possibilities.

Managerially, it can be said that the ability to scale

the order of acquisition of a set of durables allows managers a convenient way to estimate market potential, or forecast sales. For example, the potential purchasers of microwave ovens are those consumers that have already acquired a washer, dryer, dishwasher, and freezer. Those consumers that have only purchased a washer are not presently potential customers for microwaves until they first purchase a dryer, dishwasher and freezer. Obviously, therefore, the market potential changes as the population progresses through the order of acquisition process. In regard to forecasting sales, Brown, Buck and Pyatt (1965) have developed a technique utilizing priority patterns that can be used to improve the sales forecasts for consumer durables.

Second, it would be possible for managers to use the order of acquisition phenomenon to direct marketing efforts. In short, if microwaves were being sold, then marketing dollars should not be wasted on consumers who have only purchased a washing machine. In this case, direct mail could be focused on recent freezer purchasers, inasmuch as their next most likely new discretionary durable would be a microwave oven.

Turning to the more theoretical applications, a researcher could use the order of acquisition scale to investigate its potential for studying the adoption of innovations. Perhaps a person's scale score could be a determinant of him adopting a new innovation. For example if one examined those consumers that have adopted trash compactors, one would possibly find that the adopters were the individuals that had a high scale score (i.e., had already acquired all other discretionary kitchen durables).

Also on a theoretical plane, one could investigate the concurrent and/or predictive validity of the scale. The scale could be investigated to see how it correlates with, and its ability to predict, other behavioral constructs.

Finally, theoretical research could be directed at techniques for minimizing the error in the scale. This may be possible by segmenting the population to see if order of acquisition varies by segments. For example, individuals entering adulthood may acquire durables in several different orders depending on such things as marital status and social class. By constructing separate Guttman scales for each segment more perfect scales should result.

In summary, it can be concluded that the study of the order of acquisition of durable goods offers a promising area to all the respective parties interested in the study of consumer behavior. Coupled with this, it appears as though the Guttman scale can be a fruitful technique for the study of the order of acquisition of durables.

Appendix

This Appendix presents a discussion of the various techniques available for analyzing the data gathered in conjunction with the identification of a unidimensional scale. Except for the Guttman approach, which is presented first, these techniques are presented in the order in which they appeared in the literature.

Guttman

The most frequent analytical technique used in scalogram analysis and the most common one operationalized in the more popular computer statistical packages is the Coefficient of Reproducibility (C_R). Related measures are the Minimum Marginal Reproducibility (C_{MMR}), Percent Improvement ($\%I$), and Coefficient of Scalability (C_S). Guttman's C_R indicates how well the data approximates a

perfect scale by examining the extent to which positive replies to "more difficult" scale items are associated with the positive replies to those which are "less difficult". Mathematically, this statistic is as follows:

$$C_R = 1.0 - \frac{\text{total number of errors}}{\text{total number of responses}}; 0 \leq C_R \leq 1.0 \quad (1)$$

Errors are said to occur when a positive response is given to a "more difficult" item and not to a "less difficult" one. As a rule of thumb, Guttman assumes a valid scale if C_R exceeds 0.85 (Guttman, 1971, p. 176).

Subsequent research noted that C_R is biased upward to the extent that the dichotomized items have extreme distributions. The C_{MMR} measure was therefore devised to indicate the minimum coefficient of reproducibility that could occur for a scale given the proportion of respondents replying positively to each of the items. It is calculated as follows:

$$C_{MMR} = \frac{\sum \text{Maximum marginal for item } i}{\text{total number of responses}} \quad (2)$$

It should be noted that C_{MMR} is in itself, a meaningless statistic. Its value comes from an examination of its relationship to C_R . This relationship is examined through the %I statistic. It indicates the extent to which C_R is due to response patterns rather than to the underlying associations of the scale items. In this regard, the percent improvement is akin to the error or measurement variance of variance analyses techniques. Mathematically it is as follows, with the larger the value of %I, the stronger the indication of a valid scale.

$$\%I = C_R - C_{MMR} \quad (3)$$

The final Guttman statistical ratio is C_S . It is calculated as follows:

$$C_S = \frac{\%I}{1.0 - C_{MMR}}; 0 \leq C_S \leq 1.0 \quad (4)$$

The denominator of this formula indicates the largest amount of percent improvement which can be obtained and the numerator represents the actual amount obtained. Therefore C_S is a measure of how close the scale has come towards achieving the maximum improvement possible. Values above 0.6 are considered necessary for scale validity (Nie, et al., 1975, p. 533).

Kuder-Richardson

Several years prior to Guttman's original reports on his scalogram procedures, Kuder and Richardson (1937) described a method of estimating the reliability of tests and scales. They described several special cases, one of which has proven useful for testing for this current study. As with their other cases, the Kuder-Richardson Equation 20 (KR_{20}) is based on the variances of the individual items of a test or scale, and on the total variance of the entire scale. This equation was given as:

$$KR_{20} = \frac{k}{k-1} (1 - V_I/V_T); 0 \leq KR_{20} \leq 1.0 \quad (5)$$

where: k = the number of items in the scale
 V_I = the sum of the variances associated with each individual item of the scale
 V_T = the total variance associated with the entire scale

Loevinger

Subsequent research has noted two defects in the KR_{20} approach. Loevinger (1948) argued that scale reliability formulas, like KR_{20} , estimate item homogeneity as well as scale or test reliability. Furthermore, Loevinger (1947) pointed out that KR_{20} has an upper limit of 1.0 only when all items of the scale were of equal difficulty. As a consequence, Loevinger developed an alternate measure of test reliability called the Coefficient of Homogeneity (L_I). L_I produces identical results as KR_{20} when all items are of equal difficulty, but corrects for situations where there is a dispersion of item difficulty. A computationally useable formula for L_I is as follows (Horst, 1953):

$$L_I = \frac{V_T - V_I}{V_M - V_I}; 0 \leq L_I \leq 1.0 \quad (6)$$

where: V_M = maximum possible variance given the distribution of item difficulty
 V_T, V_I = same as for KR_{20}

Horst

Later discussion by Horst (1953) demonstrated that L_I really estimated the average item correlation for a test or scale, corrected for dispersion of item difficulty. Additional sophistication by Horst resulted in a better measure of reliability in that it incorporated total scale reliability. His Corrected Kuder-Richardson Equation 20 (KR^*_{20}) is calculated as follows:

$$KR^*_{20} = \frac{V_T - V_I}{V_M - V_I} (V_M/V_T); 0 \leq KR^*_{20} \leq 1.0 \quad (7)$$

Green

A different approach to estimating the reliability of a scale was introduced by Green (1956). It depends not on the calculations of item and test variances, but rather on the summary statistics of the sampling results obtained when a scale is designated. A researcher first estimates a scale for the items of interest, ranking them in order of ascending difficulty with item 1 being the least difficult. Next, the number of positive and negative responses are identified for each item. Although there are $k-1$ orders of possible error responses for a scale of k items, Green argued that, at most, just the first two orders contributed significantly to the reliability coefficients of a scale. A first-order error would be one where a respondent answered positively on an item of greater difficulty, say item $g+1$, while he responded unfavorably on item g . The index g is calculated over the ranked set of items. A count of all such first-order errors for the g th item would be denoted as $n_{g+1,g}$, meaning this many respondents possessed the $g+1$ st item, but not the g th item. Extension of this discussion and notation to second-order error counts is obvious.

Green presented two alternative estimates of the reliability of a scale which he called Rep_A and Rep_B . He showed the equivalence of these measures with the assumption that item error counts are independent statistics. Because it is computationally much less difficult, the Rep_B estimate has become more popular among social scientists. The Green-B Index of Reproducibility (R_{GB}) is as follows:

$$R_{GB} = 1.0 - \frac{1}{Nk} \sum_{g=1}^{k-1} n_{g+1,g} - \frac{1}{2Nk} \sum_{g=2}^{k-2} (n_{g+2,g})(n_{g+1,g-1}) \quad (8)$$

where: N = the number of respondents to the test (scale)

k = the number of items in the test (scale)
 n = the number of errors for the particular item-order interaction
 g = the item index across the set of ranked items for the scale

Although not explicitly stating so, Green implied that this index should be tested as though it were the original Guttman R_G . Thus, a value of R_{GB} in excess of 0.85 suggests that a valid scale has been identified.

Green also introduced the Index of Consistency (I) to serve as a measure of the homogeneity of the developed scale. This index is calculated as follows:

$$I = \frac{R_{GB} - R_I}{1.0 - R_I} \quad (9)$$

where: R_{GB} = Green B Index of Reproducibility (defined above)
 R_I = Expected Coefficient of Reproducibility (defined below)

R_I is the scale reproducibility that is expected by chance if a set of items possessed their observed popularities, and they are also mutually independent. Thus, this index indicates the extent to which an estimated R_{GB} is representative of a valid scale for the observed items. A negative value for I indicates a degree of negative correlation among some or all of the items in the scale. The equation for R_I is as follows:

$$R_I = 1.0 - \frac{1}{N^2} \sum_{k=1}^{k-1} (n_{g+1})(n_g) - \frac{1}{4} \sum_{k=2}^{k-2} (n_{g+2})(n_{g+1})(n_{g-1}) \quad (10)$$

where: N, k, n, g = same as for R_{GB}

Paroush

In addition to the approaches just discussed, another method for judging the validity of a scale has been suggested by Paroush (1965). In this approach, the scale items are also ordered by their ranked popularity. A point-correlation matrix for each pair of ranked items is then calculated. If this matrix has a simplex structure, the hypothesized scale is accepted. A simplex structure is one where the values of the matrix entries decrease as one moves away from the matrix diagonal, either horizontally or vertically.

Summary

Discussed have been several measures of scale reliability or reproducibility found in the literature of the social sciences. These measures vary not only in how they are constructed, but also in their ability to deal with scales where items are believed to differ in degree of difficulty. It is not the intent of this Appendix to discuss in detail the relative merits of these measures; rather, each of them has been calculated for this current study as a measure of scalability of discretionary kitchen durables.

AN INVESTIGATION INTO THE CAUSAL LINKS
BETWEEN ATTRIBUTION SCHEMA AND DECISION-MAKING

Richard Mizerski, University of Cincinnati
Stephen Green, University of Cincinnati

Abstract

An Interpersonal Replication technique (Bem, 1967) was used to test the hypothesized causal links between perceived attribution schemata and confidence in market information, belief and affect strength, and purchase intention. The results strongly support the validity of a causal link and reveal the differential impact of schema complexity upon consumer information processing.

Marketing has applied the concepts of Attribution Theory in a variety of areas such as children's reactions to television advertising (Robertson and Rossiter, 1974), and advertiser credibility (Settle and Golden, 1974). While the applications may differ, they all probe the general area of how consumers process market information in order to make consumption decisions.

Output of the Attribution Process

The behavioral nature of this process has been suggested by Fishbein and Ajzen (1975), and tested within the marketing environment by Mizerski (1975). These studies suggest that through the process of attributing the causes for events (e.g., product experience, word-of-mouth information, and advertising), beliefs about the stimulus product are formed which then might prompt the development of affect (Mizerski, 1975).

More specifically, Attribution Theory suggests that individuals more readily accept, and are more strongly influenced by, information about an entity if they attribute the report to the entity being described. Applying this to the marketplace, a consumer would perceive that information about a product was accurate and useful the more he believed the content of the information was "caused" by the product being described. For example, suppose the information that a particular brand and model of automobile has good gas economy is perceived to be the result of ("is caused by") the information source actually getting good gas economy with that automobile and telling the receiver about it. If the receiver felt this was the case, he would attribute the information to properties of the stimulus object - a stimulus attribution.

In many cases, however, the consumer may have some doubt about whether the information was "caused" by actual product performance. The receiver may suspect that other causes such as the source's conflict of interest (e.g., the source is selling his own automobile), lack of expertise or specific product knowledge, or some other individual bias (e.g., the source always prefers to speak favorably about the brand) prompted the information. In these latter situations, the receiver makes circumstance (properties unique to the situation or circumstance) and/or person (personal or dispositional properties of the person) attributions, and generally finds the information much less suitable for making inferences about the product.

Measures of Attribution

Research applying these concepts to marketing (see Settle, 1973, and Burnkrant, 1974, for a review) has had a number of limitations. First, causal attributions in marketing research are seldom measured directly. Instead, the strength of the stimulus attribution is often in-

ferred using measures of confidence or credibility. However, research by Newton (1973) and Mizerski (1974) seriously question the validity of this technique.

A second limitation of this research is that it typically elicits the degree of stimulus attribution only, which is not necessarily the lone factor of importance. Consumer perception of what is suitable/useful information is largely determined "... by the configuration of factors that are plausible causes of that information" (Kelly, 1973, p.108). In other words, the type and mix of causes (causal schema) the consumer perceives can also tell us a great deal about how he or she will interpret and process product information.

The Concept of Causal Complexity

In an attempt to overcome these problems, Mizerski (1975, 1977) developed a scale that elicits an individual's causal schema in terms of (1) multiple types of perceived causes, and (2) the relative importance of individual causes in the schema. These values are then transformed into a measure of entropy or an "H" statistic. This transformation provides a measure of the complexity of the subject's causal domain.

As an example, Figure 1 shows five hypothetical individuals' causal allocations among five possible causes for information about a product.

FIGURE 1
HYPOTHETICAL CAUSAL ALLOCATION OF INFORMATION

Perceived Cause	Receiver				
	A	B	C	D	E
(1) Stimulus Attribution	100%			50%	100%
(2) Person Attribution #1		100%		50%	100%
(3) Person Attribution #2					100%
(4) Circumstance Attribution #1			100%		100%
(5) Circumstance Attribution #2					100%

The measure of causal complexity would designate subjects A, B and C the least complex (causally simple), subject E the most complex, and allocations such as D in between.

Theoretical Rationale for the Differential Influence of Causal Schema

The literature (e.g. Mizerski, 1975, 1977) suggests that the five causal schemata shown in Figure One should prompt significantly different cognitive responses in the areas of confidence in the schema, confidence in the information, belief, affect strength and behavioral intention.

Confidence in the causal schema. The literature dealing with the measure of entropy (of which causal complexity is derived) suggests that consumers would be most confident in a causally simple allocation since individuals are less certain/confident in an array with a "broad distribution" than a "sharply peaked" one (Jaynes, 1957). If one considers a consumer's decisions on the number and allocation of cause to be a causal array (see Mizerski, 1975, for a more thorough discussion), an individual should have more confidence in causally simple schemata (receivers A, B, and C) than with the complex schema

represented by E. Also, since we are suggesting schema confidence only at this point, there should be no differences between the three simple schemata on this dimension. H₁: All causally simple schemata will evoke significantly stronger confidence in the schema than a causally complex schema.

Confidence in market information received. A consumer should believe that information about a product was more accurate, and thus have more confidence in that information, the more he assumes that the content of that information was caused by the product being described. Therefore, the less causality attributed to the product evaluated (the stimulus cause), the less confidence he or she will have in the rating information.

H₂: A causally simple stimulus attribution schema will evoke significantly stronger confidence in the product information than causally simple non-stimulus attribution schema (e.g., person or circumstance attributions, receivers B and C)

H₃: A causally simple stimulus attribution schema will evoke significantly stronger confidence in the product information than a causally complex schema (e.g., receiver E in Figure One).

Strength of belief, affect and intention to purchase. In an approach consistent with other researchers, Fishbein (1965, p. 107) has stated that "... a belief about an object may be defined as the probability or improbability that a particular relationship exists between the object of belief and some other object, concept, value, or goal." This definition of a belief appears to be one result of an attribution (Ajzen and Fishbein, 1975; Mizerski, 1975). Kelley (1973, p. 107) notes that attribution is a part of the process "...by which man 'knows' his world, (and) has a sense that his beliefs and judgements are veridical."

It would seem to follow that if an individual made a strong attribution about information concerning product characteristics to a stimulus cause, that would manifest itself in a strong belief that a relationship existed between the product and those characteristics. In Fishbein terminology, the stimulus attribution attaches a higher probability that the information was related to the product. Therefore, the stronger the stimulus attribution, the more extreme the belief. In situations of complex attributions, such as receiver E in Figure One, Kelley (1973, p. 113) suggests that "...the role of a given cause in producing a given effect is discounted if other plausible causes are also present." Therefore, a large number of person or circumstance attributions should discount (in the consumer's mind) the possibility of a stimulus cause.

A substantial amount of research on expectancy - value attitude models suggests that an attitude or affect toward an object is a function of (1) the strength of the individual's beliefs about the object, and (2) the evaluative aspect of those beliefs. While expectancy - value models differ somewhat, each uses some measure of instrumentality or belief strength as a basis for predicting affect. If causally simple subjects form more extreme beliefs, the differential in belief strength should manifest itself in a stronger affect toward the product.

Just as affect has been suggested to be a function of the salient beliefs about a product, a consumer's intention to purchase has been linked to his or her cognitive and affective responses (Lutz, 1977). Although the intention to purchase can be rather distant in both time and number of intervening variables from belief and affect formation, it may also directly respond to differences in causal schemata. Therefore, the following hypotheses will be tested.

H₄: A causally simple stimulus attribution schema will evoke a significantly stronger belief about, affect toward, and intention to purchase the product than

causally simple nonstimulus attribution schemata.

H₅: A causally simple stimulus attribution will evoke significantly stronger belief about, affect toward, and intention to purchase the product than a causally complex schema.

The Question Of Cause And Effect

While the results of previous research (Mizerski, 1975, 1977) appeared to establish a correlational relationship between causal complexity and other processes such as belief formation, there was no evidence that differences in the subjects' attributional schemata caused the differences in confidence, belief strength, etc. In fact, it became apparent that the present paradigm was incapable of testing that question since all the phenomena were cognitive, unobservable behaviors and all were elicited by the same stimulus (i.e., product information). Therefore, even though the present authors strongly believe that the causal schemata preceded and "caused" the beliefs, there was little available evidence to defend that position. How could this question of cause and effect be answered?

A review of the Dissonance Literature, which had undergone a similar problem of investigation that probable causes underlying observed behaviors in experiments, revealed a unique approach developed by Bem (1965). His technique was referred to as an "interpersonal replication paradigm," and it appeared to offer a valid approach for investigating the causal links under study.

Bem's analysis of dissonance, and the present analysis of causal schemata rest upon the single experimental generalization, "that an individual's belief and attitude statements and the beliefs and attitudes that an outside observer would attribute to him are often functionally similar in that both sets of statements are partial 'inferences' from the same evidence..." (Bem, 1967, p.186). Bem gave his subjects information about the treatment a single subject received in a dissonance experiment, and then asked how that subject would have responded. He then argues that when his subjects replicate the dissonance finding, the same process that was operating for his observer was also operating in the dissonance subject. With slight modification, a similar interpersonal replication paradigm was developed for the purpose of testing the preceding hypothesis and to determine whether it seems reasonable to argue that the subjects' causal schemata in the original Mizerski research (1975, 1977) caused the differences in belief and affect.

Methodology

Original Study

In Mizerski's (1975) original experiment, subjects were provided with evaluative rating information on one of three salient attributes for either a fictitious automobile or motion picture. The information was presented in the form of personal ratings that were supposedly made by another individual who was randomly chosen to test and evaluate the product. Following the information treatment, the subjects were asked to allocate the probable cause for the bogus "rater's" opinion (the information treatment) on a causal complexity scale shown in Figure 2. They were then asked to indicate their confidence in the allocation, beliefs about the product, and affective response to the product.

FIGURE 2

How much do you feel that each of the following reasons contributed to the product rater's opinion about the automobile's gas mileage? Note: Any of the following could account for 0% to 100% of the opinion.

- 1. The automobile itself _____%
 - 2. The influence of other people's opinions _____%
 - 3. An effort to please or antagonize the interviewer _____%
 - 4. The personality of the product evaluator (natural tendencies to be critical or complimentary) _____%
 - 5. A general bias for or against automobiles or the brand _____%
- TOTAL _____%

Interpersonal Replication I

Following the basic approach of Bem (1967), an experiment was developed in which subjects (University of Cincinnati undergraduate Business students) would be provided with the same product information as in Mizerski's original study. They were then told to assume that they made one of four possible causal allocations: (1) causally simple to the product - a stimulus attribution, (2) causally simple to a person attribution - "the influence of other people's opinions," (3) causally simple to a circumstance attribution - "the personality of the product evaluator . . .," or (4) a causally complex attribution which provided approximately equal allocation to each possible cause (refer to Figure 2). Ninety four percent was allocated to each simple attribution, with one or two percent allocated to the remaining causes. In the complex treatment, between 18 and 22 percent were allocated to each of five causes.¹

After being provided with the rater's information that the automobile tested rated "superior" on gas mileage and the treatment causal allocation, the subjects were asked to respond to several questions. The first question asked "How much confidence would you have in your assignment of percentages for the product rater's opinion about the automobile's gas mileage" (confidence in the schema). The second question asked "How confident do you think you would be that the product rater's opinion of the automobile's gas mileage was accurate; i.e., that the automobile actually had superior gas mileage?" This measured the subjects' confidence in the rater's opinion. The subjects' responses were gauged on a nine point scale that ranged from "No confidence" (#1) to "Complete confidence" (#9).

They were then asked a question about the strength of their belief that the automobile had superior gas mileage (unlikely--#1, to likely --#9), and the strength of their affect toward the stimulus product (extremely low appeal --#1, to extremely high appeal--#9). Finally, they were asked, " . . . If you felt that an automobile's gas mileage was very important, what do you think is the probability that you would actually consider purchasing this automo-

¹Originally, the simple causal allocation treatments had the total 100% allocated to the relevant simple cause, with an equal 20% allocated to each of the five potential causes in the causally complex treatment. However, pretests showed that the subjects inferred that the causal allocator " . . .did not take enough time" with the task using those percentage allocations.

bile if you were in the market when it is introduced?" Their response was scored on a scale that ranged from "very low probability" (0%) to "very high probability" (100%). All hypotheses were tested with a one-way analysis of variance, with each replication tested separately.

Interpersonal Replication II

After the initial interpersonal replication experiment was completed, it was felt that the experiment should be expanded so that results from treating all the potential simple causal schemata could be examined. Therefore, a second experiment treated the following allocations: (1) causally simple to the circumstance - "An effort to please or antagonize the interviewer;" (2) causally simple to the person - "A general bias for or against automobiles;" (3) the same causally simple to the product; and (4) causally complex schemata provided the subjects in the first interpersonal replication study.

The first interpersonal replication was run on two undergraduate marketing classes; the second experiment used two undergraduate management classes. Both samples closely approximated the backgrounds of the individuals in Mizerski's original study. The treatments were randomly assigned to the subjects, with each subject exposed to one of four treatments in each experiment. Because of the similarity in methodology, the results of the two studies will be discussed together in the text.

Results

Confidence in the Schema

In an effort to simplify presentation of the data, the results of both experiments are provided in Table I. Standard deviations of the mean scores are shown in parentheses, with cell sizes reported to the left.

The first hypothesis proposed that there would be no significant differences between the simple causal schemata, that they would all prompt stronger confidence in the schema than the complex schema. The mean scores from both studies (the first column of Table I) show only partial support for the hypothesis. The simple attribution to the product was the only simple schema that prompted significantly stronger confidence than the causally complex allocation ($t=2.34$, $df=46$, $p<.01$; and $t=3.43$, $df=58$, $p<.001$ for study I and II, respectively).

It was found that the simple attribution to the product also prompted significantly stronger confidence in the schema than the other simple attribution ($t=3.20$, $df=46$, $p<.001$, and $t=5.64$, $df=58$, $p<.001$). This latter finding was not expected since the literature strongly suggests that the more simple the attribution, the more confidence the attributor should have in the schema (i.e., a simple attribution is a simple attribution for this dimension).

TABLE 1
MEAN SCORES FOR DEPENDENT MEASURES

Treatment/Causal Attribution	Confidence in the Schema *	Confidence in the Opinion *	Belief Strength*	Affect*	Intention**
Experiment I					
11 Simple to the product	6.46 (1.76)	6.62 (1.45)	6.23 (2.06)	7.11 (2.04)	69.23 (26.91)
11 Affect to please interviewer	4.69 (2.09)	3.45 (1.86)	3.64 (1.43)	5.36 (2.61)	57.27 (19.62)
11 General bias for or against	4.31 (2.66)	3.85 (2.15)	4.31 (2.01)	6.09 (2.19)	56.39 (24.36)
13 Complex attribution	5.54 (1.66)	4.62 (1.94)	4.92 (1.65)	6.36 (1.19)	62.23 (20.72)
Experiment II					
13 Simple to the product	6.27 (2.21)	6.53 (1.88)	6.29 (2.21)	7.40 (1.24)	61.33 (24.16)
13 Influence of other's opinions	3.27 (2.28)	3.13 (1.81)	3.40 (1.50)	5.67 (2.06)	46.00 (27.62)
16 Personality of rater	2.56 (1.99)	2.81 (1.27)	3.06 (1.23)	5.44 (2.22)	45.00 (28.75)
16 Complex attribution	3.94 (1.76)	3.18 (1.32)	3.63 (1.15)	4.61 (1.90)	45.00 (21.99)

* Scale ranges from 1 (low value) to 9 (high value).

** Scale ranges from 0% (very low probability) to 100% (very high probability).

Confidence in the Accuracy of the Rater's Opinion

The second hypothesis suggested that the subjects would have more confidence in the accuracy of the rater's opinion when using schemata reflecting simple allocations to non-product causes. The mean scores in both studies are in the appropriate direction, (See Table 1) and the results of planned comparisons ($t=4.60$, $df=46$, $p<.001$; and $t=7.13$, $df=58$, $p<.001$) support the hypothesis.

The third hypothesis, that subjects who received the simple causal allocation to the product, would have more confidence in the accuracy of the rater's opinion than those who received a causally complex schema, was also supported ($t=2.73$, $df=46$, $p<.005$; and $t=5.86$, $df=58$, $p<.001$).

Strength of Belief, Affect, and Intention to Purchase

The fourth hypothesis proposed that subjects receiving a causally simple stimulus attribution schema will produce stronger belief, affect, and intention to purchase mean scores than subjects receiving causally simple person or circumstance schemata. Hypothesis Five went on to suggest that the same differential strength of the simple stimulus attribution schema would also be reflected over those subjects who received a causally complex schema. The easiest way to evaluate the results is to discuss one element at a time, across the two experiments, since significant differences were observed.

Both hypotheses were supported in the two experiments for the measure of belief strength. Subjects receiving the simple stimulus attribution schema formed significantly stronger beliefs than subjects under the simple circumstance and simple person treatments ($t=3.57$, $df=46$, $p<.001$; and $t=5.18$, $df=58$, $p<.001$), and stronger than subjects receiving the causally complex schema ($t=1.82$, $df=46$, $p<.037$; and $t=3.93$, $df=58$, $p<.001$).

As noted earlier, the formation of beliefs has been discussed as a direct response of the attribution process.

On the other hand, the development of affect and intention to purchase is a partial function of the beliefs about the stimulus object. One would expect somewhat weaker relationships with the attribution schema used.

As hypothesized, the subjects receiving the simple stimulus attribution schema formed significantly stronger affect than subjects with simple non-stimulus schemata ($t=2.31$, $df=46$, $p<.013$; and $t=3.11$, $df=58$, $p<.002$). However, the prediction that a simple stimulus attribution schema would also prompt stronger affect than a causally complex schema was not fully supported in both experiments. While the mean scores in the two experiments were in the appropriate directions (see Table 1), they failed to reach significance ($t=1.15$, $df=46$, $p<.128$) in experiment #1, while there was strong support for the hypothesis ($t=3.81$, $df=58$, $p<.001$) in the second experiment.

Similar results were found for the subjects' intention scores. Although the mean scores comparing the simple stimulus schema to other causally simple non-stimulus schemata (hypothesis 4), and to causally complex schema (hypothesis 5) were in the appropriate direction, hypothesis four was supported marginally ($t=1.43$, $df=46$, $p>.079$) and hypothesis five was not supported ($t=0.77$, $df=46$, $p>.44$) in the first experiment. Both hypotheses, however, were supported in the second experiment, ($t=1.81$, $df=58$, $p<.038$, and $t=1.74$, $df=58$, $p<.044$).

Summary And Conclusions

The results strongly support the hypothesis that differences in the complexity of causal schemata can cause differences in other cognitive responses. Specifically, those individuals using a causal schema that reflected simple allocations to the product (stimulus attribution) responded with significantly higher levels of confidence in the accuracy of the information they received, stronger beliefs that the product possessed the characteristics assigned it by the information source, and a stronger affective response to the product than individuals using a complex causal schema or schemata reflecting a simple non-stimulus attribution. In addition, those subjects using a simple-product schema demonstrated a stronger intention to purchase the product than subjects using a simple-circumstance or simple-person attribution schema.

The comparison of simple-product and complex schemata on intention to purchase, however, yielded equivocal results. Although it is not clear why the subjects using the simple-product schema formed stronger intentions to purchase than subjects using a complex-schema in the second study only, one could speculate that several factors might have been operating. First, as previously noted, intention to purchase is only partially a function of beliefs and therefore not as directly related to schemata. Thus, it may be that this phenomenon is more tenuous and difficult to capture experimentally. Also, one should note that all the findings are stronger with the second study than in the first. This discrepancy may be due to the fact that Study One was conducted in marketing classes where the students were more familiar with marketing concepts and research, and therefore may have been "test wise" and wary in their responses.

The failure of hypothesis one, that all simple schemata will evoke stronger confidence in the schema than the complex schema, may have been due to the nature of that question more than any "real" psychological process. In pretesting the instruments, it was found that the subjects had a great deal of difficulty understanding the intent of the question concerning confidence in the schema. After many iterations on that measure, it was felt that it had been made clear. Debriefing, however,

revealed that subjects had confused the confidence in the schema measure with the confidence in the accuracy of the rater's opinion measure (these two responses correlated .54, $p < .001$, when the treatment means were removed from the scores). Therefore, any interpretation of the confidence in the schema data appears problematic.

Nonetheless, it is apparent that differences in causal schemata complexity can cause differences in other important cognitive processes. To the extent that the process revealed in our "observers" is the same process that occurs in individuals who generate their own causal schema (as Bem, 1967, and these authors would argue), there are clear implications for marketing strategy. If one can devise advertising formats that elicit a simple-product causal schema, as opposed to simple nonproduct or complex allocations, the consumer should be more likely to be confident that the product information is accurate, as well as form stronger beliefs about the product's characteristics. Similarly, the consumer should have a stronger affective response toward that product and might (but not necessarily) develop a stronger intention to purchase the product.

Research is presently underway in an attempt to identify the varying capacities of advertising formats to elicit a simple-product schema in consumers. Other research might focus on the effects of different media presentations upon the complexity of evoked schemata or investigate the possibility of causal complexity existing as an individual difference construct.

SOME ISSUES IN DESIGNING CONSUMER INFORMATION STUDIES IN PUBLIC POLICY

R. Bruce Hutton, University of Denver
Dennis L. McNeill, Arizona State University
William L. Wilkie, University of Florida

Abstract

In order for the consumer researcher to make significant inputs for public policy decisions regarding information provision, he must be aware of the nature of the policy environment and the kind of research that will best fit its needs. This paper addresses several issues of importance in doing policy related research and describes two specific studies in the area of energy information undertaken at the University of Florida's Center for Consumer Research.

Introduction

The content and availability of product information for use in evaluation and decision making by consumers is a major topic of interest and concern among various groups -- marketers, policymakers, consumer educators, and consumer researchers. At issue is the availability and subsequent use of information by which consumers can make more "informed" choices (e.g., objective information representing specific physical features). Programs to provide such information have been created in a broad range of government agencies, including the Environmental Protection Agency, Department of Transportation, Food and Drug Administration, and Federal Trade Commission. Current initiative is reflected in the 1975 Energy Policy and Conservation Act (EPCA) whose basic mandate is to "conserve energy supplies through energy conservation programs . . ." (EPCA, 1975). One of the major priorities of this program is the establishment of labeling rules for major durables, specifically in the area of energy consumption. For the consumer researcher to provide relevant input to such decisions, his research paradigm should reflect the special problems in policy oriented research.

Trade Regulation Rule Influence

Day (1976) notes that we are certain to see an increase in the disclosures of efficiency performance data in the future. The primary vehicle for operationalizing future information provisions will likely be through the Trade Regulation Rule (TRR) power of the Federal Trade Commission (FTC). In effect, TRR's allow a public agency to require particular marketing practices to be performed by all marketers in a given product or service category (Wilkie and Gardner, 1974; Wilkie 1975c). This approach by the FTC will require policy decision inputs at a number of different stages. Wilkie (1975) has delineated six stage process of TRR development:

- (1) Selection of product classes.
- (2) Identification of relevant product characteristics.
- (3) Development of standards and test methods.
- (4) Determination of reporting format.
- (5) Provisions for dissemination.
- (6) Assessment of effectiveness.

The different stages represent different levels of importance for the consumer researcher. Stage 1 is crucial because priority concerns and program objectives are formulated here. Stages 2 and 3 will be primarily undertaken by technical experts. Stages 4, 5 and 6 provide the major opportunities for consumer research.

There are both major and complex questions about the

need for TRR's, especially in a cost/benefit sense. Expected benefits from TRR's can be classified into two major types: (1) administrative/legal benefits, and (2) economic/social benefits (Wilkie, Hutton, and McNeill, 1975). TRR's are expected to make the regulatory process more efficient by removing the need for case by case adjudication and to provide marketers with better guidelines for what is expected of them. In the second case, TRR programs should bring the system more towards the idea of the "fully informed consumer" and to give him more objective information for product/brand decisions. At the time of this writing, TRR proposals aimed at increasing consumer information were underway in a number of areas, including: nutritional information in food advertising, OTC drug advertising, used automobiles repair information, standardized product warranties, comparative price disclosures for life insurance policies, detergent cleaning ratings, and energy consumption labels for household appliances. Each of these areas involves millions of consumer purchases and potential for considerable improvements. Consumer research is obviously relevant for program decisions.

Purpose of this Paper

The design and conduct of research for public policy needs has been a focus of attention at the University of Florida Center for Consumer Research. A series of experiments have been conducted which deal specifically with the area of consumer product information. In designing these studies, the authors have encountered several important issues of likely interest to both the academic researcher and policymaker. The purpose of this paper is to examine these issues, show how they have influenced two particular studies dealing with consumer impact of "new" product information, and to provide some general suggestions for others' consideration of this research area.

Preview of Issues

In any research project, decisions will have to be made regarding the focus of the research, design issues, data collection, and analysis. In policy related research, while some issues will be unique to the public policy field, the majority of decisions to be made will be of the same type as any research project. However, the final approach the researcher takes will be different in many cases because he or she is addressing the research to policy needs. The subsequent policy-related approach carries with it a series of issues and problems, the combination of which is not faced in the normal research program. Major areas of concern for such policy related research are presented in Table 1.

The Role of Policy Objectives

In any research setting, it is crucial for the researcher to have the focus of the study clearly in mind. In the case of research applied to policy needs, an understanding of policy objectives is a necessary condition to defining the problem and establishing the reasons for investigation.

Wilkie, et.al., (1975) state that vague or unspecified objectives by the policymaker can easily allow differing research thrusts, designs, and measurements supposedly aimed at the same policy decisions. The risk is that

TABLE 1

Some Public Policy Research Issues	
Issue	Areas of Concern
1. Role of Policy Objectives	-- Problem definition -- Basic v. applied research -- Stimulus -- Unit of analysis -- Criteria
2. Research Design	-- Design format (task orientation) -- Validity -- Demand characteristics
3. Data Collection	-- Focus groups -- Measurement and scales -- Sampling
4. Data Analysis	-- Levels of significance -- Statistics

some of these will be inappropriate for the policy or program mandate. Consider, for example, the fundamental problem of determining dependent variables for studying the effect of information on consumers. A natural tendency would be to choose brand choice or at least attitude and intentions as appropriate variables. But these may not be appropriate criteria. For example, if the goal of the recent energy program is to reduce demand, this would not be reflected in brand shifts as much as model shifts. This point is also made by Bettman (1975) who states that the choice of criterion variables is a function of intent of the information provision. If the intent is that the information be used in a specific manner, attitudes and behavior become more important relative to recall, knowledge, and awareness. If the intent is that consumers should be aided in perceiving and processing the appropriate information but no commitment concerning their use of it, recall, knowledge, and awareness variables become crucial.

Once the researcher understands the basic problem, he must define for himself the rationale for investigating the area (e.g., timely, theoretical significance, practical significance, instrument development, clarification of existing perspectives, stream of research). Based on the reason(s), the decision to be made is whether the focus of the research will be problem or theory oriented. Wilkie (1975) addresses this issue in his discussion of basic v. applied research. The criteria for choosing may be established as:

<u>Applied</u>	<u>Basic</u>
<ul style="list-style-type: none"> • primarily responsive to and reflective of the policy setting • results offer useful perspectives to the policymaker and marketer • enhance knowledge of the way consumers perform 	<ul style="list-style-type: none"> • derived from theory • tight testing of hypotheses • lack of direct short run benefits to the policymaker

Once the researcher has decided these fundamental questions, more specific issues arise concerning questions of appropriate stimuli, units of analysis, and criteria.

Should the researcher choose to focus on the programs, the stimulus chosen for study should meet a set of criteria based on policy needs. The product class chosen would be a function of: (1) the state of knowledge of the consuming public and subsequent sample, (2) characteristics of product use, and (3) the presence of within product class variance. That is, the product class should show variability along the dimension to which

the program is directed.

The unit of analysis in addressing policy questions is usually the individual as opposed to the product. Some experiments done in the information provision area focus on shifts in choice (e.g., Houston, 1972; Isakson and Mauizi, 1973; Russo, et.al., 1975); therefore, the unit of analysis is necessarily brand, which does not measure information use directly. For most information programs however, policy-oriented research will focus on the individual consumer level at early stages.

In the past, criteria for evaluating the effects of information have tended to be market share or brand switching behavior. The appropriateness of utilizing these measures alone in evaluating information provision can be questioned, especially when one recognizes that the consumer is faced with a new environment and brief exposure to the information. In such a limited exposure, the use of brand choice places a great deal of responsibility on this level of impact. As with other marketing research, it is more advisable to measure the effects of information at different levels of response using multiple dependent measures (Day, 1976; Heeler and Ray, 1972). Multiple dependent measures will most likely require multiple tasks, with emphasis on realistic content and order.

Research Design

The choice of the appropriate experimental design is, of course, dependent on a number of factors. However, in policy related research, stress is placed on external validity.

The key, then, is to make the experiment more valid externally without losing internal validity. Only two experimental designs meet the criteria for internal validity and control at least one source of external invalidity -- Solomon four-group design and posttest-only control group design (Campbell and Stanley, 1963). Because of the cost involved in running the Solomon-four, the posttest only is usually preferred. Both of these designs control for the possible interaction of testing and X (i.e., the experimental treatment). However, two other interactions are also a problem. It is possible that any effects demonstrated hold only for that unique population from which the groups were selected (interaction of selection and X). In order to reduce this problem the researcher should increase the number and types of groups used. The other interaction involves the effects of recent events on subject responses (interaction of history and X). For example, an experiment on energy information done immediately following the presentation of President Carter's energy program might produce a responsiveness to X not to be found on other occasions. Consequently, it is desirable for policy research to lead, not lag, the phenomena under study.

The other major concern for the researcher in this area involves demand characteristics. For the policy researcher two factors are especially relevant. First, the subject is placed in a changed information environment. Consequently, exposure to new concepts may cue him in terms of the focus of the study. Second, the experiment set up to have the subject engage in multiple tasks is open to demand characteristics if one task cues subject response on other tasks in ways not intended by the researcher. Consequently, the flow of tasks and measures is a primary consideration for the researcher. For an excellent summary of demand characteristics in lab experiments and how to deal with them, see Sawyer (1975).

Data Collection

Focus group interviews can play an important part in the development of the policy research format, with primary

purposes being to: (1) Explore the current state of consumer knowledge and attitudes toward the stimulus; (2) Obtain a better understanding of the consumer language used in thinking about the stimulus.

The results of the focus group interviews will provide important information for the development of scales for subject response. Scale construction should be a function of the population under a study and not the desired analysis procedures. Obviously scales and tasks should be set up so they can be understood by all subjects. Unfortunately, this may not always be possible, especially when dealing with some segments of the population. In order to minimize this problem, scales should reflect as much as possible the language of the consuming population and real world choices.

Other important questions in the research design involve sampling procedures. In order to provide policy guidance, it is obviously desirable to use subjects which reflect a realistic population of consumers for the program at issue. Lab experiments will normally not be feasible with probability samples, but neither are they normally very useful with college sophomores. One guide might be to use real consumers, attempting to include a broad range of demographics within the sample.

One economical (time-wise) approach is to solicit "intact groups" such as social, religious, and educational organizations. (This will, however, often require within-session assignments to different conditions, which will impact on the design and operationalization of the study itself.) If this approach is taken, the researcher should vary the nature and demographic character of the groups chosen, use as many groups as possible, and have no single group dominate the sample.

Real consumers, while providing more relevant data, do present some formidable design problems when compared to college students. Special care must be taken to prevent difficulties the subjects might encounter with certain abstract concepts and with a potential reactive response to being placed in a "testing" mode. These problems require careful development of instructions and tasks and attention by those involved in the conduct of the experiment. Some guidelines we have developed based on recent experiences include:

- Provide complete assurance regarding the anonymity of subject responses. This will help reduce the feeling of being tested and graded.
- Researcher should be ready to accept the fact that some segments of the population just may not be able to do all tasks. This may reflect the study's demands rather than the program being studied; it may be necessary to do a separate study for these segments.
- Non-responses are a fact of life. Some subjects will refuse to make a "best estimate" or "guess" because they feel that would be dishonest or a form of cheating.
- It may be beneficial to provide the subjects with familiar surroundings (i.e., go to their church, club, etc.). Since the researcher is now out of his familiar setting, he should be ready to meet a variety of unforeseen occurrences. Examples these authors encountered include a subject's breaking into tears, a blind subject, mothers missing directions because of a 5 year old's nature call, and confrontation with an inebriated by-stander. Dealing with these kinds of factors certainly approaches art more than science.

Data Analysis

The relationship between the issues being discussed is not one of independence. Naturally, many of the factors discussed previously will affect the data analysis stage (e.g., non-responses, scale construction, etc.). However, there are several specific points that should be advanced:

- The type of people and responses they might normally make will influence the analysis procedure. For example, in the construction of appropriate scales, the result may, in the interest of realistic alternatives, be a nonmetric, as opposed to metric scale.
- There is a need to determine in advance the accepted level of significance. Typically is set at the "sacred" .05 or .01 level. In fact, a number of criteria should be used to determine the appropriate level (Labovitz, 1970). In dealing with issues and samples of the paper above, less stringent significance levels may be justified. In any case, it is helpful to report the actual level attained and overtly provide the researcher's judgment as to the meaning of the obtained result.
- In the case of multiple tasks and measures, analysis should be done in light of other responses. For example, a complexity of information measure was taken on a standard seven point bipolar scale. The results showed no difference across groups with all groups judging it "simple." A clear case of easy to understand information? Subsequent tasks involving the use of the information showed the groups acted differently, and suggesting that many subjects, in fact, may not have recognized the complexity of the information and only dealt with it in a superficial manner. Additional items and analyses can be included to address these possibilities.

Issues Specific to Energy Labeling

In light of recent developments (e.g., CIA report on energy resources, President Carter's energy program, development of a Department of Energy), issues of the effects of energy labeling of appliances on consumer response have become particularly relevant.

Energy Programs

The Voluntary Labeling Program resulted from a Presidential directive in April 1973. This program was established within the Department of Commerce to deal exclusively with major energy consuming household appliances. Its general purposes were:

- (1) Encourage manufacturers (including private brand labelers) to voluntarily provide consumers with information concerning the energy efficiency or energy consumption of major durables.
- (2) Encourage consumers to utilize the information when evaluating products by providing, at the point of sale, energy information presented in a uniform manner and readily understandable in order to facilitate product comparisons.

Early success included the fact that 24 manufacturers representing an estimated 95% of room air conditioner sales in the U.S. were participating in the program as of 1975 and generally favorable consumer attitudes were

exhibited toward such labels. In 1976 this voluntary program was abolished by the Energy Policy Conservation Act, and was replaced by a mandatory labeling program under the primary jurisdictions of the FEA and FTC.

The Energy Policy and Conservation Act (EPCA) passed in December 1975, reflects a broad range of programs. Included as important thrusts are efforts on product testing, labeling, energy standards, and consumer education. The Act requires that labels disclose, for each model, (1) the estimated annual operating cost and (2) the range of alternative's estimated annual operating costs. In addition the FEA has the power to prescribe energy efficiency standards to any type or class of covered products. However, it is stipulated that resulting energy savings must outweigh any increase in price or maintenance expense, lessening of product performance, or negative effects on competition in order to be implemented. Finally, the FEA will also carry out a program to educate and encourage consumers to use such information in conserving energy.

Disclosure of Energy Use Data: Study A

The purpose of this research was to address and examine certain consumer information processing issues within the Energy Act's formal programs of standardized energy consumption disclosure. The issues surrounding the energy labels are important, in that the form and content of the labels may well effect the impact of the program on consumers. This research focused on two central questions:

- (1) Will the presence of energy consumption data on labels attached to major home appliances be likely to assist the consumer in purchase related activities?
- (2) Is the reporting format required under the Energy Act the best way to disclose energy consumption?

The first question is important from a program evaluation perspective, and, in addition, will provide a frame of reference for the investigation of the format question. The impact of the disclosure, given the early stages of program development and the timing of this research, should provide insights into the potential impact of the program and whether it appears wise to proceed.

The second area of interest is the format of the disclosure, an area which appears to have been infrequently researched. Particular issues of interest regarding the energy labeling format were:

- Unit of Measurement -- The required disclosure is in dollars. The unit of measurement question is important in light of program goals. For this study the units of measurement under investigation were the dollars required by the EPCA and the kilowatt per hour (KWH) alternative.
- Comparative Disclosure -- The EPCA requires a new dimension of product performance when it requires comparative energy use for similar products. Effect of this additional information was investigated.
- Time Period for energy use computation -- The required time period is in annual terms. The issue is one of magnitude, for the time period used can inflate the model consumption figures. For this study a comparison of monthly and yearly time periods was conducted.

• Degree or Specificity of disclosure -- A crucial aspect of the disclosure of energy use is the ability of the consumer to identify those attributes of the products which account for energy use. The impacts of explicit -- by feature -- disclosure of energy use were also assessed in the study.

Energy Use Data/Policy Research Issues

The combinations of each of these issues required too many experimental cells for the limited resources of the study. Rather than eliminate controllable decision variables, it was decided that certain combinations should be dropped, these determined in light of that combination's realistic chances of actually being used by the program. Readers will note that this decision incurs costs in terms of our subsequent ability to disentangle main effects of the format variables mentioned above. On the other hand, it does allow us some assessment of more variables than would otherwise have been possible. Six conditions were run in the study, ranging from control, with no energy use information, to annual dollars with a range, broken down by feature. The design was completely randomized, after-only, with a control condition and five disclosure conditions.

The product class chosen, refrigerator-freezers, is an interesting (and relatively straightforward) one from the program perspective. The product occupies a prominent place in the home and accounts for a significant proportion of average household energy use. The use of the product is relatively constant across households, reducing the variation in actual consumption as a function of household and geography. In addition, the variability in energy utilization is predominantly associated with features, rather than only brand, choice.

In determining the tasks and measures, the program's objectives played an important role. The goals of this particular program are overtly to reduce the demand for energy. One research focus thus should be on consumers' behaviors re: energy. However, as noted earlier, features are more significant than brands here, such that research tasks had to be altered from the normal stress on brand preference or choice. To assist in more detailed decisions, focus groups were conducted, providing inputs for the language and attributes included in stimulus development.

Table 2 charts the conduct of the experiment. The purpose of the experimental tasks was to allow for a complete profile of energy use impact through multiple dependent measures, while the subjects encountered the information in realistic situations. This set of tasks and measures took slightly over one hour; a fuller description is available in McNeill (1977).

Essentially, the tasks reflected three stages of information exposure and use. The initial exposure required the subject to acquire the information (ala Jacoby's "information board") by pulling tabs attached to four individual model displays. (Models had been designed to allow research inferences as to how well the information was being communicated and used.) In this way, the subjects learned about the models and the researcher could follow "where the subject's eyes go" when evaluating the model. The subjects were then asked to evaluate the models based on unaided recall of the information they had acquired. The second level of information exposure was a second visit to the same models, now allowing external memory while pursuing the evaluation tasks. The final level of information effect was a unique operationalization of the choice dimension. This requested the subject to "build" their own personal model of refrigerator-freezer feature by feature, with a number of subsidiary measures taken afterward. This series of experiment tasks provided responses to the in-

formation across a wide range of impacts, allowing a reasonably comprehensive analysis of effects. Results and conclusions are detailed in McNeill (1977).

Results

Given the comprehensive design of this study with its multiple measures and tasks, a detailed explanation of findings is beyond the scope of this paper. Overall, the results of this study should prove useful to both policymakers and consumer researchers. The presence of energy consumption data had a significant impact on consumer's information processing responses. After the initial shopping task (involving information acquisition) the product preferences, overall impressions, and energy use judgments of the experimental subjects were in the hypothesized direction. This was also found in evaluative judgments in the presence of the information on the second shopping trip task. Essentially, the nature of the results shows that the higher the energy use the lower the model evaluative judgments. This is supportive of the energy use impact potential in light of both the intent and content of the disclosure.

The second question under study concerned the format of the information and the relationship of format to consumer information processing response. The format variable which produced differential response was the comparative disclosure. Given that the goal of this disclosure was to provide more effective relative judgments of model performance, a set of specifically designed scales were developed. The comparative judgments reflected the comparative disclosures (in the case of relatively high energy use) on the likelihood of finding a better value, the worth of additional shopping, and purchase recommendations. While the other format variables did not produce significantly different responses, there were no format variables which appeared to hinder the consumer response in terms of the goals of the disclosure. The format question, however, is an important one and must be investigated from other perspectives in order to make completely profile this decision for the policymaker.

Life Cycle Cost: Study B

While present policy consideration is focused on the format questions discussed above, it may be that a more comprehensive information scheme is much more meaningful. This index, termed "life cycle cost," provides a framework for the summary presentation of three product dimensions -- price, energy, and service costs (M.I.T., 1974a). Life cycle cost (LCC) is defined as the discounted sum of all dollars paid for an average product during its useful life (i.e., purchase price + energy cost + service cost). In essence, LCC provides the consumer with an organized and consistent way of processing all product cost information by incorporating the three cost dimensions within a consistent time frame (i.e., average product life) and common units of measurement (i.e., dollars).

Our study was aimed at exploring the impact of LCC, as a new information form, on consumers. Specifically, the study compared the existing consumer information environment -- with its emphasis on purchase price -- to a new environment providing LCC data. In addition, the study stressed multiple tasks and measures aimed at more comprehensive evaluation of information effects, attempting to account for the fact that such a program would not have been encountered before.

M.I.T. Report

Background for, and development of, the LCC concept is described in the monograph "Productivity of Servicing Consumer Durable Products," authored at M.I.T. under an

Energy Information Preferences

NSF-RANN grant. The report asserts that consumers fail to recognize energy costs in appliances, do not seek out energy and service related information during product evaluation, and instead opt for increasing use convenience at the expense of increasing energy consumption. Since higher prices may be necessary for the introduction of energy conserving design changes, a shift in consumer perceptions of cost from sole reliance on initial purchase price to a long-run total (LCC) cost appears necessary for the market to operate so as to

reduce energy consumption. The nature of presumed consumer impacts from LCC information is presented in Wilkie and Hutton (1977).

LCC Policy Research Issues

The combination of a new conceptual framework for cost and a policy orientation provided this study with a number of challenging issues. First, the introduction of a new concept such as LCC provides the consumer with a different environment in which to operate. Multiple tasks were needed to reflect different levels of consumer response expected within the proposed new environment. Index figures for LCC had to be realistic, which required technical advice and a series of product cost calculations on refrigerator-freezers, which were chosen for this study for much the same reasons as noted earlier. Also, major concern was again with factors in the product that relate to cost (i.e., features). In the case of refrigerator-freezers this would include size, frost free, automatic ice maker, power saving switches, etc. Stimuli are identified as models (combinations of features) since they reflect the different cost combinations more so than brand by brand comparisons of the same model types.

The research design was a posttest-only control group design. Besides the LCC condition, an energy/year condition was included to reflect the EPCA mandated program. Both experimental groups represent a changed environment from today. Intact groups were used, so random assignment to conditions was done within groups instead of among the total subject population.

A flow chart of the experiment is given on the bottom of Table 2. Design of the tasks and measures involved some difficult trade-offs among policy concerns, research control, analytical needs, and subject's capabilities and motivations. Some examples: (1) how many models to present? (2) whether, and how, to introduce budget constraints, (3) whether scales should be balanced versus skewed when dealing with arguably positive or negative concepts, (4) how to assess basic capabilities (e.g., computation skills) without overtly testing, (5) how to represent negative costs (savings), (6) how to introduce this new information together with some education on it, while minimizing demand characteristics, and (7) determination of appropriate criteria by which to reach summary conclusions, given the large number of measures. Details of these decisions are available in Hutton (1977).

Results

Once again, given the extensive design of the study with its multiple measures and tasks, a detailed explanation of findings is beyond the scope of this paper. For a complete analysis of results see Hutton (1977). In general, however, the strongest results were seen in tasks reflecting levels of consumer response in a more cognitive as opposed to behavioral sense. The study provides support for the provision of more comprehensive objective information. By letting control group responses represent what consumers know going into a buying situation and LCC responses what is learned, the differences indicate that consumers do learn from the presentation of such information. In fact, control group responses show a significant underestimation of the magnitude of operating costs. There is also evidence that what is learned by the consumer is more than a specific cost figure but rather a different conceptual view of product cost from the one dimensional association with price toward a multidimensional long run concept.

From a policy standpoint, it is important to know the impact of a proposed provision along various dimensions of utilization. Can they utilize the information correctly or does it result in confusion, misinterpreta-

tion, or ignoring of the information package? Findings along these lines are equivocal. Consumers do utilize some aspects of the information, even lower educated ones, but not without certain negative consequences. In addition, there is some indication that consumers will evaluate models and features which conserve energy more favorably and energy consuming features less favorably with the availability of energy cost data. In terms of purchase behavior, it appears that subjects are willing to pay for energy savings but not at the expense of certain conveniences and not without actual cost data for price/energy saving trade-offs. Overall, the evidence shows that consumers' existing knowledge in the area of energy and its relation to products and other costs is sadly inadequate, but the provision of objective information of the type explored in this study holds promise as a valuable decision making tool for consumers.

Conclusion

The public policy environment provides a unique opportunity for consumer researchers, if he or she is aware of factors that distinguish policy-oriented research from that done for other purposes. In particular, four "generalizations" may be useful for empirical researchers considering research in this area:

- Policy objectives are crucial in determining the research approach. In the short run, emphasis is necessarily placed on problems solving. But, in the long run, research addressing broader issues of CIP is necessary for a fuller understanding of consumer information use as well as for assessing the effects of information.
- Experiments show particular promise as a vehicle for both research approaches.
- For the policy-oriented researcher, the design is very much a function of the population under study and the problem to be addressed.
- Task environment, measures, and stimulus vehicles are particularly important because of the stress on external validity. Careful attention should be paid to all three in the interest of realism and to counter potential demand characteristics.

Anyone taking these seriously will find ample challenge in terms of research creativity, as well as having the opportunity to contribute something useful to society, our profession, or both.

POTENTIAL CONTRIBUTIONS OF CONSUMER RESEARCH TO ANTITRUST DECISION MAKING*

Paul N. Bloom, University of Maryland

Abstract

A review is presented of several antitrust issues that might be resolved with the help of consumer research. Some research methodologies that could be used to examine these issues are also suggested. It is concluded that consumer research could play an important role in antitrust decision making.

Introduction

Numerous authors have written about the need for consumer research to help public policy decision making (Wilkie and Gardner, 1974; Rosch, 1975; Hunt, 1976). These authors have stimulated a growing volume of research studies designed to assist policy making in the consumer protection area (Day and Brandt, 1974; Jacoby, Speller, and Kohn, 1974a, 1974b) and other more "functional" areas (Richie and LaBreque, 1975) such as pollution control (Kinnear, Taylor, and Ahmed, 1974), transportation (Brown and Schary, 1977), and energy conservation (Reizenstein and Barnaby, 1977). However, one area of public policy decision making that has tended to be overlooked by consumer researcher is antitrust policy. Although several authors have recognized that consumer research could aid antitrust enforcement efforts (Wilkie and Gardner, 1974; Howard, 1977; Day and Shocker, 1977), very little research has been done with the specific goal of helping antitrust decision making. Moreover, rarely have consumer researchers considered whether there are antitrust implications in the findings of any of their studies.

In an effort to stimulate more research and thinking about antitrust on the part of consumer researchers, this paper contains a discussion of several areas where consumer research could contribute to antitrust decision making. The focus of the discussion is on how consumer research could help to resolve some of the less traditional issues that have arisen in current antitrust cases involving the four major ready-to-eat breakfast cereal manufacturers, the legal and medical professions, and ReaLemon. However, the discussion also briefly covers how consumer research could help to resolve more traditional antitrust questions involving subjects such as tying agreements, defining market boundaries, and parallel pricing.

It should be noted that the following is not intended to provide an exhaustive survey of antitrust issues that might be resolved with the help of consumer research; nor is it intended to provide an exhaustive review of previous consumer research findings that could contribute to the resolution of antitrust issues. The discussion is merely intended to suggest a few antitrust issues that are ripe for consumer research, and to point out some previous research efforts that might illustrate methods for resolving these issues.

Table 1 contains an outline of the types of antitrust issues or questions that consumer research could help to resolve. The body of the paper is organized to follow this outline. The concluding section of the paper contains a short discussion of some of the practical

*This research was supported in part by a grant from the Bureau of Business and Economic Research of the University of Maryland.

problems that could arise in trying to expand the role of consumer research in antitrust decision making.

TABLE 1

Selected Antitrust Issues that Consumer Research Might Help to Resolve

- I. Case Selection Issues
 - A. When is an industry or firm performing poorly?
 - B. Do the expected benefits from filing a suit or complaint exceed the expected litigation costs?
- II. Case Resolution Issues
 - A. Structural Characteristics Questions
 1. What is the relevant market?
 2. How high are product differentiation barriers to entry?
 3. Are there economies of scale in advertising?
 - B. Anticompetitive Practices Questions
 1. Are brand proliferation and product differentiation strategies exclusionary?
 2. Is intensive advertising exclusionary?
 3. Is advertising pro-competitive?
 4. Are shelf-space allocation programs exclusionary?
 5. When is the integrity of a firm's product damaged?
 6. When are two products of like grade and quality?
 7. When is parallel pricing justified?

Case Selection Issues

The procedures followed by the Antitrust Division of the Justice Department and the Federal Trade Commission in selecting antitrust cases are not well-defined or widely understood. Clearly, consideration is given to a host of factors in deciding whether to take action against a given industry or firm. Among the factors generally considered are: the structure, conduct, and performance of the suspect industry; the likelihood of winning the case; the amount of agency resources needed for litigation; and the political pressures favoring or

opposing a suit or complaint (Green 1972). There are at least two ways consumer research could help to make the case selection process more efficient and equitable.

First, consumer research could be used to develop improved measures of the "performance" of an industry or firm. At present, the antitrust enforcement agencies utilize performance measures suggested by industrial organization economists. These include measures of allocative efficiency (rates of return on equity), technical efficiency (production costs), and so on (Stern and Grabner, 1970). An additional performance measure that could be of value to the agencies is "consumer satisfaction" (or dissatisfaction). The techniques currently being developed by consumer researchers to measure consumer satisfaction, through monitoring consumer complaints and other procedures (Aiello, Czepiel, and Rosenberg, 1977; Handy, 1977), could be used by the agencies to detect which industries or firms are producing relatively undesirable outcomes through their methods of competition.

Second, consumer research could be used to estimate the social benefits of winning alternative antitrust cases before a complaint or suit is filed. These estimates could help the enforcement agencies decide whether it would be a wise investment of public funds to litigate a particular case (Hunt, 1976). The kinds of research that would help to make these estimates would be essentially the same as the kinds of research needed to determine the effects of certain questionable business practices or the effects of certain proposed antitrust remedies. These research areas are discussed in the following sections.

Case Resolution Issues

Once an antitrust suit or complaint has been filed, consumer research could help to resolve a wide range of issues. Testimony and evidence drawn from consumer research studies could help the courts, administrative law judges, and FTC obtain (1) a more accurate picture of the structural characteristics of a given industry and (2) a better estimate of the anticompetitive effects of certain business practices. Potential research contributions in both of these areas are discussed at length below.

Structural Characteristics Questions

One of the most basic questions that must be answered in any antitrust case is: What is the relevant market? This question must be answered before concentration ratios can be computed, injured competitors can be identified, or other important judgments can be made. Historically, the courts have determined relevant markets by looking at evidence such as cross-elasticity of demand figures, statements and memos from employees concerning who they see as their competitors, and descriptions of manufacturing processes (Day, Massy, and Shocker, 1977). But several observers have recommended that more attention should be paid to consumer perceptions of competing products in determining relevant markets (Stern and Grabner, 1970; Day and Shocker, 1977).

In a recent paper, Day and Shocker (1977) review an assortment of consumer research approaches that could be used to obtain consumer perceptions of market boundaries. They recommend the concurrent use of several of these approaches in defining any given market. Suggested approaches include (1) the study of brand-switching rates (to see which brands are used as substitutes for one another), (2) the use of decision sequence analysis to obtain protocols of brand choice processes (Bettman, 1971, 1974) (to see which other brands are considered when making a choice), (3) the

use of direct consumer judgments of substitutability, perhaps employing techniques such as the "dollar metric" approach of Pessemier et al. (1971) (to see how much money consumers would want before substituting one brand for another), and (4) the use of perceptual mapping techniques. Etgar and Jain (1976) demonstrated how this last approach might be used when they employed multi-dimensional scaling and cluster analysis techniques to identify market boundaries for beverages.

In addition to helping to identify the competitors in a given market, consumer research could be useful in determining the extent of product differentiation in the market or the height of product differentiation barriers to entry. Barriers of this type are said to exist when brand loyalty makes it difficult for new brands to attract buyers without spending large sums on advertising and promotion (Bain, 1956; Comanor and Wilson, 1974). Whether these barriers exist has been an issue in several antitrust cases--the most notable being the cereal case (Root, 1972).

Research on the degree of brand loyalty in several different industries could shed light on the height of product differentiation barriers in any one of those industries. The existence of relatively strong brand loyalties in one industry would indicate that differentiation was great and that entry barriers were relatively high in that industry. Data on brand loyalty could be obtained from consumer surveys, panel diaries, and experimental investigations. The last approach might make use of procedures similar to those used by Ehrenberg and Charlton (1973, 1976) to assess how difficult it is to use various marketing tactics to overcome brand loyalty. They have conducted several longitudinal, quasi-field experiments on repeat-buying, using door-to-door salespersons to administer treatments and obtain measures.

Another structural characteristic of a market that could be important in antitrust cases, and that could be studied through consumer research, is the size of economies of scale in advertising. Such economies could serve to bar entry by smaller competitors by putting them at a cost disadvantage. The possibility that such economies could emerge was cited by the Supreme Court as a reason for voiding the merger of Procter and Gamble and Clorox (Fusilier and Darnell, 1971).

Economies of scale in advertising can emerge if quantity discounts are offered for media purchases or if some minimum number of advertising messages must be received by consumers before the advertising becomes effective--i.e., a threshold level of advertising expenditures must be reached, above which increasing returns to advertising can be obtained (Comanor and Wilson, 1974). Experimental studies with consumers could conceivably be used to gain insights into whether economies of scale in advertising can emerge because of a threshold effect. Some of the research that has been done to examine how consumers react to repeated persuasive communications over time (Ray and Sawyer, 1971; Mitchell and Olson, 1977) could possibly be extended to study the economies of scale issue.

Anticompetitive Practices Questions

The focus of the discussion in this section is on business practices that have been accused of being exclusionary or restrictive in recent antitrust cases. While the use of deceptive or misleading practices has also been an issue in several recent antitrust cases, the need for research on the competitive effects of these practices will not be elaborated upon here. Consumer researchers have already recognized the need to study the effects of deceptive and misleading practices (Gardner, 1975; Russo, 1976), although previous

research has tended to be most concerned with how these practices hurt consumers as opposed to competition.

Four practices that have been accused of having exclusionary effects in the cereal case are: brand proliferation, product differentiation, intensive advertising, and shelf-space allocation. In a trial currently in progress, the FTC staff is presenting a complex set of interwoven arguments to convince an administrative law judge that the use of these four practices has allowed the four largest manufacturers of ready-to-eat breakfast cereals to exclude entry and maintain a "shared monopoly" (FTC Complaint Counsel, 1976). The arguments of the FTC staff are summarized (and somewhat simplified) below, accompanied by a discussion of how consumer research might be used to test the validity of these arguments.

The FTC staff is first arguing that the major cereal manufacturers (Kellogg, General Mills, General Foods, and Quaker) have essentially used brand proliferation and product differentiation to monopolize every profitable "position" in the "product space" of the cereal market. Describing a multi-attribute product space of the type presented by Lancaster (1975), the FTC staff claims that:

1. All profitable positions in the product space are currently occupied by brands of the major manufacturers.
2. With so many brands competing to let consumers know where they stand in the space, the costs to a new brand of getting the attention of consumers and establishing itself in a preferred location in the space are very high.
3. With so many brands already established in preferred locations in the space, it is virtually impossible for one brand to create enough preference for itself to obtain a share of the cereal market large enough to take advantage of economies of scale in production. This means that to attain competitive production costs a new firm will need several successful brands established in multiple locations across the product space. The promotional costs or lower prices needed to establish several brands in preferred locations in the space serve to deter entry.
4. The entry of a new firm in an unoccupied, profitable position would only attract the introduction of new, established-firm brands in that position.
5. The proliferation of numerous differentiated brands confuses consumers and makes it difficult for them to recognize the physical similarities that exist among brands. This makes it more difficult for new brands to become established in preferred locations in the space--particularly private labels that are meant to be seen as copies of existing brands.

Testing the validity of the above arguments would surely be a challenging task. Nevertheless, there are several consumer research approaches that might prove helpful. For instance, perceptual mapping or multidimensional scaling techniques could be used to determine whether, from the perspective of a representative sample of consumers, all desirable locations are occupied in the product space for the cereal market. If "ideal points" were found that are not being served by existing brands, then the FTC staff would have a weaker case. In addition, perceptual mapping techniques could be used to test how confused consumers are about the attributes of different brands. If the perceptual maps of cereal brands obtained from consumers did not differ greatly from maps drawn using objectively-measured characteristics, the argument about consumer confusion could be questioned.

Some insights into the validity of the above arguments could also be obtained by conducting more general (less case-specific) experimental studies with several classes of products. Experiments could test whether increasing the number of alternative brands in a product category produces effects such as:

1. Increased confusion for consumers when processing information about the brands. The research being done on "information overload" (Jacoby, Speller, and Kohn, 1974a, 1974b) suggests that this does, in fact, happen, but more research on this matter is definitely needed.
2. Increased difficulty in using persuasive communications to alter the cognitive structures of consumers and establish a brand in a preferred location in the product space. The research that is being done on the use of persuasive communications to alter cognitive structures or perceptual maps (Olson and Dover, 1976; Lutz, 1975; Moinpoir et al., 1976) could be extended to test whether having more brands means that more communications are needed to change beliefs, salient attributes, ideal points, and so forth.

If these experiments found that increasing the number of brands did not increase confusion or the difficulty of "positioning" brands in desirable locations, then the arguments against brand proliferation and product differentiation would be weakened.

Finally, studies about the variety-seeking or novelty-seeking behavior of consumers (Venkatesan, 1973; Raju, 1976) could also prove helpful in evaluating the arguments about brand proliferation and product differentiation. If it were found that consumers obtain more satisfaction over time when large numbers of differentiated brands are made available--because they tend to try out more brands--then a case could be made for claiming that brand proliferation and product differentiation produce important social benefits.

Intensive advertising is another practice being attacked in the cereal case. The FTC staff is arguing that this practice excludes entry to the industry in the following ways:

1. It supports the brand proliferation and product differentiation activities.
2. It allows existing large firms to take advantage of economies of scale in advertising which new small firms cannot obtain.
3. It creates brand loyalty which makes it difficult for new brands to attract customers--i.e., product differentiation barriers to entry are created.

The latter two charges are arguments that have frequently been offered by economists who view advertising as being anticompetitive (Bain, 1956; Comanor and Wilson, 1974).

As discussed earlier, consumer research could help to establish whether economies of scale in advertising or strong brand loyalties exist in a given market. To be sure, the discovery of advertising scale economies would indicate that the use of intensive advertising was probably having exclusionary effects. However, the discovery of strong brand loyalties would not necessarily suggest anything about the effects of intensive advertising. Loyalty could be created by many factors other than advertising. In fact, attempting to isolate the role that advertising plays in creating consumer brand loyalty represents an exceedingly difficult research problem.

Although it might be possible to use experimental procedures such as those used by Ehrenberg and Charlton (1973, 1976) to determine whether intensive advertising can create strong brand loyalties, it would probably be more fruitful to use consumer research to evaluate, in a general way, several arguments that will probably be offered in the cereal case in defense of the use of intensive advertising. These pro-advertising arguments have been offered by economists such as Brozen (1974), Ferguson (1974), and Nelson (1974, 1975) to counter claims that advertising is anticompetitive. If these pro-advertising arguments are shown to have some validity, then the case against intensive advertising would be weakened (or vice versa). In addition, evaluations of these pro-advertising arguments would probably prove helpful in reaching decisions about the appropriateness of permitting advertising in the professions. Interestingly enough, the FTC and Antitrust Division have essentially adopted these pro-advertising arguments in their cases against lawyers, doctors, pharmacists, and optometrists.

Economists such as Brozen and Nelson have basically argued that advertising is pro-competitive because it makes demand curves more elastic. It does this, in the case of goods which can be evaluated without actually trying them (Nelson's "search" goods), by providing inexpensive information to consumers and making it cheaper for them to comparison shop. With more comparison shopping being done as a result of advertising, consumers will react more sharply to price changes and thus encourage more price competitiveness on the part of sellers.

In the case of goods which cannot be evaluated without actually trying them (Nelson's "experience" goods), it is argued that advertising still makes demand curves more elastic, but for somewhat different reasons. Advertising informs consumers about which brands are the "best buys" (i.e., the lowest price per unit of utility). It does this, according to Nelson (1974, 1975), because the best buys will be the most heavily advertised brands. Heavier advertising would be done for the best buys basically because it does not pay to advertise a bad product and because most firms set their advertising budgets on a percentage of sales basis. With consumers knowing which brands are best, they can limit their sampling or trial of brands to a relatively small, homogeneous group and not be forced to consider a broad range of heterogeneous brands. Consumers will therefore react more sharply to price changes of brands in their "evoked set" when advertising exists than they would without advertising--since they will be more likely to notice price changes when less brands are considered for trial. Thus, advertising should produce more price competitiveness among sellers.

The pro-advertising authors have generally turned to studies using aggregate archival data to find support for their arguments. Two supportive studies that have frequently been cited are the works which found prices of eyeglasses (Benham, 1972) and prescription drugs (Cady, 1975) to be lower in states that permitted advertising of these goods. However, experimental studies obtaining data directly from consumers might also prove useful in evaluating the pro-advertising arguments. Experiments could be set up to study how the information-acquisition strategies, brand choices, and post-choice satisfaction of consumers are affected by varying (1) the amount of advertising available in a product category (none, moderate for a few brands, intensive for a few brands) and (2) the type of product category ("search" vs. "experience" goods or tangible vs. intangible goods). These experiments could attempt to measure the costs of search incurred by subjects under various experimental conditions by charging the subjects fees for information obtained (the fee for using

advertising information would be set relatively low). Information display boards (Berning and Jacoby, 1974; Jacoby et al., 1976), verbal protocols (Bettman and Jacoby, 1976; Bettman, 1971, 1974), and eye-movement measures (Russo and Doshier, 1976) could all be used to obtain a better understanding of how advertising information is processed. The pro-advertising arguments would tend to be supported if the treatment groups which were exposed to brand advertising incurred lower search costs, examined a smaller set of advertised brands, chose brands which were better buys, and obtained more satisfaction.

Shelf-space allocation is the final practice that is being challenged by the FTC staff in the cereal case. The four major manufacturers have been charged with tacitly agreeing to persuade retailers to utilize a single shelf-space plan (Kellogg's) which: (1) gives their brands "better" locations at the center of the aisle and relegates other brands to "poorer" locations at the ends of the aisle, (2) has the brands of each manufacturer displayed in a different grouping, making it more difficult for consumers to compare similar brands (e.g., corn flakes) of different manufacturers, and also making it more likely that consumers will select second brands made by the same company which manufactured their first selection, and (3) has their brands "billboarded" in the displays (several facings are put next to one another), getting them more attention and impulse purchases. Clearly, experimental consumer research studies in either simulated shopping environments or real-world supermarkets, along the lines of work done by Cox (1970) and Curhan (1972), could be used to test the validity of these arguments.

While the previous discussion has focused on business practices that have been questioned in the cereal case and the cases involving the professions, there are many other practices that have been challenged in antitrust cases that could be evaluated using consumer research approaches. For example, surveys of consumers could probably provide guidance in cases involving tying agreements and dealer restrictions. Surveys of consumer attitudes and preferences could help to establish whether a manufacturer or franchisor could use the defense that the integrity of its product has been damaged when these restrictive practices have not been used. Similarly, surveys could be used in price discrimination cases to help determine whether consumers see two products as being of "like grade and quality" (Day, Massy, and Shocker, 1977). In addition, experiments with consumers could probably provide guidance in cases involving parallel pricing. Experiments on the sensitivity of consumers to price cuts in a certain market, or on consumer perceptions of a price-quality relationship, could help to establish whether the sellers in that market could defend parallel pricing behavior by arguing that consumers do not respond to lower prices.

Case Remedy Selection Issues

Since many antitrust cases are concluded by voiding a merger or acquisition or by requiring firms to discontinue the use of an anticompetitive practice, the type of research discussed in the previous sections would obviously be useful in selecting case remedies. However, other forms of consumer research might prove helpful for locating effective case remedies that fall somewhere in between the restructuring of industries (which rarely is done) and the ordering of firms to discontinue the use of a practice (which may not restore competition to its former, pre-violation state). An example of this type of remedy is one currently being sought by the FTC staff in both the ReaLemon case and the cereal case: the royalty-free licensing of brand names and trademarks to new firms.

The FTC staff believes that royalty-free licensing will encourage new manufacturers to produce and market popular brands (e.g., ReaLemon reconstituted lemon juice, Rice Krispies cereal, Cheerios cereal), while at the same time discourage existing manufacturers from using practices such as brand proliferation, product differentiation, and intensive advertising. New manufacturers could obtain a valuable brand name at no cost, while existing manufacturers would no longer have an incentive to spend large amounts marketing a brand because they might only be helping a competitor by doing so. The result would presumably be more price competition among groups of homogeneous brands.

An implicit and crucial assumption that seems to exist in the arguments for royalty-free licensing is that consumers will react in a similar manner to Safeway's ReaLemon or Kroger's Rice Krispies as they have to Borden's ReaLemon and Kellogg's Rice Krispies. Such an assumption could probably be tested using experimental consumer research approaches. If it were found, for example, that a company name can serve to differentiate a product in the eyes of consumers almost as well as a brand name, then the new remedy would most likely prove to be ineffective for encouraging more competitive activity.

It might also prove useful to turn to past consumer research for ideas for additional antitrust remedies. For example, it has been found that information presentation format can have a significant effect on the way consumers acquire and process information (Bettman and Kakkar, 1977; Russo et al., 1975)--i.e., that certain displays will lead consumers to process information by brand and others will encourage processing by attribute. It has also been found (in a study of cereal brands) that processing by attribute is more characteristic of consumers who exhibit low brand loyalty (Jacoby et al., 1976). These findings suggest that an effective remedy in the cereal case might be one which required supermarkets to display cereal brands in a way that encouraged attribute processing of information--perhaps by arranging brands according to types of ingredients or by erecting signs which compare brands on certain attributes (with one attribute per sign). More attribute processing by cereal customers might conceivably lead to less brand loyalty, more comparative shopping, and more competition among cereal manufacturers. Of course, experimental tests of this remedy would be needed, since low brand loyalty might lead to attribute processing without the reverse being true.

Conclusion

Consumer research can clearly play an important role in the enforcement of the antitrust laws. There are many case-specific studies that could be done to help resolve individual antitrust cases. Moreover, there are a number of more general studies that could be done that might provide insights applicable to several cases. In particular, studies of the effects of brand proliferation, product differentiation, and intensive advertising could provide valuable guidance in attempts to resolve either present cases, like those involving the cereal industry and the professions, or potential future cases involving the manufacturers of automobiles, detergents, or other highly differentiated consumer goods.

Whether antitrust lawyers will be willing to submit the results of consumer research studies as courtroom evidence is another issue. As several authors have pointed out (Hunt, 1976; Gardner, 1974), there are substantial problems associated with submitting consumer research in court. It is also unclear whether a willingness to use consumer research results will be exhibited by those involved with selecting new cases or devising new remedies. These lawyers and economists generally have a

weak understanding of the measurement techniques and research approaches used by consumer researchers. Nevertheless, given the growing tendency of FTC officials to utilize consumer research results in consumer protection decision making (Brandt and Preston, 1977), the prospects seem reasonably good for also seeing some increase in the use of consumer research in the antitrust area. Word-of-mouth advertising for consumer research by personnel in the FTC's Bureau of Consumer Protection seems likely to spark the interest of antitrust enforcers at the FTC's Bureau of Competition and Bureau of Economics, as well as at the Justice Department's Antitrust Division. Thus, if consumer researchers can begin to supply research findings that antitrust people find relevant and timely, the use of consumer research in antitrust decision making could expand rapidly.

Abstract

Public policy is concerned with protecting the consumer from false, deceptive, and/or misleading brand information. This concern has led to a situation where a manufacturer may be required to disclose some brand information which may be discrepant with the consumers' currently held beliefs about the brand (i.e., corrective advertising, affirmative disclosure, ad substantiation). Little is known about the effects of such expectancy-discrepant information on consumers. This study investigates three areas of potential impact of expectancy-discrepant information on consumers--consumers' brand image/comprehension, consumers' brand perception in relation to an "ideal" brand, and consumers' psychological feelings about a brand selection decision. Two information disclosure formats are studied.

Introduction

Recently there has been extensive discussion, both in the marketing and social issues literature and in governmental hearings and meetings, regarding the appropriate role of policy-makers in consumer protection. This discussion has centered around determining the priority of issues appropriate to consumer protection programs. At the heart of much of this discussion lies the problem of availability of purchase-relevant information to the consumer and his/her use of this information in making purchase decisions. The discussion to follow focuses on one particularly crucial case of information availability, the case involving the disclosure of brand information contrary to or discrepant with the consumer's preconceived expectations about a brand. The effectiveness of two disclosure formats is compared.

Public Policy Interest

The concern of policy-makers with the quality of the consumer "information environment"² is not so much with how consumers interpret and use the information made available to them but rather whether or not purchase-relevant information is available to consumers if they want to use it in their brand choice decisions. As a result, information available about a brand may or may not be relevant to a particular consumer's decision to buy that brand. In addition, this information may or may not paint an accurate and realistic picture of the brand and its characteristics, i.e., the information may be false, deceptive, and/or non-existent. Upon search for and consideration of brand information, consumers may find

themselves in any of four situations:

1. They find they have no prior knowledge about the brand and thus no prior expectations about its contents, quality, performance, etc.
2. They find they have accurate and sufficient knowledge and expectations about the brand and need no further information to confirm their beliefs.
3. They find they have roughly accurate knowledge and expectations about the brand, but desire further confirmation to increase their confidence in their brand evaluations.
4. They find they have inaccurate knowledge and information about the brand and need new information to point out this discrepancy and convey accurate facts about the brand.

The second situation, where consumers have accurate and sufficient product information, may be the ideal from a consumer protection point of view. However, advertisers often find themselves facing consumers in either the third situation for established products where consumers have accurate but insufficient information to make a decision or the first situation for new products where consumers have insufficient information to make a decision. Thus, in some cases, for their own best interests, commercial sources can be expected to "fulfill" consumers' information needs. The issue of strict availability of information to consumers is obviously important then in the first and third cases above. The Nutrition Advertising Rule (39 Fed. Reg. 39482, 1974) and other affirmative disclosure actions have been proposed to assure the availability to the consumer of purchase-relevant facts when insufficient information or no data have previously been available to consumers.

However, it is in the fourth situation, where misinformation abounds, that public policy should place its regulatory emphasis. To correct erroneous product conceptions necessarily involves the disclosure of new information. For those consumers who have formed their product beliefs and/or brand comprehension on earlier inaccurate information, this new information is likely to be discrepant with their expectations about the brand. In this situation, the minimization of consumer deception and/or consumer biases founded on incorrect information can come from the discovery of the most effective way of correcting erroneous perceptions, images and/or product knowledge.

Effects on Consumers of Disconfirmation of Expectations

Studying the effects of disconfirmed expectations on consumers' product evaluations has been of interest from a marketing management point of view in attempting to maximize customer satisfaction with a product. Past research has used four theoretical models to predict the effects on product evaluations and customer satisfaction of discrepancies between expectations and actual or objective product performance:

1. Cognitive dissonance theory would suggest any discrepancy between actual and expected performance would be minimized by the consumer by adjustment of his perception of the product's performance to be more in line with his

¹The author would like to acknowledge the guidance of Harold Kassarjian and James Bettman, UCLA who served as dissertation committee chairman for the experimental study from which this paper was excerpted. Appreciation is also expressed to Kenneth Miller, University of Utah whose comments on earlier drafts of this paper were invaluable.

²The term "information environment" is used here to denote the entire array of product-related data available to the consumer. The term is adapted from James R. Bettman, "Issues in Designing Consumer Information Environments," *Journal of Consumer Research*, Vol. 2 (December 1975), pp. 169-177.

expectations of its performance, thus resulting in satisfaction.

2. Contrast theory suggests the consumer will magnify any discrepancy in performance between expectation and reality and will experience dissatisfaction with the actual performance.

3. Generalized negativity theory suggests that any discrepancy between expectation and reality will result in a negative evaluation of the product and a dissatisfied consumer.

4. Assimilation-contrast theory suggests that if the disparity between expectation and reality is small the consumer will assimilate the difference by perceiving the product's performance in line with his expectations. However, if the disparity is large the consumer will contrast or magnify the perceived disparity. Thus, a discrepancy could result in either a satisfied or a dissatisfied consumer.

Studies using these four theoretical models as bases for investigation have concluded that brand claims should not be overly exaggerated nor overly understated but rather, should be consistent with the actual attributes, quality, and performance of the brand. This honesty about the brand appears to create a high level of customer satisfaction with the brand once it is "experienced" (Anderson, 1973; Cardozo, 1965; Olshavsky and Miller, 1972).

An equally important question is how exposure to expectancy-discrepant information (other than experiential information) effects consumers' brand evaluations and subsequent satisfaction with the brand. Consumer protection legislation may involve requiring advertisers to give consumers information which is discrepant with consumers' current beliefs and expectations (especially through the use of remedies such as corrective advertising). In fact, it could be argued that there is little need for policy makers to be concerned with giving consumers information consistent with their current knowledge and beliefs if these are accurate.

When consumers have been given false or deceptive brand information, public policy may require the dissemination of information to correct any misconceptions based on the previously inaccurate information (i.e., corrective advertising). In effect, policy may require that consumers be given information disconfirming the expectations about a brand created through previous communication of false or deceptive information. Of interest then are the effects on consumers' brand evaluations of information deliberately designed to disconfirm their expectations. Exposure to such information could cause several quite different effects. Consumers could:

1. Believe the new information and change their attitude toward or perception of the brand.
2. Not believe the new information, mentally reject it, and continue believing what they had previously believed.
3. Not believe the new information but be curious about the discrepancy and seek further information to clarify the confusing situation.
4. Become confused and uncomfortable, not knowing what to believe (Maloney, 1962).

These possible reactions differ in their desirability from the point of view of the public policy objective underlying the information disclosure requirement. Thus, they have very different implications for public policy formulation. It is therefore critical to determine which reaction is the most likely response and whether the format of the disclosure influences the response.

A Test of the Effects of Two Formats for the Disclosure of Expectancy-Discrepant Information

The Experimental Design

Past research on information processing suggests that the degree to which new information is perceived as discrepant with currently held beliefs might be influenced both by the amount of new (discrepant) information presented and by the format of that information, i.e., its complexity/simplicity (Jacoby, et.al., 1974a,b; Russo, 1975).

As part of a more extensive investigation of the effects of amount and format of information on consumers' product evaluations, an experiment was designed in which respondents were assigned to groups receiving different amounts of purchase-relevant information in different formats (Scammon, 1976). The proposed Trade Regulation Rule on Nutrition Advertising (39 Fed. Reg. 39482, 1974) provided an appropriate framework for this analysis since its guidelines suggested different disclosure formats (%Recommended Daily Allowance or adjectival descriptions of the nutrient content) and several amounts of information (zero, four, or eight nutrients) which advertisers might be required to use when presenting nutrition claims about their products.

It was necessary to be able to introduce information discrepant with preconceived notions about the test brands. To do this, two brands of peanut butter (Skippy Peanut Butter and Koogole Peanut Butter Surprise) were selected. Skippy was significantly more well known than was Koogole and Skippy had a well established image in the minds of consumers. Skippy was rated significantly more well-known, more wholesome, and higher on nutrition value than was Koogole by a control group receiving no nutrition information on either brand (see Table 1).

TABLE 1
Brand Image Profiles
Mean Ratings of Brands on Selected Attributes¹

<u>Attribute</u>	<u>Skippy</u>	<u>Koogole</u>
Wholesome/unhealthy	1.98 ²	3.36
High on Nutrition/low on nutrition	1.98 ²	3.40
Well Known/unknown	1.38 ²	3.24

¹The control group was used as a surrogate measure of pre-exposure image of the test brands. Differences in means between the two brands significant beyond the .01 level of significance.

²5-point scale with 1.0 indicating the most positive response.

To maximize the possibility of image change, during the experiment Skippy was portrayed as the "nutritionally inferior" brand, an image discrepant with the one revealed by the control group. The information on Koogole was left unmodified so it was not discrepant with Koogole's current image.

The nutrition information was presented to respondents in 30-second color commercials for the two brands which had been modified by superimposing replicas of nutrition labels with the appropriate formats (% RDA or adjectival descriptions) and amounts (zero, four, or eight nutrients) of nutrition information over the last six seconds of the commercials as proscribed in the Nutrition Advertising Rule (see Figure 1).

The Experimental Procedure

Subjects were selected on a quota basis from a group of California residents and tourists participating in a commercial television pilot preview test. During the preview test data were gathered on demographic and socioeconomic variables as well as frequency of purchase, importance of, and last brand purchased of peanut butter. Twelve subjects at a time were asked to stay after the preview to participate in a focus group interview. During this interview they were shown three 30-second commercials -- a control commercial, then the two test commercials (the test commercials were reversed in presentation order during 1/2 of the sessions to guard against any order bias). After exposure to the commercials, subjects responded to a short questionnaire regarding the test commercials including questions about their brand choices and brand preference, their images of the test brands, and their feelings about the decision situation. These responses were analyzed by comparing groups exposed to the information in the two different formats. Where appropriate, the responses were analyzed separately for Skippy (expectancy-discrepant condition) and for Koogle (non-discrepant condition).

Following the experiment, subjects were debriefed. Subjects were given a letter explaining the use of false brand information and giving subjects the real brand data.

The findings reported below and their implications for public policy are discussed in the context of a situation where consumers currently have inaccurate information which needs to be corrected before they can make accurate brand choice decisions. The major concern is with finding an effective method for communicating expectancy-discrepant information in such a manner that consumers come away with accurate brand perceptions. Secondly, interest is in discovering how consumers deal with this discrepant information, i.e. how they feel about their decision situation and their information environment.

Findings and Public Policy Implications
From the Study

Assuming one major role of public policy in protecting consumers is to point out areas where consumers' product knowledge is either insufficient or inaccurate, data from this study indicate adjectival descriptions communicate more effectively with consumers than do percentage contents data.

The More Nutritious Brand

After exposure to nutrition information in one of the two test formats (percentage RDA or adjectival descriptions), subjects were asked to identify the "more nutritious" brand in order to judge the communications effectiveness of the disclosures. An overall chi-square test of the difference between the observed and expected experimental cell frequencies for those subjects choosing each brand as the "more nutritious" one revealed a significant difference between groups exposed to the two different information formats regardless of the amount of information they were exposed to (Tables 2 and 3). Examination of the data suggests that the adjective format is superior to the percentage format in helping respondents identify the "more nutritious" brand.

TABLE 2
Percentage of Respondents Choosing Each Brand as "More Nutritious"

Amount of Information	Choice of "More Nutritious" Brand by Information Format					
	Percentage		Adjective			
	(n)	Koogle	Skippy	(n)	Koogle	Skippy
Control Group No Nutrient Information	28 ^a	17.8	82.2	30	0.0	100.0
Four Nutrients plus Calories	60	10.0	90.0	60	32.2	67.8
Eight Nutrients plus Calories	60	11.7	88.3	59 ^a	30.5	69.5

^aThe 60 respondents in the original control group were randomly assigned to one of two 30-respondent control groups each of which was used as a control for one of the two information format manipulations. The sample for the percentage format control group contained 28 respondents and the sample exposed to information on eight nutrients via the adjective format contained 59 respondents in this case (three of the respondents gave no response to the question under analysis).

Koogle	18	37
Skippy	130	112
Totals	148 ^a	149 ^a

$\chi^2 = 7.08$; d.f. = 1; $p < .01$.

^aTwo respondents in the percentage group and one respondent in the adjective group gave no answer to this question.

Brand Image In Relation to an Ideal Brand

After exposure to the nutrition information, subjects were queried regarding the perceived distance of each of the test brands from their "ideal" brand. Subjects were simply asked to indicate how close each of the test brands was to their "ideal" brand on an overall basis rather than attribute by attribute, the method that has been used in several past studies (Jacoby, Speller, and

Kohn, 1974a, b). Theoretically, if nutrition is an important attribute and a brand is perceived as nutritious, it should be rated as "close to" the ideal. Conversely, the "less nutritious" brand should be seen as "far from" the ideal. Thus, it was expected that, following exposure to the most effective format for the nutrition information, Koogle would be seen as closer to the ideal and Skippy as further from the ideal. It appeared that for Koogle, the unknown brand for which the information presented to subjects was not discrepant with pre-exposure knowledge, the nutrition information neither moved the brand closer to nor further from the ideal brand no matter what the format of the information. Analysis of variance of the mean perceived distance scores between groups revealed a non-significant main effect for format (Tables 4 and 5).

TABLE 4
Perceived Distance of Koogle from Ideal Brand^a

Information Format:	(n)	Per-centage	(n)	Adjec-tive	Marginal Means
<u>Amount of Information:</u>					
Control Group -- No Nutrient Information	20	3.12	20	3.65	3.39

However, the information presented to respondents on Skippy, the well-known brand, disconfirmed subjects' preconceived notions and/or expectations about the brand. Respondents entered the experiment with a strong pre-exposure preference for Skippy.³ The disclosure information portrayed Skippy as a "less valuable" product than subjects had expected. Analysis of variance of the mean perceived distance score of Skippy from the "ideal" brand revealed a significant difference between groups exposed to the two different information formats regardless of the amount of information they were exposed to. Skippy was perceived as further from the "ideal" by those exposed to adjectival information than by those who saw percentage information (Tables 6 and 7).

TABLE 6
Perceived Distance of Skippy from Ideal Brand^a

*** p = .001, * p = .05.

These data suggest that the FTC and other regulatory agencies may want to develop different information disclosure requirements for new and for established products. However, in recommending the use of adjectival disclosures, the regulatory agencies must be cautious that their proscriptions and remedies are not punitive in nature. The danger with using adjectival disclosures is that they appear to facilitate downward evaluations of products.

Consumers' Psychological Feelings

A related problem arises when considering the effects of expectancy-discrepant information (i.e., disclosures designed to correct an erroneous perception of a well-known brand) on consumers' subjective-psychological feelings. How can consumers be expected to deal with the resulting conflict, discomfort and dissatisfaction? Will they abandon any thoughts of purchase of the brand described? Will they continue buying the brand they have always bought? Will they stop buying that type of product altogether assuming one brand is just like the others? Or will they seek additional information to quiet their discomfort and dissatisfaction?

³Using the responses of subjects in the control group that saw no commercial messages as surrogate indicators for the experimental groups' pre-exposure brand evaluations showed 93.7% of the respondents preferred Skippy over Koogle.

Subjects in this test were asked to indicate whether they preferred Skippy or Koogle. They then were asked to rate their certainty regarding their choice, their confusion during the decision-making process, their satisfaction with their decision, and their desire for more information. These ratings were on 5-point scales with 1 representing the most positive response.

By comparing the experimental groups on their mean scores on these subjective state scales, analysis of variance revealed significant differences for satisfaction and desire for more information (Tables 8 and 9) between the groups exposed to the two different formats.

TABLE 8
Mean Subjective State Scores

^bAnalysis of variance performed excluding the control group.

-- = not significant ** p = .01 * p = .05

The data from this study suggest that those respondents receiving adjectival disclosures are less satisfied with their choices than are those receiving percentage disclosures. This decreased satisfaction appears to result in a desire for more additional information, probably to clarify the discrepancy evident between the new information and prior brand expectations. If this desire for additional information leads to actual search for information, it may not be too unreasonable to expect consumers to seek additional information. Consumers may look

for information to "validate" the adjectival labels attached to various products. Once validated, these labels might be used with more confidence in the future.

Summary

In designing legislation and judicial remedies to protect consumers, major concern of policy makers lies in the prevention of deception or the correction of images based on deceptive or misleading information. Both of these objectives can be obtained through communication of the true facts about brands on the market. Policy may thus require the communication of information discrepant with commonly held beliefs about a brand.

This study attempted to determine which of two alternative information disclosure formats would be most effective in communicating expectancy-discrepant information to consumers. The data indicate that an adjectival format is superior to a percentage format in helping respondents identify the "more nutritious" brand, in increasing the perceived distance between the "less nutritious" brand and the "ideal" brand, and in creating a lower level of satisfaction with the chosen brand which appears to be related to a desire for more information. It appears that with respect to the effects hypothesized in this study, exposure to expectancy-discrepant information may cause consumers to reevaluate their attitudes toward a brand or, at least, desire further information to clarify the discrepancy revealed. Both of these effects are desirable from a consumer protection point of view when considering a situation where currently held consumer beliefs are based on erroneous information.

Further research is needed to evaluate the effects of expectancy-discrepant information on consumers and to evaluate the impact of adjectival descriptors over time.

SHOPPING TIME AND LEISURE TIME: SOME PRELIMINARY
CROSS-CULTURAL COMPARISONS OF TIME-BUDGET EXPENDITURES

Douglass K. Hawes, University of Wyoming
Sigmund Grønmo, Norwegian Fund for Market and Distribution Research
Johan Arndt, Norwegian School of Economics and Business Administration

Abstract

The findings reported herein represent an attempt to consumers' use of time for shopping, and the impact of shopping time on other categories of time expenditure. The results showed great similarity in the time spent on shopping in Norway and in the United States, but wide differences in the use of time for other activities.

Introduction

Two papers presented at the 1976 Association for Consumer Research Annual Conference dealt with the topic of time budgets in consumer behavior (Arndt and Grønmo, 1977; Hawes, 1977). As pointed out in both of these papers, the subject of time budgets and their impact on consumption behavior has been an underresearched area (Jacoby, et al., 1976; Arndt, 1976). It is undeniable that time underlies all human activities--in one way or another, the clock dominates behavior. While a person may add to his money budget and, at least in the short run, his energy budget, one's time budget is immutably fixed at 168 hours per week.

This brief research report builds upon the two aforementioned 1976 ACR papers and presents a comparison of selected time budget expenditures in two countries--Norway and the United States. One does not have to read very deeply into the consumer/buyer behavior literature to realize the paucity of cross-cultural comparative consumer behavior studies.

A growing interest in this type of study can, however, be identified (Plummer, 1977). Without the knowledge of consumer behavior in different cultures it is difficult to develop general theories of this behavior. The lack of knowledge in this area has led to inefficiencies in resource allocations as well as socio-political conflicts. These effects have been strengthened by the growth in the operations of multinational corporations in various parts of the world (Sheth & Sethi, 1973). Neither the concept of the "universality of cultural traits" nor the concept of the "distinctiveness of each culture" seems to be a satisfactory approach in the study of consumer behavior. In this area, the question rather is: what is universal and what is distinct? It is on this basis that this paper hopes to make a contribution.

Background

The reader is referred to the papers by Arndt and Grønmo (1977) and Hawes (1977) for a detailed discussion of the earlier research streams which led to those two papers. Briefly, Arndt and Grønmo posit a "time expenditure approach to consumer behavior...viewing consumer behavior as a household management area in which members of the household interact and allocate tasks to maximize satisfaction of the input of the scarce resource time (or its equivalent money)" (p. 230). They develop a theoretical paradigm which positions the variable "Orientation to Shopping" "as a hypothetical construct intervening between 'Time Spent on Shopping' and a set of antecedent variables believed to be correlates of 'Orientation to

Shopping'" (p. 230). The authors go on to suggest that certain activities are less amenable to contraction or expansion in time consumption than other activities, given an autonomous change in another activity, such as shopping. The authors then investigate the accuracy of the model using Norwegian data, including time expenditure elasticity for those with "long" shopping time versus those with "short" shopping time.

Hawes focused on leisure-time (truly, discretionary time) expenditures and presented American data on nine categories of leisure-time pursuits cross-classified by demographics. His approach was more descriptive, atheoretical, and applied, and approached the usage of time from a demographics-based market segmentation perspective. He then presented some data on male and female respondents' inclinations about what they would do with a) an extra two hours in the day, and b) with a three-day weekend every week.

While leisure-time patterns have been used as a basis for measuring life style, shopping-time has been considered as an important dimension of shopping behavior. For several reasons we may expect that a relationship between these two variables exists:

- Shopping may influence the duration of leisure-time. For instance, purchase of goods may be a means to reduce the time spent on housework. Besides, the amount of time spent on shopping affects the amount of time available for leisure. Conversely, the amount of time available for shopping may be affected by variations in leisure-time.
- Shopping may influence the "content" of leisure-time. How the leisure-time is used, depends to some degree on consumption and purchase of goods.
- On the other hand, shopping may be influenced by the "content" of leisure-time. For instance, TV-watching and newspaper reading may stimulate shopping because of the advertisements in the media.
- Some people find a leisure component in shopping, which may be perceived as recreation, entertainment or a socializing activity.

Focus of This Paper

Given a) the findings of these two aforementioned papers, b) the potential of cross-cultural comparative research in aiding in the development of comprehensive explanatory models of consumer choice behavior (Arndt, 1976), and c) the approximate, but feasible, comparability of the two data bases involved--it was decided to examine the differences in various categories of time expenditures for Americans spending "long" or "short" amounts of time shopping, and the expenditures of time by Norwegians for various leisure-time pursuits. Therefore, the following two research questions are addressed in this paper:

1. How does the time spent by Norwegians on shopping and on selected leisure-time pursuits compare with the time spent by Americans on the same categories of activities when both sets of respondents are segregated by the same or similar demographic categories?
2. How does the time spent by Americans on selected leisure-time activities vary with time spent shopping in comparison with Norwegians? "Short" shopping time is defined as less than or equal to 30 minutes per day (3.5 hours per week); "long" shopping time is defined as more than 30 minutes per day for both data bases.

In both life style and shopping behavior we find variations between groups and nations. One purpose of this analysis, then, is to study the relationship between leisure-time patterns and shopping-time in various social (demographic) groups in the USA and in Norway.

Data Bases

The source of the Norwegian data is the Time Budget Survey conducted by the Norwegian Central Bureau of Statistics in 1971-72. The design of the survey and other findings are presented in Statistisk Sentralbyrå (1974, 1975b) and Grønmo (1976). A total of 3,040 persons completed a time usage diary and participated in before-and-after interviews. This figure represents a response rate of 58 percent. Only the married persons in the Norwegian sample are included in the following analysis. This is done in order to maximize the comparability between the Norwegian and the American data. Further details on the methodology are outlined in Arndt and Grønmo (1977).

The source of the American data was a nationwide sample of 1000 households participating in Market Facts Inc. (Chicago) Consumer Mail Panel. Two thousand identical, 20-page, color-coded questionnaires were sent out to these households in the summer of 1973, so that both the male and female head-of-household could independently respond. There were a total of 1115 usable responses, or a response rate of 56 percent. Further details on this methodology are presented in Hawes (1977).

Both surveys collected demographic data including respondent's age, education, total annual household income, occupation (males) or employment status (females), household size, and population density/degree of urbanization. The number of hours the respondent spent at work each week was also determined.

Results

Based upon the respondents in the Norwegian and the American surveys, some interesting similarities and differences appear, reflecting differences in overall life-style between the two countries. Investigation is continuing into the social and cultural bases for these similarities and differences. The following discussion will focus on some of the more interesting similarities and differences.

Female Respondents

Tables 1 and 2 contrast the time spent on shopping and on various leisure-time pursuits by Norwegian and American women. The first similarity of note is the approximately equal amount of time spent shopping by females in both countries. The same basic patterns hold across the demographic variable categories in both countries with, for example, the greatest amount of time in the respective category being spent by women aged 35-44, those who

are full-time homemakers, and those who are better educated. There is a statistically significant drop in hours spent shopping by Norwegian women in rural areas (versus central city areas), and among those who work 45 hours per week or more (versus 29 hours per week or less), that does not show up in the American data.¹ This is probably a function of differences in geography, transportation, retailing dispersion and work/living locations between the two countries.

Overall, Norwegian women spend from one-half to about three-quarters as much time playing with their children as do American women. The differences are very great when examined in relation to the hours per week spent at work. In the extreme categories of this variable, American women devote from four to almost thirteen times as much time to their children than do Norwegian women. Interestingly, while there is a significant drop with increasing income in the number of hours spent with children by American women, just the reverse pattern holds in Norway.

With the exception of those in the lowest income category and retirees, Norwegian women spend about half as much time reading newspapers and magazines as do American women. In these two particular categories, respondents in both surveys spent about the same amount of time on this activity. As one might expect, in both countries the greatest amount of time (in the demographic category) spent reading newspapers and magazines is in the smallest family size (2), and among those working the fewest hours per week in their job.

Norwegian women watch approximately one-third to one-half as much television as American women. Interestingly, while television viewing among the American respondents peaks in the under-25 age category and declines through the 35-44 category, in Norway, viewing increases with age and peaks in the 55-and-over category. These differences may be explained by variations in the number of TV-programs available. While Americans can choose among several programs all day, Norwegians have no such choice between parallel programs. Furthermore, in Norway TV-programs are transmitted during only part of the day. In both countries, viewing is least (across education levels) among those with a college education, declines with increasing family size, and shows no significant difference between the two extreme categories of hours per week spent at work.

Norwegian women spend approximately one-fifth to one-half as many hours per week on hobbies, games and crafts as do American women. There is a much greater decline in these activities with increasing income in Norway than in the United States. In both samples, the greatest amount of time is spent by those in the oldest age category, and increasing education is associated with a decrease in the amount of time spent on these activities. Interestingly, participation in these activities reaches a minima around 35-40 hours per week of employment and increases on both sides of this range. There appears to be a phenomenon, more apparent in the United States data, that women who work long hours also find time for a number of other activities. Whether these women are merely "hyper," have great energy and involvement, or are basically "workaholics" cannot be determined from the small sample involved.

Norwegian women spend a great deal more time (two to

¹"Significant" refers to differences significant at the .05 level or greater (two-tailed) in the Norwegian data, and .1 level or greater in the American data. The differences in sample size suggest the differences in cut-off level of significance. In many cases, the level of significance far exceeded the .05/.1 level.

three times as much) visiting friends or relatives than do American women. In both countries, visiting is highest in the youngest age category and least among college graduates, and is little affected by the hours per week spent at work. In the United States sample, visiting dropped significantly between families with one child and those with three or more; in Norway, family size had no significant affect.

It is in the area of sports and athletics that the greatest differences between the two countries emerge: very simply, Norwegians are "doers" and Americans are spectators. Norwegian women spend from two to four times as much time participating in sports or athletics than American women. While the American women spend only .6 to 1.1 hours per week as a spectator, this figure represents three to five times as much time as the expenditures of Norwegian women. While the data from both countries shows the same basic age-participation pattern, there is a much greater proportional increase in participation among Norwegian women with a college degree over those with only high school degrees than is the case in the

United States. In both countries, participation is not significantly affected by family size or total household income.

Women in the United States sample indicated that they spend much more time in non-sports-related entertainment outside the home--from three to more than seven times as much--than their Norwegian counterparts. In both countries, it is the youngest, best educated, highest income women who go out the most in comparison with those in the other categories of these demographic variables. Larger families do not deter women from going out in either country. Again, American women who work long hours are much more likely than their Norwegian counterparts to find time for this type of leisure-time activity.

Male Respondents

By and large, it is evident from Tables 3 and 4 that the same patterns hold in comparing the time expenditures of Norwegian and American males as was found in comparing

^cHours per week refers to hours spent at "primary job." Only those respondents with one job are included here.

females from the two countries. Although Norwegian men spend slightly more time per week shopping than their American counterparts, the absolute values are very similar. There is some indication that college educated Norwegian men spend disproportionately more time shopping than American college educated men. Also, time spent shopping holds up much better in Norway among those working 50 or more hours per week, than it does in the United States.

American men spend from approximately two to five times as much time playing with their children as do Norwegian men. In examining education and income, one notes that in Norway, the greatest amount of time with children is spent by those in the highest income and education categories; in America, the most time is spent by those in low-to-moderate income groups and with a high school/some college education. In both countries, the amount of time spent playing with children does not increase signifi-

cantly as more than one child enters the family. As one might expect, rural males in both countries spend the least amount of time playing with their children--probably because there is a less clear-cut distinction between working with and playing with the children.

Norwegian men, like their wives, spend about two-thirds as much time reading newspapers and magazines as their American counterparts. This holds except in the lowest income categories and among retirees, where the time spent reading is quite similar in the two countries. Across income categories, the greatest amount of time in this activity in the United States is in the highest income bracket; in Norway, it is in the lowest income bracket. There are wide differences across specific occupational categories in both countries.

Norwegian men are again similar to their wives, in that they watch about one-half to two-thirds as much televi-

^bNumber of respondents in the demographic category segment.

sion as American men. While in Norway, the least amount of time in front of the TV set is spent by those under 25; in America, both those under 25 and those over 55 spend the most time watching television. In both countries, those with a college education watch the least television, as do those with one child and those who work more than 50 hours per week. There is a significant drop in television viewing with increasing income in the United States; in Norway there is no significant difference across income categories.

Overall, American men spend from three to five times as much time on hobbies, games and crafts than do Norwegian men. There is a significant increase in this activity in the United States as one moves into the 55 and over age category; in Norway there is no significant age effect. In both countries, clerical/sales workers are relatively more heavily into this activity than any other type of

active worker, and there is a decrease in time spent on this activity with increasing family size. The hours per week spent at work also has an effect on time for hobbies, etc. in both countries. Central city residents in the United States spend significantly less time on this activity than do "urban" (suburban) residents; in Norway, there is no effect due to location of residence.

As one might expect after examining the data on Norwegian women, Norwegian men also spend from two to three times as much time visiting friends or relatives than do American men. In both countries, visitation time is greatest among those under 25 and among those in the lowest income categories. In Norway, however, there is a distinct drop among those over 55, while in America there is an increase as one moves into this age category. Hours per week spent at work has no significant effect on time spent on this activity in Norway, while it does

^bNumber of respondents in the demographic category segment.

^cHours per week refers to hours spent at "primary job." Only those respondents with one job are included here.

in the United States.

While both Norwegian and American men under 25 spend about the same amount of time participating in sports or athletics, by the higher ages Norwegian men are spending three to four times as much time in these pursuits than American men. Overall, Norwegian men spend about one- and one-half to two times as much time participating than do American men. This is about half the difference between Norwegian and American women implying that, relatively speaking, Norwegian women are much more athletically inclined than American women. In both countries, clerical/sales workers are among the heaviest participants, as are those with one or two children, those in central cities, and those with a work week which is not excessive.

As was noted with the women, American men spend much more time at spectator sports--from four to ten times as much--than do Norwegian men. It may be noted that in both

countries clerical/sales workers are into spectator sports as well as participatory sports relatively more heavily than other occupations.

American men spend from five to seven times as much time in "other" entertainment outside the home than do Norwegian men. This difference is consistent with the differences in time spent on entertainment between American and Norwegian women.

Differences in Life Style and Similarity in Shopping Time

In our comments, males and females have been treated separately. The main reason for this is the traditional spousal role differentiation, which is found in both cultures and most demographic categories. Mainly because of the differences in employment status and time spent at work, the total amount of time spent on all activities in Tables 1-4 is smaller for males than females. In particular, married women spend more time shopping

and playing with their children than do married men.

At the same time, however, our analysis indicates very clearly some cross-cultural differences in use of time, which are reflected for both women and men as well as in most of the other demographic categories. Compared to Norwegians, Americans spend more time playing with their children, reading newspapers and magazines, watching TV, engaging in hobbies, games and crafts, and attending sporting events and entertainment. Americans spend less time than Norwegians visiting with friends or relatives, and participating in sports or athletics.

Despite these variations in leisure-time patterns, indicating different life styles, there is a remarkable similarity between the two countries in shopping time. Our second research question focuses upon the relationship between shopping time and time spent on other activities within each country.

Relations Between Shopping Time and Time Spent on Other Activities

Tables 5 and 6 present the mean times spent on sixteen time budget categories by those who spend less than/more than 30 minutes per day. This time break corresponds to

Arndt and Grønmo's (1977) "short shopping time" and "long shopping time" respectively. The 30 minute figure was based on the basic 15 minute interval into which the day was divided in the Norwegian survey for activity recording purposes. Based on structural conditions in Norway, it was felt that breaking on 15 minutes was too short and breaking on 45 or 60 minutes was too long. A sensitivity test was run on both sets of data, breaking at 15 and 45 minutes per day in the Norwegian sample and 2.5, 3.0, 4.0 and 4.5 hours per week in the American sample. The results did not differ markedly from breaking at 30 minutes per day (3.5 hours per week).

Shopping may be considered more or less a mandatory activity, and given that total available time is fixed, "increases or decreases in shopping time will affect the time available for other activities" (Arndt and Grønmo, 1977). On the other hand, shopping time is not necessarily the causative variable. The amount of time available for shopping can be affected by, for instance, the amount of time spent on work. Certain activities are more elastic than others for most people and hence will show more effect for long and short shopping times than others. Arndt and Grønmo (1977, p. 234) found that overall, long shopping time was negatively related to time spent at income-producing work and positively related to

household work and family care, personal needs, and leisure. Both males and females were aggregated in the analysis, however, and the category "leisure activities" subsumed many different pursuits. It would be both conceptually and, hopefully, operationally useful to know how time spent on various activities varied between sexes in both countries and also on specific leisure-time pursuits.

In examining Tables 5 and 6 one sees that for both males and females in both countries, long shopping time (more than 3.5 hours per week) is significantly positively related to time spent on housework, necessary home maintenance, and lawn care, and negatively related to time spent at income producing work (and, in Norway, other work related activity). In the United States, long shopping time is significantly positively related, for both males and females, to time spent on personal care, reading newspapers and magazines, watching television, hobbies/games/crafts, and visiting with friends or relatives.

In Norway, long shopping time is significantly positively related among the males to time spent eating meals, on hobbies, games, and crafts, and visiting with friends or relatives, and negatively related to time spent commuting to and from work, and time spent participating in sports or athletics. For the Norwegian females, long shopping time is significantly positively related to time spent reading newspapers and magazines and entertainment outside the home (other than sporting events), and negatively related to time spent sleeping or napping,

commuting to and from work, participating in sports or athletics, and "other major activities."

Finally, in the United States, long shopping time is significantly positively related among the females to time spent eating meals and time spent attending sporting events as a spectator, and negatively related to time spent commuting to and from work. For the males, long shopping time is negatively related to time spent playing with the children.

These patterns suggest that in both countries the "heavy" shopper (those who spend a long time shopping) spend less time at work and more time at home in relatively sedentary activities (eating, reading, television viewing, hobbies, etc.), or in visiting friends or relatives either at home or away. In the United States these people also spend more time on personal care than the "light" shoppers. In Norway, this sedentary pattern includes less time participating in sports or athletics and in "other major activities." All in all, the picture is one of a segment of the population for whom the social-psychological aspects of shopping (getting out, interacting) are important, and for whom discretionary time may be both more abundant and more of a burden than a blessing. The question for them is how to spend their time, not how to save it.

Conclusion

The results of this comparative study add further support

to the theoretical paradigm proposed by Arndt and Grønmo (1977), namely that time spent on shopping varies between different consumer categories and directly affects the time spent on other activities. The indications are that there may well be a non-economic "Orientation to Shopping" intervening construct between antecedent or determining conditions and actual shopping behavior measured by time spent on shopping. The American data supports the earlier Norwegian findings quite well.

The importance of these findings lies in several areas. First, it is an addition to the small but growing body of comparative, cross-cultural buyer behavior knowledge. Second, it adds further credibility to the caveat that "what works here, may not work over there."

Third, it provides some reference data for evaluating how the increased wealth of Norway (due to the growth in production in the North Sea oil fields) may affect Norwegian consumption patterns. Finally, there are a number of research opportunities implicit in these results, which, basically, only scratch the surface of the similarities and differences between consumers in both countries. There is a glaring need to investigate the "why" question in all of its social and cultural ramifications.

How do these findings change anything? This is difficult to address in absolute terms. Certainly they suggest the importance of considering a time expenditure approach to buyer behavior decision processes. They also suggest that non-traditional, non-economic variables may play a more important role in buyer behavior than previously recognized. Studies of the role of time in buyer behavior have truly been few (Jacoby, et. al., 1976). It is also, of course, difficult to relate to "proprietary" cross-cultural studies filed away in corporate research departments.

Some of the actions suggested by these results have been alluded to above. Other appropriate actions include a) comparing these behavior patterns in Norway with those in other Scandinavian countries, b) analyzing the activities of retail stores designed to facilitate the latent "social" aspects of shopping, c) expanding the cross-national exchange of data. There is a wealth of state-collected secondary data waiting to be examined from the perspective of someone in a different country.

PERSONAL VALUES: A CROSS CULTURAL ASSESSMENT OF SELF VALUES
AND VALUES ATTRIBUTED TO A DISTANT CULTURAL STEREOTYPE

J. Michael Munson, University of Santa Clara
Shelby H. McIntyre, University of Santa Clara

Abstract

This research investigates the potential of a particular value assessing instrument, the Rokeach Value Survey (RVS), to distinguish cultural differences in personal value structures. Results suggest personal values can be productively employed by international marketers to discriminate peoples of culturally diverse backgrounds. A discriminant analysis disclosed significant differences in the self values held by people from three cultures: Thailand, Mexico and the United States. Additionally, the stereotype held of an average American's personal values differed significantly across the three cultures. The discriminant functions derived from responses to the RVS were able to correctly classify 65% of the people according to their cultural background as compared to a chance level of 22%.

Introduction

The determination of cultural differences is an important element in formulating international marketing strategy. In view of the increasing participation of American corporations in the international market place, and the threat of growing competition from foreign multinational corporations, knowledge and identification of culturally related differences in buyer behavior is a critical concern for marketing research. A fundamental area where cultural differences should be identified is in the culturally generalizable aspects of personality, attitudes, and personal values. Until recently, there has been little empirical research devoted to the analysis of values and their relation to consumer behavior. Research which has been done has focused solely on the values held by people in the United States (Scott and Lamont, 1974; Vinson and Munson, 1976; Henry, 1976; Vinson, Scott and Lamont, 1977).

While it is a widely accepted notion that cross cultural differences in values do exist, there is little empirical evidence actually documenting such differences or suggesting the particular form or pattern they take. In order for international marketers to assess possible cultural differences in values, a methodology and instrumentation is required which permits systematic comparisons of sufficient sensitivity to disclose those differences which might exist. Although there are a variety of segmentation techniques available which the marketer might consider for initially investigating cultural differences, such as benefit segmentation (Haley, 1968), activities, interests and opinions (Wells and Tigert, 1971), life style (Plummer, 1971), motivation research (Pernica, 1974), or cultural assimilators (Fiedler, Mitchell, Triandis, 1971; Worchel and Mitchell, 1972), each has serious limitations. Although all these techniques, except cultural assimilators, have been frequently applied to domestic marketing problems, their application to cross-cultural research is limited. Their conspicuous absence in the sphere of international marketing research stems in large measure from either the vast amounts of data each requires or their difficulty to implement in terms of effort, time and money. For example, to develop a meaningful AIO battery, might require the researcher to generate as many as 300 initial items (Wells and Tigert, 1971). Although cultural assimilators, which are self-administered programmed culture training manuals, provide an apparently effective

method for assisting members of one culture to interact and adjust successfully to members of another, they too require considerable start-up effort. The training manual is composed of a number of "critical incidents" which are elicited from either Americans or foreign nationals. Each incident describes some specific intercultural occurrence or event that made a major difference in each respondent's attitude or behavior toward members of the other culture. The time required to prepare a battery of 75-100 such incidents is approximately 800 man hours (Fiedler, Mitchell, Triandis, 1971).

On the other hand, an approach to segment international markets based on personal value analysis might present fewer limitations. If cultural or subcultural groups were initially found to be dissimilar in their basic value orientations, the marketer might then consider the follow-up use of more complex and costly techniques such as AIO or benefit segmentation. Based on the above, the objectives of this study are primarily four-fold:

- a) to provide empirical evidence that cross-cultural differences in personal value structures do exist.
- b) to investigate the utility of a particularly value assessing instrument, the RVS for disclosing differences in cultural values.
- c) to investigate the extent to which stereotypes of Americans differ across cultures.
- d) to determine the extent to which a person's own value system differs from his stereotype of a person from a different culture.

Personal Values

Domestic Research

The notion that values are of central concern in understanding consumer behavior has been pointed out by a number of researchers (Rosenberg, 1956; Lessig, 1975; Vinson and Munson, 1976; Vinson, Scott and Lamont, 1977). Rosenberg suggests attitudes are derived from values: "the attitude object tends to facilitate the attainment of a number of important values." Similarly Lessig (1975) asserts that attitudes stem in part from the value subsystem and are the expression of values toward given situations and objects. Vinson and Munson (1976) emphasize the centrality of personal values: "they represent the most basic element of the consumer's cognitive world, they structure the individual's perception and understanding of himself, significant others and of the objects and behavior which constitute his psychological environment" (p. 316).

Recent research has shown that not only are values differently held by specific groups of Americans, but more importantly to marketers are findings which suggest values are linked through attitudes to product attributes (Vinson and Munson, 1976; Vinson, Scott and Lamont, 1977; Munson, 1977). Vinson et al (1977) suggest a linkage may exist between general or global values and both more domain specific values relating to specific product qualities as well as subsequent product attribute

evaluations. Vinson and Munson (1976) found parents and their university age children exhibited significantly different preferences for automobile attributes which seemed to be related to their respective underlying value structures. For example, university students attributed significantly greater importance than their parents to the values of "an exciting life" and "pleasure" while their parents placed significantly greater importance on "family security" and being "responsible" (values reflecting standards of social and individual responsibility). Parents emphasized those attributes which signified utilitarian or functional characteristics associated with automobile ownership (e.g., quality of warranty, service required, handling) while students were more concerned with aesthetic and socially observable features (e.g., styling, prestige, luxury interior).

If values serve to segment buyers and are also tied to product attribute evaluations among a rather homogeneous population (e.g., people from the same general culture) one might expect these values to offer even more potential for segmenting peoples of diverse cultural background. This statement however presupposes that the values really do vary significantly across cultures.

Cross Cultural Research

It is a cardinal rule of marketing that it is always easier to appeal to existing cultural wants or expectations than to try to change the culture or to create new needs (Kassarjian and Robertson, 1973, p. 454). If marketers hope to formulate more effective product and promotional strategies for international markets, they must become sensitive to the core values of any given country, and their role in consumption differences. Available research evidence would seem to suggest that success or failure for the international marketer might be related in at least two primary ways to personal values. The first way concerns the importance or centrality ascribed to particular values by another culture, while the second way concerns inappropriate cultural stereotyping of the marketer's culture by the target culture. A few examples will illustrate the types of situations in which a marketer could make the first kind of error. The highly fragmented retail structure in France, with separate shops for fish, meat, pastries, etc., seems to be influenced by traditional French values. The desire to retain family control over the store and maintain status within the community may be more important than showing much profitability. Within American society, the business behavior of many small retailers appears similarly motivated. Wittreich (1962) found owners of small proprietorships were often less concerned with profitability than achieving the feeling of status, prestige, or family security through owning their businesses.

An example of marketing failure related to inappropriate cultural stereotyping is provided by Kitano (1969) in writing about the Japanese-American sub-culture he comments (p. 100), "To many people, Japanese culture suggests mainly tea ceremonies and flower arranging. As often happens, the quaint, the unusual, and even the trivial become so firmly associated in people's minds that complex explanations of behavior are often built upon pursuits that may in fact represent only the interests of a select population." Cultural stereotypes and folklore can be deceiving and perhaps even harmful to the marketer. He should guard against both the possibility of his own inaccurate perceptions of other cultures, or mistakenly assuming the attribution by other cultures of a favorable or specific stereotype of Americans. Chinese visitors to this country are surprised to learn that Americans attribute chop suey to the Chinese, as are Italians upon learning we consider pizza to be an Italian food (Kassarjian and Robertson, 1973).

One approach which might be particularly well suited for assessing values has been developed by Rokeach (1968-69), who views values as having to do with preferable modes of conduct and end-states of existence. The distinction between modes of behavior and end-states of existence implies a differentiation between means and ends or between what Rokeach calls "instrumental" and "terminal" values. Instrumental values relate to modes of conduct and represent a single belief which is personally and socially preferable in all situations with respect to all objects (e.g., ambition, independence and self control). Terminal values are a single belief that some end-state of existence is personally and socially worth striving for (e.g., leading an exciting life, family security and pleasure).

The ability of the Rokeach paradigm to differentiate the value orientations of various domestic groups has been very impressive (Rokeach, 1973). For example, various combinations of terminal and instrumental values have been found which significantly differentiate men from women, "hawks" from "doves," policemen from unemployed blacks (Rokeach, 1968-69). Additionally, some research has been done on the validity and reliability of the RVS itself. Both Rokeach (1973) and Robinson and Shaver (1971) reported relatively high test-retest reliability coefficients for the instrument over three week intervals. Vinson, Munson, and Nakanishi (1977) derived factor structures which clearly indicate the existence of two distinct value categories. A factor analysis of interval scaled importance ratings for each of the items in the RVS yielded 6 factors composed of terminal and 5 factors composed of instrumental values. With only one exception, there was no overlap of instrumental values loading on terminal factors or vice versa.

Hypotheses

It was felt that an adequate demonstration of the utility of the RVS in conducting cross cultural research could be achieved by testing its ability to discriminate between groups which were known to represent differing cultural backgrounds. An attempt was made to include both groups whose cultural backgrounds were assumed to be very different from that of a baseline American group and a second group whose heritage was assumed to be distinct from the American culture, but perhaps somewhat less so. These considerations and the availability of subjects resulted in the selection of Thais and Mexicans. Additionally, evaluations of a common object, the average American stereotype held within each culture, was felt to provide a further test of the sensitivity of the RVS to distinguish perhaps more subtle differences. The following null hypotheses were developed:

- H1: across cultures there will be no differences in the personal value systems of Thais, Mexicans or Americans.
- H2: across cultures there will be no difference in the personal value system each culture attributes to an average American (American Stereotype).
- H3: Within a culture, there will be no difference between that cultures' own value system and the stereotype value system it attributes to an average American (American Stereotype).

While it was strongly anticipated that self value structures might differ markedly between cultures, it was less clear how evaluations of the personal values of the stereotype of an average American might vary. It was felt that cultural norms might serve to not only

identify acceptable behaviors, but also to identify acceptable attitudes toward members of another culture. One might expect the pressure on an individual to be very great to conform to his own cultural's stereotype of another culture. Acting incorrectly, holding the "wrong" stereotype, could meet with social disapproval. One might also anticipate greater homogeneity of the perceptions found within a specific culture than between diverse cultures regarding perceptions of a common third object. Such perceptual homogeneity within culture and heterogeneity across culture could reflect, in part, a) the individual's acceptance of important norms within his own culture, b) cultural perceptual biases and/or c) differences in the information available to members of different cultural backgrounds.

Method

Sample and Instrument

Subjects were drawn from three separate populations. The Thai sample consisted of 32 people selected from a listing of 162 members of the Thai Students' Organization in Los Angeles. A sample of 63 Mexicans was obtained from the members of several Mexican-American organizations in and around the greater Los Angeles area. A sample of 75 Americans was obtained from graduate business students at a large Western university. An attempt to match the samples on major demographics was made. The three samples were very similar with respect to age (25-35 years) and education level (college graduates). A major difference occurred for religion, with the Thai group being 82% Buddhist, while the Mexican group was 85% Catholic, and the American group was primarily Catholic and Protestant.

All respondents completed a questionnaire containing the 36-item RVS and a separate page requesting traditional demographic data. The perceived importance of each value was measured using a seven point Likert-type scale. Each subject provided information on the importance he attributed to each of the 36 values (Self evaluation), as well as his perceptions of the importance placed on each value by an average American (Thai-American stereotype, Mexican-American stereotype and American-American stereotype).

Results and Discussion

Given that one of the main objectives of this study was determination of the capability of personal values as measured by the RVS to reveal cultural differences, stepwise discriminant analysis was employed. The criteria used for controlling the stepwise entry of variables was both the minimum Wilks' lambda and the maximum Mahalanobis distance between groups. The Mahalanobis criterion seeks to maximize the Mahalanobis distance between the two closest groups. The Wilks' lambda criterion is the overall multivariate F ratio for the test of differences among group centroids. The variable which maximizes the F ratio also minimizes Wilks' lambda, a measure of group discrimination.

Ten of the original 36 values were selected using this stepwise procedure (Table 1). The ten values produced a very high degree of separation between the six classification groups as indicated by the final Wilks' lambda (.205), and the canonical correlations for the first five discriminant functions. The square of the canonical correlation indicates that the first discriminant function explains approximately 49%, the second, 30% and the third, 24% of the variance in the grouping variables. Thus the first three functions are highly correlated with the groups while the last two are moderately correlated.

The eigenvalue is a measure of the relative importance of each function. The sum of the eigenvalues is a measure of the total variance existing in the discriminating variables. Expressing each eigenvalue as a percentage of the total sum of eigenvalues indicates the relative importance of the associated function and is shown in the column designated Relative Percentage (Table 1). The Wilks' lambda associated with each function is an inverse measure of the discriminating power in the original variables which has not yet been removed by the discriminant functions. Wilks' lambda was .892 after the 5th discriminant function was derived, which approximates a chi-square of 37.74 ($p < .001$). A lambda of this magnitude or smaller has a $p < .001$ of occurring due to chances of sampling even if there was no further information to be accounted for by the fifth discriminant function.

The relative contributions of the 10 discriminating variables to the respective functions can be seen in Table 2. The first function would seem to primarily represent individual characteristics with an emphasis on the values "broadminded" and "sense of accomplishment" which are over 1.5 times as important as "equality" or "responsibility." F2 is largely composed of "obedience" and "salvation," both making negative contributions. F3 appears most related to "true friendship" and "responsibility," both making negative contributions. Several variables make approximately equal contributions to F4, with "national security" and "responsibility" being the largest negative and "ambitious" the largest positive contribution. F5 is predominately related to "equality."

Discriminant Classification Table

After a discrimination procedure had been established it was of interest to determine whether the discriminant function was useful in classifying people using their scores on the personal values into their own cultural group. The classification matrix (Table 3) provides a convenient method of summarizing the number of correct and incorrect classifications made by the discriminant function. The diagonal elements denote the number of correct classifications (hits) and the off-diagonal elements denote the number of incorrect classifications (misses).

The classification power of the discriminant procedure is quite encouraging in that 65% of the cases are correctly identified as compared to an expected 22% if group assignment were to the most frequent category (i.e., the maximum chance criterion). Morrison (1969) argues in favor of a more lenient chance model which he calls the proportional chance criterion. Under this latter chance model, the chance criterion is adjusted to take into account the fact that some classifications are being made to the smaller groups. In our case, this proportional chance criterion would yield a 13% chance hit rate. However, we utilize the more conservative criterion of 22% in light of the fact that the Thai sample size was judged to be insufficient to permit the use of both an estimation and validation sample. To statistically test whether the 65% hit rate was better than the 22% maximum chance criterion a Q statistic was calculated (Press, 1972). The Q value exceeded a value of $X^2 = 10.82$ ($p < .001$), hence the classification procedure does significantly better than chance.

Hypothesis 1, 2 and 3 regarding the differences in the self value and stereotype value structures between cultures were tested by comparing the centroids derived for each group in the five dimensional discriminant space. The centroids represent mean discriminant scores for each group on the respective discriminant functions.

The F ratios based on the Mahalanobis distances between all pairs of group centroids were significant beyond the $p < .001$ level. Therefore one can reject the hypotheses that the value profiles from any two groups are equal. The significance of these findings suggest at least the following conclusions:

1. Self value systems do differ markedly across the three cultures studied.
2. Conceptions of American stereotypes also differ markedly across cultures. Apparently there is not one universally held American stereotype.
3. Within cultures there are significant differences between self value systems and those values attributed to an American stereotype.

Given that the primary thrust of this research was on the ability of personal values to discriminate various cultural groups, and the applicability of the RVS to this task, it was not the intent to focus on differences in specific isolated value items. However, readers interested in making specific comparisons are referred to Table 4 which presents mean importance ratings on both self value and American stereotype value structures for each culture. The univariate F ratios indicate that at least one pair of the groups are significantly different on each value. Some interesting differences in the evaluations of both instrumental and terminal values are observable across the three groups. For

example, This rate the terminal values of "a comfortable life" and an "exciting life" as significantly less important than either Americans or Mexicans. However they attach significantly greater importance than Americans to those terminal values related to social harmony - that is, "world at peace," "national security" and "family security." On the other hand, This attach significantly less importance than Americans to the instrumental values of "ambition" and "imagination."

Conclusion

Personal values represent the most fundamental element of the consumer's cognitive world. They enable the individual to structure his perception and understanding of himself, of significant others and of the objects embodied within his psychological reality. Inasmuch as it has been repeatedly observed that values are antecedent to many types of behavior, one might expect differential value orientations to manifest themselves in differential overt behavior. Knowledge of the value orientations held by a specific group may help in understanding, explaining, or perhaps predicting subsequent attitudes and behavior. However there is a limited empirical research, outside the current study, which focuses on either value measurement or their potential usefulness to those engaged in international marketing.

The findings of this study indicate that personal values can be productively employed to discriminate peoples

TABLE 3
Classification Matrix

Actual Group ^a	No. of Cases	Predicted Group					
		Thai Self	Thai American	Mexican Self	Mexican American	American Self	American Stereo
Thai Self	32	18 56.3%	2 6.3%	6 18.8%	3 9.4%	2 6.3%	1 3.1%
Thai American	32	6 18.8%	16 50.0%	3 9.4%	2 6.3%	4 12.5%	1 3.1%

Percentage of Grouped Cases Correctly Classified: 65.0%

^aThai Self, Mexican Self and American Self are the Self evaluations derived from each respective culture. Thai American, Mexican American and American Stereo are the stereotypes of an average American held by each respective culture.

with culturally diverse backgrounds. Significant differences in the self value orientations were observed between three cultural groups: Thais, Mexicans, and Americans. Significant differences were also found between the three groups in the stereotype each culture holds of an average American's personal value system. Additionally, within each culture significant differences were observed between a person's self values and those he attributed to an average American. Discriminant functions derived from responses to the Rokeach Value Survey were able to correctly classify 65% of the people according to their cultural background, significantly better than the 22% expected by chance.

Because of the robust ability of values to distinguish among peoples of different culture, value analysis may represent a convenient and economical technique to aid in market segmentation strategies. The RVS might offer marketers and researchers a valuable tool for identifying normatively based cross cultural differences. It is easily administered and could be employed to develop a profile of a general population or profiles of individual segments prior to the application of other more expensive and complex segmentation techniques. Value analysis should become an increasingly important area of research for the international marketer.

Abstract

Interviews conducted with new automobile purchasers in the U.S. and Norway are analyzed in this study. Correlates of information gathering activities and the size of the evoked set in the two samples are compared. Similar patterns of relationships are found in the two samples. The Norwegian respondents generally reported higher levels of search which seems consistent with known structural differences between the two cultures.

Introduction

Even though the influence of culture upon consumer behavior is widely acknowledged, cross-cultural studies of the consumer's decision process are conspicuous by their absence (Nicosia and Mayer, 1976). While there are notable exceptions (Douglas, 1976; Pfaff and Blivice, 1977), the costs and difficulties of cross-cultural research seem to have dissuaded most consumer behavior researchers from initiating investigations spanning national boundaries (Sheth, 1974).

Both theoretical and managerial concerns dictate pursuing studies in a number of different settings. From a scholarly point of view, such studies offer an invaluable arena for developing and testing theories. It is frequently held that models of consumer behavior capture fundamental human decision processes (Markin, 1974, p. 55). If so, these models should be applicable in a wide range of situations if the background variables are known. Such beliefs cannot be tested if empirical studies are only conducted within the relatively homogeneous confines of a single society. Our confidence in the generality of a theory is heightened if its descriptions of a process are found to be accurate in a wide range of settings.

More pragmatically, given the rising importance of multinational businesses, cross-cultural studies are vitally important to the marketing manager. Many foreign markets are rapidly developing from a state of scarcity to one of abundance (Sheth, 1974). Consumers in a growing number of countries have a wide range of choices among products and brands. They have, perhaps for the first time, the opportunity to make consumption decisions. Just as was the case in the United States (Engle, Kollat and Blackwell, 1973, p. 46), as goods become plentiful it becomes imperative to develop an understanding of the factors influencing consumers as they make their choices.

Further, efficiency in the employment of marketing resources requires the identification of similarities as well as differences between cultures (Douglas, 1976). If the multinational firm is to succeed in truly developed markets, it must realize economies of scale in the application of its marketing efforts that are not available to its national or regional competitors. If the multinational corporation serves only an *ad hoc* collection of discrete national markets that must be approached independently, it will be at a disadvantage. Without some offsetting competitive advantage, the larger firm merely adds layers of overhead costs that must eventually be borne by each of the local operations. If it is to become a truly viable institution in a world of developed economies, the multinational firm must be able to serve individual markets at least as efficiently as its nation-

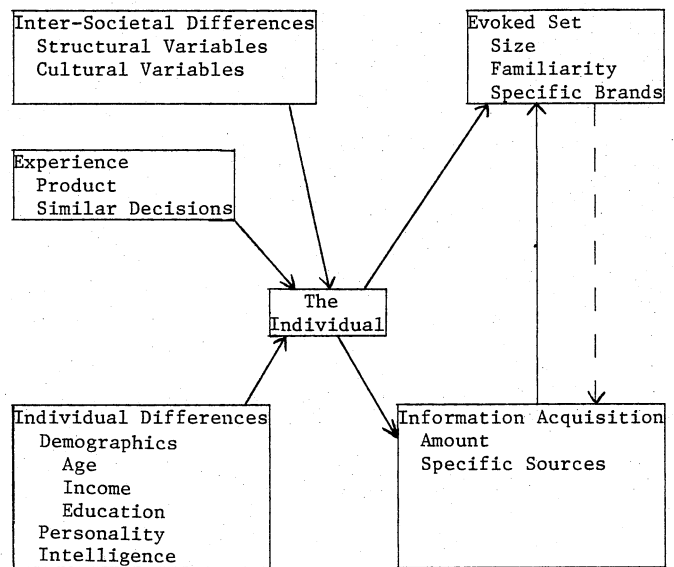

al counterparts. It would be desirable to identify cross-national similarities that can be used to segment markets and develop common marketing strategies.

Detailed explorations of cross-cultural similarities in consumer decision processes will entail large-scale and expensive research efforts. Before considering or recommending such an undertaking, one should wish to see some indications of the likelihood of its success. This paper represents a modest attempt at such a demonstration. Converging findings from studies of automobile decision making in two different cultures are discussed.

A Simplified Model

Extensive models of the consumer decision process have been presented by a number of authors (Nicosia, 1966; Howard and Sheth, 1969; Engel, Kollat and Blackwell, 1973). These are overly elaborate for the present purposes, given the state of the art in cross-cultural studies of consumer behavior. We will constrain the discussion to the simpler model shown in Figure 1. At the beginning of any decision problem the consumer has stored in his mind a bundle of attitudes, beliefs, knowledge, evaluative criteria, etc. These result from the unique characteristics of the society within which he lives, individual differences among the members of that society (e.g., personality, intelligence, and demographics), his previous experience with the product and the making of similar decisions.

FIGURE 1
 A Simplified Model of the Consumer Decision Process

Societal differences are viewed as being of two sorts. First, there are the more measurable structural differences such as income levels, the general development of the economy and the availability and cost of the product and product related information. Secondly, there are the more ephemeral aspects of culture including norms, values and mores, etc.

These exogenous or background variables are fixed at the onset of the decision task. They are shown as influencing both the acquisition of information and the formation of the evoked set, that limited group of alternatives actively considered by the decision maker (Howard and Sheth, 1969, p. 26). Information gathering may vary both in terms of the overall level of activity and the consultation of specific sources. Evoked sets may be analyzed in terms of their size and the balance between familiar and unfamiliar brands as well as according to the specific brands which they contain.

Information seeking should influence the size and composition of the evoked set. Finally, a feedback relationship is shown, since the perceived satisfactoriness of the evoked set would be expected to affect the course and duration of information seeking activities.

Studies of these relationships in distinctly different cultural settings are discussed in the following sections. It should be emphasized that our concern does not lie with demonstrating the presence or absence of between-culture differences with respect to the level on any variable. Rather, we are interested in exploring cross-cultural similarities in the relationships between the different sets of variables.

The Studies

Two nearly contemporaneous studies are compared and contrasted here. The United States study was conducted in St. Louis, Missouri. Data for the Norwegian study were gathered in Bergen, Norway.

Samples

Norwegian Study. Personal interviews averaging 45-60 minutes were conducted with a sampling of new car registrants during the late fall of 1969. Time and financial constraints forced limitation of the sample to Bergen, Norway's second largest town. Individuals were selected from transcripts of new car registrations. After as many as four recalls, completed questionnaires were obtained from 101 of the 138 individuals drawn for the sample. Five of the interviews could not be used because the automobiles were found to have been purchased for some commercial purpose or due to incomplete data.

United States Study. The data for this study are from personal interviews with 387 household heads residing in the St. Louis metropolitan area. A standard cluster-area probability sampling procedure was used to select a sample of dwelling units in the metropolitan area. Interviews were conducted by the Public Opinion Survey Unit of the University of Missouri in the Spring of 1966. Up to four interviewer calls were made at each selected dwelling unit. The response rate of 77 percent of attempted interviews appears reasonable for a large metropolitan area and for a high proportion of nighttime interviews. Respondents were asked to recall and describe all cars owned and previously owned by themselves and their family. Next, each respondent was asked to describe the decision leading to his or her most recent purchase. The analysis reported here is based upon data from those 132 household heads whose most recent purchase was a new car, who owned at least one car before the most recent purchase, whose brand choice was not restricted by special deals, and whose answers to the questions used were ascertained.

Measures and Analysis

Each study gathered a large amount of information about the individual, his automobile ownership history and his most current auto purchase decision. A number of questions reflecting on the relationships shown in Figure 1 were common to both studies. These are reproduced in Appendix A.

It seemed desirable to make minimal assumptions about the level of measurement. Even though some variables were measured on an interval scale, Kendall's Tau, which requires only ordinal measures, was used throughout the analysis unless another statistic is indicated.

Findings and Discussion

The patterns of findings shown in Tables 1-4 are supportive of the notion that similar processes operate in the two cultural settings. Where differences are noted at least some explanation can be offered in terms of the effects of structural differences.

Demographic Variables and Evoked Set Size

The relationships between demographic variables and the size of the evoked set are shown in Table 1. The similarities between the two studies are striking. Age and education are significantly related to evoked set size in both studies; income is found to be lacking in explanatory power. The direction of the significant relationships is as expected. As the individual ages, he accumulates experience with the product and product related decisions and he develops a more completely formed preference ordering (Howard and Sheth, 1969, pp. 26-29). The elimination of marginally interesting brands, coupled with a finite upper limit on the number of brands of automobiles available, would lead to smaller evoked sets. Similarly, a positive relationship between evoked set sizes and education was anticipated. If the educational system is successful, it should develop an individual with heightened capabilities and inclinations to retain and manipulate information. An educated person would be expected to discover and consider more alternatives than one not so favored.

Demographic Variables and Information Seeking

These relationships are shown in Table 2. The pattern is much the same as that noted in Table 1. Age shows significant negative correlations with all measures of information seeking. Similar arguments to those advanced in the preceding paragraphs apply here; as the individual develops greater total experience he has less need to gather information specifically for the present decision.

With one nonsignificant exception, the relationships with education are, predictably, positive. The fact that a far greater number of significant correlations are found in the Norwegian study does not admit to simple explanations. Perhaps this reflects the emphasis upon consumer education found in Scandinavian educational systems (Thorelli, 1977).

The findings as to the effects of income seem confusing. The Norwegian data show consistently negative signs. This would support a hypothesis that the higher the income the lower the perceived risk and, hence, the need to acquire information as a risk reducing mechanism (Engel, Kollat and Blackwell, 1973, p. 587). This hypothesis would not explain the United States data where the sig-

nificant relationships are positive. In this instance availability may be the key. The significance of advice results from the tendency of higher income persons to consult with individuals having technical or professional expertise; income is negatively related to discussing the purchase with friends, relatives and co-workers (data not shown). Higher income persons may have easier access to those with professional knowledge of automobiles. A similar situation may prevail with brochures. A substantial number of those reporting they had read brochures indicated that these had been mailed to them by the seller without any initiative on the buyer's part. Since they are attractive prospects, this may reflect the fact that higher income consumers are likely to find themselves on a large number of mailing lists. The interesting thing is that these unsolicited brochures were not only received, but also read and remembered.

^aKendall's Tau
*p ≤ .10, one-tailed test
**p ≤ .05, one-tailed test
***p ≤ .01, one-tailed test

The (nonsignificant) negative sign found for test driving in the United States data may be reflecting the influence of compliance rather than education. Paraphrasing one respondent, "The salesman is supposed to get you to test it, so you drive it a few blocks so he doesn't get in trouble." Perhaps less educated respondents are more easily cowed by auto salesmen.

Information Seeking and Evoked Set Size

It was expected that the level of information seeking would be positively related to the size of the evoked set. Two considerations gave rise to this prediction. First, both the level of information seeking and the evoked set are believed to be associated with the complexity of the decision process. Small evoked sets (approaching one) and minimal information gathering are characteristic of routine response behavior (Howard and Sheth, 1969, p. 528). Problem solving (limited or extended) is believed to be associated with larger evoked sets and more active efforts to acquire information.

As shown in Table 3, this expectation is supported by both sets of findings: larger evoked sets are positively related to more intense information gathering. With the exception of advice, stronger relationships are found for the Norwegian respondents. This can, perhaps, be explained by structural differences between the two societies. At the time of the studies automobiles were two or three times as expensive in Norway as in the United States and incomes were roughly 30-40% lower. As a result, a far smaller proportion of the households owned a car. Since the Norwegian buyer was committing a larger proportion of his income to a product with which he was less familiar than his United States counterpart, he

would be expected to engage in more extensive problem solving.

Summary

The case for cross-national studies of consumer behavior was argued in the introduction. Such studies are needed both for theory development and for the managerially useful insights which may be gained. A simplified model was then presented. Findings from studies of Norwegian and American automobile purchasers on the relationships contained in this model were then compared. Differences in the level or intensity of information search activities were noted. It seemed that these differences could be attributed to structural differences between the two cultures. However, the most notable findings were the similarities in the nature of the relationships between variables. There seemed to be strong indications that similar underlying processes were operating in these quite different societies.

Appendix Questions Asked of Respondents and Their Coding

	Norwegian Study	U.S. Study
Advice	"Did you seek any advice from others when you were buying the car?" ¹	"Did you hear anyone talk about this make of car or ask anybody's advice before you bought it?" ¹
Brochures	"Did you study any brochures before purchase?" If yes. "For which car(s)?" ¹	"Did someone selling the car call or write or give you some literature...?" "Did you, yourself, go out to look at the car, or get some literature...?" ¹
Dealer Visit	"Did you visit any dealer(s)?" If yes. "Whom?" ³	"Did you, yourself, go out to look at the car, or get some literature or talk to someone who was trying to sell it?" If yes. "Was it just one contact, or were there several?" ^{1,2}
Test Driving	"Did you test drive any car(s) before purchase?" If yes. "Which ones?" ³	"Did you drive this car or a similar model before you bought it?" ¹

Appendix (con't.)

	Norwegian Study	U.S. Study
Advertisements	"Did you study any advertisements for any car before purchase?" If yes. "For which cars?" ¹	"Did you hear or see anything about this car on television or radio, in a newspaper, magazine, or buying guide?" If yes. "Was it an advertisement, or a story that you remember?" ¹
Total	Sum of sources coded above. ³	Sum of sources coded above. ³
Income	"As an estimate, what was your family's income last year before taxes?" ³	"Which of these categories best describes your total family income before taxes last year?" ³
Education	"Did you continue your education after public school?" If yes. "How many years?" ³	"How many grades of school did you finish?" ³

¹Dichotomous coding: named --- did not name this source

²Coded as only one visit --- more than one visit

³Coded as interval data

SELECTING PARETO OPTIMAL SUBSETS FROM MULTIATTRIBUTE ALTERNATIVES

James B. Wiley
Wayne State University and University of Florida

Abstract

Previously, Green (1974) illustrated the use of fractional replication procedures for selecting multiattribute alternatives for conjoint measurement studies of consumer choice. This study suggests the information laden choices in conjoint measurement are among alternatives in pareto optimal subsets. Pareto optimal subsets are those in which no alternative "dominates" another on every attribute. Procedures for selecting pareto optimal subsets are illustrated.

Introduction

How do consumers choose among multiattribute alternatives? Recent studies by Green and Rao (1972), Green, Carmone, and Wind (1972), Fiedler (1972), and Bettman, Capon, and Lutz (1973, 1974) have investigated this question using the techniques of conjoint measurement (Krantz and Tversky, 1972), trade-off analysis (Johnson, 1974), or functional measurement (Anderson, 1972). At the core of the many similarities among these three techniques are the following four fundamental premises: a) individuals (or other decision-making units) assign "partworths" to attribute levels, b) "utility" is a function of these partworths, c) choice is proportional to utility, and d) although the individual may be unable to articulate the partworths, they may be inferred from numerous choices among alternatives having characteristics which are varied in systematic ways. In this paper we use "conjoint measurement" in a generic sense, to refer to the general problem of inferring "partworth's" from choices.

Conjoint measurement is a recent development in mathematical psychology that is concerned with resolution of the joint effect of a set of attributes (measured at the ordinal level) into separate, independent contributions, which are measured at the level (asymptotically) of interval scales with common unit. That is, it is concerned with the effect of two or more independent variables on the ordering of a dependent variable. The approach is designed to solve a fundamental scientific problem, that of determining the rules by which a set of independent variables can be combined and used to predict values for a dependent variable. In the behavioral sciences, however, only rarely can one measure the dependent variable at the interval level, let alone the independent variables. In order to bridge this discrepancy between technical feasibility and scientific objective, conjoint measurement is used to determine whether there exists any rescaling of the dependent and independent variables, that when combined according to a hypothesized composition rule, would yield results consistent with the observed ordinal data structure. Alternatively, conjoint measurement may be used as a scaling method. When used as a scaling method, one tries to solve the measurement and composition rule problems together by fitting scales that obey the stated composition rule to some suitable approximation (Green and Wind, 1973).

With the additive conjoint measurement algorithms, such as Kruskal's MONANOVA (1965), an additive composition rule is assumed. Then, the above four premises can be represented as follows. The utility $U(x)$ of some multiattribute alternative $x = (x_1, x_2, \dots, x_n)$,

expressed as an n -component vector, is defined as,

$$U(x) = f(x) = \sum_{j=1}^n u_j(x_j) \quad (1)$$

where u_j is a real-valued function of x_j , and x_j is the "level" of alternative x on the j (th) attribute.

As Dawes and Corrigan (1973) point out, additive models typically are applied to problems in which it also is reasonable to assume that the real-valued function u_j (1) is conditionally monotonic over x_j (which also implies an a priori ordering over x_j .) That is, given two alternatives, $A = (x_1, x_2)$ and $B = (x_1, x_2')$, then

$$U(A) \leq U(B) \text{ iff } (x_1, x_2) \leq (x_1, x_2') \quad (2)$$

which implies utility is monotonic with x_2 and, in general, with x_i . As a consequence, we can speak of an alternative, A , "dominating another alternative, B , whenever

$$x_i > x_i' \cap x_j \geq x_j' \cup (x_i \geq x_i' \cap x_j > x_j') \quad (3)$$

Under such conditions, choice of $A = (x_i, x_j)$ must obtain by virtue of the assumptions of the model and a priori information regarding the setting. Since an alternative that is equal to or greater than another alternative on every attribute must be chosen by assumption, it follows that valuable information for scaling purposes (as distinct from model testing) is gleaned from choices among sets in which no alternative "dominates" another. Alternatives in such sets are said to be Pareto optimal. This paper describes how to select Pareto optimal subsets of multiattribute alternatives constructed from p^p factorial series. This series includes three attributes at three levels designs, four attributes at four levels, five attributes at five levels and so forth. Pareto optimal subsets for the 3^3 through the 6^6 series are reported. A desirable property of the reported sets is that all subsets selected from the reported sets will also be Pareto optimal. As a consequence, Pareto optimal subsets can be organized according to balanced incomplete block designs (BIBD's), with the alternatives within blocks Pareto-optimal.

An Example

Suppose we wish to determine the relative importance of transportation characteristics. Conversations with experts and traffic managers as well as a review of the literature suggests three dominant service criteria; reliability, rate, and transit time. Further conversation with experts suggest the following levels are realistic for a given origin/destination/commodity shipment:

Reliability	on days late			
	time	1	2	3
A	95%	3%		
B	88%	8%	2%	
C	80%	12%	4%	2%

Rate	
A	\$1.13/cwt.
B	1.54/cwt.
C	1.95/cwt.

Normal Transit Time	
A	2 days
B	4 days
C	6 days

For example, one alternative may cost \$1.13 per hundred weight, take six days normal transit time, with an expectancy that 95% of the time it will arrive on or before the sixth day and a 3% chance it will arrive on the seventh day. There are 27 such alternatives that can be constructed from this 3³ design.

Aside from the so-called "alphabet routes" which it is said once were favored for some commodity shipments, it is reasonable to assume that a decision-maker would prefer a cheaper, quicker, more reliable alternative to a more expensive, slower, less reliable alternative. Informative choices, therefore, are among alternatives that require the decision-maker to forego performance according to one criteria in order to gain performance according to another criteria. Requiring the decision-maker to rank order the following alternatives requires such choices.

A PARETO OPTIMAL SUBSET OF 3³ DESIGN

Alternative	Reliability	Rating	Transit Time
1	(A) 95% 3%	(B) \$1.54/cwt.	(C) 6 days
2	(A) 95% 3%	(C) 1.95/cwt.	(B) 4 "
3	(B) 88% 8% 2%	(A) 1.13/cwt.	(C) 6 "
4	(B) 88% 8% 2%	(C) 1.95/cwt.	(A) 2 "
5	(C) 80% 12% 4% 2%	(A) 1.13/cwt.	(B) 4 "
6	(C) 80% 12% 4% 2%	(B) 1.54/cwt.	(A) 2 "

While the above list is not exhaustive (for example, the alternative B(2), B(2), B(2) could be added, the alternatives do comprise a balanced, pareto optimal set which can be constructed following a simple heuristic.

How to Construct Balanced Pareto Optimal Subsets

A simple procedure for constructing a balanced set of Pareto optimal alternatives is based on cyclic hyper-graeco-latin square designs. This somewhat awesome term describes the straightforward generalization of latin square designs with multiple factors. For example, a cyclic graeco-latin square of a 3³ design can be represented as:

		COLUMNS		
ROWS	1	2 3	2 3 1	3 1 2
	2	3 1	3 1 2	1 2 3
	3	1 2	1 2 3	2 3 1

The position in a given cell refers to attribute and number in that position refers to attribute level. Three alternatives are represented in a given row or column and these three alternatives are Pareto optimal. To return to the above example, the first row represents alternatives 1, 4 and 5 respectively of Table 1.

The above design can be represented as a composite of the following three latin squares:

TABLE TWO
ELEMENTS OF COMPOSITE DESIGN

(1)	(2)	(3)
1 2 3	2 3 1	3 1 2
2 3 1	3 1 2	1 2 3
3 1 2	1 2 3	2 3 1

Square (1) comprises the elements in the first position, square two comprises the elements in the second position, and square three comprises the elements in the third position. The tables are constructed using a one-step cyclic permutation of the numbers in the design. That is, the next design in the sequence is constructed by moving the first number of the current design to the extreme right, simultaneously moving all other numbers to the left (Winer, 1962). A composite design constructed from cyclic elements is balanced in the sense that each attribute level appears once and only once in a cell and once and only once in each position in a row or column. Thus, a row or column of a composite design represents a balanced Pareto optimal subset; i.e., every attribute and attribute level is represented and no alternative dominates another.

The remaining alternatives of Table 1 can be constructed by interchanging the second and third arrays of Table 2 to yield a new composite design:

		COLUMNS		
ROWS	1	1 3 2	2 1 2	3 2 1
	2	2 1 3	3 2 1	1 3 2
	3	3 2 1	1 3 2	2 1 3

The first row of the above design represents alternatives 2, 3, and 6 respectively of Table 1. With the addition of the alternative comprised of the second level of each attribute, the set will remain Pareto optimal, but it will no longer be balanced. The set of seven alternatives will be exhaustive, however, in the sense that each of the remaining 20 alternatives that can be constructed from the 3³ design will be dominated, or will dominate at least one of the seven alternatives in the Pareto optimal set. In this sense the seven alternatives represent the largest Pareto optimal subset that can be constructed from a 3³ design.

Constructing Sets for Larger Designs

While Pareto optimal subsets can be constructed for larger designs following generalizations of the procedures discussed above, the exercise is cumbersome and can become quite laborious. However, if we note that each attribute level will occur once and only once in each alternative generated by such procedures, a simple, easily programmable rule can be explicated which facilitates identification of desired alternatives.

This is the rule. For p^p designs select alternatives whose attribute levels sum to $\binom{p+1}{2}$. Since each level occurs once in an alternative, the sum of the levels will be the same for all alternatives. For example, in Table 2, if the letter (A) is replaced with the value one, (B) with the value two, and (C) with the value three, it is clear that for each of the six alternatives in Table 1, the sum of the attribute levels is six. Likewise, the desired alternatives from a 4⁴ design will have attribute levels which sum to ten, the desired alternatives from a 5⁵ design will have attribute levels which sum to 15, and so forth. The Pareto optimal alternatives based on cyclic hyper-graeco-latin squares will form a subset of the alternatives generated following the above rule. The remaining alternatives

identified are those in which a given attribute level appears more than once. For example, the alternative characterized by the second level of each attribute (2,2,2) of a 3^3 design is such an alternative. The second level appears three times, but the sum of these levels is equal to six, as required by the rule.

Table 3 presents Pareto optimal subsets for the 3^3 , 4^4 , and 5^5 factorial series. The sets are complete for the 3^3 and 4^4 series. As indicated in the above discussion, the 3^3 series contains seven alternatives, six of which are balanced in the sense that each level appears once and only once in an alternative. The 4^4 series contains 44 alternatives, 24 of which are balanced. The 5^5 series contains 381 elements. Only the 120 balanced elements are reported in order to conserve space. The 6^6 series is presented in Table 4. There are 4332 alternatives in this series, 720 of which are balanced. Only the seed balanced alternatives are listed.

Organizing According to BIBD's

Even restricted to Pareto optimal subsets, collecting choice data vis-a-vis the selected alternatives can become a formidable task. Twenty-one pairwise comparisons are required for the 7 alternatives in the 3^3 series. Two hundred and seventy-six pairwise presentations would be required for the 24 balanced alternatives in the 4^4 series. However, the 24 alternatives can be conveniently organized into six blocks of four alternatives each, such that the incidence of attribute levels is balanced within blocks and within the entire design. The following blocks illustrate this property.

Alternative	Block					
	(1)	(2)	(3)	(4)	(5)	(6)
1.	1234	1243	1324	1342	1423	1432
2.	2341	2431	3241	3421	4231	4321
3.	3412	4312	2413	4213	2314	3214
4.	4123	3124	4132	2134	3142	2143

Note that the blocks are constructed by cyclic permutation using the first six balanced elements of the 4^4 series (listed in Table 3). The balanced alternatives in the 5^5 series can be organized into 24 blocks of size five following similar procedures. The 6^6 series required 120 blocks of size six. Only a small fraction should be assigned a single subject and these should be replicated. Most subjects will find ranking six Pareto optimal 6 attribute alternatives a challenge.

In each of the above cases, the subject is required to rank the alternatives within blocks in order of preference. The resulting data can be analyzed "non-metrically," or following procedures suggested by Gulliksen and Tucker (1961), McKeon (1961), Wiley, MacLachlan, and Moynour (1976), or Green and Carmone (1977).

FOUR METHODOLOGICAL PROBLEMS IN MULTI-ATTRIBUTE
ATTITUDE MODELS¹

Michel Laroche, Simmons College

Abstract

Four methodological problems are identified: two dealing with the scaling decision, i.e., origin and range; and two dealing with the relation among attributes, i.e., interaction and halo effects. Two procedures are proposed in order to improve the specification of the multi-attribute attitude models and our understanding of the process of attitude formation, as well as their predictive abilities.

Identification of the Problems

There has been a great amount of research in marketing on multi-attribute attitude models inspired by the work in social psychology of Rosenberg (1956) and Fishbein (1967). Basically, consumers evaluate competing brands on a certain number n of attributes according to the following multiplicative rule:

$$A_j = \prod_{i=1}^n a_i B_{ij} \quad (1)$$

where:

A_j is the consumer's attitude toward brand j ;

B_{ij} is the strength of belief i about brand j , i.e., the probability that brand j is associated with attribute i ;

a_i is the evaluation of attribute i .

Some problems appeared, as researchers tried to implement the previous model or to compare its performance with additive or other nonlinear models. Excellent reviews of these attempts are available in Wilkie and Pessemier (1973) and in Einhorn and Gonedes (1971). The four major problems could be described as follows:

1. The problem of the origin of the scales used in measuring B_{ij} and a_i . As it was correctly pointed out by Schmidt and Wilson (1975), by choosing between unipolar (for example, from 1 to 5) and bipolar (from -2 to +2) scales for each concept, the researcher is able to manipulate the correlation between A_j and the summation of $a_i B_{ij}$'s. This is so because (1) is basically a nonlinear model, and a transformation of its variables by manipulation of the scales is likely to modify the functional form by which it is represented. If we note that the coefficient of correlation between two entities is unaffected by linear transformation of these entities, we can see that this problem of the origin of the scales will not affect the performance of linear models of attitude formation.

2. The problem of the range of the scales used in measuring B_{ij} and a_i . Most of the published studies have used the same range for all the concepts, usually scales with 5 or 7 points. As Etter (1975) correctly remarked, the model (1) will be sensitive to variations in the range of these scales, and the introduction of scale transformation parameters could improve its per-

formance. This is so for the same reason as before, i.e., (1) is basically a nonlinear model.

3. The model (1) does not take into account the interaction among the different attributes. In effect, the algebraic rule contained in (1) is equivalent to assuming independence of the different effects. It is evident that this is very often not the case. Sheth (1974) proposed a two-step procedure: a reduction of the dimensions by using a decomposition procedure of the different beliefs followed by a regression analysis in order to determine the weights of the underlying independent beliefs. But this method assumes homogeneity among the respondents and does not solve the problem of the origin. Besides, the derived dimensions are often difficult to interpret.

4. It has been observed that respondents tend to indicate higher beliefs about a brand according to the general attitude toward this brand. This phenomenon is the halo effect, and it represents a serious methodological problem in multi-attribute attitude models (see Beckwith and Lehmann, 1975).

This paper will attempt to provide some alternatives in order to obviate some of the problems which have just been identified.

The Problem of the Origin

When studying consumer behavior, the researcher selects a scale in order to measure a given phenomenon, such as the strength of a belief or the evaluation of an attribute. The phenomenon is assumed to exist independently of the type of scale used. For example, we feel the same way today, whether the temperature is expressed in Celsius or Fahrenheit. Faced with bipolar adjectives, the respondent indicates his position by checking one of the possible alternatives. Then, the researcher attributes numbers to these alternatives. As long as this measure is used in an additive way, no problem arises. But in multi-attribute attitude models, researchers are trying to multiply such measures and in order to do so ratio scales are needed. In physics, absolute temperatures had to be introduced when temperature was one of the multiplying variables in a given law. Similarly, it is necessary here to determine the position of the origin of the scale for each concept. It becomes a parameter to be estimated when applying the model (1), in the same way as regression parameters are obtained. That is, the origins for the a_i 's and the B_{ij} 's are the ones which maximize the correlation coefficient between the calculated and the measured attitudes.

This approach is superior to the arbitrary determination of these parameters which has been found in the literature. For example, completely different predictions could result from such an initial choice, as is illustrated in Table 1 with an hypothetical example. As is evident in this case, the determination of the origin is not only a question of calibrating a tool; it is essentially a very important element of model specification.

¹This research is part of a project supported by the Laboratoire de Recherche of the Faculté des Sciences de l'Administration of the Université Laval, Québec.

TABLE 1

With the same data, different predictions are made according to the scales chosen.

		i = 1	i = 2	A _j
Bipolar model	B _{i1}	0	1	1
	B _{i2}	-1	0	2*
	a _i	-2	1	
Mixed models	B _{i1}	3	4	-2
	B _{i2}	2	3	-1*
	a _i	-2	1	
	B _{i1}	0	1	4*
	B _{i2}	-1	0	-1
	a _i	1	4	
Unipolar model	B _{i1}	3	4	19*
	B _{i2}	2	3	14
	a _i	1	4	

* Highest predicted attitude

In order to illustrate one of the procedures proposed in this paper, a set of data was collected for 75 persons selected in a shopping center of Québec. The questionnaire used dealt with the choice between two competing brands of cola in the large size category: the 53 oz. bottle of Pepsi and the 40 oz. bottle of Coke. Four criteria were used: economy, ease of manipulation, brand reputation and ease of storage in the refrigerator. The bipolar adjectives used were "bad description good/description" for the strengths of beliefs and "not important at all/very important" for the evaluations. Both were collected on a 5-points scale. The raw data were then transformed by varying the origin for each set of scales, and the transformed data were used in (1) in order to obtain the predicted attitude which was correlated with the measured overall attitude. The correlation coefficients thus obtained are presented in Table 2. The results illustrate dramatically the effect of changing the codifications of the data used in (1).

In effet, the model (1) should be rewritten as

$$A_j = \sum_{i=1}^n (a_i - a)(B_{ij} - B)$$

where a and B are constants to be determined.

In Table 2, one can find the correlation for the bipolar model (a = 3, B = 3), the mixed models (a = 0, B = 3; a = 3, B = 0) and the unipolar model (a = 0, B = 0). Further analysis leads to the following conclusions:

1. The best model for Pepsi alone is a = 0, B = 4.4 for which the correlation coefficient is equal to .6450;

2. The best model for Coke alone is a = 2.1, B = 3.5 for which the correlation coefficient is equal to .6188;

3. The best model for both is a = 1.1, B = 3.8 for which the coefficients of correlation are respectively .6277 and .5942. This was obtained by maximizing the sum of both correlation coefficients.

Finally, it can be shown that Anderson's averaging model is relatively unaffected by the problem of the origin. This would explain why this model performs in a more consistent manner than the model (1). Basically, one can generally describe the averaging model as follows (Anderson, 1970):

The evaluation scale is a weight variable w_i, which one can define as

$$w_i = \frac{a_i - a}{\sum_{i=1}^n (a_i - a)}, \quad (3)$$

which leads to

$$\sum_{i=1}^n w_i = 1.$$

These weights then combine in a multiplicative fashion with the strength of belief in order to yield the attitude A'_j:

$$A'_j = \sum_{i=1}^n w_i (B_{ij} - B) \quad (4)$$

By decomposing (4) and rearranging terms, one finds:

$$A'_j = \sum_{i=1}^n w_i B_{ij} - B.$$

This last expression shows that the coefficient of correlation between A'_j and the measured attitude would be independent of B, which is the origin of the belief scale. But the correlation coefficient is still dependent upon a, which is the origin of the evaluation scale. Intuitively, one would expect a to be the lowest value of that scale. This was borne out experimentally on the same set of data as before. The procedure was the same as before: a was varied, and for each value of a the correlation coefficient between predicted and measured attitudes was computed. The origin a was determined to be equal to 1, and the corresponding coefficients of correlation were respectively for Pepsi and for Coke equal to .6436 and .6114. It is worth noting here that these coefficients are very close to the ones obtained previously for Fishbein's model. This might suggest that, with proper adjustment of the scales, their predictive abilities are similar.

Limitation of the method

This procedure for determining the origin of each type of scale, i.e., a_i and B_{ij}, suffers from one implicit assumption: that all attributes have the same origin on the same scale. Although this is intuitively appealing, it should be tested, and the previous method could be adapted in order to fit the following model:

$$A''_j = \sum_{i=1}^n (a_i - a_{oi}) (B_{ij} - B_{oi}). \quad (5)$$

This would necessitate the estimation of 2n parameters instead of 2.

The Problem of the Range of the Scales

The same arguments as for the origin can be used to defend the need for a determination, at least implicitly, of the range of the scales used to measure a_i and B_{ij} . But there is one major exception for which this problem does not arise. If one assumes that all the a_i scales have the same range r_1 , and that all the B_{ij} scales have the same range r_2 , then the analysis of the behavior of the correlation coefficient shows that any uniform change of range for each group would not affect it. This result is a major difference with the previous problem.

On the other hand, if the ranges of, say, the a_i scales depend on the nature of the attribute, they become parameters to be estimated. This is what was done implicitly in the second phase of Sheth's method, and his regression coefficients represent the product of the average evaluation by a range adjustment factor (Sheth, 1974). One can say that, in general, one of the main advantages of multiple regression in this context is its ability to adjust for the misspecification of the range of each scale. This property will be used later in conjunction with the method of orthogonal polynomials.

Interactions Among Attributes and the Halo Effect

The model represented in (1) assumes that each attribute is processed by the consumer independently of the other ones. This would justify the manipulation of a selected attribute in order to improve the attitude toward a given brand. However, this is not often the case. For most products it is likely to find high correlations among attributes on the a_i and B_{ij} dimensions. For example, in the case of these soft drinks, we should expect an interaction between the manipulation and the storage criteria. Then, the question in terms of attitude change becomes one of direction and degree of modification of the related components of (1). If an induced variation in one of the attributes produces changes in the same direction on all the related attributes, then there will be some positive attitude change. But, if the induced variation produces opposite changes, then it will be necessary to determine, if possible and if desirable, the approximate amount of stimulation that would lead to positive attitude change.

A particular case of interaction effects among attributes is due to the halo effect (Beckwith and Lehmann, 1975). In their paper, Beckwith and Lehmann suggest the introduction in the application of the model (1) of the average attitude A^* as a proxy variable for this effect. It can be argued that a better proxy variable for the halo effect is the attribute of brand reputation. The higher the reputation of the brand, the more likely it will be overvalued on certain attributes. The main advantage of using this variable is that in doing so we better capture individual differences. In addition, it is possible to study the interactions involving the halo effect as will be shown in the next section.

Application of the Method of Orthogonal Polynomials

Methodology

The method of orthogonal polynomials developed by Laroche (1974) from the work of Fisher (1958) is particularly useful in the context of empirically determining the consumer's decision rules. Its major advantages are as follows:

1. It adapts itself to the two problems associated with the scales, i.e., origin and range.
2. It decomposes the effects into independent entities: main and interaction.
3. All interactions can be introduced into the analysis.
4. The halo effect can be determined more precisely.

The same data as before are used in this application. For each attribute, the main effects are calculated (linear, quadratic and cubic). To summarize, the method consists of decomposing the effect of x on y into a trend or linear component, a quadratic component uncorrelated with the trend, and a cubic component uncorrelated with the previous two. On the interaction side, and this is the important part, the effects of x and z on y are decomposed into two main effects or trends and an interaction component uncorrelated with the trends of x and z . Thus, for each set of attributes, an interaction component is calculated. All of

TABLE 3

Regression Results for Pepsi and Coke Using the Method
of Orthogonal Polynomials

Brand	Regression Coefficients (t-values)								Constant	R
	(1) Economy		(2) Manipulation		(3) Brand Reputation		(4) Storage			
Pepsi	P_1	$P_1 \times a_1$	P_3	$P_3 \times a_2$	a_3	$a_3(\text{cubic})$	$P_3 \times a_4$	$a_3 \times a_4$	(e)	(F)
	.325	.862	.711	2.78	-.328	-10.91	-3.21	-1.93	.6026	.8118
	(2.73)	(1.76)	(7.90)	(3.19)	(-2.65)	(-3.38)	(-4.11)	(-3.83)	(.1909)	(16.2)
Coke			C_3	$C_3 \times a_2$			$C_4 \times a_4$			
			.740	-.996			.815		.6974	.7160
			(7.71)	(-2.32)			(2.52)		(.2022)	(25.2)

where a_1, a_2, a_3, a_4 are the evaluations; P_1, P_2, P_3, P_4 are the beliefs for Pepsi;

C_1, C_2, C_3, C_4 are the beliefs for Coke.

these components are then entered into a stepwise regression, and the resulting coefficients are presented in Table 3.

Major findings

1. The criterion of economy is independent of the other criteria, including the halo effect. It is significant only for the most economical brand, i.e., the 53 oz. bottle of Pepsi. On that dimension, since the only significant terms are the strength of belief (main) and the interaction (bipolar), the model used by the consumers is a mixed one: roughly bipolar on the evaluation (a_1) and roughly unipolar on the strength of belief (P_1). This is consistent with the previous overall result.

2. The previous finding for a_1 is also true for a_2 and a_4 for both brands.

3. For both brands, the reputation of each one on the main effect is the most important criterion. The halo effect is apparent by the significant interaction of brand reputation with manipulation in the case of Coke and with manipulation and storage in the case of Pepsi. In particular, for Coke the more important the criterion of manipulation is, the lower the attitude toward Coke is. Similarly for Pepsi, the more important to the consumer both attributes of manipulation and storage are, the lower the attitude toward Pepsi will be.

4. Among all the nonlinear components introduced in the stepwise regression, the only significant one is a_3 (cubic). This last term, coupled with the linear trend a_3 , shows that there is a complex negative reaction against the brand Pepsi since the more important this criterion is, the lower the attitude toward Pepsi is.

5. In the case of Coke, the criterion of storage seems to follow a bipolar model. In fact, for both products and for all the attributes, this is the only case for which the decision rule is close to the one suggested by Fishbein (1967).

Discussion

This last empirical approach to the determination of the process of attitude formation is probably more fruitful than the comparison of several possible models which could be premature. A strategy of accumulating empirical results of the kind presented in this paper would provide researchers the raw material upon which to build better models of attitude formation or to more adequately adapt existing models or formalize existing theories. This task would also require a more explicit elicitation of the basic assumptions upon which models are elaborated. A case in point is the assumptions underlying the scaling decision, the multiplicative rule, and the additivity of the products.

Summary

Four methodological problems were identified in the context of multi-attribute attitude models, more precisely the linear compensatory model. Two were related to the scaling decision, i.e., the origin and the range of the different scales used to measure the evaluations and the strengths of beliefs. A procedure was proposed in order to obviate these problems. It was based upon a numerical search with the correlation coefficient as the objective function. Two other problems were related to the relationship among attributes, i.e., the interaction and the halo effects. It was proposed that the application of the method of orthogonal polynomials would be very useful in order to incorporate and analyze all four issues. The empirical results are very promising, and they suggest that a better understanding of attitude formation would be reached if we accumulated such findings. These would provide the building blocks for constructing better models, both in terms of explanation and prediction.

MEASURED ATTRIBUTE WEIGHTS CAN MAKE A DIFFERENCE

Richard A. Werbel,
University of Illinois at Circle Campus

Abstract

This study compares the correlation between stated attitudes and attitudes generated by the linear compensatory model using measured attribute weights to the same correlation using uniform weights. Unlike previous studies, attempts were made to minimize both an implicit weighting effect and a positive correlation between or among beliefs. In addition, a new approach of measuring attribute importance was used to minimize any systematic response bias. The correlations were substantially greater with measured weights than uniform weights.

Introduction

A large number of studies have been conducted which compare a compensatory multi-attribute model with uniform importance weights to one with measured weights.¹ Bass and Wilkie (1973) summarized the results of 15 earlier studies and other studies have been published since this review (for example, Dubois, 1974; Holbrook and Hulbert, 1974; Houston and Gillespie, 1974; Pekelman and Sen, 1974; Wildt and Bruno, 1974; and Mazis, Ahtola, and Klippel, 1975). This author was able to find only one study in which the correlation between stated and generated attitudes was dramatically higher with measured weights (Pekelman and Sen, 1974). Thus, the evidence to date indicates that uniform weights can predict attitudes about as well as measured weights.

Yet, it might be premature to conclude that uniform weights actually are used by consumers in forming attitudes. First, and probably most important, attitudes generated by a uniform weights model may be quite similar to those generated by measured weights, even when there is a large difference between measured and uniform weights. Second, methods used to measure weights may suppress true differences between measured and uniform weights. Both of these conditions are discussed in the following section.

In this study, attempts were made to increase the probability that attitudes generated by uniform weights differed from those generated by measured weights when a large difference between uniform and measured weights existed. In addition, a new procedure for measuring attribute importance was used. It was expected that this method might generate more accurate weights than methods used previously.

It has been argued that there is little reason to be concerned with attribute importance because the "value" component of Fishbein's model incorporates both attribute importance and the degree of deviation from an ideal point (Cohen, Fishbein, and Ahtola, 1972). Although it is likely that attribute importance is incorporated into this component, it seems desirable from a diagnostic standpoint to attempt to isolate all attitude components. For example, it might be relevant to know the distance between the ideal point and a cognitive belief to determine the likelihood of changing the cognitive belief.

Explanations for the Inability Of Measured Weights to Outperform Uniform Weights

If a belief toward a brand on one attribute is reasonably similar in an affective and relative sense to beliefs toward the same brand on other salient attributes, a model with weights substantially different from uniformity will tend to generate the same attitudes as a model with uniform weights (Beckwith and Lehmann, 1973). Although it is difficult to identify the number of studies in which this problem has existed because the correlation usually has not been reported, only Holbrook and Hulbert (1974), and Pekelman and Sen (1974) seem to have in large eliminated it.

Sheth and Talarzyk (1972) argued that there may be a greater spread of beliefs toward various brands on an attribute that is important than on one that is unimportant. In this situation, since attitudes would tend to be consistent with affective beliefs on the attribute or attributes with the greatest spread when uniform weights are used, attitudes generated by uniform weights would tend to be similar to those generated by measured weights. This "implicit weighting" effect has been reported in previous studies (Sheth and Talarzyk, 1972; Beckwith and Lehmann, 1973; Wilkie and Weinrich, 1973; Holbrook and Hulbert, 1974). Perhaps it is most significant that Wilkie and Weinrich discovered an implicit weighting effect because cognitive beliefs were used rather than affective ones and because some of the attributes included were reasonably objective. Based upon these results, the implicit weighting effect might have existed in other studies even though it was not reported.

There is a second explanation for implicit weighting that has not been advanced previously. The use of a number of reasonably specific attributes underlying the basic attribute of quality along with a single price attribute results in greater weight being attached to quality when uniform weights are used. If some consumers combine perceptions on reasonably specific attributes into a single "quality" perception and if quality has greater weight than price, an implicit weighting effect will exist.

Beckwith and Lehmann (1973) indicated that measures of attribute weights might not coincide with true weights. Using regression estimated weights to generate attitudes, they examined the correlation between generated attitudes and the group of stated attitudes which were used to determine the regression weights. Since the difference between the average correlation coefficient using regression estimated weights and that using stated weights was not that large (.095) it can be assumed that stated weights were similar to regression estimated weights and/or the existence of such factors as a positive correlation among beliefs resulted in suppressing the influence of weights upon generated attitudes. Although Beckwith and Lehmann did not indicate the association between regression estimated weights and stated weights, the existence of both a positive correlation among beliefs and an implicit weighting effect indicates that there may have been a reasonably substantial meas-

urement error.

Scott and Wright (1976) and Hughes and Guerrero (1971) compared regression estimated weights with stated weights. In both of these studies, the difference between the two sets of weights was rather large. For example, Hughes and Guerrero found that the computed weight for the performance of automobiles was 57.3 compared with a stated weight of 43.6 using a base of 100. Furthermore, regression estimated weights were more extreme than stated weights in both studies. Thus, there is some evidence that the use of direct questions to measure attribute importance results in a systematic response error which reduces the difference between attitudes generated by uniform weights and those generated by true weights.

Methodology

Undergraduate students in two sections of Principles of Marketing at a large midwestern university were questioned about their attitudes, beliefs, and the importance attached to various evaluative criteria. The product category examined was automobiles. The specific cars included were the 1) Chevrolet Chevette, 2) Ford Pinto, 3) Chevrolet Monza, 4) Ford LTD, and 5) Chevrolet Malibu. Due primarily to one of the methods used to measure attribute importance described later in the paper, an interactive computer program was used for the questioning process.

The two attributes used in the study were quality and price. The selection of quality and price as attributes should be explained, as quality has not been used in any previous studies, and because usually more than two attributes have been included in previous studies.

Before selecting quality and price, the decision was made to only include two attributes. This was done for three reasons. First, the use of two attributes lessens the likelihood of a positive correlation among beliefs existing, as it is difficult to select negatively correlated attributes when more than two attributes are used.² Second, any increase in the number of attributes might reduce the differences in the weights between attributes, particularly when a constant sum approach is used to measure weights. This argument is based on the assumption that it is reasonably unlikely that a weight of zero will be assigned to an attribute by a respondent. Third, for the reason mentioned in the previous section, the use of two attributes lessens the likelihood of an implicit weighting effect.

Once the decision was made to use two attributes, quality and prices were selected because it was expected that they would be negatively correlated. Furthermore, because only two attributes were used, it was important to use a rather broad attribute, such as quality, which would incorporate more specific attributes.

²It was thought that the positive correlation could be minimized by selecting attributes that were likely of being negatively related. An overestimation of the degree of negative correlation would have likely resulted in uncorrelated beliefs, while the attempt to select uncorrelated beliefs might have resulted in positively correlated beliefs. Furthermore, although the use of negatively correlated beliefs tended to result in similar attitudes being generated by two sets of weights when the rank orders of the attribute weights were equivalent, their use tended to result in attitudes generated by uniform weights different than those generated by nonuniform weights.

Prior to answering any questions, respondents were given information dealing with the price, seating capacity, gas mileage, safety upon collision, and seating comfort of each car. A photograph of each car also was presented. This was done to lessen the likelihood of the existence of a positive correlation among beliefs because the low-priced objects were rated "low" on the nonprice information. Furthermore, the presentation of the price information made it possible to use objective price beliefs.

With one exception, an attempt was made to present accurate information. The exception was that all cars were depicted as equal in terms of gas mileage. If the correct information regarding gas mileage had been presented and if respondents had integrated this information into the quality dimension, the positive correlation between beliefs might have increased. The possibility of this information being integrated into a price dimension would have made it difficult to use objective price beliefs. It was thought that a positive correlation might be less likely of existing with objective price beliefs than with normalized or nonnormalized price beliefs.

Respondents were instructed to assume that all the information presented was accurate, including that pertaining to gas mileage. They were also told that they did not have to use this information if they did not feel it was relevant, and that they could use information dealing with attributes not included if they felt it to be relevant.

After the above instructions were presented, respondents were questioned about their attitude toward the act of purchasing five different cars. First, they were asked to rank the objects. Using a four-point scale, they then were asked to indicate the extent that they were less likely to purchase the brand ranked second than the brand ranked first. This question was repeated for the third and second, fourth and third, and fifth and fourth brands. Answers to these questions were used to construct an interval-type attitude scale.

Ten-point scales were used to measure beliefs. This particular scale was selected to lessen the probability of an implicit weighting effect by restricting respondent choice to some extent. At the same time, it was thought that this scale provided sufficient choice to allow the perceived relative differences between objects to be reflected. The scale endpoints were labeled "medium to higher quality," "lower quality," "lower priced" and "medium to higher priced." The term "medium" was used to encourage use of extreme scale values.

In addition to perceived or nonnormalized beliefs, two other types of beliefs were used in the analysis. Normalized beliefs with both price and quality were used along with objective beliefs with price.

Both the reason and method of normalization used in this study differ from previous studies. In this study, normalized beliefs were calculated to equalize the quality spread between the lowest and highest ranked objects with the price spread for each respondent. This was done to lessen the possibility of an implicit weighting effect. Although this type of normalization might alter the perceptions of respondents, its use might be justified when an implicit weighting effect exists because of the differential weighting of attributes. In addition, the sensitivity of generated attitudes to changes in the relative spread of beliefs across attributes could be examined with this type of normalization.

This normalization was accomplished by giving the object that was perceived as highest in quality, (lowest in price), a value of 1 and the object that was perceived

as lowest in quality, (highest in price), a value of 10. The criterion used in altering the beliefs of the other objects was the preservation of the relative differences in nonnormalized beliefs between objects.

Objective beliefs were used with price to lessen the possibility of the existence of a positive correlation between beliefs. Objective price beliefs were determined by converting actual prices into a ten-point scale in which the object with the lowest price was given a value of 1 and the object with the highest price a value of 10. The actual prices presented to respondents were \$2900 for the Chevette, \$3100 for the Pinto, \$3900 for the Monza, \$4700 for the LTD, and \$4900 for the Malibu. Objective price beliefs were 1.0, 1.9, 5.5, 9.1 and 10.0. Another method that might have been used would have involved equating the spread of objective price beliefs with the spread with either nonnormalized quality or price beliefs, while preserving the relative price differences indicated by the actual prices. After examining the initial results, the decision was made to use the procedure indicated primarily because it allowed one to examine the impact that a price spread greater than a quality spread had upon the correlation between stated and generated attitudes with automobiles.

Two measures were used to measure attribute importance. One approach involved asking respondents directly to provide a numeric weight for both quality and price which indicated the relative importance of these two attributes. Respondents also were instructed with this approach that the sum of the weights for quality and price had to be equal to 1.0. With the exception of using a constant-sum scale, this approach is virtually identical to those used in previous studies. A new approach was used to measure attribute importance because, as indicated previously, the above approach may not be valid. This new approach involved asking either question (1) or (2).

- (1) How much less would (Y) have to cost than (X) for you to be just as likely to purchase (Y) as (X)?
- (2) How much more would (X) have to cost than (Y) for you to be just as likely to purchase (X) as (Y)?

X and Y were two of the five brands included in the study. Although the specific brands included could change from respondent to respondent and/or question (2) to question (1), X always was perceived as higher in quality than Y. Respondents were given nine specific prices to choose among in answering these questions. Answers were scaled for further analysis. The lowest price had a scale value equal to 2 and the largest price had a scale value equal to 10. Question (1) or (2) was repeated for each respondent with a different pair of brands. Mean weights were then calculated. These mean weights were used in generating attitudes using "trade-off" weights.

Equations (1) and (2) were used to algebraically determine the weights for quality and price.

$$(B_{qyk} - B_{qyk} + 1) W_{qk} + B_{pxk} W_{pk} =$$

$$(B_{qyk} - B_{qyk} + 1) W_{qk} + B_{pyk} W_{pk} \quad (1)$$

$$W_{qk} + W_{pk} = 1.0 \quad (2)$$

Such that:

W_{qk} = weight of quality (q) for consumer k;

W_{pk} = weight of price (p) for consumer k;

B_{qyk} = consumer k's nonnormalized quality belief toward the higher quality brand included in question (1) or (2);

B_{qyk} = consumer k's nonnormalized quality belief toward the lower quality brand included in question (1) or (2);

B_{pxk} = scale value for price given by consumer k in response to question (1) or (2); and

B_{pyk} = scale value for price of base brand in question (1) or (2). This value was equal to 1.0 for all respondents.

It should be noted that the difference between B_{qyk} and

B_{qyk} influences the possible range of values that W_{qk}

and W_{pk} can assume. For example, if the difference

between B_{qyk} and B_{qyk} is equal to 1, W_{qk} cannot assume

a value less than .5 or greater than .9. This potential

problem was solved by asking questions (3) and (4).

3. If you had to buy either (brand perceived as highest in quality) or (brand perceived as second highest in quality) and (latter brand) costs _____ less than (former brand), which brand would you purchase?
4. If you had to buy either (brand perceived as lowest in quality) or (brand perceived as highest in quality) and (former brand) costs _____ less than (latter brand), which brand would you purchase?

Answers to these two questions were used to determine whether question (1) or (2) would be asked, and to determine the proper difference between X and Y in question (1) or (2) in terms of nonnormalized quality beliefs.

With both questions, the price changed from respondent to respondent as the specific quality difference between the two brands in the questions changed. This was done to establish a consistent range for W_{qk} and W_{pk} .

With question (3), the price was selected to determine whether W_{qk} was greater or less than approximately .67.

With question (4), the price was selected to determine whether W_{qk} was greater or less than approximately .30.

Respondents who selected the higher quality brand in both question (3) and (4) were asked question (1) if a pair of brands existed with which $B_{qyk} - B_{qyk}$ was be-

tween .5 and 2.49. Respondents who selected the lower quality brand in question (3) and the higher quality brand in question (4) were asked question (1) if a pair of brands existed with which $B_{qyk} - B_{qyk}$ was between

2.5 and 5.49. Although these two groups of respondents both were asked question (1), the allowable range of the difference between the quality beliefs of the two brands included in the question was different. This was done because the first group indicated in their answers to question (3) and (4) that the weight for quality was greater than .67, while the second group indicated that the weight for quality was between .30 and .67. Respondents who selected the lower quality brand in both question (3) and (4) were asked question (2) if a pair of brands existed with which $B_{qyk} - B_{qyk}$ was greater

than 5.49. Respondents in all of the above groups were not asked either question (1) or (2) if two brands did not exist with which $B_{qyk} - B_{qyk}$ was in the proper

range. Respondents who selected the higher quality brand in question (3) and the lower quality brand in question (4) were eliminated from the final analysis because this answer pattern indicated that the respondent's weights were quite unstable.

It was thought that this approach, which is termed the "tradeoff approach," might lessen or eliminate the response error with the "direct approach" primarily because the tradeoff approach does not directly ask respondents to evaluate the importance of an attribute. To clarify this reason, it is thought that when making a purchase decision, consumers do not need to think about the importance of an attribute unless a tradeoff exists. If a tradeoff exists, consumers might attempt to resolve the specific tradeoff, rather than directly evaluating the importance of an attribute. For example, if Brand "A" costs 10¢ more than Brand "B" and is perceived as somewhat higher in quality, a consumer will try to determine whether the perceived quality difference in favor of Brand "A" is large enough to compensate for its higher price.

The tradeoff approach was used rather than regression estimated weights primarily because a unique set of weights cannot be calculated using multiple regression when beliefs are positively or negatively correlated. A unique set of weights will exist with the tradeoff approach when beliefs are correlated. In addition, weights can be calculated using only two objects with the tradeoff approach and it is not necessary to use a holdout group of objects for model testing. This last factor is an advantage because of the practical problems involved in using a holdout group of objects (Pekelman and Sen, 1974).

Results of the Analysis

The analysis primarily consisted of using equation (3) to generate attitudes for each object used in the study.

$$A_{jk} = \sum_{i=1}^m W_{ik} |B_{ijk} - I_{ik}| \quad (3)$$

such that:

A_{jk} = consumer k's attitude toward object j,

W_{ik} = importance weight given attribute i by consumer k,

B_{ijk} = consumer k's cognitive belief toward object j on attribute i, and

I_{ik} = consumer k's ideal point on attribute i.³

Four different combinations of beliefs were used: 1) nonnormalized quality and price beliefs; 2) normalized quality and objective price beliefs; 3) nonnormalized quality and objective price beliefs; and 4) normalized quality and price beliefs. With each of these four

³In defining and determining the ideal points for quality and price, the attempt was made to isolate the use of price by consumers to determine quality beliefs through such factors as status or worksmanship, from its use as a primary economic criterion. Thus, the ideal point was defined as the most preferred level of an attribute, all other things being equal. With this definition, the ideal point with both quality and price was equal to 0.

combinations, three sets of weights were used; 1) direct weights; 2) tradeoff weights; and 3) uniform weights. In each of these 12 instances, Pearson product-moment correlation coefficients were calculated for each individual respondent. Mean coefficients were calculated and selective comparisons were made.

Although affective beliefs could have been used rather than cognitive beliefs and ideal points, the use of cognitive beliefs allowed the use of objective price beliefs. Furthermore, it is more consistent to use cognitive beliefs with the method of normalization used than affective beliefs. As mentioned earlier, this method should be used if the difference in the relative spread of beliefs across attributes exists because of the relative importance of the two attributes. This condition is more likely of existing when cognitive beliefs are used.

The decision to use the city block version of the model rather than the Euclidean distance version, or some other distance formulation, was a rather arbitrary one. Only one distance formulation was used because it was thought that the difference between the average correlation of generated and stated attitudes using one version of the model and the same correlation using another version of the model would not be affected by the particular distance formulation used.

88 students completed the questioning process. 19 of the 88 students were eliminated from the analysis because attribute weights could not be determined using the tradeoff approach. More specifically, they were eliminated either because their answers to questions (3) and (4) indicated that they had highly unstable weights, or because they did not meet the criterion used to select the brands to be included in questions (1), (2), (3), or (4). These students had an average Pearson product-moment correlation coefficient with uniform weights quite similar to that for the 69 respondents included in the analysis, but had a coefficient with direct weights about .18 less than that for the 69 respondents.

The means of Pearson product-moment correlation coefficients for the twelve versions of the model are presented in Table 1. In summarizing the correlations,

Table 1

MEAN OF INDIVIDUAL CORRELATIONS BETWEEN STATED AND GENERATED ATTITUDES

Combination of Beliefs Used	Tradeoff Weights	Direct Weights	Uniform Weights
Nonnormalized Quality and Price Beliefs	.6881 ^a	.6648	.3807
Normalized Quality and Objective Price Beliefs	.7017	.6408	.2024
Nonnormalized Quality and Objective Price Beliefs	.6393	.4822	-.1095
Normalized Quality and Price Beliefs	.7080	.7024	.2759

^a N = 69 in all instances

when other factors are held constant the correlations were substantially greater with direct and tradeoff weights than with uniform weights. The differences ranged from .2841, which was the difference between uniform and direct weights using nonnormalized beliefs for both quality and price, to .7488, which was the difference between uniform and tradeoff weights using nonnormalized quality beliefs and objective price beliefs.

The use of various combinations of beliefs to lessen an implicit weighting effect had a rather substantial impact on the difference between uniform and measured weights (i.e., the combination of direct and tradeoff weights). The implicit weighting effect was greatest when nonnormalized beliefs were used with both quality and price. Here the average difference between uniform and measured weights was .2958. The implicit weighting effect was least when nonnormalized quality beliefs and objective price beliefs were used.⁴ Here the difference between uniform and measured weights was .6703. The use of either normalized quality and price beliefs, or normalized quality and objective price beliefs resulted in an implicit weighting effect between the two extremes above. Here the difference between uniform and measured weights was .4491.

In evaluating these differences dealing with the implicit weighting effect, it should be noted that the average difference between the spread with quality and the spread with price was 1.4 when nonnormalized quality and price beliefs were used, and 2.1 when nonnormalized quality and objective price beliefs were used. The Pearson product-moment correlation coefficient between 1) the difference between a) the spread of nonnormalized quality beliefs measured by the difference between the brand rated lowest in quality and the brand rated highest in quality, and b) the spread of nonnormalized price beliefs measured in the same manner, and 2) tradeoff weights was .33.

If all other factors are held constant, the difference in the average correlation between measured and uniform weights was only somewhat larger when tradeoff weights were used than when direct weights were used (.0617). However, the average correlation with tradeoff weights was a good deal greater than the correlation with direct weights when nonnormalized quality beliefs and objective price beliefs were used (.1571). Since the mean difference between direct and tradeoff weights was reasonably large (.158), it appears that the average correlation with the other three versions of the model was not particularly sensitive to the differences between direct and tradeoff weights. In explaining the reasons for the lack of sensitivity, it is again necessary to mention that the vast majority of respondents stated that they were more likely of purchasing the higher quality automobiles. Although the tradeoff weight for quality was greater than the direct weight for quality with 68 percent of the respondents, the direct weight for quality was greater than or equal to .670 percent of the time that tradeoff weights were greater than direct weights. In this situation, direct weights would predict that the higher quality cars would be most likely of being purchased unless the price spread was greater than the quality spread. The price spread was greater only when nonnormalized quality beliefs and objective price beliefs were used.

Finally, since the mean correlation coefficient between

⁴Although the use of normalized beliefs might minimize the implicit weighting effect in some instances, the use of nonnormalized quality beliefs and objective price beliefs minimized it here because the vast majority of respondents seemed to attach greater weight to quality than price.

nonnormalized quality and nonnormalized price beliefs was -.8442, differences in the average correlation between various versions of the model were not suppressed by a positive correlation between beliefs.

Summary And Conclusions

The results of this study indicate that when the correlation between stated and generated attitudes is used as a criterion of validity, it is more appropriate to use measured attribute weights than uniform weights. Although this difference between measured and uniform weights might have been greater than differences in previous studies partly because of situational differences, it is doubtful that these completely explain the differences among studies. The differences also may be due to 1) a reduction in the positive correlation between beliefs 2) a reduction in the implicit weighting effect, and 3) the use of a new approach for measuring attribute importance. Although it is likely that the positive correlation and the implicit weighting effect were substantially greater in many of the previous studies, the results of this study suggest that even moderate differences among studies in terms of the correlation between beliefs and the implicit weighting effect can substantially alter the results.

Although the procedures used to reduce the positive correlation between beliefs and the implicit weighting effect were successful in this study, there are instances in which these procedures should not be used, or in which they will not be successful.

Consumers may perceive a positive correlation between beliefs based upon an objective analysis. Although this author made the attempt to select brands, evaluative criteria, and a product in which this situation would not exist, there may be good reason to investigate attitude formation when the correlation exists. It is recommended that an approach such as examining the extent that an attitude model correctly predicts attitude change be used in this situation (Bettman, Capon and Lutz, 1975).

With respect to an implicit weighting effect, the use of various measures of beliefs to alter the relative spread of beliefs across attributes might not be successful. One approach used was equalizing the spread across attributes. Yet, as mentioned previously this approach might have suppressed the difference in the average correlation between tradeoff and direct weights. The use of nonnormalized quality beliefs and objective price beliefs reduced the implicit weighting effect only because there was a high degree of respondent homogeneity in terms of the relative importance of quality and price.

The issue of whether the difference between measured and uniform weights found in this study is atypical is worthy of discussion as it relates to the external validity of these results. The difference between tradeoff and uniform weights was .236 and .163 between direct and tradeoff weights. Since the majority of the respondents attached more importance to quality than price, these differences might have been reduced substantially if respondents actually had to spend their own money. Yet, price might have become substantially more important than quality in this situation rather than the weights approaching uniformity. In addition, it is possible that respondents may have utilized rather extreme weights to allow them to differentiate clearly among objects. More specifically, since the price differences between objects tended to be similar to the quality differences, the use of uniform weights would have resulted in all objects being virtually equivalent in terms of the probability of purchase. On the other hand, one might argue that there will tend to be a dif-

ference between measured and uniform weights when respondents are allowed to select the brands used for the evaluation after being told that they should select those brands that they actually consider in making a purchase. If respondents make a selection among brands that tend to differ on one or two attributes (e.g., evaluate only subcompact automobiles or steel belted radials), one might expect that the weight of this attribute or attributes would be a good deal higher than the weight of other attributes.

Finally, since the results of this study indicate that there is a possibility that measured weights may be quite superior to uniform weights, it is relevant to ask whether there are any disadvantages in using measured weights rather than uniform weights. Other than eliminating the need to ask a single question or a limited number of questions to ascertain measured weights, which does not seem to be a very significant disadvantage, there appear to be no disadvantages in using measured weights rather than uniform weights.

ASSESSING THE IMPACT OF INCREASED
PRODUCT SAFETY ON CONSUMER UTILITY

Stephen C. Burnett (student), Indiana University

Abstract

One of the costs of product safety regulation may be its effect on consumer utility. The paper presents a pilot application of conjoint analysis as a methodology for measuring the consumer utility impact of proposed safety regulation. Pending government decisions on minimum wet braking standards for bicycles and flame-resistant standards for clothing were selected for the analysis.

Introduction

Since the creation of the U.S. Consumer Product Safety Commission (CPSC) in 1972, there has been an increasing awareness among marketers that growing public and private concern over product safety will have significant implications for marketing programs. This raises questions about the probable effects of product safety regulation and how marketing should respond. Some of the suggestions offered include incorporating safety testing in new product planning (Trombetta and Wilson, 1975), product safety as a competitive strategy (Edwards, 1975; Loudenback and Goebel, 1974), and more stringent labeling and record-keeping procedures (Jensen, Mazze, and Stern, 1973). In addition to assessing the marketing implications of product safety, there has also been an increasing interest in how consumer research can assist in product safety policy decisions (Staelin and Pittle, 1977; Miller and Parasuraman, 1974) and public policy decision-making in general (Day, 1976; Wilkie and Gardner, 1974).

While consumer research in the product safety area has not been overly abundant and its focus has been somewhat fragmented, as would be expected at this early stage, the research issues emanating from the regulatory role of the CPSC are becoming more apparent. For products within its authority, the Commission has several policy alternatives including: (1) mandatory safety regulation, (2) voluntary industry standards, and (3) consumer information/education campaigns (CPSC, 1976a). Although all of these alternatives require some knowledge of consumers' behavior in order to be evaluated for effectiveness, the specific research issues raised by each are quite different.

It has been reported that only 20% of the total incidence of consumer product-related injury and death is addressable by improved product design (Staelin and Pittle, 1977). The remainder is a consequence of consumers carelessly using relatively safe products. Because of this fact, consumer information and education has become a highly attractive policy alternative and one that has begun to benefit from ongoing consumer research. A continuing project reported by Staelin (1977), Staelin and Weinstein (1974), and Thompson (1974), has concentrated primarily on whether information and education can enhance safer consumer behavior in using products. Although the researchers have found that knowledge of safety principles correlates positively with safer product use behavior, the direction of causality between knowledge and behavior remains unresolved.

A second policy alternative available to the Commission is to encourage and assist industry trade associations in the development of voluntary minimum safety standards. Despite their regulatory cost appeal, benefits of voluntary standards are obviously dependent upon the degree

to which they are implemented. Whether improved safety standards will be incorporated in products without government mandate raises the question of safety marketability. The previously cited study by Staelin and Weinstein (1974) attempted to gauge the importance of safety in purchase decisions. Their findings suggest that either because of the demand characteristics or the multidimensional nature of safety, its saliency as a product attribute varies with how its importance is measured. Using open-ended questioning, safety was found not to be an influential decision variable. However, when subjects were asked to rate the importance of safety as one of eight predetermined purchase variables, it took on a more central role in the respondents' purchase decisions. A similar result has been reported by Kuehl and Simon (1973).

Objective

The final CPSC policy alternative and the focus of the present study is to set minimum safety standards and require compliance under the threat of fines and even criminal prosecution. While this action eliminates much of the uncertainty in the actual delivery of safer products to consumers, its evaluation requires an estimation of the costs and benefits expected to accrue to consumers from a Mandatory Safety Regulation (MSR).

Consumer benefits from an MSR may take several forms, but primarily these are reduced probabilities of injury and death. There are numerous components of MSR costs. From a macro-economic perspective, some of these costs are fairly tangible such as additional resources to produce the product and expenditures for monitoring and enforcing the standard. Other cost components such as industry disruptions and increased industry concentration are more difficult to quantify.

Another cost of an MSR may be its net effect on consumer utility. As used here, utility refers simply to the total value a consumer derives from the consumption of a good or service. The concept of utility has its origins in economics, but with the growing popularity of multidimensional scaling techniques, it has more recently been applied to marketing decisions (Green and Wind, 1975; Green and Wind, 1973; Green and Rao, 1971). For a particular MSR, there may be several potential sources of utility impact. One of these is generally a price increase although an increase in price may be only one of many utility tradeoffs a consumer must make in order to obtain the utility of enhanced safety. The proposed MSR for flame-resistant treatment of clothing provides a good illustration.

The CPSC estimates that an MSR requiring all consumer apparel to meet proposed minimum flame-resistant standards would require an average price increase of 25%. In addition, the following garment performance characteristics would be affected: (1) a reduction in the wash and wear properties of some garments, (2) a reduction in the variety of fabrics available and wearer comfort, (3) a decrease in the average life of treated fabrics, and (4) some limitations on styling variations (CPSC, 1976c). Assuming that consumers derive utility from any of these attributes, then this particular MSR may have a utility cost if the increase in utility from having flame-

resistant clothing fails to offset the disutility from decreases in the performance of other product characteristics.

It is useful to note that the question of trading off utility as posed here is not concerned with whether a safety feature or performance standard is an important purchase decision variable in an absolute sense. For example, the degree to which a bicycle has the capacity to stop under wet conditions may have only minimal influence on most bike purchase decisions. Nevertheless, if utility derived from improved braking at least offsets the disutility of the price increment necessary to provide better braking, then there is no net utility cost to the consumer even though color, style, and retail outlet are the major purchase determinants. The objective of the present study was to explore the problems and potential of conjoint analysis as a technique for assessing such net utility costs. Pending CPSC decisions on minimum wet braking standards for bicycles and flame-resistant standards for clothing were selected for the application.

The idea of measuring the utility cost of government regulation is not new. Walker, Sauter, and Ford (1974) provided a conceptual framework, and Walker and Sauter (1974) used Thurstone's Law of Comparative Judgement to interally scale consumer preference for alternative retail credit contracts. The researchers' hypothesis was that regulation reducing consumer credit interest rates may cause retailers to compensate for lower interest charges by requiring higher down payments and monthly installments plus increasing the price of the merchandise. When these strategic "secondary effects" are taken into account, total consumer utility may be decreased by the credit regulation.

In terms of the type of public policy evaluation issue addressed, the present study parallels the works cited above. There are, however, two distinctions: one with respect to the requirements of the policy area, the other with respect to methodology. For consumer credit regulation, utility tradeoffs result from strategic responses of retailers. Because of the uncertainty concerning what these changes would be, Walker and Sauter (1974) had to rely on rough estimates. Given this constraint, their conclusions hold only to the extent that these approximations reflect how retailers would actually respond. For product safety decisions, there fortunately is somewhat less imprecision in determining both the product characteristics that would be affected and by what amounts. Product modifications are conducive to the use of engineering tests and prototypes which provide relatively accurate estimates of performance tradeoffs.

The second difference between the two studies concerns the flexibility of Thurstone scaling versus conjoint measurement. Both scaling models may require identical subject tasks when scaling the average utility for a group of consumers. In fact, Curry and Rogers (1977) recommend using the two methods in tandem when aggregating responses across subjects. If there is an interest in utility at the individual subject level, however, the Thurstone model requires each stimulus or product concept to be presented to a subject a large number of times (Torgerson, 1958). With conjoint measurement the scaling of individual respondents is much easier since the stimuli must be judged only once. Because individual subject comparisons were important to the present study, conjoint measurement was the preferred technique.

Study Design

Since the purpose of the study was exploratory, a convenience sample of 40 undergraduate students was used. This made it necessary to select products with which students are familiar. Ten-speed bicycles and shirts or

blouses were thought to meet this criterion fairly well. Also, a preliminary questionnaire indicated that two-thirds of the subjects owned 10-speed bicycles. As previously noted, the flame-resistant standard now pending before the CPSC would affect a garment's price, durability, and easy-care characteristics (CPSC, 1976c). The only impact of the proposed wet braking standard for bicycles is an estimated price increase of 10% (CPSC, 1976b).

Factor Descriptions and Level Specification

The general procedure in conjoint analysis is to have subjects judge in terms of their preference or some other criterion a series of product descriptions or scenarios. The products systematically differ on several attributes (factors) by specific amounts (levels). With a subject's preference ranks as input, the conjoint measurement algorithm derives interally scaled utility weights (part-worths) for each factor level. With an additive scaling model, such as Kruskal's MONANOVA used in this study, the sum of the part-worths must preserve the original rank orders (Green and Wind, 1973).¹ To determine the degree to which a subject's utility is altered by paying \$150 rather than \$165 for a particular product, one only needs to examine the absolute change in part-worths for the two prices relative to the changes in part-worths of the other factor levels. The greater the relative utility change, the greater the utility attached to the product attribute.

A critical design aspect of conjoint analysis is the specification of the factor levels. The relative utility of a factor is a direct function of its levels. For example, the part-worth of a lower price could be increased dramatically by selecting polar price levels such as \$100 and \$300 as opposed to \$100 and \$120. Thus, when scaling the utility of a proposed safety feature versus the utility of tradeoff attributes, it is crucial that objective criteria exist for selecting the factors and their levels.

For the present study, limited CPSC test reports were available to guide factor level specification. The only quantitative estimates published by the Commission were anticipated price increases for the two safety feature proposals. For this reason, factor levels were set based on data from recent Consumer Reports tests of 10-speed bicycles and men's shirts. Because of this limitation, the relative utilities of the factors reported later in the paper should be interpreted solely as an illustration of the informational value of conjoint analysis. Different factor levels or different ways to operationalize the factors could produce different findings from those obtained here.

Exhibit 1 lists brief descriptions of the bicycle factors and their levels. For both shirts and bicycles, four factors at two levels were used for a 2⁴ full factorial design. Since the wet braking standard causes only a price tradeoff, in theory braking and price factors would have sufficed. However, because prior studies (Kuehl and Simon, 1973; Staelin and Weinstein, 1974) suggest that the topic of safety may be subject to demand characteristics, two additional moot factors were used in conjunction with price and braking. This was done to insure that respondents would be unaware of the study's purpose and to make the task more realistic.

¹MONANOVA is a popular nonmetric model and has been found to be appropriate in a variety of studies. It should be noted that other methods are also suitable for analyzing conjoint data (e.g., see Cattin and Wittink, 1977).

EXHIBIT 1

Bicycle Factor Descriptions and Levels

<u>Form A Factors</u>	<u>Levels</u>
(1) <u>Price</u> --refers to the retail price of the bike rounded to the nearest dollar	\$150 and \$165
(2) <u>Overall Pedaling Ease</u> --refers to the overall reward the rider receives from his or her pedaling efforts	rated Fair and Very Good
(3) <u>Wet Braking Ability</u> --refers to the maximum number of feet required to stop from 15 mph with wet wheels	20 and 50 feet
(4) <u>Frame Quality</u> --refers to whether major frame joints were reinforced and how well fork ends were attached to the frame	rated Fair and Very Good

<u>Form B Factors</u>	<u>Levels</u>
(1) <u>Price</u> --refers to the retail price of the bike rounded to the nearest dollar	\$150 and \$165
(2) <u>Handling Precision</u> --refers to how obedient the bike was and how much rider attention it demanded	rated Fair and Very Good
(3) <u>Wet Braking Ability</u> --refers to the maximum number of feet required to stop from 15 mph with wet wheels	20 and 50 feet
(4) <u>Shifting Ease and Precision</u> --refers to how certain the shifting mechanism was at arriving at the right gear and how much rider attention and effort was required to find the desired gear	rated Fair and Very Good

The hypothesis to be tested was that Form B subjects would attach higher utility to a flame-resistant feature than Form A subjects because of greater knowledge of clothing fire hazards.

This hypothesis and its conceptual underpinnings are far too simplistic to yield substantive conclusions. Knowledge of a product's hazard potential could be manipulated on several dimensions such as the probability of injury to a specific subject or to people in general. Moreover, both the probability of an injury and its severity could influence safety feature preference to different degrees. The strength of the statement could also have implications for utility. The study's mild manipulation of knowledge was included in the design primarily to illustrate the technique's potential for experimentation with safety knowledge. Complete descriptions of the shirt/blouse factors and levels are shown in Exhibit 2.

EXHIBIT 2

Shirt/Blouse Factor Descriptions and Levels

(1) <u>Price</u> --refers to the average retail price of the garment rounded to the nearest dollar	\$12.00 and \$15.00
(2) <u>Durability</u> --refers to the average number of years the garment should last under normal use and suggested laundry procedures	1½ and 2 years
(3) <u>Flame-Resistant Characteristics</u> --refers to whether or not the garment would actually ignite or catch fire when exposed to an open flame	yes and no
(4) <u>Wash and Wear Properties</u> --refers to whether or not the shirt or blouse retained its original shape and did not require ironing after proper washing and tumble-drying	yes and no

The inclusion of moot factors raises the important methodological question of whether different sets of moot factors will alter the relative utilities of the price and braking factors. To address this question, subjects were randomly assigned to one of two groups (labeled Forms A and B). Form A subjects received overall pedaling ease and frame quality as moot factors while Form B subjects were given handling precision and shifting ease. Although any bicycle attributes would have served equally well, all four of the moot factors were characteristics of bicycles tested by Consumer Reports.

Before discussing the subject's task, one other aspect of the factor descriptions should be mentioned. Past research on safety knowledge and safer product use behavior has not explicitly dealt with the effect of safety knowledge on product choice behavior. To explore how conjoint analysis might be helpful in examining a link between a consumer's knowledge of a product's hazards and preference for a safety feature, subjects were also randomly divided into two groups for the shirt/blouse task (again labeled Forms A and B). Both groups were told in the instructions that a garment was rated as flame-resistant if it would not ignite when exposed to an open flame. The Form B instructions, however, contained the following introductory sentence to the flame-resistant definition:

"Because some 28,000 people are burned annually from clothing fires, Consumer Reports tested each garment for flame-resistant characteristics."

Subjects' Task

The task required of the subjects was divided into two sections. They were first asked to rank in terms of their preference all 16 product combinations. To simplify the ranking task, subjects were instructed to sort the products into high and low preference piles, to rank order each pile, and then to finally combine both piles into one strict rank. The subjects' second task was to provide self-explicated factor importance weights. This was accomplished with a constant sum scale. They were asked to divide 100 points among the factors such that the point assignments indicated the relative degree to which each factor and its levels influenced their product preference.

The reason for obtaining self-explicated factor importance weights was to check for convergent validity. Deriving the relative importance of product attributes from rank orders of product scenarios is a distinctly different measurement method from having subjects directly report this importance. The extent to which the two measures correlate should be indicative of convergent validity. The instructions and tasks for bicycles and garments were identical.

Analysis of Results

The initial step of the data analysis was to identify subjects who either could not perform the ranking task or whose decision rules were inappropriate for MONANOVA's additive composition rule. The criteria for identifying and eliminating these subjects from additional analysis were stress values and factor directionality. Stress is the badness-of-fit measure of the scaling model to the original data. Factor directionality refers to whether a subject's utility increases or decreases in the hypothesized manner with changes in a factor's levels. For both products, an increase in price was hypothesized to lower utility while increased utility was expected for the higher levels of all other factors.

Of the total number of rank orders submitted to MONANOVA ($n = 35$ for bikes, $n = 40$ for garments), only three subjects exhibited stress values greater than the .15 cut-off point. Five subjects violated hypothesized directionality. The low percentage of subjects eliminated is evidence that the subjects could perform the task as requested and that the additive composition rule of MONANOVA was adequate. In fact, 82% of the total rank orders had stress values of less than .01.

The means and standard deviations of the MONANOVA and self-explicated factor importance weights are shown in Table 1. The method for obtaining self-explicated weights has been discussed, but the MONANOVA factor importance weights require explanation. Based on a subject's 16 rank orders, the output of the model is eight intervally scaled utility values--one for each factor level. Since these part-worths comprise an interval scale with unique origin and unit for each subject, it is not permissible to compare part-worths across subjects. It is necessary therefore, to convert the part-worths for each subject into four ratio scaled factor importance weights (FIW). These are computed by simply dividing the absolute value of the change in the two part-worths of each factor by the total absolute value of changes in part-worths for all four factors. Factor importance weights may be interpreted as the percentage contribution of a particular factor to a subject's total utility for all factors.² As an illustration, if subject X's FIW for price is 25 compared to 50 for subject Y, then Y may be said to attach twice as much utility to the lower price than X. Also, Y's utility for the lower price is equal to his combined utility for all other factors.

From Table 1, it is apparent that the standard deviations of the MONANOVA factor weights were high relative to the mean values. This is a strong indication that it may be inappropriate to compute an average group scale since subjects tended to have quite different utility functions. Because the sample was demographically homogeneous, the high variance may suggest the existence of utility profile segments resulting perhaps from non-demographic variables. An extension of the study, which would help better understand safety feature utility, would be to form clusters of subjects with similar factor importance weights. These clusters could then be examined for systematic differences in such variables as attitudes toward safety, product experience, and safety knowledge and behavior.

Another interesting finding is evident when the means of the self-explicated weights are contrasted with the MONANOVA weight means. For bicycle Forms A and B separately

and the combined shirts/blouses forms,³ the self-explicated price factor weights were greater than the MONANOVA price weights. Similarly, subjects tended to overestimate the importance of the durability factor for garments compared with the importance of durability as reflected by their preference ranking behavior. It is not completely apparent why price and durability were overestimated. One could perhaps speculate that price and durability are common and rational product attributes which may not influence product preference to the extent that self-report measures would imply. Despite these differences, the product moment correlations for the MONANOVA and self-explicated weights shown in Table 2 were statistically significant ($p < .05$) for all factors. This agreement is evidence of the convergent validity of the two measures.

One last aspect of the individual MONANOVA factor importance weights should be noted. For bicycle Form A and B groups, the utility of improved wet braking more than compensated for the disutility of the 10% price increase when averaged over subjects. Conversely, the utility of the flame-resistant feature was far outweighed by the utility of price, durability, and wash and wear properties. This finding is consistent with the CPSC's opinion that consumers probably would not be willing to forego the benefits of these attributes for a flame-resistant feature (CPSC, 1976c). Again, these findings should be regarded solely as illustrations of the methodology because of the high degree of subjectivity in the factor level specification.

The question of whether different sets of moot factors would affect the relative factor importance weights of price and wet braking was examined by using analysis of variance. The criterion variable was the ratio of the price and wet braking factor weights. Form A or B, bike ownership, and sex were specified as the independent variables. As shown in Table 3, neither main- nor interaction-effects were significant at any commonly used significance level, suggesting that moot factors can be added to make the task more realistic without affecting the stability of the relationship between the factors of interest.

Analysis of variance was also used to test the hypothesis that garment Form B subjects would have greater flame-resistant factor weights from Form A subjects because of more knowledge of clothing fire hazards (Table 4). Sex was included as an independent variable because it was thought the sex of the respondent could interact with the manipulated knowledge. The results show, however, that while the main-effects of knowledge and the interaction-effects of sex and knowledge were not significant, sex as a main-effect was highly significant ($p = .001$). The average flame-resistant factor weight for females was 23 compared with an average weight of 9 for males. An ANOVA run for the wet braking factor weights revealed that sex had no significant effect for that safety feature. These findings seem to suggest that safety utility should be treated on a product and consumer specific basis.

Conclusions

Limitations

For both public policy and marketing strategy decision-making, conjoint analysis has several limitations. Foremost among these is the artificiality of the subjects'

²Another measure of a factor's importance is the percentage of total variance it explains.

³As discussed later, garment Form A and Form B groups did not significantly differ on any of the factor importance weights and were aggregated for the bulk of the analysis.

task. Respondents are not making market place decisions but rather indicating preferences for abstract descriptions of products which differ on a small number of attributes. While this procedure may be preferable to self-report measures of attribute saliency, the question remains whether conjoint analysis conclusions will be manifested in purchase behavior. Such a limitation is not overly troublesome from the standpoint of assessing the utility impact of a proposed safety regulation. It is, however, quite pertinent for the bicycle manufacturer who must estimate the sales response to the 10% price increase which will accompany improved braking performance.

Another limitation of the technique is the possibility that a product attribute may be imputed to possess utility solely as a consequence of its inclusion as a factor. A consumer may have never considered a garment's flame-resistant properties, yet may feel it must somehow be important since the researchers selected it for the task.

The potential for distorted conclusions from inaccurate factor level specification has been repeatedly emphasized. A second source of error which could cause inappropriate conclusions is the reliability of the scaling technique. The time frame of the study prohibited a check of test-retest reliability. However, the finding that garment Form A and B groups displayed no significant differences on any of the factor importance weights is weak evidence of reliability. Before conjoint analysis is used for conclusive research, reliability should receive additional attention.

Extensions

Throughout the report several extensions of this study's very basic application of conjoint measurement have been recommended. In addition, the technique has the potential for assisting policy makers in identifying the utility costs for specific products within a product category. The finding that a student's utility for a shirt or blouse would be substantially reduced by a flame-resistant feature is hardly surprising. But would the same conclusion be reached for pajamas and robes? Or would the utility impact be the same for elderly consumers where the probability of clothing fires are higher? With larger, more heterogeneous samples and multiple products within product categories, conjoint analysis has the capability for answering these questions. Depending on the utility costs, it could be that a clothing flammability standard should not apply to all types of apparel, but instead only to those where consumers are more willing to make the necessary utility tradeoffs.

Product safety regulation has been justified on the basis that consumers are unable to make tradeoffs between the benefits derived from using a product and the hazards this use may entail (Jones, 1973). By combining existing CPSC information with findings from conjoint analysis applications, this question can be empirically tested. From its national information system, the CPSC has product specific estimates of injury probabilities for various socio-economic classes of consumers. The degree to which consumers with different injury probabilities for a given product have concomitant factor importance weights for a safety feature designed to reduce these hazards may be an indication of whether consumers are capable of incorporating safety in their purchase decisions.

TRANSPORTATION ATTITUDES OVER TIME:
A LONGITUDINAL APPROACH¹

Mark I. Alpert and Linda L. Golden
The University of Texas at Austin

Abstract

Research into consumer transportation modal choice attitudes is receiving increased emphasis. This paper compares public modal choice criteria reflected at the peak of the "energy crisis" with those obtained one year later. Despite a relaxing of gasoline lines, no significant changes in ecological variables were noted, and other travel criteria remained constant. Public transportation remains perceptually inferior to private, and resistance to several mass transit subsidy plans may be increasing.

Marketing and Consumer Psychology have recently begun to find application in attempts to model and promote mass transportation usage and public support (Blattberg and Stivers, 1970; Business Week, 1974; Hille and Von Cube, 1963; Hille and Martin, 1967; Mundy, Cravens and Woodruff, 1974; Sheth, 1975). Many of these studies have stressed the need to identify attitudes relevant to modal choice decisions and then tailor a marketing mix toward target markets of potential riders (and, occasionally, toward non-riding supporters of the mass transit system). However, little has been done to test the reliability of the scales that have been used to measure these attitudes toward transportation and its features. Techniques that have been developed elsewhere have been employed in this problem area, thinking that validity and reliability can be generalized across products. This may be true, but it would be useful to know if the attitudes that have been measured are relatively stable over time. Modifying an existing transportation system to build in benefits revealed as important deficiencies at one point in time might take so long that by the time the political and system problems have been negotiated (at great expense—e.g., BART), public attitudes may have changed and anticipated support may not develop. Therefore, we need to know whether the attitudes revealed in one study are still salient when measured again, say, a year later. If so, planning may be more secure. If not, one might extrapolate from longitudinal changes what will be the trends in attitudes and relative importance of modal choice criteria, so that these changes in the "ideal system" may be properly anticipated and programmed.

In the spring of 1974, when most of this study's first year's data were collected, the "energy crisis" was first being widely perceived by the public, with lengthened gasoline station lines, rapidly rising prices for gasoline, and increased rhetoric about the Arab oil embargo, self-sufficiency, and related issues. By the time Spring of 1975 had come, gas lines were a (temporary?) thing of the past, and talk of gasoline rationing was not heard amongst the general public. Accordingly, it seemed appropriate to explore whether the general public in the survey area might still seek the same configuration of transportation features, including the relatively high determinance of energy savings and low pollution per passenger. Comparisons could also be made between the relative desirability of various funding proposals for public transportation, given changes in economic and political circumstances of these two years. Changes in perceived images of private autos, buses, and the differences between the two, could also be monitored to see whether public transit was perceived as "gaining" significantly, due to changes in public attitudes transit improvements, or some combination.

Clearly, studying trends in attitudes and transit priorities over a two year period in one study area does not constitute a sufficient data base for generalizing about long-term trends. However, it was felt that some insight into sensitivities to "the energy crisis," and possible changes in a variety of criteria for modal choice might be gained through examining a community's responses to the same questions one year "after the crisis". To the extent that results can be generalized to the broader United States culture, trends (or stability) in this area might be indicative of broader, transportation-relevant societal trends as well.

Method

Sample and Data Collection

The findings reported in this paper are drawn from questionnaires administered to two separate samples of adults in Austin, Texas, a medium-sized (population about 300,000) southwestern city.

Like most cities built after the automobile, there is a relatively small central city surrounded by generally low density housing and decentralized centers for shopping and major industry. The city has grown very rapidly in the last ten years, and most of this resembles the kind of urban sprawl perhaps exemplified by Los Angeles. However, there remains a central employment-shopping attraction because of the centrally located University of Texas campus (42,000 students), and state capital complex. In addition, there has been a recent surge of downtown renewal and an attempt to establish evening theater and other entertainment.

Similar to other decentralized cities, travel patterns reflect the dominance of the car. According to the city's own surveys over 97% of trips are taken in private automobile. The bus service is marginal in areas of higher usage—lower income to downtown, but service is generally sparse throughout the rest of the city, with routes along major arteries, but relatively infrequent headways especially in off peak times.

During April through June, 1974, 252 usable responses were obtained from adults who were contacted in a stratified by census-tract (quotas proportional to population) area random sample of city households. Interviewers enumerated households within each census tract, with starting points determined by the researchers selecting random blocks within tracts and random corners and walking directions within blocks. Every third household was approached, with provisions for call-backs, staggered interviewing hours, and alternately selected male and female respondents (18 years and over). Due to the length and complexity of the survey instrument, interviewers were essential in insuring cooperation and providing clarifications to questions. To increase the

¹We gratefully acknowledge the support of the Department of Transportation program of University Research, Contract DOT-OS-30093.

speed and candor of responses, respondents filled out their own questionnaires, except in those households where translation to Spanish necessitated a more active role by the bilingual interviewers.

Data were collected in the same manner one year later, except that the sample size was trimmed by about one-third (159 usable responses), and certain sections of the questionnaire (not relevant to this analysis) were modified. While a longitudinal study ideally involves obtaining data from the same persons during two or more different time periods, this approach was varied for this study. We decided to apply similar criteria for sample selection in both years, but not to attempt to interview the same households.² It was felt that persons who were willing to respond a second time to our questionnaire, after having spent 45 minutes doing so a year earlier, were likely to be more positively biased toward public transportation than were those who merely completed the process one time. A lower response rate was also likely, and this would increase survey costs while lowering reliability. Inability to contact people who had moved since the first interview would also bias results, since original respondents were contacted door-to-door, and not from a year-old list. The study, thus, is longitudinal in the sense that similarly selected samples are used to generalize parameters for the survey area in 1974 versus 1975. Given the care that was taken to choose samples representing the community adult population, it is argued that differences between the mean responses for the two survey years would represent community attitude changes over time, provided these differences were significantly greater than those that could be allowed due to random sampling fluctuations. (Some demographic differences between the two samples were observed, but as will be discussed, these had minimal impact on the key comparisons between respondents for the two survey years.)

Overview of Questionnaire and Data Analysis

Part One of the questionnaire first obtained information concerning respondents' traveling frequency for trips to work (or school, if students) and mode usually selected. Next, subjects were asked to assume they were choosing a transportation mode for trips to work or school, and to evaluate 27 modal attributes (e.g., economy, convenience, energy use per passenger...) in two distinct ways. Initially, they were to indicate the relative importance of each attribute on a five-point scale ranging from "no importance" (scored as 1) to "extremely important" (scored as 5). Then, they indicated how much difference they perceived among various transportation modes in terms of each attribute listed. Five-point rating scales were again used, ranging from "no differences" (1) to "extreme differences" (5). Scale positions had been previously found to be approximately equal intervals (Myers and Warner, 1968).

Scales for these importance and difference perceptions were multiplied together for each respective attribute and respondent, to obtain a measure of the "determinance" (Alpert, 1971; Myers and Alpert, 1968) of that attribute. Potential determinance scores for each subject and attribute thus ranged from 1 (no importance, no differences) to 25 (extremely important, extreme differences).

This combining procedure is based on the assumption that the relative weight of a specific attribute in determining whether or not a particular transportation mode is

²Walking directions from starting points were arbitrarily shifted ninety degrees to minimize the chance that the same persons might be contacted two years in a row (none were).

selected is a function of the combined effect of the importance of the attribute to travelers and the amount of perceived variation among alternative modes, in terms of that attribute. For example, avoiding traffic congestion was perceived as important, but it probably lacks determinance because many modes (in the survey area) are perceived as equally free from (or subject to) traffic congestion. Accordingly, perceptions of this attribute of local transportation modes probably do not influence modal choices nearly as much as, say, dependability, which has both importance and perceived variation among modes.

After providing these importance and difference perceptions, respondents next rated a personal car along five-point semantic differentials (e.g., Economical: _____: _____: _____: Expensive) to indicate its suitability for these commuter trips in terms of each of the above 27 attributes. This format was also used to secure ratings of a bus's attributes for the same trip purpose.

Respondents indicated their attitudes toward financing public transportation, as well as transportation's role in city planning, pollution, and so forth. This section also contained a "would you use city mass transit if improved..." question which was used to identify non-users of public transportation who would be likely switchers to an improved system. Comparisons between this segment and the rest of the sample(s) have been reported elsewhere, and provide insight into segmentation strategies for public transportation marketing. Two additional questionnaire sections obtained media and demographic data to assist in this segmentation. In this paper the demographic data are used to compare the two years' samples, to see if demographic differences across samples might influence on the divergence (or lack thereof) of findings for the different survey period.

Results

Table 1 presents a descending ranking of the determinance scores of the 27 characteristics of transportation modes for work/school trips, as rated by the 1974 sample. The "z-values" represent the comparison of the mean determinance rating for each attribute with the mean for all attributes, adjusting for the standard deviation of these ratings, and the number of persons rating each attribute. This is not a strict statistical test, since the true universe mean and sigma are unknown, but it provides a reasonable cut-off for "how high is high." The right-hand column summarizes the results of comparing the perceived images of cars vs. buses for commuter trips, in terms of attributes such as economy, dependability, and the like. (Table 4, below, gives mean scores for each).

One can note that for the ten attributes which were significantly high in determining modal choices, buses were viewed as superior in six and cars in only four. Table 4 provides statistical details and mean image profiles for these comparisons, which were analyzed using analysis-of-variance, with repeated measures (bus vs. car) for each dependent variable (Veldman, 1967). While a more precise quantification of the utility model underlying modal choices is being estimated by currently ongoing conjoint measurement research by the authors, Tables 1 and 3 may be interpreted to show that cars had sufficiently large perceived superiorities along highly determinant attributes (such as convenience and dependability) that more than offset the perceived superiorities (typically smaller in magnitude) of buses in features less determinant of modal choice. Further, since this set of features was drawn from traits generally considered to be positive benefits in transportation modes, one might argue that virtually all of

them are desired, albeit only ten, were seen as exceptionally desirable. Across the set of 27 features, cars were seen as superior in 16, buses in nine, and two features were non-differentiating.

While specific policy recommendations cannot be made without directly analyzing the determinant attributes for potential switchers to public transit (rather than the general public), this longitudinal study sought to compare general community attitudes and criteria for modal choice. Overall changes would be important indicators of general community trends, independent of their importance to various sub-segments of transportation interest. Table 2 shows a remarkable degree of similarity between the profile of determinance scores derived during the two years. Observation of the means for each attribute for both years (averaging the product of importance x perceived differences for each attribute, within each sample), shows almost identical statistics for both years. Attempting to discriminate Year One versus Year Two respondents on the basis of these 27 variables would be futile, since the Wilks Lambda statistic evaluated by the linear discriminant analysis model has an estimated 97 percent probability of being due to chance or sampling fluctuations. In other words, one could not assert that the general profile of criteria for modal choice changed from 1974 to 1975 without taking a 97 percent chance of being incorrect. Furthermore, not one of the attributes was rated as significantly more or less determinant in 1975 than in 1974, even though at the .05 level of significance one would expect between one or two such fluctuations due to chance. Of specific interest is the fact, shown in Tables 2 and 4, that energy usage and pollution remain important criteria (and perceived advantages of public transportation), one year after the temporary peak in the "energy crisis." Freedom

from repairs and parking problems may be gaining, but not significantly so, and these kinds of variations have to be considered due to sample fluctuations. Should any trends develop over a longer time span, changes in determinance of various features may prove relatively favorable or unfavorable to public transportation. At this point, the relative modal choice criteria in this community seem stable and retain the mix of attributes in which public transportation was initially seen as superior in some traits and inferior in others. Next, let us examine whether changes in the relative ability of these modes to provide these features changed during this one year period.

Tables 3 to 6 provide considerable detail regarding relative images of cars versus buses during both years, as well as changes in car image and changes in bus image over time. Examining these data, one would have to conclude much the same things as were said above about criteria for modal choice. Not only were the determinance scores stable, but people's perceptions of the relative ability of buses versus cars in supplying these attributes were essentially stable during this time period. The 1974 mean profiles of car versus bus shown in Table 3 indicates patterns of relative superiority for cars in convenience, privacy, dependability and the like, and relative superiority of buses in avoiding parking problems and repairs, as well as ecological advantages. The 1975 mean profiles of car versus bus shown in Table 4 show that the same basic patterns of pluses and minuses were noted one year later. In general, where there was a low probability of obtaining sample means for car versus bus images due to changes for a particular attribute in 1974 (right-hand column in

²p < .01

Table 3), there was always a low probability of attributing the perceived gap between the two modes as rated in 1975, in terms of the same attribute (right column in Table 4). In other words, where significant differences were found between the two modes' characteristics in one year, these tended to be observed in the next year.

The reason for this is implied by the relative stability

of car and bus perceptions during this time frame. For example, a discriminant analysis of the 1974 versus 1975 perceptions of car attributes for commuting indicated that there was a 67% probability that the differences obtained between profiles of mean scores were due to change. Thus, one could not conclude that car image changed significantly during this time period without taking more than an acceptable risk of being mistaken (the type-I error probability would be far more than the usual .05 level). The profiles of mean scores for car images in 1974 versus 1975 are almost identical. (The mean scores for cars and buses overtime may be deserved in different form in Tables 3 and 4. Due to lack of significant differences and space limitations tabular presentation of the discriminant analyses are not presented here.)

There was even more stability in the perceived image of buses as a commuter mode in this area. The Wilks Lambda statistic for overall discriminability of the 27 attribute ratings for 1974 versus 1975 was again nowhere near statistically significant (alpha=.85). For both the car and bus images, given the lack of overall significance between profiles for the two years, and given no more than three attributes that appeared to change significantly at the .05 level, (with 2.7 expected changes out of 54 comparisons, due to chance), it would be unwise to attempt to attribute any meaning to either of the "perceived changes" for either mode. Perhaps as conditions in the environment change more dramatically, and as more people begin to utilize public transportation, changes in the relative utility of the two major modes might be reflected in their perceived images. During the 1974 to 1975 time frame in this major southwestern city, no significant changes in perceptions can be reliably reported.

The last two tables show the only instance of real variation between the data for the two survey years, although here, again, the practical significance of these differences for transit planning purposes is quite marginal. In Table 5, we note that there were found significant changes, from 1974 to 1975, in mean desirability scores for seven of the ten evaluated financing alternatives for public transportation. All of these shifts were in the direction of lower desirability for various subsidy plans. However, the relative ordering of these alternatives was virtually unchanged from 1974 to 1975, with a Spearman rank correlation coefficient of .976 (significant at beyond the .01 level). Moreover, the frequently proposed subsidy from the "highway trust fund" is still relatively favorably received, provided the subsidy is a relatively minor part of the non-rider burden (one or two cents tax per gallon.) "No-fare" plans for riders continued to lack popular support, only "more so" than before, and attitudes toward electric bill subsidies are the most negatively perceived financing mechanism. The increasing resistance to property and electric bill tax subsidies may be partially due to increased unemployment in the study area (and in the U.S.) from 1974 to 1975, along with a dramatic increase in electric utility bills.

Table 6 suggests that the generally more conservative approach to tax and other subsidies for public transportation might also be partially due to differences in the demographic composition of the second year sample. Compared to the respondents from 1974, the 1975 group was significantly less female (50 percent versus 62 percent), older (mean age about 37 versus 35.7), longer residents in the city (mean about 6 months longer), and less educated (by about one-half year of formal education). Most of this difference is probably due to tighter controls over the representativeness of the sample, since the 1975 group is somewhat more representative of the universe. However, it should be noted that although statistically significant, most of these differences are

slight, and apparently had impact more on the financing attitude profiles than on the modal choice criteria and mode images. To check this, we correlated demographic variables with the other survey questions, with particular attention given to the correlations with age, education, sex and time in the city, as large correlations with these variables might have confounded the changes(or counteracted what would have been changed, where none were reported). The results indicate that little effect can be attributed to demographic

variations between the two samples. The highest correlation between any of these four variables and criteria for modal choice showed that more educated people sought more convenience than did less educated people. Thus, convenience should have become less determinant in 1975, given a less educated sample (and it did drop slightly, but not significantly). However, the shared variation between education and need for convenience was less than 8 percent ($r = .28$), and may have been partially offset by the negative correlation between convenience and time in city ($r = -.136$), and the slightly longer average time in the city for the Year Two group. The vast majority of correlations between demographic variables (where sampling differences were found), modal choice criteria, and modal perceptions were not statistically significant, and where so, involved between 3 percent to 5 percent shared variance between demographic variations and choice criteria. Thus, for practical purposes, one

could take either 1974 or 1975 data as representative of the average resident's criteria in modal choice. (The exception would be that non-response bias affects both groups and probably overstates the receptivity to public transit and its funding, but this effect is probably constant throughout the time period.)

Inspecting the correlations between these four demographics and financing attitudes also showed some slight correlations, although again most were not significant. For example, the correlation between the willingness to pay one or two cents per gallon from the gasoline tax as a public transit subsidy (which both years' data indicate is the preferred subsidy method, if there is going to be one) correlated .038 with sex, .043 with age, -.108 with education, and .147 with time in the city. With such small correlations, little impact on the mean attitude towards this method can be attributed to demographic fluctuations in the samples. However, the less educated and longer-in-city 1975 group might have raised the mean slightly (indicating slightly less favorable attitude than before). Similarly, the

slightly stronger correlations between these demographic variables and attitudes toward substantial use of the highway trust fund versus riders paying the entire cost, shows a slightly greater effect of more conservative demographics in 1975 influencing some of the slight shift in this direction regarding financing alternatives. However, again, the highest demographic correlate is .248, or about 6 percent shared variation between "time in city" and resistance to using the highway trust fund for public transit. The overall attitude toward this mechanism was still neutral to positive, and whatever impact these small correlations with demographic variations might have had on some mean score shifts between 1974 and 1975 was minimal. The relative preferences for financing alternatives were virtually unchanged, and modal choice criteria and perceived mode images were similarly stable.

Conclusions

In spite of fluctuations in the general perceived importances of the inflation, the economy, and "energy crisis" from Spring, 1974 to Spring, 1975 (Opinion Research Corporation, 1974; 1975), there seems to have been little movement in the basic determinant attributes of modal choice. Further, the general image gaps between private versus public transportation modes in this study area remained roughly constant over the interval. Given the rather large disparity between cars versus buses for the average respondent, who has considerable discretion, it is not surprising that significant modal switching did not occur. Our data indicated a modest increase in car-pooling activities and slightly bigger car purchases. Given the current environmental conditions, and perceived benefits of private versus public transportation (especially in dependability, convenience, and flexibility) for this survey area, relatively major changes will be needed either in the perceived attributes of public transportation (or perhaps over time in the relative determinance of attributes in which public transportation is already seen as superior) for any amount of modal switching to occur. At the margins some potential switchers may be converted by treating them as a distinct market segment. The general procedure would involve those persons now using private transportation who indicate a high likelihood that they would switch to an unproved public transportation system. An approach describing a procedure for the identification of potential switches and their determinants of modal choice, plus appropriate promotional strategies aimed through media to which these persons were shown to be differentially exposed, is discussed in Alpert and Davies (1975).

Aside from this relatively small group as likely switchers, the average respondent is still rather far from altering his/her life-style to the extent that conversion to public transportation implies at present. Implementing changes in the attributes shown as determinants of modal choice in both years is more likely to bring about shifts in travel patterns and modal choices. Many of these changes may be expensive, but our data suggest a public willingness for tapping the highway trust fund, particularly if increased utility in public transportation is produced, in terms of attributes sought by the travelers (and to some extent lacking in private transportation).

If further research indicates the same kind of stability in modal choice criteria as was shown here, improvements in the system characteristics will become even more important for generating behavioral changes. If public desires are stable, the system must become more responsive; the data presented here indicate that criteria are not changing in any significant way so far. This simplifies the planning process, although it may also suggest promotional campaigns to alter criteria. At present, the available public transportation system is

not seen as sufficiently competitive to private alternatives. In this study area, the gaps were not closed from 1974 to 1975. Additional research in other areas should be done to check for generality. In addition, it is possible that trends may be observed in further research that can monitor the public's modal choice criteria and their evaluation of alternative modes' abilities to meet them, as both programmed and unplanned changes occur in the relevant transportation system and its environment.

ENERGY CONSERVATION, PRICE INCREASES AND PAYBACK PERIODS*

William H. Cunningham, The University of Texas at Austin
Brondel Joseph, The University of Illinois at Chicago Circle

Abstract

This research examines consumers' responses to price increases in gasoline and electricity as well as their willingness to accept various payback periods for investments in insulation and solar energy equipment. The results indicate that consumers will conserve energy in response to significant price increases in energy although they are not willing to wait extended periods of time to recover investments in energy saving equipment.

Introduction

Examination of consumer response to various incentives designed to encourage energy conservation is just beginning. Preliminary findings in the area are not encouraging. The response given first and foremost by consumers is that the most acceptable energy policies are those which require the least inconvenience, the least personal cost, and the least change in lifestyle (Cunningham and Lopreato, 1977; Doering *et al.*, 1974; Gottlieb and Matre, 1976; Grier, 1976). Bartell (1974) reports greatest public acceptance for behavioral regulation such as the 55 m.p.h. speed limit, a required reduction of 10 percent in electricity use, and reserved freeway lanes for buses and car pools. In addition, several studies are available which deal with the impact of price adjustments on various income sectors of society (Berman and Graubard, 1973; Berman, Hammer, and Tihansky, 1972). The major suggestions emerging from these analyses are, not surprisingly, that high-income groups display a greater ability than low-income groups to reduce electrical consumption, both direct and indirect energy expenditures are regressive in nature, and the ability of low-income groups to reduce their consumption of energy is relatively low.

In summary, not very much is known about consumer reactions to conservation incentives. The objectives of this research are first to examine consumers' reactions to price increases in gasoline and electricity and second to analyze the payback periods that consumers are willing to accept to invest in insulation and solar energy. The data is broken down by income groups because federal legislation has been proposed with energy incentive provisions which impact on family's taxable income. Also most incentive systems are in some way based on price and therefore it seems reasonable to focus the present research on consumers' ability to respond to the price mechanism.

Methodology

The data for the study were collected through a mail questionnaire sent to residents in five communities: Austin and El Paso, Texas; Flagstaff and Prescott, Arizona; and Albuquerque, New Mexico. These cities were selected to represent various types of communities in the Southwest. The subjects were selected from the consumer billing records of the local natural gas company. Every tenth residential consumer on the firm's mailing list was chosen for the sample. Twelve percent of the residential customers serviced by the electric utility in Flagstaff and Prescott are all-electric home customers; three percent of the customers

of the utility servicing Albuquerque are all-electric customers, as are nine percent in Austin, and one percent in El Paso (Federal Power Commission, 1975). While it cannot be assumed that all of the remaining residents supplement their electrical energy with natural gas, it is highly likely in this region of the country that the vast majority use some natural gas and are therefore part of the population sampled.

Ten thousand questionnaires were mailed with an accompanying letter explaining that consumers were being asked to participate in a study sponsored by The University of Texas at Austin and that responses would be reported only in aggregate form. A response rate of nearly 25 percent yielded 2,403 codable returns for analysis.

The subjects were broken down into the following six groups based on their total annual family income: (1) <\$5,000; (2) \$5,000-9,999; (3) \$10,000-14,999; (4) \$15,000-19,999; (5) \$20,000-24,999; (6) >\$25,000. They were asked to state what their reactions in terms of fuel use would be to nine price increases varying from five percent to more than 150 percent in gasoline, and electricity. The response categories which were presented included: (1) "no reduction," (2) "slight reduction," (3) "moderate reduction," (4) "substantial reduction," (5) "maximum possible reduction," and (6) "would no longer use." The data are presented such that a score of 1 equals no reduction, a score of 2 equals a slight reduction, and so forth.

The subjects were also questioned on what would be the maximum amount of time that was acceptable to them to recover various levels of investments in insulation and solar energy equipment through savings in their energy bills. The response categories included: "less than one year," "1-2 years," "3-4 years," "5-6 years," "7-8 years" and "more than 8 years." F-tests were used to determine if significant differences existed between the respondent groups, with respect to their reactions to each price increase and payback periods.

Results

Price Increases in Gasoline

Figure 1 compares the mean responses of the total sample along with the mean responses of each of the six income groups to price increases in gasoline ranging from 5 percent to 150 percent. It is apparent that even a 5 percent increase in the price of gasoline elicits some energy-conserving reactions on the part of all income groups. A 10 percent increase generates a mean response from all consumers of 1.95, just below the "slight reduction in the use of gasoline" category. A 30 percent increase in the price of gasoline elicits a mean response score of 3.01, which is virtually equivalent to "moderate reduction in the use of gasoline." A 50 percent increase elicits an average response of 3.58, which is midway between moderate and substantial reduction. It is important to note that while there is wide variation by income group, the average score for the total sample on a 100 percent price increase is 4.0, which is equivalent to "substantial reduction in the use of gasoline."

Figure 1

Consumers' Responses to Percentage Price Increases in Gasoline

The patterns reflected in Figure 1 are interesting, particularly since they are basically consistent with the data on electricity. In the first place, a 50 percent price increase marks a threshold level in terms of consumer response. Price increases up to 50 percent elicit markedly rising levels of reported conservation. After the 50 percent mark, however, the response levels off, and little further conservation is reported. It is not possible to determine whether this pattern is due to consumers' refusals to cut back on gasoline use past "substantial" reduction, or whether consumers simply find it difficult to believe that price increases up to 150 percent over present levels would occur. Average gasoline prices in the southwest had already risen 30 percent from October 1974 to October 1975 when the survey was taken. Consumers may have viewed the hypothetical increases above 50 percent as unrealistic.

A second pattern involves the low price responsiveness of the lowest and the highest income groups, or conversely, the high responsiveness of the middle-income consumers. This finding is consistent with earlier work (Grier, 1976). The assumption is widespread that low-income groups cannot do much about their energy use and that high-income groups will not. The present findings tend to bear out that assumption.

These consumers whose total family income is below \$5,000 per year are by far the least price responsive. Their conservation efforts tend to level off after the 30 percent price increase in gasoline. The gap between the responses of this group and those of the other groups is substantial. The difference between the mean response score of the lowest income group and the mean score of the sample at the 100 percent hypothetical price increase, for instance, is .91 (4.0-3.09). It is difficult to say why the pattern of response is not linear. That is, why is it that low-income people do not indicate "maximum" reduction in use at 30 percent

price increases instead of responding with only "moderate" reduction? Any explanation here is post hoc, but it may reflect the attitude that "there is nothing more we can do." Low-income people use much less fuel than other groups of consumers, so that a moderate reduction in that use does not signify the same thing as a moderate reduction among more affluent consumers.

Consumers with yearly family incomes above \$25,000 are the least price responsive at the lower levels of increase (5-30%). At the 30 percent level they become more responsive than the low-income group, but it is not until the 100 percent increase that they draw close to the middle-income groups. At all hypothetical price levels, the consumers in the \$15,000-19,999 category show the most reported behavioral change. The differences in response by income group are statistically significant (see Table 1) as well as substantively clear from the graphs. It is apparent that price increases are much more effective incentives for some groups of people than for others, and that the high energy users are not those most affected.

Table 1

Results of Analysis of Variance for Gasoline and Electricity Price Increases

% Price Increase	F-ratio ^a Gasoline	F-ratio ^a Electricity
5%	7.34	6.28
10%	10.49	5.48
20%	11.41	7.01
30%	9.16	6.33
40%	9.74	8.37
50%	11.57	9.35
75%	12.19	9.88
100%	11.60	11.50
150%	10.45	11.41

^aAll F-ratios are significant at the $p < .000$ and all have 5 degrees of freedom.

Price Increases in Electricity

The responses of consumers to price increases in electricity are quite similar to their responses for price increases in gasoline. Figure 2 indicates that the mean response for the total sample for percentage price increases in electricity is practically linear for 5 percent to 50 percent. Consumers are willing to make only the most modest conservation adjustment to a 5 percent price increase. However, they appear increasingly price responsive up to a 50 percent price increase, which elicits a mean response for the entire sample of 3.4, substantially in excess of "modest reduction in the use of electricity." Increases above 50 percent elicit additional conservation, although the behavior curves begin to level off. For the 100 percent to 150 percent price increases, the sample's mean response barely changes.

Analysis of variance significantly differentiates the income groups based on responses to the various price increases (see Table 1). The lowest income group (<\$5,000) is the most responsive to a 5 percent increase in the price of electricity, with a mean score of 1.72. This pattern quickly shifts, however, with additional price increases in the range from 30 percent to 150 percent.

Figure 2

Consumers' Responses to Percentage Price Increases in Electricity

With two exceptions (the 5 percent and 75 percent price increases), the most responsive subjects to price increase were in the \$15,000 to \$19,999 income group. For both 100 percent and 150 percent price increases, the consumers in this group indicated, as a whole, that they would make more than a "substantial reduction in the use of electricity."

The patterns of response to price increases in electricity are similar to those for gasoline. The highest and lowest income groups are the most responsive. Degree of reduction in use is virtually the same for the two fuels.

Payback Periods for Insulation

The subjects were presented with five investment capital alternatives for insulation: \$100, \$200, \$300, \$400, and \$500. As Figure 3 indicates, the mean responses for the entire sample show a linear pattern. For an investment of \$100 the sample as a whole indicated that investment should be recovered in approximately one year. Each \$100 of additional investment means that investors will wait approximately eight additional months for recovery. As a result, for an investment of \$500 the sample, as a whole, responds that investment recovery must be made in approximately four years.

It is interesting to note from Figure 3 that the six income groups are dichotomized in their responses. On one hand there are those consumers in the two lowest income segments (<\$5,000 and \$5,000-\$9,000), who clearly must be able to recover even small amounts of investments in insulation very quickly. As an example, the lowest income segment feels it can wait no longer than approximately six months to recover expenditure of \$100 on home insulation. For an investment of \$500 this group would be willing to wait only a little longer than one and one-half years to recover the investment.

On the other hand, the four wealthiest segments of the population are rather similar in their behavior towards

Figure 3

Maximum Acceptable Time to Recover Investments in Insulation

the insulation. They are willing to accept longer periods of time to recover investments from savings in insulation. As an example, the fourth highest income segment (\$15,000-\$19,000) is consistently willing to wait longer than any other income group to recover the cost of insulation. For an investment of \$100 they feel they need to recover this investment in just under one and one-half years, while an investment of \$500 finds them willing to wait more than four and one-half years to recover their expenditures on insulation. Table 2 indicates that the six income groups are significantly different in terms of their responses.

Table 2

Results of Analysis of Variance for Capital Investments in Insulation and Solar Energy

Investments Alternatives	F-ratio ^a Insulation	F-ratio ^a Solar Energy
\$100.00	13.05	---
\$200.00	15.85	---
\$300.00	19.23	---
\$400.00	18.95	---
\$500.00	20.57	7.32
\$1,000.00	---	13.99
\$3,000.00	---	15.50
\$10,000.00	---	22.23
\$15,000.00	---	23.57

^aAll F-ratios are significant at the p < .000 level and all have 5 degrees of freedom.

Payback Periods for Solar Energy

The subjects were asked what would be the maximum amount of time that they would be willing to wait to recover capital investment through savings in energy bills from solar energy equipment. The required investments were: \$500, \$1,000, \$10,000, and \$15,000.

As Figure 4 indicates, the mean responses to the solar energy investments are curvilinear. For a \$500 investment the subjects are willing to wait slightly more than one and one-half years. In the same manner, for a \$1,000 investment the average acceptable time period is more than two and one-half years. However, as the investment increases in size the consumers are not willing to wait for proportional time period increases to recover their investment. For example, a \$10,000 investment finds the average subject willing to wait only slightly more than four and one-half years. For a \$15,000 investment the average subject is willing to wait only a little longer than five years.

Figure 4

Once again, the lowest two income segments tend to react in the same manner while the highest four income segments also tend to respond to the questions similarly. Although this pattern of responses also occurred in the examination of the insulation data, it is much more pronounced with the solar energy data.

The responses for the two lowest income groups change substantially from \$500 to \$1,000 to \$3,000 investments. As an example, the second highest income group felt it should recover its \$500 investment in solar energy in slightly under one and one-half years while for an investment of \$3,000 they are willing to wait more than two and one-half years. However, for investments from \$3,000 to \$15,000, the lowest two income segments do not vary greatly. The second lowest group is willing to wait only three and one-half years to recover a \$15,000 investment in solar energy.

In contrast with the pattern of the two lowest income segments, the upper-income segments were more willing to accept substantially longer time periods to recover their investments in solar energy equipment. As Figure 4 indicates, there are few differences among the response patterns for the three highest income groups. The third highest income segment's behavior is very similar to the top three, although it is distinguishable in all cases. The highest three income groups are willing to wait more than four and one-half years to recover a \$3,000 investment in solar energy equipment. For an investment of \$15,000, each of the three highest income segments are willing to wait more than five and one-half years. Table 2 indicates that there were significant differences among the income groups' responses to the solar heating and cooling investment questions.

Implications

There are several important implications from the present study. First, conservation of gasoline and electricity can be achieved with price increases. While this finding is not surprising, it is important to know the price levels which are most encouraging of conservation. In each case an increase of 50 percent appears to be the point below which substantially less conservation occurs and above which little additional conservation occurs. It is, however, interesting to note that President Carter's proposed five cent per gallon gasoline tax, which would be imposed in January of each year when the nation's consumption of gasoline exceeds the previous year's target, seems to result in little more than a redistribution of income. The data is quite clear that a five cent price increase per gallon of gasoline will not have a material effect on gasoline consumption.

Second, it is possible to identify different conservation patterns on the part of the six income groups to changes in the price of the gasoline and electricity. Although each income group displayed a curvilinear reaction to the price increases, the \$10,000-\$14,999, \$15,000-\$19,999, and \$20,000-\$24,999 income groups were generally the most willing to conserve energy. As an example, at price increases from 75 percent to 150 percent these groups scored above the average for the entire sample on conservation efforts for both fuels. In contrast, the lowest income segment (<\$5,000) was normally the least willing to conserve; the next least willing to conserve was the wealthiest segment of society. Although it is not possible to know exactly why this pattern takes place, it is reasonable to speculate that the low-income consumers are already conserving energy and are just not in a position to conserve more energy, while the upper-income people are simply not as concerned about the cost of energy as is the sample as a whole.

Third, as was the case for responses to price increases, clear patterns emerge in responses concerning recovery time for costs of energy-saving investments. In this case, however, the two lowest income groups are distinctly split off from the other groups. Low-income consumers do not seem likely to make investments that require long payback periods. The middle and upper-income groups are more willing to wait longer periods of time to recover their investment. However, even for large investments (on solar energy equipment, for example), consumers generally expect a recovery time of less than six years. This seems to indicate that long-term life cycle energy savings from home improvements will not be effective inducements and that more direct approaches must be made to lower initial investments.

Conclusions

The present study has shown that consumers seem to be willing to conserve energy in response to price increases. This may appear to be in conflict with the recent study done by Willenborg and Pitts (1977) which found that the price mechanism was not very effective in reducing consumption of gasoline when prices are increased gradually over time. However, the present study was done after the price increases that Willenborg and Pitts were studying had taken place. In addition, the present study does not imply that the mandated price increases must take place gradually. This research does seem to indicate that the price mechanism will work quite effectively up to a 50% price increase. After this point, if further conservation efforts are required, additional steps such as allocation of fuels will have to be employed.

The study also found that consumers are not willing to wait very long to recover their investments in energy saving equipment. Since the retrofitting of homes will probably not result in payback schedules which are acceptable to most consumers the federal government should consider the use of its tax depreciation, direct tax write off, and income credit powers to stimulate the adoption of energy saving equipment.

AN EXPERIMENTAL EXAMINATION OF DECEPTION IN LABELING:
CONSUMER RESEARCH AND PUBLIC POLICYMAKING

Philip G. Kuehl, University of Maryland
Robert F. Dyer, George Washington University

Abstract

This study expands knowledge about potential sources of marketplace deception in two ways. First, conceptual and methodological insights evolving from research in deceptive advertising are applied to the empirical study of deception in labeling. Second, since existing U.S. Department of Agriculture labeling regulations affecting actual consumer meat products are examined in the study, consumer research input to public policymaking processes are illustrated.

Introduction

The subject of deception in advertising, packaging, and labeling has emerged as a highly visible public policy-related issue among consumer researchers in recent years. Three major factors have contributed to such widespread interest in examining marketplace practices which exhibit the potential to deceive consumers.

First, the so-called consumer movement has focused much of its recent emphasis on encouraging business firms and public sector institutions to implement policies (i.e., the "right to be informed") which strengthen the availability of consumer information in the marketplace. Second, public sector institutions like the Federal Trade Commission (FTC) and Food and Drug Administration (FDA) have pursued policies to reduce deceptive practices in the marketplace. Similarly, agencies like FDA and the U.S. Department of Agriculture (USDA) have funded large-scale consumer research studies to examine a variety of product packaging and labeling policy alternatives (e.g., open-dating provisions; product storage and usage instructions; disclosure of ingredients statements; nutritional labeling; "package inserts" with consumer information; and "safety" caps and injury prevention packaging in poisons, medicines, etc.). Third, many companies have initiated activities in support of consumers' rights to product information in the marketplace by sponsoring innovative consumer education programs. In the Washington, D.C. metropolitan area, for example, Giant Foods, Inc. has embarked on a series of such consumer education activities (under the leadership of Esther Peterson who is now Special Assistant to the President for Consumer Affairs) which focus on improving the consumers' ability to make intelligent purchase decisions.

Objectives

While the preceding factors highlight general concern about alleged deceptive practices in the marketplace, conceptual and empirical studies published by consumer researchers to date have focused primarily on the issue of deception in advertising. As a result, there appears to be a need for research which expands this existing research tradition to include other sources of potential deception. The present study helps to fulfill this need by providing insights on two major objectives.

1. To determine if conceptual and methodological knowledge about deception in advertising is applicable to measuring deception in consumer product labeling

2. To provide consumer research input to public policymaking processes by examining whether or not existing USDA-approved labeling is likely to stimulate falsely based consumer beliefs associated with the attributes of two alternative meat products

Since the conceptual objective of the study relates to over 25 major articles dealing with defining deception in advertising, the following discussion summarizes this body of knowledge and assesses its applicability to measuring deception in labeling. Next, the public policy related objective of the study--which involves actual USDA labeling regulations for "ham" and "turkey-ham" products--is discussed. The study methodology, findings, and conclusions are presented in the remaining three major sections of the paper.

Conceptual and Methodological Framework

The framework for the conceptual and methodological approaches used in this study evolves from published literature on deceptive advertising. This academic research tradition can be classified into three major types of contributions.

Preliminary Methodological and Conceptual Insights

Results from four studies in the literature (Hunt, 1972 and 1973; Dyer and Kuehl, 1974; and Kassarian, Carlson, and Rosin, 1975) provided two basic insights on conceptualizing and measuring deception from a methodological perspective. First, all of these authors recognized that experimental research designs (*vis-a-vis* cross-sectional studies) are the most appropriate methodological framework for investigating deception. In other words, these studies illustrate a need for empirical research in consumer deception to be based upon "cause and effect" research designs--where degrees of alleged deception can be directly related to specific stimuli (i.e., either a product label or an advertisement).

The second methodological insight from these early studies in deceptive advertising concerns the selection of appropriate dependent variables to measure deception. In all of these studies, such broad or "global" variables as consumer attitudes toward the "product brand" or "brand manufacturer" were used. In other words, traditional aggregate consumer response variables were used in these studies. While this measurement approach reflected the "state of the art" at that time, other academicians recognized a need to conceptualize innovative variables for examining deception which are more precise and reliable in nature.

Defining Deception in Conceptual Terms

Conceptual contributions to defining consumer deception encompass two major themes. First, many authors (Aaker, 1974; Armstrong and McLennan, 1973; Cohen, 1969 and 1972; Dillon, 1973; Permut, 1974; Ford, Kuehl and Reksten, 1975; Rosch, 1975) developed typologies for classifying and measuring characteristics of alleged deceptive practices. In essence, these authors have illustrated that the term "deception" is multidimensional in nature and that it is possible to define a variety of different forms of deception (i.e., the "blatant lie,"

the "partial truth," "claim-fact discrepancy," the "false certification," etc.). These discussions suggest that empirical research on deception must recognize the specific type or form of deception represented in the alleged misleading stimuli *vis-a-vis* adopting an aggregate meaning for the term "deception."

Second, several other authors (Jones, 1971; Wilkie and Gardner, 1974; Jacoby and Small, 1975; Brandt and Preston, 1976) developed conceptual frameworks for examining deception within the policymaking processes of public sector institutions like the FTC and FDA. In essence, these authors developed approaches for empirically defining consumer deception in an operational context that is consistent with traditional legal doctrine based approaches.

Brand Beliefs: Concepts and Research

The preceding two dimensions of academic work on defining and measuring consumer deception were valuable in stimulating a growing professional dialogue in the subject area. However, it was not until the contributions of Wilkie and Gardner in 1973 that the "belief" component of the generalized Fishbein attitude model was recognized as an appropriate and precise variable to measure the effects of alleged deceptive practices in the marketplace. In proposing the use of brand attribute "beliefs" *vis-a-vis* overall attitudinal variables to study deception, these two authors suggest that consumer beliefs about specific product attribute claims in specific marketing stimuli should be used to measure deception. Related to this study, a product label may be viewed as stimulating an "incorrect" or "misleading" consumer perception about selected product attributes (e.g., the ingredients of the product) but may not mislead the consumer on other product attributes (e.g., the nutritional value of the product).

The conceptual efforts of Wilkie and Gardner have spawned four research efforts to date (Dyer and Kuehl, 1974; Mazis and Adkinson, 1976; Kuehl and Dyer, 1976; and Kuehl and Dyer, 1977). In each of these studies, classic experimental research designs have been used to measure consumer "beliefs" about specific claims made about the product in a firm's promotional efforts. Further, the relatively consistent results from these studies support the views of Wilkie and Gardner that consumer beliefs--measured within an experimental research design--should be used to assess the impact of alleged deceptive marketing stimuli.

Summary Conclusions

The preceding discussion has highlighted the major conceptual and empirical contributions which consumer research has made to the study of deception in advertising. In relating this work to the present study, the following summary conclusions are appropriate:

1. An experimental research design should be used to study deception--so that consumer response measures can be directly related to specific claims made in product labeling through a "cause and effect" methodology.
2. Consumer "beliefs"--examined on a specific product attribute basis--should be used to measure deception in labeling.
3. The specific type of deception reflected in alleged misleading statements about the product must be identified. In this study, it appears *a priori* that labeling used for "turkey-ham" meat products is a "claim-fact" discrepancy. In other words, consumer perceptions of the "claim" that "turkey-ham" is made from a combination of meat and poultry products are not supported by the

technical "fact" (i.e., this product is made only from turkey meat).

4. The research should be consistent with viable public policymaking alternatives in the agency with jurisdictional responsibility for the alleged deception. In this study, for instance, deception in labeling should be related to potential, (a) pre-market, (b) post-market, and (c) consumer education policy actions at USDA.

Public Policy Framework

The framework for the public policy objective of the study encompasses two classes of issues. From a general perspective, it should be noted that product labeling--as a point-of-sale marketing stimulus--is receiving increased attention among public policymakers at the present time. For instance, FTC recently has instituted hearings on "information disclosure" proposals affecting non-prescription drug product labeling regulations. Similarly, the FDA had undertaken a systematic review of food product labeling policies related to provisions of the Fair Packaging and Labeling Act. As a result, research which examines product labeling as a potential source of consumer deception contributes knowledge in support of this increased policymaking activity.

From the perspective of USDA policymaking, the study extends the work of Miller, Topel, and Rust (1976). Their empirical work, which focused on USDA labeling regulations affecting beef grading, supported the view that there is a need to investigate the meat labeling practices and that USDA should reconsider the "... role it plays as a source of information to food marketers and consumers alike" (Miller, Topel, and Rust, 1976; p. 31).

In relating this viewpoint to the present study, the USDA's promulgation of two regulations affecting the labeling of "ham" and "turkey-ham" meat products provide the specific focus for the experiment. First, USDA policymakers have adopted a dictionary-based definition for the technical term "ham" (i.e., the thigh cut of meat from the hind leg of any animal). Second, USDA has approved the terminology "turkey-ham" for the labeling of a meat product which includes only turkey meat (i.e., no "ham" meat).

The justification for this label wording approval, according to USDA, is based on two major policy arguments. First, since the term "ham," in USDA parlance, refers to a cut of meat (i.e., the thigh portion of the hind leg of any animal) rather than a type of meat (i.e., smoked and cured pork meat), it is technically correct to associate "turkey" and "ham" wording on a product label. Second, while turkeys have only two legs, USDA has decided that the wings of this bird constitute two additional locomotive extremities on the body. As a result, meat taken from the thigh portion of the turkey leg can be labeled with the term "ham."

Although this USDA logic appears unduly naive from a consumer research view, the major issues in USDA policymaking are clarified by the following questions:

1. Do consumers, as a result of their exposure to USDA approved product labeling, exhibit beliefs about specific "turkey-ham" product attributes which are not supported by factual evidence on this product?
2. Do consumers, as a result of their exposure to USDA approved product labeling, exhibit beliefs about specific "turkey-ham" product attributes which are supported by factual evidence on this product?

3. What are consumer perceptions or understanding of the USDA definition of the term "ham"?

Methodology

The Experimental Design

The basic experimental design used in the study is an "after-only control group" approach. This design was chosen for three major reasons. First, this design contains two basic factors needed for classic experimental research (i.e., (1) "control" and "experimental" groups, and (2) random assignment of respondents to the two groups). Second, this design is particularly well-suited for multi-site field interviewing since the administrative and supervisory procedures needed to support this design are not complex (i.e., as a result, potential errors in the implementation of the experiment are reduced). Third, this design is especially appropriate to examine the major policy issues in the study. In other words, "ham" product labeling can be viewed as a "control" variable in the experiment since it is the traditional meat product for which "turkey-ham" is a substitute. Furthermore, if consumers are deceived by the "turkey-ham" label wording (i.e., the experimental variable) it is likely that the effect of such deception most likely will be a decreasing market share for "ham" meat products.

FIGURE 1
The "After-Only with Control Group" Experiment Design

Pre-Experimental Data Collection (Phase 1)	Experimental Data Collection (Phase 2)	Post-Experimental Data Collection (Phase 3)
S_1	$\left\{ \begin{array}{lll} R_H & X_1 & O_1 \\ R_{T-H} & X_2 & O_2 \end{array} \right\}$	S_2

where:

- S_1 = general attitudinal data on food knowledge for products other than "ham" or "turkey-ham,"
- R_H } random assignment of all study subjects at
 R_{T-H} } each site to either the control group (i.e., "ham" package) or the experimental group (i.e., "turkey-ham" package),
- X_1 = "ham" product label
 X_2 = "turkey-ham" product label } exposure
- O_1 } = specific label attribute beliefs for the
 O_2 } "ham" and "turkey-ham" labels, and
- S_2 = sociodemographic data for all study subjects.

Study Procedures

Four interviewing sites (i.e., New York, Chicago, Kansas City, and Los Angeles) were used to implement the study design. At each site, the following procedures were used:

1. Professional interviewers were recruited and trained in the methods and procedures to be used in the study. All of the interviewers were employed by local, independent interviewing services in each city.

2. A nonprobability sample of 100 respondents was selected for the study at each site (N=400). None of the respondents were paid to participate in the study.
3. Each respondent at each site was assigned a number from "1" to "100" and the Phase 1 data (general food knowledge) was collected from all respondents.
4. In Phase 2, odd numbered respondents (i.e., the "ham" product group) examined the ham package and label. The even numbered respondents (i.e., the "turkey-ham" group) followed the same procedure by examining a "turkey-ham" package and label. After examining their respective package and label, a seven-point, seven item attribute scale was used to obtain belief data. The attributes examined in the study included:
 - a. Nutrition Beliefs
 - b. Packaging Safety Beliefs
 - c. Product Content Beliefs: "Pork" Meat Only
 - d. Product Content Beliefs: More Than One Meat
 - e. Product Content Beliefs: Some "Turkey" Meat
 - f. Product Content Beliefs: "Turkey and Ham" Meat
 - g. Product Content Beliefs: Turkey Meat Only
5. Actual product packages and labels were used in the experiment: ITT Gwaltney Ham and Rich's Turkey-Ham.
6. Phase 3 (sociodemographic data) was collected from all respondents.

Data Analysis

Traditional data analyses were conducted on the study data in the following ways:

1. Phase 1 data were: (a) tabulated to provide general insights on respondent food knowledge, and (b) statistically analyzed to ensure that the "turkey-ham" and "ham" groups were equivalent in terms of general food knowledge.
2. Phase 2 data were analyzed by T-Tests which statistically examined whether or not consumer beliefs about "turkey-ham" and "ham" are significantly different as a result of exposure to the two product labels.
3. Phase 3 data were: (a) tabulated to provide a general profile on overall study respondent sociodemographic characteristics, and (b) statistically analyzed to ensure that the "turkey-ham" and "ham" groups were equivalent in terms of sociodemographic characteristics.

Results

Table 1 presents the product attribute beliefs of respondents which were generated through the experimental procedures used in the study. This discussion is followed by findings illustrating the general food knowledge and sociodemographic characteristics of the respondents. The discussion is organized in terms of the major public policy issues presented previously.

TABLE 1
"Ham" Group and "Turkey-Ham" Group Beliefs

Product Attributes	Ham Beliefs (N=200)	Turkey-Ham Group Mean Beliefs (N=200)	T-Test Significance
1. The food product in this package is <u>relatively nutritious</u> for people to eat.	4.72	4.66	.75
2. The package for this food product meets all federal government <u>safety standards</u> for food packaging.	6.16	6.25	.47
3. The food product in this package is made <u>only from "pork"</u> meat.	4.00	1.74	.001
4. The food product in this package contains <u>more than one type of meat</u> .	4.02	4.75	.001
5. The food product in this package <u>contains some "turkey"</u> meat.	1.63	5.24	.001
6. The food product in this package contains <u>both "turkey" and "ham"</u> meat.	1.70	4.31	.001
7. The food product in this package is made <u>only from "turkey"</u> meat.	1.16	3.35	

Consumer Attribute Beliefs Not Supported by Factual Evidence

Attribute: More Than One Type of Meat. After their exposure to the ham label, respondents in the "ham" group tended to believe (\bar{X} -4.02) that the product they examined did not contain more than one type of meat product. On the other hand, respondents who were exposed to the "turkey-ham" product label tended to believe that this product did contain more than one type of meat product (\bar{X} -4.75).

In general, the factually "correct" answer on the seven-point scale for respondents in both the "ham" and "turkey-ham" groups is "1" since, in fact, both of the representative products contain only one type of meat (i.e., "ham" and "turkey" meat respectively). Stated differently, respondents in each group who perceive correctly that the product package and label they have examined has only one meat ingredient should have indicated a low number on the seven-point scale (i.e., a higher number on the seven-point scale would suggest that a consumer is likely to believe that the product has more than one meat product as an ingredient).

In the present data, the statistically significant lower belief scores for the "ham" group respondents--(compared to "turkey-ham" group respondents)--suggest that ham group respondents tended to correctly perceive that the ham product is made only of one meat product. Conversely, the statistically higher mean belief values for turkey-ham group respondents (compared to ham group respondents) suggest that these consumers believe the turkey-ham product is made of more than one meat product. Since ham group respondent beliefs (evolving from their exposure to the ham product label) agree with "fact,"

while turkey-ham group respondent perceptions do not agree with "fact," it appears that consumers are deceived and misled by the "turkey-ham" wording in the label in both package size categories.

In summary, it appears consumers are deceived in their beliefs about the "more than one type of meat" attribute of the turkey-ham product--based on the exposure to the label on the product. Consumers are not deceived in their beliefs about the "more than one type of meat" attribute of the ham product--based on their exposure to the label on the product.

Attribute: Both "Turkey" and "Ham" Meat. As expected, the "ham" group respondents do not believe that the ham product contains both turkey and ham meat since the mean belief value is extremely low (\bar{X} =1.70). On the other hand, the "turkey-ham" respondent group mean value (\bar{X} =4.31)--a significantly higher belief value than the ham group--suggests that respondents believe the turkey-ham product to contain both turkey and ham meat.

This finding suggests that ham group respondents, based on their exposure to a ham product label, correctly perceive that ham does not contain both turkey and ham meat. Conversely, the significantly higher mean belief score from the turkey-ham group respondents suggest that there respondents believe that turkey-ham contains both ham and turkey meat--a perception which does not correspond to the actual ingredient mix of the product. In other words, the "correct" answer for respondents being exposed to both product labels should be "1" on the seven-point scale. This pattern is much more characteristic of "ham" product group respondents than "turkey-ham" group respondents.

In summary, it appears that consumers are deceived and misled by the "turkey-ham" wording on the label in both package size categories. Consumers are deceived in their beliefs about the "turkey and ham" attribute of the turkey-ham product. Consumers are not deceived in the beliefs about the "turkey and ham" attribute of the ham label product.

Attribute: "Turkey" Meat Only. The "ham" group respondents produced an extremely low mean belief score (\bar{X} =1.16) when asked if ". . . the food product in this package is made only from turkey meat." However, the low mean belief value produced by "turkey-ham" group respondents (\bar{X} -3.35)--which is significantly higher than the ham group belief values--suggests that consumers are deceived by their product label for this attribute.

The "correct" answer for the "ham" respondent group is, in fact, a "1" on the seven-point scale since the ham product does not contain any turkey meat. Conversely, the "correct" answer for the "turkey-ham" respondent groups is, in fact, a "7" on the seven-point scale since the turkey-ham product contains only turkey meat. In essence, the very low group beliefs for the ham group show consumers have a correct perception of reality. On the other hand, the higher belief mean for the turkey-ham group should have been much closer to the upper limit (i.e., a "7" on the scale). In other words, "turkey-ham" group respondents do not believe that turkey-ham is made only from turkey meat, when in fact, this is the only ingredient of the product.

In summary, it appears that consumers are deceived and misled by the turkey-ham wording on the label in both package size categories. Consumers are deceived in their beliefs about the "turkey only" attribute of the turkey-ham product--based on their exposure to the label on the product. Consumers are not deceived in their beliefs about the "turkey only" attribute of the ham product--based on their exposure to the label of the product.

Consumer Attribute Beliefs Supported by Factual Evidence

Attribute: Nutrition. Based on their exposure to the package label, "ham" group respondents ($\bar{X}=4.72$) did not have a statistically significant higher belief than the "turkey-ham" group respondents ($\bar{X}=4.66$) that ". . . the food product in this package is relatively nutritious for people to eat."

Since the mean scores representing consumer beliefs (i.e., evolving from the label) about the nutritional value of the products based on exposure to the labeling are correct in terms of technical evidence, it is reasonable to conclude that consumers in both groups were not misled or deceived by the product labels. In other words, both products are, in fact, relatively nutritious to eat and most consumer correctly perceive this fact.

In summary, it appears that consumers are not deceived in their beliefs about the "nutritional" value attribute of the two products--based on their exposure to ham and turkey-ham labels.

Attribute: Federal Government Safety Standards in Packaging. There is no statistically significant difference between beliefs held by ham group ($\bar{X}=6.16$) and turkey-ham group ($\bar{X}=6.25$) respondents on the attribute that ". . . the package for this food product meets all federal government safety standards for food packaging" based on their exposure to the package label.

Consumers in both groups hold equally strong and equivalent beliefs that the packaging technology--which represents federal government standards--results in "safe" (in terms of purity or contamination) products. Further, all belief data is "high" on the seven-point scale which is "correct" in a normative sense. In summary, consumers are not deceived in their beliefs about the "packaging safety" attribute of two products--based on their exposure to ham and turkey-ham labels.

Attribute: "Pork" Meat Only. The mean value ($\bar{X}=4.00$) of consumers exposed to the "ham" label was significantly higher than the mean value ($\bar{X}=1.74$) of the turkey-ham group respondents.

Since the "ham" products are made only from pork meat and respondent belief scores show recognition of this fact (i.e., a relatively "high" belief score) and since turkey-ham products are not made only from pork meat and respondent beliefs are consistent with this fact (i.e., with relatively low belief scores) it is reasonable to conclude that consumers in both groups were not misled or deceived by the product labels. In essence, it appears consumers are not deceived in their beliefs about the "pork meat only" attribute of the two products--based on their exposure to ham and turkey-ham labels.

Attribute: Some "Turkey" Meat. The belief scores of the "turkey-ham" group respondents ($\bar{X}=5.24$) are significantly higher than the belief scores for the "ham" group respondents ($\bar{X}=1.63$) for the attribute that ". . . the food product in this package contains some turkey meat."

The consumer belief data, in terms of the "turkey-ham" and "ham" group scores on the seven-point scale, reflects an acceptable pattern of results in terms of marketplace reality. In other words, respondents who were exposed to the turkey-ham product label tend to believe there is actually turkey meat in the product (i.e., producing a mean belief value in excess of "5" on the seven-point scale). Similarly, respondents who were exposed to the ham product label tend to believe that there is no turkey meat in the product (i.e., producing mean value near "1" on the seven-point scale). These data suggest that consumers are not deceived in their beliefs about the "turkey" meat attribute of the two products--based on their exposure to ham and turkey-ham labels.

General Food Knowledge Data. Less than one percent (.7 percent) of the sample respondents felt that the term "ham" meant a "cut of any animal," while a majority (51.7 percent) felt the term "ham" referred to a "cut of pork meat" and another (28.5 percent) felt this term referred to a "cut of ham meat." Further, only 3.2 percent felt ham referred to the "smoked and cured thigh of any animal," while 11.2 percent said it was a "smoked and cured thigh of swine." These data suggest that the term "ham" refers to pork or ham meat and very few believe this term applies to a "cut from any animal" or the thigh portion of any animal.

For general comparative purposes, it should be noted that 78.6 percent of the respondents correctly associated the term "hot dog" or "frankfurter" with beef and/or pork products. Very few (.5 percent) of the respondents felt these products are made of poultry products. Similarly, 91.9 percent of the respondents correctly perceived that a "chicken hot dog" is made: (a) only of chicken, or (b) some combination of chicken and beef or pork.

Sociodemographic Data of Respondents. The following statements summarize the results from the sociodemographic questions included in the study. It should be noted that post-experimental analysis of these data indicated that there was no statistically significant difference between "ham" group and "turkey-ham" group respondents in terms of any of those characteristics.

1. About one-third of the sample (31.5 percent) were between 25 to 34 years old, while 17.0 percent and 16.0 percent were between 35 to 44 years old and 45 to 54 years respectively. Persons in the under 25 year-old age group (15.5 percent), 55 to 64 year-old group (12.5 percent), and 65 and older (8.0 percent) accounted for smaller segments in the sample.
2. One-half (50.0 percent) of the respondents came from families with annual incomes between \$10,000 and \$19,999. On the other hand, about one-quarter (23.5 percent) of the families in the sample had incomes in excess of \$20,000 per year, while 20.8 percent of the sample families had incomes less than \$10,000 per year.
3. Nearly all of the sample respondents (90.2 percent) were the head of their household (31.0 percent) or their spouse (59.2 percent). Nearly two-thirds (64.0 percent) of the respondents were female.
4. Almost one-half (49.0 percent) of the respondents were from families with 2 to 4 members, while one-quarter (25.0 percent) of the respondents were from two person families. Few of the respondents were from one person (9.7 percent) or 5 or more person families (16.0 percent).
5. Nearly one-half (49.0 percent) of the respondents were high school graduates and 21.2 percent had some college experience. About one-fifth (18.2 percent) held a college or advanced/professional degree.
6. Over one-half (52.0 percent) of the sample were employed--on a full-time (33.5 percent) basis or as part-time (18.8 percent) employees.
7. About three-quarters (73.0 percent) of the respondents were white and 11.0 percent were non-white. Less than one-tenth (6.3 percent) were Spanish-speaking.

Summary and Implications

Data from this study suggest three summary findings. First, consumers incorrectly believe--after examining an actual product package and label--that "turkey-ham" products: (1) contain more than one type of meat, (2) contain both "turkey" and "ham" meat, and (3) do not contain only "turkey" meat. This causal relationship between exposure to the "turkey-ham" wording on the product label and these incorrect consumer beliefs suggest that this label is a source of "claim-fact" discrepancy deception. On the other hand, consumer beliefs about "turkey-ham" nutritional, packaging, pork meat content, and turkey meat content attributes appear to correctly reflect available scientific evidence. Second, consumers who were exposed to "ham" product label wording did not exhibit false beliefs about any of the seven product attributes measured in the study. Third, study data indicate that very few consumers correctly perceive the technical definition of "ham" used by the USDA. The implications of these findings are presented in terms of the two major study objectives.

Conceptual and Methodological Implications

Three major implications related to research in consumer deception are suggested by this study. First, the study results indicate--on a preliminary basis--that selected conceptual and methodological perspectives from the existing research tradition in advertising deception are applicable to the study of potentially deceptive label wording. In other words, falsely held consumer beliefs associated with specific product attributes represented in product label wording were identified by the study methodology.

Second, future research should extend the findings from this study in two ways. First, additional research on potentially deceptive label wording in other consumer product categories should be conducted to provide documentation of the present study results. Second, other forms of marketing stimuli which may represent sources of marketplace deception--sales catalog product and pricing descriptions, point of sale materials, consumer brochures, etc.--should be investigated. In this way, knowledge on the sources and impact of consumer deception will be broadened in a meaningful way.

Third, the present study illustrates that previous laboratory-based approaches to the study of deception can be applied to "real world" products and consumers in a field experiment context. This factor illustrates that increasing degrees of external validity in research on deception can be achieved by consumer researchers. As such, the credibility of consumer research input public policy decision-making on issues involving deception is strengthened. In stating these consumer research implications the authors recognize also that future research must overcome the major limitations of the present study (i.e., non-probability sampling processes were used at four subjectively selected interviewing locations; testing effects related to exposure to products in a single category; "one time" analysis *vis-a-vis* longitudinal analysis, etc.).

Public Policymaking Implications. Findings from this study suggest that USDA should review its policy position of allowing the "turkey-ham" wording on the label of products in this category since consumer beliefs about the ingredient or content attributes of these products are incorrect. Within the framework of existing policy alternatives at USDA, a post-market regulatory strategy--whereby this wording is removed from the label--would seem to be an appropriate remedy. Conversely, USDA labeling policies for "ham" products do not stimulate incorrect attribute beliefs, and as a result, it appears that no regulatory action affecting the wording on these labels is needed.

These two post-market policy implications are supported by two additional long run considerations. First, since many new combination or multi-ingredient meat products are introduced in the marketplace each year, USDA should consider developing a continuing and on-going program of consumer research in product labeling using: (1) experimental methodologies, and (2) belief variables. Such a research program would gather empirical data on product labeling (in all USDA jurisdictional product categories) in support of pre-market regulatory policies at USDA. The objective of such a program would be to reduce the likelihood of consumer deception emanating from product label wording by preventing such labeling from reaching the marketplace.

Second, since consumers appear to relate the term "ham" to pork and/or ham meat products, the USDA should review the appropriateness of its dictionary-based definition within the context existing consumer knowledge and terminology. The alternative policy approach at USDA--which does not seem to be cost-effective based on findings in this study--would involve a large-scale consumer education program designed to promote a consistent relationship between the public policy definition and consumer understanding of the term "ham." In any event--the preceding discussion of post-market, pre-market, and consumer education implications emanating from this study highlight three potential roles consumer research can fulfill in public policymaking processes in agencies like the USDA.

EVALUATION OF FOOD LABELING POLICIES
THROUGH MEASUREMENT OF CONSUMER UTILITY

Roger Best, University of Arizona
Jim McCullough, University of Arizona

ABSTRACT

Food labeling continues to be a controversial topic among consumers, nutritionists, manufacturers, educators, and agencies of the government. The difficulties that have been experienced in past in terms of food labeling awareness, usage, and understanding as well as the consumers right to know more about the composition of food products will effect future food labeling policy decisions. The method of conjoint analysis presented in this paper offers a way of evaluating consumer preferences for existing and alternative labeling policies and method of inferring the degree of satisfaction that would be derived under alternative policies by any given segment of consumers as well as by the market in general.

INTRODUCTION

Underlying public policy decisions concerning food product labeling is the assumption that greater quantities of more detailed information will permit consumers to make improved brand choice decisions (French and Barksdale, 1974). Motivation for better food labeling was outlined at the 1969 White House Conference on Food, Nutrition, and Health, and the United States Food and Drug Administration (FDA) has subsequently required additional label information. Current policy requires one of the following formats for food products.

1. Ingredient and Nutrition Labeling: For products which have been fortified with additional nutrients and/or food products making a nutritional claim.
2. Ingredient Labeling: For all other food products. (Nutrition labeling of these products is voluntary but if disclosed must follow the format prescribed by the FDA).

Under this policy labeling formats have had limited success. Consumer understanding and usage of label information has been disappointing. Nevertheless, there are many who favor even more detailed disclosure of food product composition and nutrition. Existing as well as proposed labeling alternatives are complex requirements which are likely to present difficulties for food manufacturers, technologists, and consumers. The objectives of this study were to: 1) discuss current and proposed food labeling with respect to consumer usage, understanding, and ability to process food labeling information, 2) empirically measure consumer utilities for existing and proposed changes in food labeling, and 3) infer the degree of consumer and overall market satisfaction with alternative food labeling policies.

FOOD LABELING: ALTERNATIVES, USAGE, & DIFFICULTIES

Ingredient labeling found on most food products provides little more than content information. Listings of ingredients in decending order based on quantity is not sufficient for purposes of making an accurate brand choice decision in many instances. For example, individuals on restricted salt diets need to know the amount of salt in a bread product, not simply that there is less salt in the bread than flour, water, and sugar. In response to this type of need, the FDA is considering a

percentage ingredient labeling requirement for most packaged foods and has already proposed percentage ingredient labeling for baby food.

The requirement for percentage ingredient labeling is not a simple change in policy and will require specification of a standard format. If the policy dictates percentage ingredient labeling, the FDA must decide whether the policy should require listing the percentage of only the "characterizing" ingredient or ingredients or the percentage of all ingredients? Or, should the policy require a format listing percentage ingredients down to some cutoff value such as 1% or 2%, after which the other ingredients would be listed in decending order? Whatever the exact format, this requirement must also take into account problems created by this type of labeling in terms of production and quality control as well as from the standpoint of consumer information processing. Percentage ingredient labeling will increase manufacturing costs and these costs will almost certainly be passed on to consumers, adding to already increasing food prices. Imposition of these costs must be reconciled with the increased benefits provided by a percentage ingredient label and the net welfare or satisfaction of all consumers directly affected by such a requirement.

Nutrition labeling has been required for the past three years for those food products to which nutrients have been added or which make a nutritional claim. However, despite the fact that most agree that nutrition labeling was an important step toward presenting consumers with better information for making brand choice decisions (Beloian, 1973; USFDA, 1974b), nutrition labeling has been a controversial policy that has been disappointing in many ways (Daly, 1976).

A number of studies, including some by the FDA have indicated that consumers want nutrition labeling, claim they would use it, but seldom actually use it or understand it correctly in brand choice decisions (Lenahan et. al., 1973; USFDA, 1974a; Daly, 1976; Day, 1976). In an early study Lenahan and his associates found that only 25% of consumers they studied were aware of the nutrition label, 15% understood it, and 10% used it in a purchase decision. An FDA study found that 33% of the consumers they interviewed looked for ingredient labeling and only 5% looked for nutrition labeling. In another earlier study, Asam and Bucklin (1973) reported that the greatest impact of detailed nutrition labeling was in a more favorable perception of product quality. In a more recent review article, Day (1976) has noted that the only apparent effect of nutrition labeling has been to increase consumer confidence in nutritionally labeled food products. The value of nutritional labeling is questioned even further by Peterson's (1976) study of consumer perceptions of nutritional value as a function of nutrition labeling, price, and color of the product in which he found that the color of a bread product was more important than price and nutritional labeling combined in determining consumer perceptions of nutritional value.

Regardless of these findings, the view held by some (Bymers, 1972) is that "the use the consumer makes of nutritional information is peripheral to the main issue of the consumers right to know." Proponents of this view advocate policies leading to increased volume and

detail of food labeling information. This raises a more pragmatic question: Do consumers have the capacity and ability to process this type of information load?

Lambert (1976) evaluated the question of capacity by taking 57 branded food products that could be considered in making up a single days menu. Using linear programming he processed the information such that the selection of brands would meet minimum daily nutritional requirements while minimizing the cost of the purchase. Facing some 54,000 pieces of information it took an IBM Model 370/165 Computer system 7 1/2 minutes of computer time to determine an optimal selection of brands. Since shoppers are faced with even greater purchasing tasks, it seems incomprehensible that the average consumer has capacity to process such large volumes of complex information accurately. With respect to choice accuracy Jacoby and his associates (1974a, 1974b) suggest that providing the consumer with increasing amounts of information may lead to a problem they have termed "information overload." When the consumer becomes overloaded with information his brand selection becomes dysfunctional and the accuracy of his choice is diminished. Considering all of these factors it seems quite possible that policies aimed at increased disclosure of the composition and nutritional value of food products may actually increase the cost of food products and lessen the ability of consumers to make improved brand choice decisions. While the question of choice accuracy under varying types and amounts of food label information has not been resolved, the purpose of this study was to measure and evaluate consumer utility for alternative labeling formats and amounts of information.

METHOD AND ANALYSIS

In this study variations in label format and information load were used to create 15 different bread labels. Bread was selected as a stimulus since it represents a familiar product and one for which the existing labeling format is well standardized. As shown in Table 1 the format of the bread labels was varied in five ways to present labels as ingredients only, ingredient plus nutrition, nutrition only, percentage ingredient plus nutrition, and percentage ingredient labeling. The information load was varied in three ways by constructing

Presenting these labeling stimuli to a consumer and obtaining their rank order preference for these different labels provides the information needed for monotonic analysis of variance, or conjoint analysis of preference data. Given the assumption that consumer utility for alternative formats and amounts of information is an additive function, this analysis of preference data provides part-worth utility functions for each component of an additive utility function. Thus, from a consumer's ranked preference for alternative labels created by variations in format and amount of information, the following utility function can be derived separately for any given consumer:

$$U = U_F + U_L$$

Where:

U = a consumer's overall utility for a given label.

U_F = a consumer's part-worth utility for a given food label format.

U_L = a consumer's part-worth utility for a given amount of labeling information (i.e., information load).

These utilities can be determined individually and used to identify different consumer segments in the market (Assael, 1976) on the basis of similar utility functions. Recognizing the idiosyncratic nature of utility functions representative of different consumer segments can aid a policy makers ability to understand the labeling preferences of any given segment, recognize the diversity of preferences for food labeling represented in the market, and infer the satisfaction or dissatisfaction of any given consumer segment as well as the overall market with alternative food labeling programs.

One-hundred and forty female household shoppers were selected at random from the telephone directory of a city with a population of around 500,000. Although this sampling frame slightly reduces the number of high and low income consumers included in the sample, no attempt was made to compensate for this bias.

Each shopper was interviewed in a 20-minute long in-home interview. During the interview the shopper was presented seven food labels that varied in terms of format and amount of information. The food label shown in

labels which contained either 4, 8, or 12 items of information. In each case two of the items of information were price and net weight. Other items were added to the label in the order they would normally appear on an actual label.

Figure 1 is typical of the food labels presented to shoppers. An overlapping Latin-Square design was used to reduce the number of stimuli that needed to be evaluated by the consumer yet retain enough information about alternative formats and amounts of information such that preferences for these stimuli could be

processed and part-worth utilities derived. Without this procedure it is quite likely that the consumer would be overburdened with this particular type of evaluative task.

The shoppers were asked to evaluate each of the seven bread labels they were presented and then rank the labels in the order they would prefer them as labels they would use in evaluating a brand of bread. After ranking the labels, the participants were instructed to use a Likert-type scale to evaluate each label on the basis of several attitudinal statements which are shown in Table 2. Following this they were asked to evaluate several more general attitudes that were thought to be common

functions for label format and amount of information were aggregated using a cluster analysis program (Diehr, 1974). Discernable clusters were then evaluated in terms of differences in attitude, demographics, or consumptive characteristics that might be unique to consumers with like preferences for bread labeling.

RESULTS AND DISCUSSION

The results of this consumer evaluation task and mathematical derivation of part-worth utilities for alternative food label formats and amounts of information provided three very distinct consumer groups. This is best seen in Figure 2 by graphs of the part-worth utility functions for each of the three consumer groups.

Group I (N = 35) was termed "label avoiders." These 35 consumers provided preferences which were analyzed and converted to part-worth utilities that showed a decreasing utility for more information and a great deal of utility for existing labeling whether it be ingredient or ingredient plus nutrition labeling. The fact that these consumers prefer a bread label with essentially two items of labeling information (shown in Figure 3) led us to infer from their part-worth utility for information load that they may in fact prefer no labeling, just price and net weight. These consumers were heavy users of white sandwich bread and predominantly blue collar families. With respect to other consumers, however, these consumers held attitudes that were more optimistic about how other consumers used food labels as shown in Table 3.

Group II (N = 36) was termed "information seekers."

TABLE 2
ATTITUDES RELATED TO A CONSUMERS PREFERRED FOOD LABEL

ATTITUDE STATEMENT	PERCENT GIVING FAVORABLE RESPONSE IN GROUPS		
	I	II	III
This information is <u>very easy</u> to understand.	76	99	98 ⁽¹⁾
This information would be <u>useless</u> in making a bread purchase decision.	18	21	16
This information <u>fully discloses</u> the quality of this product.	48	45	58
I would <u>not</u> have much faith in this information.	42	33	35
The majority of this information is simply <u>not</u> necessary.	21	12	29
This type of information is <u>needed</u> to determine the real value of a bread product.	76	87	87
The information presented on this label is <u>easy</u> to read.	98	91	99

among bread purchasers (these are shown in Table 3). Finally, the participants were asked several demographic questions relating to the occupation of the major wage earner, family structure, and questions concerning their consumption of bread products.

Ninety-nine usable questionnaires were obtained. There was no evidence that respondents whose results could not be analyzed were different than the 99 consumers examined. Individual preference rankings were analyzed using MONANOVA (Kruskal and Carmone, 1968) and part-worth utility function derived for each of the 99 consumers. Consumers with like or similar part-worth utility

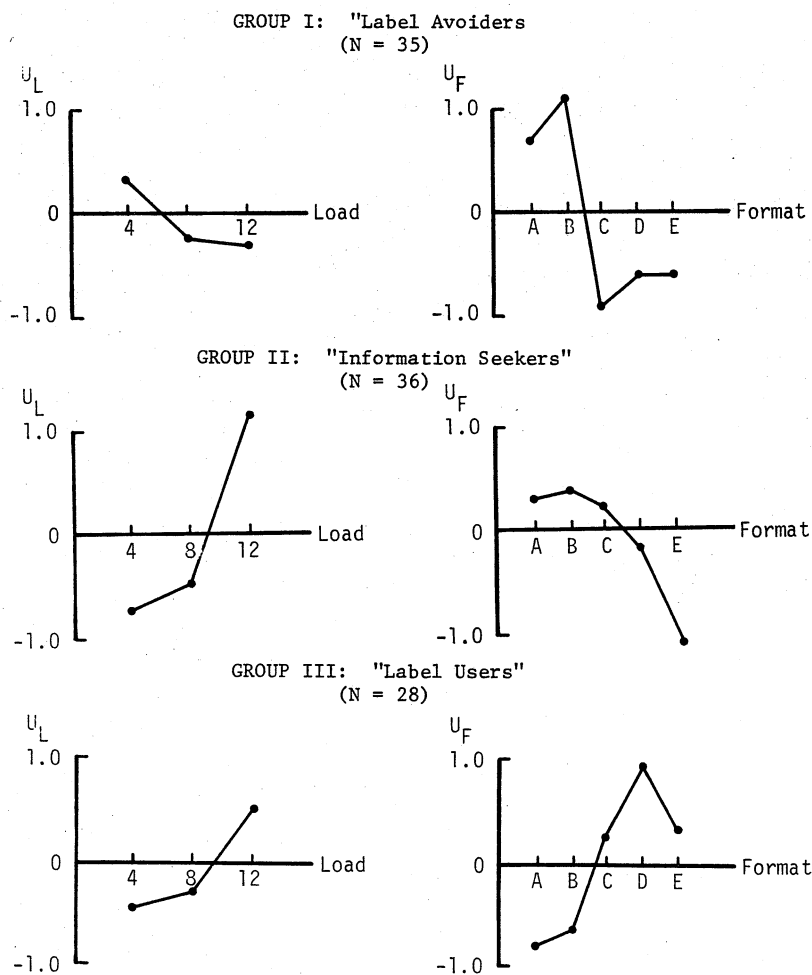

These 36 consumers exhibited a very strong preference for increasing amounts of information. However, they would be most satisfied with the existing format of labeling information as their utility for more detailed information diminished very acutely as shown in Figure 2. Thus, given this overwhelming preference for more information with existing format the food label in Figure 3 for the group termed "information seekers" depicts the label this group preferred the most. This group of consumers were predominantly white collar workers and consumed very little white sandwich bread, but considerably more whole wheat bread, and were more pessimistic about other consumers use of food labels.

Group III (N = 28) was termed "label users." This consumer segment preferred greater amounts of information in greater detail. This would be a group least satisfied with existing labeling requirements and the one most likely to be satisfied with an FDA move to percentage ingredient plus nutrition labeling. Based upon their part-worth utilities for more and detailed labeling information these consumers were termed "label users" and their preferred food label based on what was presented in this study is shown in Figure 3. Members of this group were also predominantly white collar workers, moderate to heavy users of white sandwich bread, and also pessimistic about other shoppers use of food product labeling as shown in Table 3.

The analysis of preference data and its value in identifying discernable differences in consumer utility for alternative food labels could be very useful in evaluating the satisfaction of specific consumer groups as well

as overall market satisfaction under alternative labeling policies. In dealing with the food labeling question, for example, examination of the part-worth utilities for various labeling alternatives among different consumer groups such as those shown in Figure 2 can provide a clear indication of the consumer satisfaction in each of these groups for policy decisions that alter the amount and/or type of labeling information provided to these consumers.

Since it is possible to segment markets on the basis of differing utilities for labeling information, it is then possible to infer the approximate satisfaction or utility each segment of the market would obtain under different food labeling policies. To make this type of inference the following measure of consumer satisfaction can be used to determine labeling satisfaction for any given consumer or consumer segment in the market.

$$CS_i = \frac{U'_F + U'_L}{U_F + U_L}$$

Where:

CS_i = consumer satisfaction of consumers in the i^{th} segment.

U_F, U_L = consumer utility for their preferred food labeling format and information load, respectively.

U'_F, U'_L = consumer utility for existing or proposed food labeling format and information load, respectively.

Market satisfaction can then be inferred by aggregating the satisfaction of each consumer segment with respect to the market share associated with the relative size of each consumer segment as shown below.

$$MS = \sum_{i=1}^N (MS_i) (CS_i)$$

Where:

MS = overall market satisfaction.

MS_i = market share of i^{th} consumer segment; $i=1,2,\dots,N$.

CS_i = consumer satisfaction of consumers in the i^{th} segment.

Utilizing these measures of satisfaction, consumer and market satisfaction with alternative bread labeling programs can be inferred for the consumer groups identified in this study. For any given consumer segment there exists a combination of format and information load that will provide consumers in that segment with maximum satisfaction. When a labeling policy corresponds to a consumer's preferred format and information load, consumer satisfaction will be maximum and indexed as 1.00 using the formula presented above. Labeling programs that are less desirable will result in less consumer satisfaction and a consumer index of satisfaction less than one. In some cases when a labeling program offers a format and information load that are essentially the inverse of the consumer's utility for labeling, the index for consumer satisfaction will take on a negative value. Weighting the consumer satisfaction index of each consumer segment by the relative size of each segment leads to an inference of overall market satisfaction. It also is 1.00 when maximized and can take on negative values under labeling programs that a majority of consumers would find very undesirable.

Utilizing these formulas and the part-worth utility functions shown in Figure 2, the following analysis is provided to illustrate the satisfaction or dissatisfaction of each consumer segment and overall market satisfaction under three different food labeling policies.

Program 1: Ingredient Labeling

A policy of ingredient labeling would correspond to a food labeling program for bread that would provide

ingredient labeling on six ingredients. With the addition of price and net weight this corresponds to an information load of eight items. Consumer satisfaction for each consumer segment and overall market satisfaction under this type of program could be inferred as:

$$CS_I = \frac{.79 - .16}{1.14 + .36} = 0.42$$

$$CS_{II} = \frac{.37 - .48}{.41 + 1.18} = -.07$$

$$CS_{III} = \frac{-.76 - .13}{.91 + .54} = -0.61$$

$$MS = (.354)(.042) + (.364)(-.07) + (.282)(-.61) = -.05$$

Program 2: Ingredient plus Nutrition Labeling

In this study this type of bread labeling policy would correspond to a format of ingredient and nutrition labeling with an information load of 12 items. Consumer and overall market satisfaction under this policy could be inferred as:

$$CS_I = \frac{1.14 - .20}{1.14 + .36} = 0.63$$

$$CS_{II} = \frac{.41 + 1.18}{.41 + 1.18} = 1.00$$

$$CS_{III} = \frac{-.64 + .54}{.91 + .54} = -0.07$$

$$MS = (.354)(.63) + (.364)(1.00) + (.282)(-.07) = .56$$

Program 3: Percentage Ingredient plus Nutrition Labeling

This type of bread labeling policy would require (on the basis of this study) 12 items of information that were in a format of half percentage ingredients and half nutritional information. Under this program consumer and overall market satisfaction could be inferred as:

$$CS_I = \frac{-.53 - .20}{1.14 + .36} = -0.49$$

$$CS_{II} = \frac{.07 + 1.18}{.41 + 1.15} = 0.78$$

$$CS_{III} = \frac{.91 + .54}{.91 + .54} = 1.00$$

$$MS = (.354)(-.49) + (.364)(.78) + (.282)(1.00) = .39$$

Based on these inferences a food labeling policy of ingredient plus nutrition labeling would provide the greatest market satisfaction of the three programs evaluated. For consumers in groups I and II their satisfaction was greatest with this type of labeling policy; group II in fact would have maximized their satisfaction for bread labeling under this type of program.

Ingredient labeling produced the least overall market satisfaction, yet it is a permissible food labeling alternative for food products not containing nutrients or making a nutritional claim. Except for consumers in group I all other consumers would be considerably dissatisfied with this type of bread labeling policy.

Program 3, a policy of percentage ingredient plus nutrition labeling would achieve a moderate overall market satisfaction while maximizing the utility for consumers in group III. However, overall market satisfaction with this type of bread labeling policy is hindered by consumers in group I who prefer less information in a simpler format. If the consumers in group I actually prefer no labeling other than price and weight, or are simply indifferent toward labeling format, then the consumer satisfaction inferred from group I is misleading and should be discounted on the basis of no interest in bread labels. If this were the case, then program 3

would provide the greatest satisfaction for bread labeling among consumers represented in this study. On the other hand, if consumers in group I prefer less information in a simpler format because they do not use it but realize that a greater quantity of more detailed information will lead to higher bread prices, then their utilities for simpler bread labels, and subsequent satisfaction under alternative programs can not be ignored in evaluating overall market satisfaction under these programs.

CONCLUSIONS

This study examined consumer responses to variations in bread labeling format and information load using consumer preferences for alternative bread labels and analysis of these preferences using the method of conjoint analysis. Application of partial preference analysis to identify differences in consumer responses offers a useful method for assessing the impact of policy decisions on the consumer and market in general. Analyzing the cost of policy decisions can be made with relative ease in monetary terms, but assessment of its impact on the consumer satisfaction can be considerably more difficult. The methodology presented in this paper offers some benefit to those needing to analyze the latter effect of alternative policy decisions.

This type of analysis is particularly useful as a segmentation tool that differentiates the market on the basis of utility. With respect to food labeling this procedure allows researchers and policy makers to evaluate existing and alternative labeling programs with regard to the idiosyncratic preferences of different consumer segments, recognize the diversity of these preferences, and infer the likely satisfaction of dissatisfaction of any given consumer segment and overall market under any specific food labeling policy. In some instances it may be possible to specify different labeling requirements based upon differences in product usage in different consumer segments of the market. Though this type of marketing program would contribute to greater consumer and market satisfaction, it is probably not feasible in most situations.

In this study we have demonstrated how preference data could be analyzed using the method of conjoint analysis and used as a tool for evaluating alternative food labeling programs. Though the results in many ways concur with previous studies, additional research is planned to validate the results reported here. In the next two stages of our research we plan to sequentially: 1) evaluate in a choice situation the choice consistency between a consumers labeling preference and the brand of bread selected when only the labeling format is varied, and 2) evaluate the degree to which a consumer with differing bread labeling preferences will pay for additional costs of information. Beyond this additional research needs to focus on the relationship between consumption and preference as well as the understanding and use of labeling on more complex products such as over-the-counter drugs, ointments, and remedies.

Food labeling will continue to be a controversial topic among consumers, nutritionists, manufacturers, educators, and agencies of the government. The difficulties that have been experienced in past in terms of food labeling awareness, usage, and understanding as well as the consumers right to know more about food products will effect future food labeling policy decisions. The method of conjoint analysis presented in this paper offers a way of evaluating consumer preferences for labeling under existing and alternative policies and a method for inferring the degree of satisfaction that would be derived under policy alternatives by any given segment of consumers as well as by the overall market in general.

CONSUMER PROCESSING AND USE OF SUPPLEMENTARY DRUG LABEL INFORMATION

F. Robert Dwyer, University of Arizona

Abstract

Right to know arguments, comprehension effects on compliance and shortcomings of verbal communications from medical staff have fostered increased interest in written patient-oriented information on drugs. This paper presents an experimental approach for the evaluation of cognitive and behavioral impacts of alternative communication designs.

Introduction

The extent of patient non-compliance with prescription drug therapy has been measured at rates ranging from 4 to 90%, with the average near 35 to 45% (Boyd *et al*, 1974). The consequences of patient overdoses, omissions, and improper mixing include deprived therapeutic benefits and distorted evaluation of therapy in addition to economic wastage.

Studies of the causes of patient non-compliance have identified several patient and treatment factors--perceived seriousness of the illness, side effects from the medication, confidence in the physician. Blackwell (1973) has reviewed the literature on compliance and concludes, however, that beyond patient and treatment factors

The most important contribution to compliance is the understanding a patient has of the illness, the need for treatment and the likely consequences of both. (p. 252)

Moreover, this point of view has been supported by recent research (Clinite and Kabat, 1976; Cole and Emmanuel, 1971; and Madden, 1973). The issue is not so clear-cut, though, as Malahy (1966) and Sackett *et al* (1975) failed to find compliance effects from increased comprehension of treatment and illness.

Nevertheless, educating patients about their prescription drugs is becoming an important component in health care. Fueled by this trend has been a growing interest in the subject of patient package inserts (PPI's)--written patient-oriented information on drugs. Recently a measure (HR 14289) was introduced before the House that would require PPI's be distributed with all prescription drugs. Another, S-1282, requiring PPI's for drugs undergoing the final phases of clinical evaluation was proposed by Kennedy in the Senate. Not unexpectedly, a good deal of political controversy accompanying the PPI interest hinges on the patient's right to know about his or her condition and treatment, versus the physician's responsibility to create a favorable clinical milieu, which is sometimes assumed to require the withholding of information on medication side effects and interactions.

Beyond the "right-to-know" stance, additional arguments advanced by PPI proponents include the shortcomings of the physician's verbal counseling of the patient: (1) verbal counseling is often forgotten, (2) the physician may be too busy to counsel, and (3) the patient's perception of his or her doctor's time-pressure may discourage patient questioning. Verbal counseling by the pharmacist has similar problems. In addition, the prescription may be dispensed to a third party (a person sent to the pharmacy by the patient), and the pharmacist who

prepares the prescription may not be the person who physically distributes the medication.

PPI opponents counter with arguments that inserts will lead to dangerous attempts of patients to self medicate. Also, the provision of cautions and enumeration of even rare side effects may foster undue anxieties in patients. Obviously, cost and distribution problems are also raised.

Fortunately, at a recent symposium in Washington, D.C., PPI proponents and opponents recognized the inadequacies of current research and agreed on the importance of addressing the following key questions:

1. What ought patients to know about the medicines prescribed for them?
2. What effect will such information have on patients and on the practice of medicine?
3. How can the information be best communicated?
4. What is the best delivery method? (Schmidt, 1976)

The purpose of this article is to address the above questions by highlighting significant findings and shortcomings of previous research in the area. Moreover, the literature review leads to a set of hypotheses that were tested in a factorial field experiment run on consumers of anti-hypertensive diuretics.

Previous Research and Experience

Several studies have examined the question of what information should be provided to patients. Smith (1975) and Hussar (1975) recommend patients be informed of the (1) purpose of the medication, (2) proper times and methods of administration, and (3) special precautions to be observed while taking the medication. Joubert and Lasagna (1975) assessed the information needs of consumers via telephone survey and found the name of the drug, its purpose, and adverse effects and cautions in normal use desired by 97, 93, and 89%, respectively. Similar percentages were obtained in a Food and Drug Administration survey of oral contraceptive users (FDA, 1975).

A recent study by Katz and Rose (1976) suggests that a reliance on survey data for assessing consumer information needs can be misleading. A majority of their respondents wanted additional information on light bulbs that, in fact, had been heretofore provided for several years. In proper perspective, it seems that asking consumers if they would like to know more about the drugs they take may be equivalent to asking them if steps should be taken to lower property taxes.

The research on the effect of amount of information on decision making may have PPI significance. As a source of health education information, PPI's should help consumers make several kinds of decisions--the decision to initiate, alter, or discontinue drug therapy or contact with the medical staff, and the "implicit" decision a patient makes every time he or she remembers or forgets to take a prescribed drug (Morris, 1977).

In simulated war games and lesser developed country economy management games, Suedfeld and Streufert (1966)

and Schroder, Driver, and Streufert (1967) consistently discovered an inverted U-shaped relationship between optimal decision making and amount of input information. Recently Jacoby and associates (1974; 1974b) have found evidence of possible overload effects in a simulated purchase situation. Although several scholars have challenged their interpretations (Summers, 1974; Wilkie, 1974a), and the external validity of the brand X attribute matrix is suspect, the overload phenomenon is nevertheless intriguing.

Indeed, the PPI concept is just one significant dimension of the accelerating interest in consumer information disclosure in a number of product categories (Wilkie, 1974b; Day, 1976). Therefore, a good deal may be learned by examining previous experiences in disclosure measures.

Field experience in non-drug information disclosure has shown little evidence of overload ("confused, dysfunctional") behavior, rather, minimal to nonuse of the policy-provided information. The interpretation of these results has primarily occupied two dimensions: (1) the compatibility of the newly disclosed information with the abilities of consumers to process (attend, comprehend, believe, and retain) this information, and to a lesser extent, consumer motivation to use the information. A brief examination of the performance of recent disclosure laws will serve to highlight these points.

The results of unit pricing experiences have shown consumer awareness to vary between 50 and 82% (Monroe and LaPlaca, 1972; Carman, 1972-73). While 5 to 38% claimed they had used the information to switch package sizes or change brands, warehouse movements reflected no such shifts. Houston (1972) bypassed the possibility that price is often a nondeterminant factor by instructing his subjects to shop for the most economical brand and size. Here, when consumers were motivated to shop "economically" unit price savings were achieved.

Before leaving the topic of unit pricing, it is worthwhile to note that a portion of the variance in consumer-reported familiarity and use of unit price information can be explained by the differences in the manner in which the information was presented. Formats have included shelf tags, computer print-outs, and display signs. Following several laboratory studies of decision making, Russo *et al* (1975) hypothesized that a single list of all brand/sizes and their unit prices is an effective presentation of unit price information. In a five-week sales test on three products there was a significant shift in sales from higher to lower priced brands within each brand subgroup (local/national).

In another area, Day (1976) argues that truth-in-lending (TIL) requirements suffer from design problems. While finding just 10% of credit buyers of durables claiming use of the TIL information, he suggests the buyer does not get the correct information when it is needed, prior to the point of decision, but after the effective oral agreement has been concluded.

Finally, an experiment by Asam and Bucklin (1973) is of considerable significance because it not only shows that attention varies by format but that consumers make product inferences that vary with the amount of detail or preciseness of (nutritional) information.

While these brief reviews of non-drug disclosure laws have served well to illustrate the importance of presenting the "right" information, in the "right" format, at the "right" level of detail, at the "right" time, perhaps even greater insights can be gleaned from the lone PPI evaluation.

Since 1970 the FDA has required that basic warnings and instructions be distributed with birth control pills. In addition, two brochures, one prepared by the American

Medical Association and the other by drug manufacturers, providing a fuller discussion of risks and benefits were distributed by the physician upon the patient's request. In 1975 the FDA contracted for a nationwide survey of former and current oral contraceptive (OC) users to collect information about distribution, readership, comprehension and reported behavioral changes induced by the inserts.

The results of this study (FDA, 1975) have been recently summarized by Morris *et al* (1977). The survey disclosed that 93% reported receipt of the PPI and 94% of those read it. Only 54% knew that OC's could cause blood clots, in spite of the fact that the inserts stated that blood clots were the most serious side effect of the pill. Also, only one-third of the OC users who reported having never received an insert were "concerned" about not getting one. The non-readers most frequently said they "always ask (their) doctor such questions."

The AMA and manufacturers' brochures were reported less widely distributed. Yet, among those who received the brochure, an equally high (95%) level of readership was reported. Interestingly, more women retained the often more detailed manufacturer-prepared brochure (50%) than the AMA brochure (16%). Only 11% report consulting either PPI or brochure on occasions subsequent to the initial prescription receipt. The brochure and insert were consulted upon instances of side effects, missed pills, or when the physician was unavailable.

Twelve percent of the current users who had read the insert reported that it had raised questions that caused them to contact their physicians. About one in seven insert readers report the insert causing either increased or decreased visits or calls to the doctor. Two-thirds of these decreased physician contacts. Among the brochure readers about the same proportion report physician contact changes. In four-fifths of the cases here, however, the action was toward reduced physician contact.

At least two policy implications from this research have been identified by the FDA. First, since patients tended to physically retain the more detailed brochures, it has been proposed that the brochure be expanded to include more detailed information related to pill use. Secondly, since the insert had nearly three times the distribution level of the physician-distributed brochure, the FDA has proposed the pharmacist directly distribute the pills and insert.

While the oral contraceptive insert/brochure experience has provided a great number of insights for the development of a full-scale PPI program, . . .

OC users are not typical of the general patient population and survey research cannot answer all critical questions. Studies of patients undergoing treatment for disease are also needed to help determine the best methods of communicating important patient information (Morris *et al*, 1977, p. 25).

Hence, Morris *et al* complete the rationale for the study described below.

Methodology

An input-output approach was employed on newly diagnosed hypertensive patients in a 3² factorial design, in a clinical setting, to determine what presentation format and what level of detail in the information contained in the insert were optimal in terms of:

1. Enhancing compliance and clinical outcome
2. Facilitating patient "processing" of the information

3. Fostering optimal levels of anxiety

Specifically, the design was employed to test the following set of hypotheses:

1. Form of presentation and level of detail of PPI information have no effect on patient compliance and clinical outcome.
2. Form of presentation and level of detail of PPI information have no effect on patient perceived experiences with side effects.
3. Form of presentation and level of detail of PPI information have no effect on patient treatment-related anxiety.
4. Form of presentation and level of detail of PPI information have no effect on patient information processing (attention, yielding, comprehension) of drug information.
5. Form of presentation and level of detail of PPI information have no effect on patient physical retention of the insert.
6. The coefficients of the likely covariates of compliance, experience with side effects, information processing, and physical retention of the PPI are all zero. These covariates include:
 - a. Attitude toward physician
 - b. Concern for health
 - c. Perceived seriousness of condition
 - d. Sex
 - e. Education, occupation, etc.
 - f. Health Locus of Control score

Treatments

Russo and company's (1975) unit pricing experiment proves the importance of the form of presentation in consumer information disclosure programs. Also, by following Bettman's (1975) line of thought in information environment design, it should be kept in mind that consumption of medication over time means possible adverse reactions or complications over time, requiring recollection of information from the medical staff or PPI. Unless the patient tape records conversations with medical personnel, the feature of external information storage is unique to the PPI. It seems desirable, then, to attempt to develop a PPI that would facilitate a patient's physical retention of it.

It is possible, however, that the creation of a widely retained insert is an insurmountable (patients misplace or dispose of a designed-to-be-retained insert) or unnecessary task (patients hold on to almost anything). If the former is the case, the focus of PPI design efforts should be on gaining and holding the patient's initial attention and interest in its contents.

In the event that neither a designed-to-be-retained insert nor the designed-to-be-attractive insert offer significant improvements in patient comprehension, retention and compliance, or if patients are motivated to attend to nearly any format, the design focus should be on minimizing the cost of the PPI.

It follows, then, that the form of presentation of drug information, henceforth designated factor A, should be tested at a minimum of three levels. The specific factor A levels are summarized in Table 1.

The information categories appropriate for patient package inserts, the literature suggests, are essentially settled. Yet to be determined, however, is the relative amount of detail an insert should provide in each of the categories.

TABLE 1
Factor A: Form of Presentation

Level	Description	Rationale Summary
A ₁	Thin, onion skin paper	Minimum cost
A ₂	6-panel, 2-fold colorful brochure	Attract immediate attention
A ₃	Page for prototype "family medical guide"	Easy reference (designed to be retained)

"Amount of detail" is a versatile phrase that can encompass a number of dimensions. Amount of detail on side effects, for example, could include gradations within the areas of (1) descriptive information, (2) remedies, or (3) causes. In this study, gradations in amount of detail have been made across the areas enumerated above. Specifically, the levels progress from "what can happen," to "what to do if it does," to "why it happens." This sequence is best defended by paraphrasing McGuire (1976): People already know side effects, risks, and medication errors are bad; people must be taught how they can cope with and avoid them.

The "whys" of side effects and precautions may have one or more of the following effects: (1) enhance/hinder the believability of the PPI, (2) soothe anxieties accompanying the medication program, or (3) foster anxiety through confusion. Therefore, their inclusion or exclusion from the PPI is a significant policy issue.

The amount of detail, henceforth designated factor B, was examined at the levels summarized in Table 2.

TABLE 2
Factor B: Amount of Detail

Level	Description	Rationale Summary
B ₁	What can happen, do's, don'ts	Descriptive information only (Minimum detail)
B ₂	B ₁ plus solutions to problems	How to cope (Medium detail)
B ₃	B ₂ plus why problem arises	Effects on believability, comprehension (High detail)

The design of the test inserts was facilitated by the information presented in the Physician's Desk Reference and Govoni and Hays (1971). Insert prototypes were reviewed by the head pharmacist and three doctors on staff at the supporting medical center. Inserts were modified in light of their remarks.

Type size was held constant across all treatments, while a graphics consultant was employed in the design of the front cover of the brochure insert, A₂. Sixty-pound green construction paper was the vehicle for A₂ and A₃ was bound in a green Duo Tang notebook. The amount of detail, factor B, levels are depicted in the Appendix.

Experimental Design

The experimental design employed in this study provided for replicates of a 3². Experimental subjects in this design were newly diagnosed hypertensive patients at the St. Louis Park Medical Center in the Minneapolis suburb. Furthermore, to facilitate cost control and minimize variance in the treatment regimen, the population of

eligible subjects was limited to essential hypertensives prescribed diuretics. Finally, due to limitations of experimenter control, only patients receiving their prescriptions at the Medical Center Pharmacy were eligible for study. The director of the Medical Center had estimated that 30% of the center-prescribed medications were dispensed at the Medcenter Pharmacy. There was no evidence indicating that those not dispensing there were different in regards to the outcome measures to be discussed below.

Inserts in coded bags were dispensed at the pharmacy by a double blind procedure. Two weeks after the receipt of the medication and insert, the patient received a letter from the pharmacist. The letter stated that unless the patient called to state otherwise a researcher from the University of Minnesota would soon call to set up a half-hour interview dealing with his or her opinions on medications, health, and health care in general. About one in six patients did not wish to be called.

The patient interview was completed approximately one month after medication and insert receipt. Patient comprehension of the insert information was assessed in Section 1, a set of 20 true-false, yes-no, and multiple choice questions. Two of the 20 questions were dummy items on topics not discussed in any insert but included to confound yea-saying.

Section 2 of the questionnaire explored the patient's recollection of receipt of the insert (aided and unaided). In addition, physical retention and recalled use of the insert were examined. Insert believability or patient yielding was measured with an itemized rating scale nested among measures of PPI complexity and completeness. Also, patients' valuations of other sources of drug information were obtained.

Patient recollection of side effects was solicited with an open ended question. The interviewer probed for the frequency of occurrence of each experienced side effect and whether or not the patient took special actions--such as calling the medical staff, ceasing medication, etc.

Section 3 employed a lead-in and probing to assess patient compliance with medication directions. This section also obtained patients' prior familiarity with the drug and family experience with hypertension.

Section 4 measured several suggested covariates of compliance and was completed by respondents by hand. Importance and belief scores were obtained on five attributes of physicians in general and the prescribing physician. These attributes, identified in patient focus groups, were: (1) knows his/her business, (2) is friendly, (3) communicates in patient terms, (4) charges reasonable rates, and (5) shows real concern for the patient.

A second portion of Section 4 consisted of items from the A-State anxiety measure developed by Spielberger *et al* (1970). This scale has been used to measure the level of anxiety raised by a situation, as opposed to the A-Trait measure which seeks to assess the anxious tendencies of individuals. The instrument has never been used to measure the anxiety caused by a communication message and should be interpreted with caution; it is possible that the interview itself fosters anxiety in individuals. Also, since it was felt that the original 20-item instrument was too threatening and fatiguing for the study purpose, a random selection of 10 items yielded a more workable instrument. Nested among the 10 items were three similar statements designed to assess subjects' degree of concern for their health.

The third portion of Section 4 was a health locus of control measure developed by Wallston *et al* (1975).

This scale has been used to examine an individual's belief in internal control of physical health or well being. In their validation efforts, the developers of this scale noted some evidence of greater information seeking among subjects classified as internals.

Finally, respondents indicated their occupation, level of education, marital status, and number of children (under 18 years) living at home.

In addition to the data obtained from patient interviews, subject deviations from the prescription refill date and changes in blood pressure readings were obtained from Medical Center and Pharmacy archive data. Blood pressure readings used were those taken closest to one month after the initial diuretic prescription was dispensed.

Results

At this point in time, data has been obtained on 30 subjects--providing approximately three replicates. This apparently small sample size is characteristic of previous research in patient education and is indicative of the difficulties encountered in such field research. Nevertheless, the data contain a number of interesting facets and are presented as preliminary in light of continuing data collection.

First, to briefly contrast this experiment with the previously reported OC experience, 100% reported receipt of the PPI on diuretics. Physical retention of the insert by hypertensives was higher (67% vs. 50%) but the OC retention rate was measured much later from the time of initial receipt. Forty-eight percent of the hypertensives (vs. 11% of the OC users) reported looking back at the insert. Most common reasons for subsequent insert consultations were to recall special cautions and side effects.

Subjects scored an average of 69% on the measure of comprehension; the most commonly missed items dealt with the drug's effects on pregnant and breast-feeding women. Overall, the inserts were rated clear and helpful. In addition, subjects rated the inserts on a par with the prescribing physician in terms of contribution to their understanding the nature of the drug.

A two-factor fixed effects analysis of variance/covariance model was examined for each of the dependent variables enumerated in hypotheses 1-6. Since there were unequal cell sizes the dummy variable regression approach was employed as covariate coefficients, interactions and main effects were tested at $\alpha = .1$. The results of these tests are addressed in the following paragraphs and are summarized in Table 3.

Two dependent variables were employed in testing hypothesis 1, which dealt with treatment effects on compliance. The number of days delinquent (early) from the compliant refill date is the variable labeled "Refill deviance" in the first row of Table 3. While there are no main effects on this measure of compliance, patients who received minimum information on onion skin were significantly more deviant.

Hypothesis 1 was also tested on a dichotomous criterion, patient self report of compliance. Here the hypothesis is rejected on the basis of significant factor B effects. In examining the coefficients from Table 3 two items deserve special notice. First, among factor levels, the largest increment in compliance comes in B_2 , in which remedies and strategies for coping are provided. Interestingly, this information was also included in B_3 , which did not foster increased compliance. Second, and related to hypothesis 6, education beyond high school is positively associated with compliance. No treatment effects on clinical outcome were uncovered.

TABLE 3
Summary of Significant Standardized Regression Coefficients for the Tested Hypotheses

Hypothesis Number	Dependent Variables	Independent Variables								Statistics						
		Factor A		Factor B		Interactions				HCON-CERN*	SEX*	EDUC*	R ²	F	Sig.	
		A1	A2	B1	B2	AB11	AB12	AB21	AB22							
H ₁	Refill Deviance	--	--	--	--	.459	--	--	--	--	--	--	.21	6.142	.02	
H ₁	Compliance Self-report	--	--	--	.358	--	--	--	--	--	--	--	.480	.39	7.070	.004
H ₂	Side Effects	.503	-.163	-.239	.225	--	--	--	--	--	--	--	.53	5.63	.03	
H ₃	Anxiety	--	--	--	--	--	--	--	--	--	--	--	--	--	--	n.s.
H ₄	Receipt	--	--	--	--	--	--	--	--	--	--	--	--	--	--	n.s.
H ₄	Nonbelief (unaided)	--	--	--	--	--	--	--	.547	--	--	--	.30	9.804	.005	
H ₄	Nonbelief (aided)	--	--	--	--	--	--	--	.655	.249	.335	--	.56	8.856	.001	
H ₄	Comprehension	--	--	--	--	--	--	--	.676	.275	--	--	.51	11.301	.001	
H ₅	Physical Retention	--	--	--	--	--	--	--	--	.488	--	--	.18	5.14	.03	

*Indicates covariates identified in hypothesis 6 were also tested.

The presence of both A and B factor effects on whether subjects experienced side effects requires the rejection of hypothesis 2. Patients receiving the onion skin and/or strategies for dealing with difficulties are more likely to notice side effects. This pattern does not seem to be related to any anxiety-inducing treatment effects as hypothesis 3 is accepted.

Hypotheses 4 and 5, dealing with treatment effects on patient information processing, are accepted in their null form. There were several occasions when, as the only model elements, main effects on insert believability, comprehension, and physical retention were significant. However, this significance disappeared as other, more powerful variables were introduced.

As attention shifts to hypothesis 6 dealing with the impact of the covariates of these processing criteria, a number of interesting relationships are revealed. First, since all experimental subjects recall getting an insert, no significant covariates were expected. However, both aided and unaided measures of insert believability (coded in terms of unbelievability) are inversely correlated with patients' attitudes toward their prescribing physician. In the aided measure, inserts prove less credible to females and patients highly concerned about their health.

Comprehension of the purpose and nature of the drug is positively correlated with patients' attitude toward their doctor and their concern for health. This latter variable is also significant in explaining 18% of the variation in physical retention rates.

Conclusions

The focus of this research has been on the measurement of end-states as they have been effected by the insert stimuli. The information processes themselves were never explicitly measured. However, the alternative approaches, direct monitoring and decision net, become unworkable in field evaluations.

Furthermore, the study does not pretend to have explored all possible vehicles of written drug information. However, the chosen factor levels were of such a diverse nature that if form of presentation effects do exist, they would have been identified in this design. Level of detail effects would seem to be easily manufactur-

able--technical names for side effects and precautions would be nearly impossible for patients to understand. The examined range of this factor was deliberately restricted to what are currently considered realistic levels from a judgmental perspective.

Also, the generalizability of these findings is limited to disease categories similar in nature and consequences to hypertension. It is likely that a patient with an acute condition requires a different insert than the chronic subjects of this study. Further research is required with patients with a variety of acute conditions.

In spite of these limitations, however, several important conclusions seem inescapable. First, on a descriptive level, several insights have been gained into patient use of supplementary drug information. These findings complement the earlier study of OC users. Moreover, the demonstrated effects of form of presentation and level of detail on patient compliance, anxiety, and understanding provide evidence for PPI program and vehicle design.

Regardless of which compliance measure is used, the data suggest that patients need information beyond the basic purpose, side effects, do's, and don'ts. Looking at patient self-reports of compliance, it is clear that strategies for coping with the possible treatment remedies are required. This information may make patients more likely to notice side effects, as does the onion skin format, but no measurable increase in anxiety is fostered by these treatments. It is also worthwhile to note that the provision of B₃ information, the why's, does not enhance compliance, affect experiences with side effects, nor foster insert credibility.

Patient information processing of the inserts is explained primarily by motivational factors--not the communication stimuli themselves. It should be noted, however, that after the motivational covariates, in several instances, factor main effects were only "marginally" insignificant. They may enter the model as the power of the tests increase with continuing data collection.

B₁ Level of Information

YOU AND YOUR MEDICATIONS

YOUR DOCTOR HAS PRESCRIBED A DIURETIC (DI-YU-RET-IK) DRUG. DIURETIC DRUGS ARE MADE BY SEVERAL DRUG COMPANIES. EACH COMPANY HAS ITS OWN NAME FOR THE DRUG IT MANUFACTURES. IT IS IMPORTANT TO KNOW THE NAME OF THE DRUG YOU ARE TAKING. READ CAREFULLY THE INSTRUCTIONS ON THE LABEL. FOLLOW THOSE INSTRUCTIONS.

IT IS IMPORTANT THAT YOU TELL YOUR DOCTOR IF YOU HAVE DIABETES, LIVER OR KIDNEY PROBLEMS, ALLERGY OR BRONCHIAL ASTHMA. ALSO, TELL YOUR DOCTOR IF YOU ARE PREGNANT OR BREAST FEEDING.

THE PURPOSE OF THIS DRUG IS TO REMOVE YOUR BODY'S EXCESS SALTS AND WATER. SOME OF THE DIRECT EFFECTS OF THIS MEDICATION ARE MORE FREQUENT URINATION, OCCASIONAL DIZZINESS, LIGHT-HEADEDNESS OR HEADACHE, AND SOMETIMES DRY MOUTH, THIRST, OR CRAMPS IN MUSCLES.

RARELY, SIDE EFFECTS SUCH AS PERSISTENT FATIGUE OR NAUSEA, STOMACH CRAMPS OR RASH OCCUR. THESE SHOULD BE REPORTED TO YOUR DOCTOR.

FINALLY, YOUR DOCTOR MAY WANT TO SEE YOU AFTER A MONTH OR MORE TO CHECK ON TREATMENT EFFECTIVENESS. CONTACT YOUR DOCTOR SOONER IF YOU HAVE ANY OF THE PROBLEMS MENTIONED ABOVE.

ANY QUESTIONS CAN BE DIRECTED TO THE PHARMACY STAFF BY CALLING:

YOU AND YOUR MEDICATIONS

YOUR DOCTOR HAS PRESCRIBED A DIURETIC (DI-YU-RET-IK) DRUG. DIURETIC DRUGS ARE MADE BY SEVERAL DRUG COMPANIES. EACH COMPANY HAS ITS OWN NAME FOR THE DRUG IT MANUFACTURES. IT IS IMPORTANT TO KNOW THE NAME OF THE DRUG YOU ARE TAKING. READ CAREFULLY THE INSTRUCTIONS ON THE LABEL. FOLLOW THOSE INSTRUCTIONS.

IT IS IMPORTANT THAT YOU TELL YOUR DOCTOR IF YOU HAVE DIABETES, LIVER OR KIDNEY PROBLEMS, ALLERGY OR BRONCHIAL ASTHMA. ALSO, TELL YOUR DOCTOR IF YOU ARE PREGNANT OR BREAST FEEDING.

THE PURPOSE OF THIS DRUG IS TO REMOVE YOUR BODY'S EXCESS SALTS AND WATER. A DIRECT EFFECT OF THIS DRUG IS MORE FREQUENT URINATION. UNLESS OTHERWISE DIRECTED, TO AVOID GETTING UP IN THE NIGHT, TAKE MEDICATION BEFORE NOON.

YOU MAY OCCASIONALLY EXPERIENCE DIZZINESS, LIGHT-HEADEDNESS OR HEADACHE. WHEN THESE OCCUR, REST A WHILE. DO NOT GET UP AND DOWN SUDDENLY. MOVE MORE SLOWLY. YOU MAY GET VERY THIRSTY AND HAVE A VERY DRY MOUTH. FRUITS AND FRUIT JUICES AND FRESH VEGETABLES ARE THE BEST REMEDY FOR THIS DISCOMFORT.

RARELY, SUCH SIDE EFFECTS AS PERSISTENT FATIGUE, NAUSEA, STOMACH CRAMPS OR RASH OCCUR. THESE SHOULD BE REPORTED TO YOUR DOCTOR. REMEMBER, THOUGH, THESE PROBLEMS OCCUR NATURALLY FROM TIME TO TIME EVEN WHEN YOU'RE NOT TAKING ANY MEDICATION. UNLESS THEY OCCUR FREQUENTLY, FOLLOW YOUR USUAL PROCEDURES OF TREATMENT. TAKING THE DRUG WITH MEALS MAY PREVENT STOMACH IRRITATIONS.

FINALLY, YOUR DOCTOR MAY WANT TO SEE YOU AFTER A MONTH OR MORE TO CHECK ON TREATMENT EFFECTIVENESS. CONTACT YOUR DOCTOR SOONER IF YOU HAVE ANY OF THE PROBLEMS MENTIONED ABOVE.

A MULTIPLE DISCRIMINANT ANALYSIS APPROACH TO THE
DEVELOPMENT OF RETAIL STORE POSITIONING

Lawrence J. Ring, University of Virginia*
Charles W. King, Purdue University

Abstract

This paper applies multiple discriminant analysis to a large-scale consumer data base, to provide an empirical analysis of the factors underlying store choice behavior for men's fashions. These findings define retail store positions in a particular marketplace and pinpoint the major competitive dimensions there.

Introduction

Understanding the clothing and apparel shopping behavior of the contemporary consumer is vitally important to effective marketing in the fashion retail marketplace. Each retailing marketplace is characterized by a wide range of stores and associated strategies and operating methods. The sum total of those strategic and tactical actions taken by a given store or chain of stores is the "product" or "image" which that store presents to the consuming public.

In general, the retailer's objective has been to create a store image which will appeal to a particular segment of the population. It has been widely held [1], [2], [3], and [4] that store "image" is produced by the joint effect of a multiplicity of store or product attributes. The major objective is to determine whether consumers perceive major differences in store appeal when faced with a choice among several (10) competing chains in a given market place. The aim here is to provide an empirical analysis of the factors underlying store choice behavior with respect to men's fashions and to contrast the strengths and weaknesses of several different retailing institutions in the city of Toronto, Canada.

Field Methodology

The data used in this study were gathered as part of a broader on-going research program in Toronto, Ontario, Canada. That program is the Toronto Retail Fashion Market Segmentation Research Program and has been described elsewhere [5] and [6]. The sample used in the analysis here was part of a specially recruited panel of husband and wife pairs in Toronto. A total of 1025 usable questionnaires were received from cooperating male panel members. The questionnaires were mailed to each panel member complete with standard self-administration instructions. Each panel member received a small gift for completing the questionnaire.

In attempting to profile the Toronto men's wear retail marketplace, it was first necessary to define a relevant set of retailers to present to respondents for their judgments across a variety of attitudinal measures.

The 1975 edition of the Toronto Yellow Pages lists over 200 separate retailers under the title "Men's Clothing and Furnishings - Retail" alone -- not including department and discount stores. The vast majority of these

*This study was made possible by funds provided by several Toronto men's wear retailers who wish to remain anonymous, and by research grants to the author from the Colgate Darden Graduate School of Business Administration and the Krannert Graduate School of Management.

stores, however, are relatively small and are single-outlet proprietorships. Therefore, it was expected that a majority of the population would be unfamiliar with stores falling into the single-outlet proprietorship category, and thus unable to comment knowledgeably about their operations.

There are, on the other hand, a small set of stores which most consumers could reasonably be expected to recognize. Toronto's three major department stores and many of its multiple-outlet men's wear chain stores would appear to have sufficient market coverage for respondents to judge them.

In addition, the mass merchandiser (department stores and specialty chain) retailers as a group appear to hold a major (and growing) share of Canadian retail men's wear business, according to the most recent government figures. In 1974, department stores and chain stores obtained 58 per cent of the sales of men's wear in Canada and had maintained an average growth rate for the past five years of 12 per cent dollar sales per year. In contrast, independent stores' dollar sales in men's wear grew only 6 per cent over the same period.¹

For the purposes of this project, ten large chains were mentioned by name (an "any other store" response category was also included to allow respondents to choose stores other than those which were specifically mentioned in the questionnaire).

The detailed store-by-store analysis dealt with fashion retailing as it relates to the major department and major specialty chain stores which are currently actively servicing the Toronto men's wear market. Each of the chains included in the analysis was operating at least six retail outlets in Toronto in 1975. In addition, it was estimated that each of the chains was obtaining gross men's wear sales in Toronto of at least \$5 million dollars per year.

What was not examined in great detail were all the remaining smaller chains and the hundreds of small independent fashion specialty stores. Table 1 represents a comparison of consumers' perceptions of the sample set of chains described above with their perceptions of the aggregated remainder of the stores servicing the Toronto men's wear market.

This comparison reveals that the 10 specific sample chains studied here were well known and held, in the aggregate, dominant positions on all of the dimensions of retail patronage which were measured in the research. On the critical dimensions of "last store shopped" and "store shopped most often", the 10 sample chains were named by approximately 70 per cent of the respondents.

Analysis

The initial analysis pass involved the computation of frequencies of mention across the sixteen measures of patronage which were listed in Table 1. The simple frequency analysis was useful for building a baseline

¹Source: Statistics Canada Documents 63-002 and 63-005, 1974.

statement of individual chain strengths and weaknesses.

Following the computation of frequencies, cross-classification analysis was performed on the determinants of patronage and other key variable sets using the share of shoppers, a surrogate for market share, as the dependent variable. The share of shoppers has historically been measured by market researchers in a variety of ways. In this project, two measures were employed:

1. Which store was visited the last time the respondent bought an article of men's wear?
2. Which store was shopped most often for men's wear?

The purpose of the cross-classification analysis was to pinpoint the strengths and weaknesses of each of the chains as perceived by their own customers for each of the patronage dimensions.

The cross-classification analysis was also useful in the development of decision rules for the grouping of the chains together for further analysis.

The final step in the analysis of the determinants of patronage in the Toronto retail men's wear market involved the construction of the "product space," that is, a spatial representation of the relative positioning of the ten chains included in this survey in Toronto.

This spatial representation was constructed through the use of multiple discriminant analysis. The mathematics of the multiple discriminant method are developed briefly later in the paper.

The objective here was somewhat strategic in nature. The technique permits the identification of potential opportunities in the existing retailing milieu. And, pragmatically, this technique can be useful in discovering directions in which any or all of the existing store images may be modified for greater sales and profitability.

Univariate Results

Univariate cross-classification analysis was used to determine the relative importance of the patronage dimensions to each of the chains covered in this project. For each chain, the cross-classification tables were restructured so that the diagonal values from the cross-classification of each patronage determinant by "store last shopped" were ordered from highest to lowest per cent of mentions. A summary of the diagonals is presented in Table 2. For example, for Chain A², ordering the data from Table 2 highest to lowest, among those who "last shopped" for men's wear at this chain ...

- 69 per cent said Chain A was "easiest to get to from home"
- 36 per cent said Chain A had the "best value for the money"
- 33 per cent said Chain A was the "best for conservative, everyday men's wear"
- 32 per cent said Chain A had the "most knowledgeable, helpful salesclerks"
- 27 per cent said Chain A had the "largest overall merchandise assortment/selection"

- 24 per cent said Chain A had the "most exciting merchandise display"
- 22 per cent said Chain A had the "lowest prices"
- 19 per cent said Chain A had the "best advertising"
- 16 per cent said Chain A was "best for current, up-to-date men's wear"
- 15 per cent said Chain A was "best for very latest, most fashionable men's wear"
- 12 per cent said Chain A had the "highest quality"

Assuming that those dimensions receiving the highest share of mentions for each chain (in this case, Chain A) were, in fact, the most important determinants of retail patronage for that chain, this ordered set of diagonals represented the "retail image" of each chain as seen by the chain's customers.

TABLE 1
Share of Mentions Given to the 10 Chains Surveyed Vs. All Others on Store Shopping Attitude/Determinants of Patronage Questions

	Survey Chains	Any Other Store	Base
Easiest to get to from home	88.9 ^a	11.1%	1021
Last store shopped for men's wear	68.4	31.6	1011
Store shopped most often	71.8	28.2	1014
Lowest prices	91.0	9.0	1010
Highest prices	92.2	7.8	1001
Highest quality	86.6	13.4	1000
Lowest quality	91.4	8.6	993
Best value for the money	88.7	11.3	999
Worst value for the money	83.5	16.5	987
Most knowledgeable, helpful salesclerks	82.8	17.2	994
Largest overall assortment/selection	95.2	4.8	997
Best advertising	91.8	8.2	970
Most exciting merchandise display	83.6	16.4	976
Best for conservative, everyday men's wear	91.5	8.5	998
Best for current up-to-date men's wear	87.9	12.1	972
Best for very latest, most fashionable men's wear	85.0	15.0	988

²Chain names have been disguised for this analysis to protect the proprietary interest of those firms who sponsored the research. Chains A, B, and C are department stores; Chains D and E are discounter/mass merchandisers; and Chains F, G, H, I, and J are men's wear specialty chains.

^aREAD: Among the respondents answering the location question, 88.9 per cent reported one of the 10 sample chains was "easiest to get to." Alternatively, 11.1 per cent reported some other store not among the 10 sample chains was "easiest to get to."

TABLE 2
Summary of Cross Classification Analyses Diagonals for
12 Determinants of Retail Patronage

Determinants of Retail Patronage	Store Last Shopped for Men's Wear									
	Chain A	Chain B	Chain C	Chain D	Chain E	Chain F	Chain G	Chain H	Chain I	Chain J
1. Easiest to get to from home	69%*	42%	34%	33%	42%	9%	50%	24%	4%	32%
2. Lowest prices	22	24	19	92	49	24	18	0	0	16
3. Highest quality	12	18	20	0	0	26	32	83	58	21
4. Best value for the money	36	55	58	39	46	66	52	40	35	47
5. Most knowledgeable, helpful salesclerks	32	35	46	25	27	49	52	89	72	54
6. Largest overall assortment/selection	27	50	51	8	26	39	24	35	15	18
7. Most exciting merchandise display	24	38	32	25	18	36	47	69	59	26
8. Best advertising	19	54	50	0	35	16	20	30	21	10
9. Store shopped most often	58	69	82	60	57	57	57	79	71	45
10. Best for conservative, everyday men's wear	33	54	58	33	27	24	27	28	27	22
11. Best for current, up-to-date men's wear	16	29	29	0	8	28	56	65	85	38
12. Best for the very latest, most fashionable men's wear	15	22	19	0	5	19	36	70	60	24

*READ: Among those who last shopped at Chain A for men's wear, 69 per cent came from Chain A's trading area, 22 per cent said Chain A had the lowest prices, and 12 per cent said Chain A had the highest quality, etc.

Looking at Chain A, for example, the highest percentage was 69 per cent, and it relates to location. This suggests that Chain A's location(s) was a major reason for shopping at this chain. Of lesser importance were "value", "conservative men's wear", and so forth. However, only on location did this chain appear particularly strong.

The univariate analysis of patronage determinants suggested that there were four kinds of chains serving the men's apparel market in Toronto. They were:

1. The discounter/mass merchandisers which appeared to be drawing their customers primarily by their low prices, but also on good value, location, and conservative everyday men's wear.
2. The department stores, which were obtaining their shoppers through good value and conservative, everyday men's wear also, but in addition because of their advertising and large overall merchandise displays.
3. The mid-range fashion specialty chains, which were drawing primarily on value, current, up-to-date men's wear, knowledgeable, helpful salesclerks, and exciting merchandise displays.
4. The high fashion specialty chains, which performed most strongly among their own shoppers on salesclerk help, high quality, very latest, most fashionable and current, up-to-date men's wear, and exciting display.

The question that remains revolves around what is the joint interaction of all the patronage dimensions taken as a whole? Therefore, the final step in the analysis

of the structure of the Toronto retail men's wear market involved the construction of the "product space"; that is, a spatial representation of the relative positioning of the ten chains included in this survey in Toronto.

Multiple Discriminant Mapping

The objective in this exercise was somewhat strategic in nature. Perceptual mapping can be used as a tool for identifying potential opportunities for both the new men's wear retailer and the currently operating retailers. In particular, this technique can be useful to the existing retailer in discovering directions in which to modify his image to produce the greatest sales gain.

In recent years the construction of geometric spacial models of particular markets has received a great deal of attention in market segmentation analysis. And, a number of techniques and combinations of techniques have been employed in constructing these so-called "product" or "brand spaces". Among the most popular tools have been discriminant analysis [9] and [10], and factor analysis [11].

The data gathered for this analysis in the project was obtained through use of the associative techniques. Simply speaking, each respondent was asked to associate one chain with each of the following questions:

1. Which store is the easiest to get to from home?
2. Which store has the lowest prices?
3. Which store has the highest prices?

4. Which store has the most knowledgeable, helpful salesclerks?
5. Which store has the highest quality men's fashions?
6. Which store has the lowest quality men's fashions?
7. Which store gives you the best value for the money in men's fashions?
8. Which store gives you the worst value for the money in men's fashions?
9. At which store do you find the most exciting merchandise display of men's fashions?
10. Which store has the best fashion advertising?
11. Which store has the largest overall merchandise assortment/selection in men's fashions?
12. Which store is best for conservative, everyday men's wear?
13. Which store is best for current, up-to-date men's wear?
14. Which store is the best for the very latest, most fashionable men's wear?

So, essentially each respondent picked "1 of n" (n=11) stores on each of the above dimensions. However, in the course of choosing one chain for each dimension and therefore ranking that chain as the best (or the worst, the largest, and so forth), each consumer assigned a rating to all the stores. That is, in the dummy variable sense, a "1" was assigned to the chosen store and a "0" was assigned to each of the other stores.

As a result, each respondent has rated each chain a "1" or a "0" on each dimension. This, in effect, constitutes approximately 1000 observations across the eleven store alternatives. Given this data, multiple discriminant analysis was chosen as the technique best suited for constructing a spacial model of the Toronto men's wear market.

In the Toronto data, respondents rated a set of eleven men's wear chains on fourteen determinants of patronage. The fourteen dimensions have been considered as the reasons taken together which account for the ways in which Toronto shoppers think men's wear chains differ from one another. The objective is to determine how these "reasons" discriminate among the set of chains.

Results

The results of the discriminant analysis were very consistent with the univariate analysis results presented earlier in this paper. Table 3 reports the structure for the eight most significant discriminant functions and the canonical correlations between the 14 determinants of patronage and the 11 group (chain) membership variables.

The structure coefficients in this table suggest that the first eight discriminant functions appear to be measuring:

1. Low quality/low price (+) versus high price (-)
2. Conservative men's wear with large assortment and advertising (+) versus very fashionable men's wear with high quality and high price (-)

3. High price, large assortment, best advertising (-)
4. Location and high price (-)
5. Worst value and location (+)
6. Very latest, most fashionable merchandise (+)
7. Low price (+) versus low quality (-)
8. Best value for the money (+)

Table 4 indicates that the first two functions accounted for approximately 83 per cent of the discrimination among the 11 Toronto chains. Additional interpretation can be obtained by locating the 11 group (chain) centroids on the discriminant functions.

Figure 1 displays both the group centroids and the determinants of patronage on the first two discriminant functions, and Table 6 presents the locations of the group centroids on the first eight discriminant functions. Here, and in Table 3, the discriminant functions have been standardized in order to adjust for the variability in the original variables and to therefore accurately report the relative importance of the variables.

Figure 1 shows the perceptual map of the Toronto men's wear market in two dimensional form. The location of each store is indicated on these two dimensions. The horizontal dimension seems to contrast low quality and low price on the right with high price on the left. The vertical dimension appears to suggest conservative men's wear with a large assortment and advertising at the top in contrast to very fashionable, high quality, high priced men's wear at the bottom.

The mean rating of each chain on each determinant can be determined by erecting perpendiculars from each centroid to each "determinant vector." For example, Chain H is viewed as the chain with the highest prices, followed by Chain I, "others", Chain G, Chain A, Chain J, Chain F, Chain B, Chain C, Chain E, and Chain D.

Figure 2 displays the territorial map of the Toronto retail men's wear market. In this figure, all space on the graph has been classified according to the store centroid to which it is closest. The territorial map clearly suggest that there are three major chain-type divisions in the Toronto market, the department stores, the specialty stores, and the discounters.

The discriminant analysis indicated that in Toronto the major competitive dimensions of the discounter/mass merchandisers were low quality, low price, and worst value for the money. The fashion specialty chains did best on high price, most fashionable men's wear, high quality, current men's wear, exciting merchandise display, and knowledgeable, helpful salesclerks. The department stores showed strongest on best assortment/selection, best advertising, best conservative everyday men's wear, best location, and best value for the money.

TABLE 3
Determinants of Patronage Correlations and Canonical Correlations for Eleven Chains in the Toronto Men's Wear Store Space

Determinants of Patronage	Canonical Correlation	Discriminant Functions							
		DFI	DFII	DFIII	DFIV	DFV	DFVI	DFVII	DFVIII

A HIERARCHICAL MODEL OF SOURCE EFFECT
IN RETAIL NEWSPAPER ADVERTISING

James G. Barnes, Memorial University of Newfoundland, Canada

Abstract

The relative source effects of retail store name, brand name and newspaper on consumer reaction to retail newspaper advertising are examined. Significant retail store and brand effects are found. Mean scores on three dependent variables reveal that retail advertisers can utilize different brand strategies in their newspaper advertising in order to obtain more positive consumer reaction.

Introduction

It has been generally accepted that the effectiveness of an advertising message in accomplishing the objectives of the communicator will depend in part on the attitudes of the audience toward the originator of the message and toward various other sources involved in its transmission. The influence of the various sources in affecting consumers' reactions to advertising will depend on a number of attitudes towards these sources. These attitudes relate to feelings of affection, admiration, fear, power, and credibility. Hovland, Janis and Kelley (1953) concluded that such attitudes are the result of a learning process.

Research by marketing theoreticians into the concept of source effect has shown that the reactions of an audience to a communication are generally affected by the audience's perception of the communicator's expertise and trustworthiness in the communications context (Cox, 1963). Aaker and Myers (1975) have also observed that in choosing a particular spokesman to represent a brand, consideration should be given to the credibility (impartiality and expertness), attractiveness (prestige), and power of the source. They add that credibility and attractiveness are the two most appropriate dimensions of source for advertisers.

One failing, however, of much research which has been done in the advertising area on source effect is that studies have generally examined the effect of a single source. A number of studies have examined the effect on a consumer's reaction to a marketing communication of perception which a consumer has of the salesman delivering the message. Jacoby, et al. (1974) have examined the effect of a smiling source. McDougall and Fry (1975) investigated the effect of retail store image on consumer reaction to retail advertisements.

A number of authors have, however, commented that the concept of source effect should not necessarily be viewed in the context of the single source. Hovland, Janis and Kelley (1953) have stated that regardless of whether a source is perceived as the originator of the message, as the channel through which the message passes, or as an endorser who is featured in the message, the same basic principles apply in that the attitudes of members of the audience toward either of these sources may influence the manner in which the message is received and behavior which may result from receipt of that message. It should be clear that, in the advertising context, a number of sources are at work simultaneously in influencing the receipt of a marketing communications message. Fuchs (1964) examined the effects of two components (company and magazine) of what he considered to be a "total source" with several natural components. He went on to speculate that source

is likely "n-dimensional" and that it is a differently-constructed total complex for each individual. This suggests that the way in which an individual perceives the several sources associated with a particular advertisement will depend on his or her past experience with the manufacturer of the product, with the retailer, and with the 'medium vehicle' used to transmit the message. Since the experiences of individuals will vary, the total effect of the complex of sources will likewise vary across individuals.

Hansen (1972) also suggests that the effect of the various source components will be variable. He concludes that the individual's perception of the source will depend partly on the medium which carries the message and partly on the company which initiates it. The relative influence of Hansen's two source components will vary with the consumer's familiarity with each. He suggests that where a nationally-known manufacturer advertises in a large magazine, the source effects may be ascribed mainly to the company but where the advertiser is not well-known and the publication somewhat more dubious, the source effect may be based more on perception of the magazine.

This multi-levelled concept of source effect is largely substantiated in the research of Fuchs (1964). Using advertisements featuring unknown products, he found that subjects' attitudes towards these products were influenced by the company sponsoring the advertisements and by the magazines in which they were carried. He also found that the greatest attitude change towards the product was accomplished by the combination of high-prestige company and high-prestige magazine, and the smallest attitude change toward the product was attributable to the combination of low-prestige company and low-prestige magazine. The attitude towards the product changed as a linear function of the prestige of the two source components.

These research results suggest that in retail advertising where the brand name of the advertised product is featured, consumer perceptions of the advertised product may be influenced by perceptions of the manufacturer. Where the consumer is not familiar with the brand name or where the brand name of the advertised product is not present, perception of the quality and value for the money involved in the purchase offer may be influenced by the consumer's attitude towards the retail store. It may be hypothesized further that only when the consumer is not familiar with either the brand name of the product or the retail store sponsoring the advertisements is the perception of the purchase offer likely to be influenced significantly by the medium vehicle which carries the advertisement.

¹ Fuchs (1964) rated each company and magazine using five semantic differential-like scales: good-bad, reliable-unreliable, trustworthy-untrustworthy, prestigious-not prestigious, and reputable-disreputable. Companies and magazines which scored high on these scales were labeled 'high-prestige' and those which scored low were labeled 'low prestige'. Possibly more appropriate labels would have been 'positive-image' and 'negative-image'.

The Hierarchical Model

It is useful to examine the several sources which may operate in an advertising context, and to distinguish sources of the product from sources of the message. In the case of a national advertiser whose advertising is carried in a popular consumer magazine, the company may be considered the primary source of both the product and the message. The magazine which carries the advertisement may be considered a secondary source of the message. If that advertisement had featured a well-known celebrity endorsing the product, that person could have been considered a tertiary source of the message. In the case of retail advertising where the brand name of the advertised product is supplied, we may regard the manufacturer of the product as the primary source of the product and the retailer as the secondary source of the product. Various middlemen may be involved in the actual physical movement of the product from manufacturer to retailer, but these are not relevant to the formation of consumer perceptions of the advertised product.

Also, in this branded retail advertisement, the retail store may be considered the primary source of the advertisement since it is seen by the consumer as the sponsor. The newspaper which carries the advertisement is a secondary source of the message and any persons featured in the advertisement as endorsers of the featured product should be considered tertiary sources of the message. Others, such as advertising agencies, may be involved in the preparation of the advertising message, but these are again not relevant to the formation of a consumer reaction to the advertised product.

In retail advertising where the brand name of the manufacturer of the product is not present, as is the case with much fashion advertising, the retail store is perceived as the primary source of both the product and the advertised message.

This study is designed to test for the presence of a hierarchical source effect in retail newspaper advertising. Because the use of an endorser in retail advertising is rare, the study concentrates on the relative impact of the manufacturer's brand name, the retail store's name, and the newspaper in influencing consumers' reactions to retail newspaper advertising. Previous research on the existence of a dual source effect (Fuchs, 1964) suggests that different source effects will operate in different contexts. For example, it is possible to test whether a brand name with a positive image is sufficient to offset a negative attitude towards a retail store in influencing a consumer's purchase decision. Similarly, it is possible to determine whether a retail store which was recently established or which enters a new market area can produce positive responses to its advertising by featuring brand name products which consumers hold in high regard. The different contexts in which a retail advertisement might appear are largely controllable by the retail advertiser. While the retailer must, for the most part, operate within the constraints of his existing store image, which may be positive, negative, or non-existent in the case of a new store, he does have some control over the brand names which he chooses to feature in his advertising, and over the newspapers in which the advertising appears. In making the selection of brand name products to appear in his advertising, the retailer may choose to feature brands which have a positive image, brands which are considered to have a negative image in the consumer's mind, or brands with which the consumer may be unfamiliar, or he may decide not to feature a brand name product in his advertising at all. Similarly, in many metropolitan markets, the retailer has a definite choice to make with respect to the newspapers in which his advertising is placed.

The implications for the retail advertiser should be obvious. Since the retailer is able to manipulate at least two of the source variables, the results of this study should permit questions such as the following to be answered:

1. Where a retailer has an established reputation and image in the trading area, is the newspaper selected likely to influence consumers' reactions to an advertisement?
2. Is it possible for an established retailer to detract from the effectiveness of his advertising by featuring in an advertisement a brand name which has a negative image?
3. In a situation where a retailer is moving into a new market and consequently has no established image, is it possible to improve reaction to newspaper advertising by featuring brand names which have a positive image and/or by advertising in a newspaper which has such an image?
4. Can a retailer whose store has an established negative image improve reaction to newspaper advertisements by featuring brand names which have a more positive image?

Hypotheses

In retail newspaper advertising, there are many different possible combinations of brand name, store name, and newspaper. It is, therefore, reasonable to hypothesize that different combinations of these variables will produce different consumer reactions. For example, a manufacturer's brand name may be present or absent; if present, the brand name may be known or unknown; and, if known, it may convey a positive or a negative brand image. Similarly, the name of the retail store appearing in the advertisement may be known or unknown; and, if known, the store image may be positive or negative. Finally, in cities where more than one daily newspaper operates, a selected newspaper may be held in high regard, or may have developed a negative image. A series of hypotheses have been developed based on the research reviewed above and on earlier study conducted by the author (Barnes, 1975).

The hypotheses to be tested in this research are as follows:

1. That the perceived source of the product will have a greater effect on the reaction than will the perceived source of the message;
2. That the brand name of the advertised product will have a significant effect on subjects' reactions;
3. That, in situations where no brand name is present or where the brand name is unknown, the retail store effect will predominate;
4. That the effect of the newspaper in which the advertisement appears will be significant only in situations where the brand name is either absent or unknown and the retail store is unknown.

Research Design

Independent Variables

The three main independent variables whose effect on consumer reactions to retail advertisements is examined

in this study are the three elements of source effect discussed above. The three main treatments are, therefore, manufacturer's brand, retail store, and newspaper. In order to incorporate the various possible combinations of brand, store, and newspaper, the following levels of each of the three main treatment variables are incorporated into the study:

- BRAND NAME:
1. positive brand image
 2. negative brand image
 3. unknown brand name
 4. no brand name present
- RETAIL STORE:
1. positive store image
 2. negative store image
 3. unknown store name
- NEWSPAPER:
1. positive image as source of information
 2. negative image as source of information

The research involves a 4 x 3 x 2 design which necessitated the preparation of twenty-four different versions of a print advertisement, each of which was exposed to subjects in one of the twenty-four cells of the design. In addition to testing the effects of these three main treatment variables, data were gathered on subjects' attitudes, interests and opinions concerning retail shopping and the mass media, attitudes towards specific stores, local newspapers and advertising in general, and certain demographic and socioeconomic information relating to the respondent and to her family.

Dependent Variables

In accordance with a suggestion made by Olson (1974), this study incorporates three dependent variables: perceived believability of the purchase offer; perceived value for the money; and motivation to act. The position of a respondent on each of these variables is considered to represent a component of her total reaction to the advertisement to which she is exposed. These three components of reactions have been included because this provides a more accurate indication of the subject's potential purchase behavior with respect to the advertised product. Insofar as the subject's reaction to the advertised purchase offer may be considered to represent her attitude toward the product in the context of the advertisement, the three-fold representation of that reaction may also be considered to correspond to Rokeach's conceptualization of attitude as "an organization of beliefs" (Rokeach, 1972). Rokeach conceived of each belief in an attitude organization as having three components: cognitive; affective; and behavioral. The dependent variables in this study may be interpreted as corresponding to these three components. The subject's believability of the advertisement may be considered to represent a person's knowledge about what is true or false, good or bad, desirable or undesirable. Perception of value for the money represents an affective dimension of the subject's reaction to the advertised product. The third dependent variable, motivation to act, clearly represents a behavioral dimension.

Questionnaire Design

The questionnaire employed in this study contained four major sections as follows:

1. Statements relating to subjects' activities, interests, and opinions concerning retail shopping and the mass media. Subjects indicated their level of agreement with each statement on a seven-point, Likert-type scale.

2. Questions relating to subjects' attitudes toward specific retail stores in the trading area, toward local newspapers, and toward advertising in general.
3. A retail newspaper advertisement to which subjects were asked to express their reactions in terms of the three dependent variables described above.
4. Demographic and socioeconomic questions relating to the respondent and to her family.

The three criterion variables (perceived believability, perceived value for the money, and motivation to act) were operationalized in the third part of the questionnaire. This part of the questionnaire contained twenty-one statements, each of which forms part of one of three scales, representing believability, value for the money and motivation to act. Subjects were asked to respond to each of these twenty-one statements on a seven-point, Likert-type scale ranging from definitely agree to definitely disagree.

The advertisement which appeared in the third part of the questionnaire featured sheets and pillow cases, as products with which female consumers would be familiar. The actual advertisement was designed by the advertising department of a local newspaper in such a way as not to reflect the advertising style of any particular retailer. The advertisement was prepared in twenty-four different versions, with each version featuring the name of a different retail store, a brand name for the advertised products, and the folio of a local newspaper.

The retail stores, brand names and newspapers featured in the advertisements were selected and labeled 'positive image' and 'negative image' based on research previously conducted in the area. Earlier store image studies were used to identify a local department store which engages in very little sale advertising and which has a very positive image in the market. This store was labeled 'positive image'. A discount store which employs a strong promotional advertising approach and which has a rather negative image was labeled 'negative image'. The assignment of these stores to their respective levels of the retail store variable was substantiated by the store image data gathered as part of this survey. A fictitious store name was used in one-third of the advertisements to represent the 'unknown' store level of the retail store variable.

A preliminary survey among female heads of households obtained data on the image of various brands of sheets and pillow cases. A brand which demonstrated high awareness and a high quality image was labeled 'positive image' and a second brand also demonstrating high awareness but a low quality image was labeled 'negative image'. A third fictitious brand name was used to represent the 'unknown brand' level of the brand name variable. One-quarter of the advertisements contained no brand name.

Earlier research studies on newspaper readership and image were used to assign the two local daily newspapers to the 'positive image' and 'negative image' levels of the newspaper variable. This assignment of the newspapers was also substantiated by data collected in this survey. Each of the twenty-four versions of the advertisement employed the same copy and prices.

Data Collection

The sample was drawn from the retail trading area of an Eastern Canadian city. This city was selected because it offers a broad range of large department and discount stores and because it has two daily newspapers. A total of 2,400 questionnaires was mailed to female heads

of households selected randomly from recent voters' lists. Completed questionnaires numbered 429, of which 402 were useable. One hundred copies of each version of the advertisement were mailed and the 402 useable questionnaires returned resulted in cell sizes ranging from fifteen to twenty-five.

TABLE 2

FACTORS PRODUCED FROM PRINCIPAL COMPONENTS ANALYSIS OF 'LIFE STYLE' STATEMENTS (n=402)

Analysis

Subjects' responses to the twenty-one statements relating to the advertisement were analysed using principal components analysis (Nie, 1975) and three factors resulted which were clearly interpretable as the three criterion variables discussed above. Sum scores on these factors constituted subjects' scores on the dependent variables. Results of this principal components analysis are presented in Table 1.

TABLE 1

FACTORS PRODUCED FROM PRINCIPAL COMPONENTS ANALYSIS OF 'ADVERTISEMENT' STATEMENTS (n=402)

	FACTOR LOADINGS	INTERNAL CONSISTENCY COEFFICIENT
FACTOR 1: Eigenvalue = 6.14907 - "motivation to act"		
This advertisement would catch my attention if I saw it in a newspaper	0.74287	0.7474
I would likely remember this advertisement.	0.71260	0.7503
This advertisement would attract many shoppers.	0.69750	0.6696
This advertisement certainly interests me.	0.66391	0.7593
I should probably buy these products now while I have the chance.	0.63864	0.7766
If I were shopping in this store today, I would probably take a look at these products.	0.61276	0.7354
Most of my friends would be interested in buying these products.	0.56120	0.7003
FACTOR 2: Eigenvalue = 1.92602 - "perceived value for the money"		
This is probably the best price at which I can buy these products in St. John's.	0.75704	0.7945
If I were to buy these products at another store, I would have to pay a higher price.	0.61662	0.6930
This looks like a pretty good deal to me.	0.55301	0.7829
These products at these prices represent good value for the money.	0.49450	0.6909
I can get a better deal than this at another store.	-0.47813	0.5860
I can get better value than this at another store.	-0.47127	0.6657
FACTOR 3: Eigenvalue = 0.89249 - "perceived believability"		
I don't believe ads like this.	0.68636	0.7257
This advertising is misleading.	0.65401	0.6657
The quality of these products is probably low.	0.59954	0.6540
I don't trust this store.	0.55621	0.6661
This is probably old merchandise that the store is trying to get rid of.	0.52398	0.5846
This advertisement is honest.	-0.42853	0.5697

The sixty "life style" statements in the first part of the questionnaire were also subjected to principal components analysis and eight factors were obtained with eigenvalues greater than unity. These eight factors are interpretable as dimensions of consumer behavior relating to retail shopping and the mass media and are important insofar as they may influence consumer reaction to advertising. The results of this principal components analysis are presented in Table 2. These eight "life style" factors and a number of demographic variables were included in the analysis as covariates since it is hypothesized that reaction to an advertisement is not a function only of the brand name, store name and newspaper associated with that advertisement, but also of certain demographic and life style characteristics of the respondent herself.

	FACTOR LOADINGS	INTERNAL CONSISTENCY COEFFICIENT
FACTOR 1: Eigenvalue = 6.16498 - "bargain orientation"		
I shop a lot for "specials"	0.78257	0.7576
I read newspaper advertisements closely, looking for bargains.	0.68378	0.7252
I consider myself a real "bargain hunter"	0.61006	0.7289
Each week I look in the newspaper for the grocery specials at the supermarket	0.60353	0.5855
It is not worth the extra time and effort it takes to shop around for bargains	-0.52881	0.6473
A person can save a lot of money shopping around for bargains	0.50125	0.6462
I like shopping at "sales"	0.48102	0.6429
FACTOR 2: Eigenvalue = 4.22661 - "quality, department store orientation"		
When I shop at a department store, I know that I get good value	0.56524	0.5881
If some brands sell really well, they must be better quality	0.48738	0.5175
High-priced products are always better quality	0.47965	0.5420
Brands which are heavily advertised are always better quality	0.46894	0.4867
When you buy something on sale, you usually don't get a good deal	0.46797	0.5201
You only get what you pay for when you shop	0.44432	0.4859
I would never buy a dress at a discount store	0.44345	0.5509
I would never buy a dress on sale	0.43583	0.4691
I do most of my shopping in department stores	0.42792	0.5924
I feel that I can trust department stores to give me a good deal	0.40372	0.5178
FACTOR 3: Eigenvalue = 3.09405 - "enjoyment of shopping"		
To me, shopping is fun	0.78390	0.7393
I love to go shopping whenever I can find the time	0.70737	0.7346
I enjoy shopping more than more women I know	0.66697	0.6511
I only go shopping when I really need something	-0.62086	0.6070
I like to browse in stores with no specific item in mind to buy	0.61971	0.6869
I love to shop for clothing	0.61920	0.6646
Shopping gives me no satisfaction	-0.48520	0.5084
I enjoy spending money	0.46676	0.5382
FACTOR 4: Eigenvalue = 2.49247 - "reliance on newspapers"		
I don't read newspapers very often	-0.81280	0.6939
I read the newspaper every day	0.76087	0.7614
I rely on newspapers to keep me up to date on what is going on in the world	0.68630	0.7462
When I read a newspaper, I read it thoroughly	0.56597	0.6869
I simply couldn't do without newspapers	0.55756	0.7077
I get more information from reading a newspaper than from watching the news on television	0.33619	0.5811
FACTOR 5: Eigenvalue = 1.99208 - "attitude toward advertising"		
Advertising is usually misleading	0.60367	0.6073
Advertising is dishonest	0.58168	0.6031
The government should prohibit advertising on radio and television in Canada	0.41199	0.6065
I generally believe what I read in department store advertisements	-0.40994	0.5199
There is too much advertising today	0.37298	0.6157
FACTOR 6: Eigenvalue = 1.54094 - "attitude toward discount stores"		
People like me usually shop at discount stores	0.65527	0.7413
I enjoy shopping at discount stores	0.64935	0.7826
When I shop at a discount store, I get good value for my money	0.62660	0.6693
I feel comfortable shopping at discount stores	0.61468	0.7718
FACTOR 7: Eigenvalue = 1.26240 - "attitude toward credit"		
I buy many things with a credit card	0.68722	0.7095
It is good to have charge accounts	0.64034	0.7236
I think every shopper should have a credit card	0.58392	0.6185
I like to pay cash when I buy something	-0.44443	0.5041
To buy anything, other than a house or car, on credit is unwise.	-0.42551	0.6086

TABLE 2 Continued

FACTOR 8: Eigenvalue = 1.00904 - "attitude toward television advertising"		
I like television advertising because it keeps me informed on new products.	0.54111	0.7772
I think television commercials are just as enjoyable as the programs	0.51105	0.6779
Television commercials are accurate in describing the product for sale	0.40179	0.6557

The data were then submitted to the BMD-12V Multivariate Analysis of Variance and Covariance program (Dixon, 1973). Since the twenty-four versions of the advertisement were distributed randomly to subjects, there was no control over the size of cells into which the returned questionnaires would fall. In order to comply with the constraint of the BMD-12V program regarding equal cell sizes, it was necessary to select subjects at random to be eliminated from those cells containing more than fifteen subjects. In all, forty-two subjects were dropped, thereby creating a sample of 360 subjects, equally distributed over the twenty-four cells of the design.

It has been possible in this study, to control the exposure of subjects to the three main independent variables. However, it is also hypothesized that a subject's reaction to an advertisement is influenced by certain demographic and life style characteristics of the subject herself. While it is not possible to select and group together subjects with similar individual characteristics, it is possible, through use of analysis of covariance (ANCOV) to determine the effect on the dependent variables of subjects' positions on these individual characteristics.

The multivariate version (MANCOV) is a useful technique in situations where more than one dependent variable is involved and the researcher is interested in determining the effect of the various independent variables on the total set of dependent measures. In this study, while the effect of the independent variables on each of the dependent measures is of considerable interest, so too is the effect of these independent variables on the subject's overall reaction to a retail advertisement.

A series of analyses of covariance were performed containing a total of sixteen covariates: eight 'life style' variables and eight demographic variables.

Results

Table 3 contains the results of the analyses of covariance performed. In the first three columns of Table 3 are reported the results of the univariate analyses of covariance performed with each of the three elements of subject's reaction as the dependent variables. The fourth column contains the results of the multivariate analysis of covariance which indicates the effect of various independent variables on subjects' overall reaction to the advertisement. The univariate ANCOV, while producing indications of effect on subjects' reactions of the retail store, brand and newspaper variables, do not take into consideration the inter-correlations among the three criterion variables and do not consider whether there are significant differences between the levels of the independent variables in terms of overall reaction to the advertisements, that is, over the set of three criterion variables.

^eThe BMD-12V MANCOV program produces an approximation of the F-statistic

The results of the four analyses indicate that no significant differences are evident between subjects exposed to the two levels of the newspaper variable. The newspaper in which the advertisements appeared had no significant effect on subjects' reaction to the advertisements. The other two main effects did, however, produce significant results.

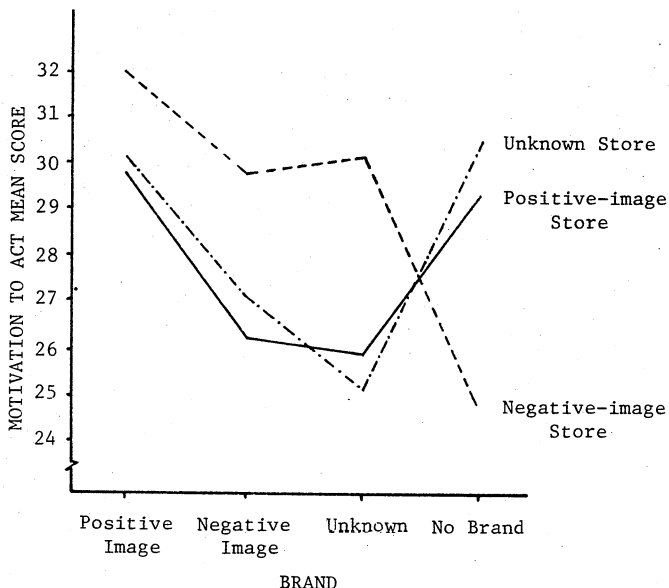

Subjects' perceived believability scores were significantly affected by the retail store sponsoring the advertisement ($p < 0.05$) and by the brand name featured in the advertisement ($p < 0.10$). Two covariates were also significant, suggesting that the extent to which subjects believed the content of the advertisement was influenced by their general attitude toward advertising ($p < 0.001$) and by the extent to which they enjoy shopping ($p < 0.10$).

Perception of value for the money was significantly affected by only one main effect. The brand name appearing in the advertisement was significant at the 0.10 level. Only one covariate was significantly related to perception of value - subjects' orientation toward department stores ($p < 0.10$).

The extent to which subjects were motivated to act was also significantly affected by the brand name ($p < 0.10$). Three covariates were significant in this analysis. Motivation to act scores were significantly related to bargain orientation ($p < 0.10$), orientation toward department stores ($p < 0.05$), and enjoyment of shopping ($p < 0.05$). This analysis also produced a significant two-way interaction (store x brand) effect. Examination of the motivation to act mean scores reveals that the retail store with a positive image obtained its highest scores where it featured a positive-image brand name or where no brand name appeared. Both the negative-image retailer and the unknown retail store obtained high motivation to act scores from advertisements featuring positive-image brands. The ability of the store with a negative image to motivate subjects dropped off somewhat where a negative-image brand or an unknown brand was featured and declined dramatically where no brand name was present. This interaction effect is depicted in Figure 1.

FIGURE 1

TWO-WAY (S x B) INTERACTION
MOTIVATION TO ACT
ANALYSIS OF COVARIANCE

The multivariate analysis (MANCOV) indicates that subjects' overall reaction to the advertisement was significantly influenced by the store sponsoring the advertisement ($p < 0.05$) and by the brand name featured in the advertisement ($p < 0.10$). All four of the covariates which were significantly related to overall reaction were 'life style' variables: attitude toward advertising ($p < 0.001$); bargain orientation ($p < 0.01$); orientation toward department stores ($p < 0.05$); enjoyment of shopping ($p < 0.10$).

Although no significant newspaper effect was found in any of the analyses, mean scores on the three dependent variables by levels of the newspaper variable were examined primarily to explore the possibility that a newspaper effect may be operating where the brand and store effects are absent (that is, where the retail store is unknown and the brand is either unknown or absent). This comparison of mean scores for the two levels of the newspaper variable produced no significant t-statistics. Even where the retail store was unknown and the brand was unknown or absent there were no significant differences between the mean scores produced by the positive-image newspaper and those produced by the negative-image newspaper.

Much information can be obtained by examining mean scores on the dependent variable across combinations of store and brand. These results are presented in Table 4. In the case of the positive-image retail store, while t-tests failed to produce any significant differences among the mean scores of the four levels of the brand variable, there is a definite pattern in evidence. For example, the positive-image store consistently, over all three dependent variables, produced its best scores where its advertising featured either a brand name with a positive-image or no brand name at all. Clearly, in the latter case, the store is able to trade on its established positive store image. Reaction to its advertisements was less positive in those situations where it featured either a negative-image brand or a brand name with which respondents were unfamiliar.

The advertisements for the retail store with a negative image produced even more significant results. In general, this store's advertising was considered less believable than that of the positive-image store. Its most believable advertisements were those which featured the positive-image brand. In terms of indicating good value for the money, the negative-image retail store's advertising produced a significantly more positive reaction where it featured a brand name with an established positive image than where it featured no brand at all ($p < 0.05$). Similar results were found where motivation to act was the dependent variable. In this latter case, a significantly better reaction was obtained even where the negative-image brand or an unknown brand was featured as compared with no brand. It would appear that the negative image of the retail store is imputed to the advertised product in that situation where the product is unbranded.

In the case of a retail store concerning which the consumer has no established image, possibly a new store being established in a market area, it was found that its advertisements were perceived as significantly more believable when the positive-image brand was featured as compared with the situation where an unknown brand was present in the advertisement ($p < 0.01$). The same significant result holds true for the other two dependent variables. An advertisement for an unknown store was more likely to motivate a respondent to act even where it featured a brand with an established negative image ($p < 0.10$) or no brand at all ($p < 0.05$) as compared with advertisements which contained an unknown brand.

TABLE 4
 MEAN SCORES ON THREE DEPENDENT VARIABLES
 BY LEVELS OF THE RETAIL STORE AND
 BRAND NAME VARIABLES
 (n=402)

	Perceived Believability ¹	Perceived Value For The Money	Motivation To Act
<u>Positive-image Store</u> (n=134)			
Positive-image brand (n=34)	17.9194	22.8142	29.3686
Negative-image brand (n=30)	18.9740	20.4258	26.1878
Unknown brand (n=35)	19.4623	22.7525	25.8550
No brand (n=35)	17.7281	23.3357	29.3567
<u>Negative-image Store</u> (n=130)			
Positive-image brand (n=36)	19.0392	25.3533 ^a	30.9470 ^a
Negative-image brand (n=30)	20.6053	23.5654	30.1765 ^b
Unknown brand (n=33)	20.1965	23.8795 ^c	29.5780 ^d
No brand (n=31)	19.9093	20.8640	25.0284
<u>Unknown Store</u> (n=138)			
Positive-image brand (n=30)	18.0667 ^e	25.8788 ^f	30.3642 ^g
Negative-image brand (n=40)	20.5969	23.2373	28.6840 ^h
Unknown brand (N=34)	22.5883	22.3114	24.5440 ₁
No brand (n=34)	20.1492	24.1562	29.3506

¹The lower the score, the more believable is the advertisement perceived.

^aResults are significantly higher for positive-image brands than for no brand at 0.05 level.

^bResults are significantly higher for negative-image brands than for no brand at 0.05 level.

^cResults are significantly higher for unknown brands than for no brand at 0.10 level.

^dResults are significantly higher for unknown brands than for no brand at 0.05 level.

^eResults are significantly higher for positive-image brands than for unknown brands at 0.01 level.

^fResults are significantly higher for positive-image brands than for unknown brands at 0.10 level.

^gResults are significantly higher for positive-image brands than for unknown brands at 0.05 level.

^hResults are significantly higher for negative-image brands than for unknown brands at 0.10 level.

¹Results are significantly higher for no brand than for unknown brands at 0.05 level.

Conclusions and Implications

The brand name main effect was found to be significant at the 0.10 level in all four analyses of covariance. The retail store effect was significant at the 0.05 level in the perceived believability ANCOV and in the MANCOV. No significant newspaper effect was found. These results lend support to the hypothesis that in branded retail advertising, the consumer's reaction is most strongly influenced by those sources which are perceived to have responsibility for the product.

The fact that the newspaper effect was not significant in any case suggests that a consumer's reaction to a branded retail advertisement is not likely to be influenced by the newspaper in which that advertisement appears. A retailer would likely not detract from the attractiveness of his advertising by running advertisements in newspapers which have a somewhat negative image. That is not to say, of course, that all newspapers are equal. While the newspaper may not affect reaction to the advertisement, the retailer must still consider other aspects of the newspapers available to him including circulation, market coverage, cost per thousand, etc.

The most important implications of this study are for the retailer. A quality retail store with an established positive store image can detract from the success of its advertising by featuring negative-image brands or brands with which consumers are not familiar. Its best results

will come from advertisements which feature brands which have a positive image or no brand at all. In this latter case, the store clearly benefits from its established quality reputation.

The opposite effect was found in the case of advertising for a lower quality store which is having image problems. This retailer would also be advised to feature established positive-image brand names in his advertising as these continually produced the most positive reaction. In fact, the negative-image retailer should use even negative-image brands or unknown brands rather than feature no brand at all. Where no brand is present, consumers apparently rely on the image of the store to evaluate the advertised product. Because of its negative image, a retail store which is held in low esteem by consumers should not feature unbranded merchandise in its advertising.

Finally, the retailer who is just establishing a store in a new market area, where he has no established store image, would also be advised to feature established positive-image brands in his advertising. Since the consumer has no image of the store, she apparently judges the advertised product on the basis of the brand name. In this study, advertisements for the unknown retail store produced a more positive reaction where no brand name was present than where either a negative-image brand or an unknown brand was present. Therefore, the retail store which is just establishing itself in a market should avoid the use of negative-image or unknown brands in its advertising.

AN EXAMINATION OF CONSUMER GROCERY STORE CHOICE:
CONSIDERING THE ATTRACTION OF SIZE AND THE FRICTION OF TRAVEL TIME

Daniel J. Brown, Oregon State University

Abstract

Location analysis, commonly known through the gravity model, suggests that consumers balance size against travel costs in choosing retail centers. In contrast to previous research, this paper reports a test of location theory using: individual consumers, individual grocery stores, and consumer panel data instead of survey reports of behavior.

Introduction

In the early decades of this century, Reilly (1931) formulated a retail "gravity model" to predict patronage decisions of rural consumers on the basis of distances to shopping towns and the sizes of those towns. In his model the proportion of trade from an area between two towns, a and b, is defined as B_a/B_b , which is a function of the product of the ratio of the sizes P_a/P_b of the centers (population) multiplied by the inverse ratio of the distances (D_b/D_a) from the intermediate place to the two towns.

$$B_a/B_b = (P_a/P_b) (D_b/D_a)$$

In the early 1960's, faced with a more suburban society, Huff (1962) introduced another "gravity model" to predict consumer choices among shopping centers. In this model, the dependent variable, P_{ij} , represents the probability that a consumer located at i will shop at center j . Predictor variables include, T_{ij} , the travel time required to get from the consumer's travel base to a shopping center, and S_j , the size (floor space) of the center.

$$P_{ij} = \frac{S_j/T_{ij}^\lambda}{\sum_{j=1}^n S_j/T_{ij}^\lambda}$$

Gravity models are still being explored in recent research (Stanley and Sewall, 1976; Bucklin, 1971; Nakanishi and Cooper, 1974).

As models of consumer behavior, they are unusual because of their simplicity. They are based on just two independent variables: the attraction of size and the friction of distance. They also embody easy to visualize, "all other things equal," relationships among variables: a negative monotonic relationship between patronage and travel time, and a positive, monotonic relationship between patronage and size.

The models are related to a theory of consumer choice which is common in the location analysis literature: the consumer weighs the benefit of size against the cost of travel in choosing retail centers. Travel is negatively evaluated because it represents costs to the consumer in purchasing goods (Bender, 1964; Downs, 1961; Kelley, 1958). These costs are measured in terms of

time, out of pocket costs and even emotional energy. On the other hand, size is evaluated positively by the consumer. The underlying attraction might be merchandise assortment as Huff (1962) suggests. In addition, there is a possibility that consumers perceive center size and merchandise prices to be inversely related.

Going beyond the basic gravity model formulation, it is recognized that the attraction of size and the friction of travel will change under different circumstances. Huff (1962), for example, showed that the λ in his model, which captures the trade-off between size and travel, takes on different values when consumers shop for different goods.

When minor expenditures are contemplated by the consumer, the preference for nearby stores would be exaggerated while the preference for size would be reduced. In such a situation, travel costs are large in relation to purchase costs and weigh more heavily in decision making.

When major cash expenditures or a number of purchases are contemplated by the consumer, the reverse is true. The preference for size is exaggerated and the preference for nearby stores is reduced. The consumer can average the cost of the trip over more dollars or more items (Christaller, 1966; Downs, 1961; Bender, 1964). In addition, an outlet which does not allow the consumer to minimize travel costs when only one product is being purchased may allow minimization over the entire trip when the trip involves visits to multiple destinations.

Research Plan

This paper reports on a test of some propositions involving consumer reactions to gravity model variables. Unlike most gravity model research, this study concentrates on a common managerial problem: understanding consumer response to the characteristics of a particular store. Most studies, in contrast, examine shopping centers or towns. Also, unlike most other studies, this research uses the individual consumer as a unit of analysis rather than an entire neighborhood. Individual level analysis has been recommended by several authors (Bucklin, 1967; and Mackay, 1970). A final distinction is that this study uses measures of actual behavior as opposed to reports of behavior from survey questionnaires.

Hypotheses

The following general questions are addressed: Do consumers react to travel friction as if it is a cost to be overcome and to size as a store benefit? Do consumers act as if the importance of these costs and benefits changes with the sizes of payoffs sought on different types of trips? Six specific hypotheses are tested.

The first two hypotheses are fundamental in the basic gravity model formulation examined in the context of grocery shopping.

Hypothesis I: Consumers will make more visits to stores nearby their homes than they will make to more distant stores.

Hypothesis II: Consumers will make more visits to larger stores than they will make to smaller stores.

The second pair of hypotheses explore single-and multiple-purpose trips. A single-purpose grocery shopping trip is made by a consumer when the grocery store is the only destination contemplated and when products are purchased only from the grocery store. A multiple-purpose trip is made by a consumer when some other destination is contemplated in addition to the grocery store.

On multiple-purpose trips, one expectation is that the consumer should be willing to incur greater travel costs. Another expectation is that the consumer should desire to concentrate purchases at a single large center rather than traveling to several different places.

Hypothesis III: Consumers will patronize stores further from their homes on multiple-purpose grocery shopping trips than the centers they will patronize on single-purpose trips.

Hypothesis IV: Consumers will patronize larger shopping centers on multiple-purpose grocery shopping trips than the centers they will patronize on single-purpose trips.

A final set of hypotheses explore convenience and major grocery shopping trips. A "convenience" trip is operationally defined to consist of the purchase of four or fewer items, which are not the specialty of the store, at a cost of \$5.00 or less. Other trips were labeled as "major" if the consumer spent eighteen percent or more of her grocery budget for a month. These cut-off points are arbitrary, but they capture the essence of the distinction being made. Of course, a number of trips did not fall into either category.

Hypothesis V: Consumers will patronize stores closer to their homes on convenience grocery shopping trips than the stores they will patronize on major trips.

Hypothesis VI: Consumers will patronize smaller grocery stores on convenience grocery shopping trips than the stores they will patronize on major trips.

Data

The basic data used to test these hypotheses were taken from a panel of 101 consumers living in a number of suburbs northwest of Chicago. The area was characterized by consistently high levels of store availability and accessibility. It also provided an array of shopping alternatives: "mom and pop" stores, convenience stores, small older supermarkets, and new larger supermarkets.

The panel consisted of white, middle class, suburban females who used the automobile to do their shopping. These women made a total of 992 visits to local grocery stores over a period of a month. Their trips provide the dependent measure in the analysis. Independent measures include: store sizes, shopping center sizes, and travel distances to stores.

Data Analysis

Three methods of data analysis were attempted. Ordinary least squares regression analysis was employed to test

Hypotheses I and II. The basic equation to be estimated was simply:

$$y = \alpha + \beta (x)$$

Hypothesis I predicts that β should be negative, and Hypothesis II predicts that β should be positive. The null hypothesis in both cases is that $\beta = 0$.

The independent variable in Hypothesis I, D_i , represents the travel distance separating consumers' homes from patronized stores. Distance is represented by 20 quarter mile intervals ($i = 1, \dots, 20$). A five mile boundary was chosen because only four of the original 992 trips were made to stores beyond that point.

For any aggregate of shops, it is not too extreme to assume an area to be served. No doubt a native of Detroit might some day buy an article in Birmingham, Alabama, or even in Hong Kong, but it is doubtful whether a retailer of interest to central place analysis takes this into consideration. It seems fair to assume that the territorial ambitions of the most aggressive of hucksters has a limit. To facilitate analysis, it will be assumed here that a local area ends abruptly at its edge, and beyond stretches the void (Curry, 1967, p. 221).

The dependent variable in Hypothesis I, $P_i - O_i$, is a combination of two variables. The behavioral variable of interest, P_i , is the proportion of total visits made to a store within a particular distance interval. The geometry of the spatial choice situation requires the inclusion of a structural variable, O_i , to correct for the "pattern of opportunity". O_i is an index showing that the proportion of the total area in the five mile range which falls within a particular interval. Each successive zone radiating outward from the consumer's home has more area and a higher probability of stores being located there. If distance were not a friction variable, then, more trips would be made to more distant stores simply because of availability.

The independent variable in Hypothesis II, S_j , is the size of the grocery store measured in square feet of floor space. Size was represented by 10 intervals containing 5,000 square feet. The dependent variable, P_j , is the proportion of total visits made to a store in a particular size interval.

Two additional methods were used to test Hypotheses III through VI. The first was a simple test of mean differences between types of trips. The analysis was based on the following hypotheses (Hays and Winkler, 1971, p. 428).

$$H_0: \bar{X}_i - \bar{X}_j = 0 \quad H_1: \bar{X}_i - \bar{X}_j > 0$$

where: X = average value
 i = consumers making one type of trip
 j = the same consumers making the other type of trip

The final method for testing Hypotheses III through VI was regression analysis using indicator variables (Neter and Wasserman, 1974, p. 304). An attempt was made to identify separate linear distance decay functions for the different trip types.

Comparative analyses are restricted to those persons who happened to engage in both types of behavior. So the sample sizes vary among tests.

Results

Patronage displays a pattern of "distance decay" envisioned in Hypothesis I, that is, more consumer visits were made to stores in nearby distance intervals than to more distant stores. The pattern is basically negative monotonic as expected. A deviation from the trend appears in the interval from 0 to 1/4 miles. Because of zoning restrictions in the study area, few homes are located this close to stores.

The following regression equation estimates the distance decay function:

$$P_i - O_i = .12765 - .01218 (D_i) \quad r^2 = .89$$

(.001)

Where: P_i = number of visits in distance interval i
 Total number of visits

D_i = travel distance separating consumers' homes from patronized stores

O_i = $\frac{\text{the area in distance interval } i}{\text{total area within 5 miles of consumers' homes}}$

The β coefficient is negative as expected and significantly different from zero ($t = 12.05$, $p < .0005$). Taking the pattern of opportunity into account, almost 90 percent of the variation in the data is explained by distance.

Considering store size in Hypothesis II, the results are not as straightforward. The pattern of patronage is approximately bell shaped over different store size intervals, so linear regression is not appropriate. The pattern is certainly not monotonically increasing as expected. Thus, the data do not indicate that consumers respond to store size as a general benefit.

Consumers who made both multiple-and single-purpose trips acted as expected in Hypotheses III and IV. The results are shown in Table 1. They chose nearer stores when they were buying only groceries and more distant stores when also making non-grocery store purchases. The difference amounts to about a ten percent increase in distance beyond the single purpose stores. However, in regression analysis, it is not possible to isolate two separate linear distance decay functions using indicator variables to represent different trip types. Consumers also chose grocery stores in larger shopping centers when making multiple purpose trips than when making single purpose trips. The difference amounts to about a 96 percent increase in size over single purpose shopping centers.

Consumers who made both major and convenience grocery shopping trips also acted as expected in Hypotheses V and VI. The results are shown in Table 2. They chose more distant stores when the amount of purchase was large and closer stores when purchase amounts were insignificant. The increase in distance is about 27 percent more for major trips than for convenience trips. Again it is not possible to isolate separate linear distance decay functions for the two different trip types. Consumers also chose larger stores on major trips than on convenience trips. The increase of major over convenience amounts to about 40 percent.

TABLE 1

DIFFERENCES BETWEEN MULTIPLE AND SINGLE PURPOSE GROCERY SHOPPING TRIPS: TRAVEL DISTANCES TO AND SIZES OF SHOPPING CENTERS PATRONIZED

	Average Difference	t	d.f.	p <
Travel Distances between Patronized Stores and Homes of Consumers	.12 miles	1.87	77	.05
Shopping Center Sizes Surrounding Patronized Grocery Stores	108,950 sq. ft.	134.1	66	.00

TABLE 2

DIFFERENCES BETWEEN CONVENIENCE AND MAJOR GROCERY SHOPPING TRIPS: TRAVEL DISTANCES TO AND SIZES OF GROCERY STORES PATRONIZED

	Average Difference	t	d.f.	p <
Travel Distances between Patronized Stores and Homes of Consumers	.31 miles	1.88	53	.05
Sizes of Stores Patronized	7,100 sq. ft.	4.60	53	.00

Discussion

The statistical tests employed in this study produce mixed although moderately successful results. Hypotheses I, IV, and VI, are supported completely. Hypotheses III and V receive qualified support. They pass the t test, but the trends envisioned in the hypotheses can not be described by separable linear functions in regression analysis.

Only Hypothesis II receives zero support. "Average" sized stores received more patronage than either larger or smaller stores. The pattern looks as if it could have been generated from a random selection process or as if the most popular stores were average size. Several explanations are possible: First, the results observed may reflect the actual pattern of available stores rather than a preference function for store sizes. Second, the preference function for store size may be non-monotonic as Baumol and Ide (1956) suggest. Size to them is thought to be attractive up to a certain point. Beyond that point increases in size mean more shopping cost for the consumer rather than better selection. Finally, Bucklin's (1967) admonishment about gravity model applications to individual stores may apply:

Doubt that mass will be adequate is brought to

mind because of difficulties experienced by researchers attempting to evaluate inter-store trading areas. At this level of disaggregation, the image content of shopping utility evidently becomes the controlling factor (p.38).

However, this final assertion seems inconsistent with the favorable result for Hypothesis VI which indicates that consumers were reacting to store size as a source of utility.

The results of this study lend credence to the general location theory postulates about consumer behavior. Consumers do appear to react to distance and store size in choosing stores. In addition, the present test is unusual. It demonstrates that location theory can be tested using individual stores and individual consumers as units of analysis. Although Huff (1966) suggests that both of these uses are possible, they are rarely seen. The test is also unique in that it uses actual behavior as a dependent variable rather than behavior reports from surveys.

The study would have certainly been improved by a larger sample size. Then both the multiple-single and the major-convenience distinctions could have been investigated simultaneously. The expectation should be that a single-purpose, convenience trip should encourage patronage at the nearest store of any size.

From a managerial perspective, an important implication lies in the realm of trading areas. Smaller trading areas will be controlled by stores which cater to convenience and single-purpose shoppers, and larger trading areas will be enjoyed by stores which cater to major trip and multiple-purpose shoppers.

What happens if the gasoline supply is restricted in the future? Two consumer options are obvious: a reduction in automobile travel or a switch to alternate modes of travel (Becker, Brown, and Schary, 1976). In the first case, carefully planned multiple-purpose trips or a small number of major trips would be in order for the consumer. The effect could be to increase the trading areas of large stores and large shopping centers.

Switching to non automotive modes of travel (bicycle, walking, and mass transit, for example) generally means that smaller amounts can be brought home from a shopping trip. Furthermore, alternatives such as walking or biking greatly increase the friction of distance. The effect could be to decrease the trading areas of stores so that the economies of scale from large operations would no longer be possible. In the case of either consumer transportation response, the effect on the pattern of retail trade can be expected to be dramatic.

PERCEPTIONS OF UNFAIR MARKETING PRACTICES:
CONSUMERISM IMPLICATIONS

Gerald Zaltman, University of Pittsburgh
Rajendra K. Srivastava, University of Pittsburgh
Rohit Deshpande, University of Pittsburgh

Abstract

Previous research in complaint behavior has ignored the perception of unfair marketing practices as an explanatory variable. Perceptions of unfair marketing practices are related to consumer complaint behavior, although differentially related across different ages. Social involvement among elderly consumers was also found to be a relevant variable. Implications of the data are discussed for public policy makers, consumer educators, and vendors.

Introduction

A critical issue in consumer education is whether perceptions of unfair marketing practices are related to consumer complaint behavior. One reason the issue is important concerns remedial action. If consumers' complaint behaviors are affected by their awareness of unfair marketing practices, then a strategy of consumer education is most appropriate. Increasing consumer knowledge of unfair marketing practices should lead to increased complaint behavior when such practices are encountered. Additionally, educating consumers in the methods of forming and presenting complaints about grievances becomes an important associated issue. These strategies have many advocates (Andreasen, 1975; Kraft, 1977), although at least some persons active in the area question the effectiveness of consumer education programs in increasing consumer knowledge or in altering their behavior (Staelin, 1977; Robertson, et al, 1974; Robertson, 1975). If consumer perceptions of unfair marketing practices are unrelated to their complaint behavior, that is, if barriers exist which prevent consumers from taking action or consumers cannot be instructed effectively, then regulatory action by public agencies may be the most appropriate direction for protecting consumers from unfair marketing practices. This approach essentially says that what consumers cannot or will not do for themselves must be done by regulatory agencies (Palumbo, 1976; Robertson, et al, 1974; Andreasen, 1975, especially Chapters 10 to 12; Feldman, 1976).

This paper is concerned with consumer perceptions of unfair marketing practices and complaint behavior. A special interest is with elderly consumers. The study is exploratory in nature, but has several important implications for consumer educators, public policy makers, and vendors who need to understand consumer complaint behavior and the factors which may lead to such behavior. One particular factor, awareness of unfair practices, which appears not to have been studied to date, is highlighted here. A second factor, social involvement, also unstudied, is mentioned briefly as well. The paper concludes with a discussion of the major implications of the data presented.

Relevant Literature

Consumer complaint behavior has received considerable attention in the literature. Wall, Dickey and Talarzyk (1977) have tried to profile consumer satisfaction and propensity to complain. A very important finding of their research is that dissatisfaction and the experience of a product performance problem was not related to

a consumer's likelihood of complaining. They found that the most effective predictors of propensity to complain were personal characteristics and internal influences. The Wall, et al study did not, however, measure consumer knowledge or awareness of unfair marketing practices. One of their findings on which we will comment later was that "younger consumers were more likely to be noncommunicators of complaints" (p. 33). This finding was not, according to the authors, a particularly strong one.

Another study by Granbois, Summers and Frazier (1977) studied consumer beliefs and expectations as they related to complaining behavior, but did not report particularly strong associations. However, beliefs about a store's willingness to provide a remedy for a complaint was the most important consumer belief variable. By and large, demographic variables such as age were not found to be of significant importance. The Granbois, et al study did not attempt to measure consumer knowledge about practices or events they might complain about.

Landon (1977) reviewed the literature related to consumer complaint behavior to develop a model of consumer complaint behavior. Interestingly, neither the literature he cites nor the model he builds considers the basic issue of whether consumers know what they should complain about.

The most relevant study to the research presented here is reported by Kraft (1977): "...consumers who believe that a firm intentionally deceived them or acted to dissatisfy them will be more likely to complain than those without this perception." Among dissatisfied consumers, those who complained were nearly twice as likely to think sellers deliberately deceived them than consumers who did not complain. This raises the important question of consumer perceptions of unfair marketing practices. Before consumers perceive deception or unfair treatment, they must perceive particular practices to be unfair or deceptive. Kraft's research appears to be the only study which touches upon this important issue.

A special concern we have is with elderly consumers. Waddell (1975) cites several reasons why elderly consumers may be particularly susceptible to fraud. These reasons include lower education than the population at large, increased concern with getting special bargains to make limited resources go further, and greater gullibility and suggestibility arising out of feelings of helplessness, low self-esteem, and loneliness. It has been suggested that the medical area is the area where consumer fraud among the elderly is greatest (Butler, 1975). Other research has focused on information usage of consumers (Klipzel and Sweeney, 1973; Schiffman, 1971) and social isolation (Schiffman, 1973). For example, Schiffman has noted the social involvement in various groups may enhance opportunities for consumption related discussions and hence persons involved in many groups have a greater chance to learn about the market. As noted earlier, Waddell (1975) suggests that the lack of social involvement may be a contributing factor to susceptibility to fraud. Social involvement may provide not only more opportunity to learn about which marketing practices are unfair or deceptive, but may also provide social reinforcement for taking complaining action and the opportunity to learn how or where to complain. Thus, we might expect the socially involved consumer to perceive

more marketing practices as unfair and to be more prone to complain.

Extant literature on consumer complaining focuses almost exclusively on product performance, the related issue of product safety, and to a lesser degree, other postpurchase activities, such as servicing and honoring of warranties (Fisk, 1970; Westbrook, 1977; Darden, 1977; Trombitta and Wilson, 1975). However, consumers may and do complain about many other factors beyond issues related to product performance. It is important therefore to consider a broad range of factors a consumer may complain about. In the next section of this paper, we shall direct our attention to these factors.

Present Research

The data addressed here concern consumer perceptions or recognition of unfair and deceptive practices and their undertaking complaint behavior. As evidenced in the review above, this has been largely unstudied in the literature on consumer complaint behavior. Moreover, this study reports on consumer recognition of unfair practices at three points: the point or stage prior to product purchase; the time of purchase stage; and postpurchase stage. This distinction does not appear to have been made before. Additionally, this study addresses the issue of age as it relates to the recognition of unfair practices and to complaint behavior. Existing evidence about the relationship of age and consumer complaining is contradictory (Wall, et al, 1977; Gaedeke, 1972; Mason and Hines, 1973; Miller, 1970).

The Sample and Data

The data on which this study is based are derived from a nationwide sample of 2,849 (4,000 questionnaires were mailed and 2,849 usable responses, a net response rate of 79%, were obtained). As the data presented here are merely a subset of a larger research focusing on the consumption problems specifically concerning susceptibility/perception/information processing/complaint behavior of the elderly with respect to fraudulent marketing practices, the sample is naturally biased towards a larger representation of the elderly age group (1771/2849 = 62.2%). In comparison with available statistics on the national level*, the following were the characteristics of the sample:

- (1) A high level of education;
- (2) Slightly unbalanced geographical distribution (lower representation in the New England and East-South Central states);
- (3) Lower representation of the black minority group;
- (4) Lower (substantial) representation of single males;
- (5) Slightly higher income level.

The data are the first wave of a three-wave study. Steps are being undertaken to ensure greater representativeness (within the nonelderly and elderly) subsamples in the remaining stages. However, as we will discuss while examining the results, most of the unrepresentative characteristics noted above are not expected to change the implications of the findings.

Variables and Propositions

The basic proposition tested here is the following: As awareness of unfair and deceptive practices increases among consumers, the propensity to complain increases.

Subpropositions may be formulated for each of three stages: (1) as awareness of unfair practices at the prepurchase stage increases among consumers, the propensity to complain increases; (2) as awareness of unfair practices at the purchase stage increases among consumers, the propensity to complain increases; and (3) as awareness of unfair practices at the postpurchase stage increases, the propensity to complain increases. To test the basic proposition and subpropositions, two variables were constructed. One variable is labelled "unfairness awareness" and is simply measured by the number of practices consumers perceive or recognize as unfair. This was constructed by counting the number of practices consumers cited in each basic stage represented in Table 1. Propensity to complain was measured by the number of complaint behaviors displayed in a critical incident of consumer dissatisfaction. The complaint behaviors which could be cited are shown in Table 2.

Table 1. Practices Perceived Unfair

Practices Potentially Perceived as Unfair	% Citing a Practice as Unfair
A. Before you buy	
Being pressured to buy a product or service other than the one advertised or wanted. . . .	72
Teaching salesmen to use hard-sell pressure. . .	58
Form letters which look as if they were addressed to you personally	53
Packaging, size, or feature differences that make it hard to compare prices directly. . . .	48
Telephone surveys (asking questions about your interests or habits before sales talk)	57
Offers of something for nothing.	68
Advertising items not available in store	62
Product demonstrations that show how easy to use, safe, or effective the product is	21
Unclear advertising, claims, or packaging. . . .	48
Free gifts, give-aways, or contests used to sell products or services.	53
B. What and when you buy	
Being pressured or forced to pay for repairs or services that others were actually responsible for.	60
Companies who change names or locations often. .	51
Being required to pay in advance or make a large down payment to get product/service.	44
Going-out-of-business sales.	33
Unexpected repairs found during servicing or inspection on a product you own.	43
Product sales that support the handicapped or children overseas.	31
Being pressured or forced to pay for repairs or services within a limited time or from a particular person/company.	34
Sales parties in a home.	27
Money-back guarantees.	13
Extra charge for sending repairmen out on weekends	44
Sales involving small monthly payments over a long period of time.	32
C. Problems after you buy	
Paid more than necessary, overcharged.	56
Being charged for undelivered product or service	47
Wrong item or service provided	48
Expensive to use, hidden costs	49
Unsafe product or service.	43
Hard to use product.	39
Repair or replacement parts not available or hard to locate	61
Being told you did not properly use or care for the product.	45
Poor or hard to read warranty.	47
Slow service/repair; repairman not polite. . . .	57

MD = 7%

Table 2. Complaint Actions Taken

Actions Taken Due to Problems Encountered	%
Stopped payment or refused to pay.	9
Decided not to buy that product/service or deal with that company again.	43
Complained to family or friends.	30
Asked for replacement or refund.	22
Complained to the person who sold me the product or service	41
Complained to the company or store	35
Complained to a consumer agency.	6
Complained to a public agency or my congressman.	5
Complained in a letter to a newspaper or magazine.	3
Considered taking legal action	8
Consulted or hired a lawyer to protect my interests.	3
I took no action at all.	23
Other.	2

The logic underlying these propositions is that the more practices consumers are aware of which are unfair, the more likely they are to recognize their being the target of unfair practices. The greater consumers' recognition of their being the target of unfair practices, the greater their likelihood of complaining. Moreover, since different unfair practices may warrant different complaint activities, we would expect the range of complaint activities to be broader as the array of practices perceived to be unfair broaden.

We also put forth the following ideas or propositions: (1) unfairness awareness decreases as age increases, and (2) complaint behavior decreases as age increases. These ideas were developed on the basis of exploratory research (not reported in the study) which included in-depth personal interviews with: (1) consumer protection/education/advisory agencies; and (2) convenience samples of individual respondents. However, reasoned arguments could easily be developed to support the opposition propositions. Such studies that do exist relevant to these propositions are contradictory, although we might expect elderly consumers to be less able to complain because of difficulty in returning to a store, having fewer resources to seek legal assistance, greater susceptibility to intimidation, and so on. Also, elderly consumers may participate less in the marketplace and thus have fewer complaints on an absolute scale. However, it was not clear that elderly consumers would have proportionately more or fewer complaints. Unfairness awareness might be expected to increase with age because of greater shopping experience. On the other hand, those who are concerned with consumerism issues and who have benefited from consumer education efforts appear to be younger people (Miller, 1970; Hustad and Pessemier, 1973).

There is an observation concerning the concept of age which the reader must keep in mind. Chronological age is usually a proxy variable. It is used in lieu of other variables which cannot be easily observed or measured. In some instances, age is an important behavioral variable itself. Examples would include an age specific drinking requirement for alcoholic beverages, age specific auto license requirements, and age specific retirement requirements. In other instances, age is simply an indicator for physical health, social attitudes and outlook, medicinal needs, experiences in one or another life situations, and so on. Thus, it is important to ask just what is meant when an observation is made that something such as awareness of unfair practices or propensity to complain varies with age? Unless this question is addressed, nothing is really being explained. Generally, little effort has been made in the consumer behavior literature to clarify what age represents in the contexts in which it is used. This makes it especially difficult to generalize about age or to compare studies involving age since the phenomenon age

is a proxy for may vary from study to study or context to context.

An attempt is made here to indicate what we believe age refers to in this study. In the case of unfairness awareness, we believe age to reflect differing degrees of buymanship skills. We do not believe that older consumers forget or become unclear about unfair marketing practices. Rather, the consumerism movement and its manifestations in classrooms and elsewhere has primarily benefited younger consumers because the movement is a relatively recent phenomenon in terms of its current salience and activity level. The consumerism movement was not pronounced when the present elderly consumer group was younger, and it does not appear to have reached them now (Waddell, 1976; Hustad and Pessemier, 1973). Thus, age may represent differential, effective exposure to consumerist activities and possibly an inability to learn new skills.

With regard to the propensity to complain, age may reflect a lower sense of efficacy or a lower expectation that anything positive may result from registering a complaint. Data in the larger study, but not reported here, are supportive of this contention and research by Klipzel and Sweeney (1971) suggests that feelings of efficacy among elderly consumers may indeed influence their behavior as consumers. Also, knowledge about how to complain may be lower among older consumers as may the physical ability to "get out" to complain.

Analysis

Table 3 contains summary data relating unfairness awareness to propensity to complain. Several subsets of data are presented in Table 3. Three subsets refer to three different points in the purchase process: before buying; when buying; and postpurchase. Three subsets refer to three different age groups: 25-34; 35-64; and 65 and over.* One subset refers to the total number of perceived unfair practices in the entire buying process for each age group. Consider, for example, individuals ranking high on unfairness awareness at the prepurchase stage. For the 25-34 age group, approximately 54 percent of those ranking high on unfairness awareness showed a high propensity to complain about their bad buying experience. For the 35-64 age group, this figure drops to approximately 38 percent. Among the 65 and older age group, only approximately 22 percent of those high in unfairness awareness were high on propensity to complain at this stage. This very same pattern holds for the purchase and postpurchase stages. Similarly, the proportion of consumers at each stage who are over 65 and who are low in unfairness awareness is greater than the comparable group among those aged 35-64, who in turn are proportionately greater than the comparable group among those aged 25-34.

The data in Table 3 support the basic proposition that as awareness of unfair and deceptive practices increases among consumers, the propensity to complain increases. Moreover, this is true for each of the three stages and, of course, for all stages combined. Moreover, we believe the implied causal direction is a valid one. As indicated earlier, being aware of unfair practices enables one to recognize them, which in turn gives the consumer a perceived cause or reason to complain, which

* The breakpoints for the age groups were determined on two considerations: (1) we were specifically interested in behavior of the elderly segment of the consumer market, which in most studies is operationally defined as 65 and over; and (2) it has been postulated that there is a stabilization in life-styles at approximately the age of 35, as by that life stage most individuals have decided their plans regarding career, marriage, etc. (personal communication, Larry Wortzel).

	100%	100%	100%	100%	100%	100%	100%	100%	100%
	(n=19)	(n=114)	(n=94)	(n=131)	(n=343)	(n=336)	(n=520)	(n=664)	(n=587)
	x ² ns at .01 level			p<.01			p<.01		

is a necessary precondition for complaining. Thus, in seeking to understand complaint behavior we must consider consumer awareness or unawareness of unfair practices. This has been largely ignored to date.

It is evident in Table 3 that age is related to unfairness awareness and to complaint behavior. This can be seen in Table 4 and in Table 5.

Table 4. Age and Unfairness Awareness

Unfairness Awareness Across All Stages				
Age	Low	Medium	High	Total
25-34	8.4	50.2	41.4	100% (n = 227)
35-64	16.2	42.3	41.5	100% (n = 810)
65 and older	29.4	37.5	33.1	100% (n = 1771)
p<.01				

Proportionately, more consumers 65 and older are represented in the low unfairness awareness category relative to the other age groups. Also, relative to the other age groups, proportionately fewer consumers aged 65 and older are in the medium and high unfairness awareness category. Overall, the age group 35-64 seems to have a modestly lower unfairness awareness than the 25-34 age group. Space does not allow us to reproduce the contingency tables for all three purchase stages as displayed in Table 3. However, the relationship between age and unfairness awareness is strongest and unambigu-

ous with regard to awareness of unfair practices after purchase. Fifty-six percent of all consumers aged 25-34 were in the high category at this stage compared to 45 percent and 33 percent for the 35-64 and 65 and older age groups, respectively. Fifteen percent of all consumers aged 25-34 were in the low category at this stage compared to 26 percent and 43 percent for the 35-64 and 65 and older age groups, respectively. Thus, it appears fruitful when considering unfairness awareness by age to distinguish among different purchase stages and the possibly unfair practices especially relevant to each stage.

The relationship between age and propensity to complain appears pronounced. The relevant data on this issue are presented in Table 5.

Table 5. Relationship Between Age and Propensity to Complain

Propensity to Complain				
Age	Low	Medium	High	Total
25-34	25.1	30.8	44.1	100% (n = 227)
35-64	34.6	35.6	29.9	100% (n = 810)
65 and older	53.9	30.7	15.5	100% (n = 1771)
p<.01				

As age increases, the propensity to complain clearly decreases. The reader is reminded that the measure of complaint propensity involved a critical incident which the respondent felt to be a particularly bad experience. Overall propensity to complain might be less for each age group. Since a critical incident approach was used, possible differences among age groups in their participation in the marketplace are highly unlikely to account for the observed differences.

It was indicated earlier that social involvement might be an especially relevant factor affecting perceptions of unfair marketing practices and complaint behavior among the elderly. Published findings about consumerism and the elderly are very few and often without specific empirical data. These studies have suggested, however, that social involvement could be relevant to consumer behavior. Individuals with many personal contacts have more opportunity to learn about causes to complain and to learn about procedures for complaining. Also, social contacts may provide needed social and psychological support or reinforcement for the act of complaining.

Space limitations do not permit a full presentation of the data concerning social involvement among the elderly and awareness of unfair practices and complaint behavior. However, some summary observations are possible. Social involvement was measured simply by the number of different organizations respondents participate in frequently or regularly. These include such organizations as church/temple groups, garden groups, senior citizen centers, clubs and fraternal organizations, volunteer work, family gatherings, and so forth. The measures of social involvement were relevant primarily to older persons and hence reference is made here only to older consumers.

Although a significant chi-square ($p < .01$) was obtained between social involvement and awareness of unfair practices, the substantive significance is modest. For example, 30 percent of those low in social involvement were low in unfairness awareness compared to 32 percent of those high in social involvement. Thus, the relationship is clear, but not of a very high order of magnitude. However, it remains debatable as to what level of difference is "substantial." One way of looking at this issue is to focus on the absolute size of the elderly segment. A percentage point in the elderly segment could mean about 200,000 people.

A relationship between social involvement and complaint activity was obtained similar to that characterizing social involvement and unfairness awareness among elderly consumers. Nearly 60 percent of the persons low on social involvement were low on propensity to complain, compared to nearly 50 percent for those high on social involvement. The chi-square statistic was significantly beyond the .01 level. The relationship between social involvement and propensity to complain is also clear, but not of a very high order of magnitude.

Further research is needed for a better understanding of the impact of social involvement on the consumer behavior of older persons. Interviewing and participant observer techniques might be especially appropriate for this task. Social involvement does appear to have an impact on awareness of unfair practices and complaint behavior. With regard to complaint behavior, a degree of spuriousness may be operating. Consumers who are able to be active in social groups by virtue of physical health, access to transportation, and so forth, may also be able to undertake the efforts necessary to complain; factors enabling a person to engage in social activity outside the home also enable a person to easily return to a store to complain. However, social involvement may still provide necessary social reinforcement for complaining. Further research is necessary to determine whether social involvement leads to avoidance of

situations which might have resulted in complaint behavior. Thus, social involvement, through its impact on unfairness awareness, may reduce the incidence of bad experiences (because the consumers know what to avoid), but once bad experiences occur, it may increase the likelihood of complaints being expressed. The data reported here are consonant with this possibility. Socially involved consumers perceive more practices as unfair and they also complain more.

Summary and Implications

The evidence from this study points up to several implications for different bodies of publics involved in the interface between marketing and society. The relevance of determining consumer awareness of unfair commercial practices and the differential activeness in the marketplace (in terms of both the perception of unfairness and the ensuing complaint behavior) among age groups leads us to make the following suggestions:

Implication No. 1. Traditional market segmentation strategy should include a component to determine how active or passive various segments of consumers are in acquiring product/service related information.

Our study has shown, for example, that older consumers are less active in terms of being aware of unfair business practices and in the means of redressing their complaints. This has consequences for consumer educators in that they should investigate which specific consumer segments are so disadvantaged with a view to developing programs to raise the general level of awareness regarding the particular ways in which unfair practices manifest themselves and the form in which to complain. Vendors should be concerned with attempting to understand how the more active consumers perceive unfair commercial practices so as to better understand their own (or their product/service) image in the eyes of those consumers. Regulatory agencies should clarify the legality of various business practices as perceived by consumers with a view to enacting legislation or implementing regulation to ensure that fairness operates in the marketplace to the satisfaction of both vendors and their customers.

Implication No. 2. The perception of unfair business practices by consumer segments should be further clarified in terms of the current legality or illegality of such practices.

Consumer educators should attempt to learn which practices are clearly illegal and which ones are just due to unclear understanding of the product/service usage. Educators can then serve to disseminate knowledge of these distinctions among the aggrieved market segments.

Vendors should try and assist consumers in the use of various products/services so as to avoid the misunderstandings that result in certain practices being perceived as unfair.

Regulatory agencies should monitor consumer complaints to determine whether regulation is required for currently illegal business practices and also whether changes in law are merited by a sufficient number of complaints regarding what was previously considered to be "legal" commercial activity.

Implication No. 3. The perception of unfair business practices by different consumer segments should be understood in the contents of specific product/service categories to which they might most clearly apply.

Regulators should determine not only what practices were seen as being unfair by consumers, but also the types of products or services which were related to these

practices. Specific industries might be more amenable to an unclear distinction between the legal and the illegal, and therefore more open to such perceptions of unfair activity.

Vendors should be interested in ascertaining whether their particular product or service requires more in terms of clarification in consumer use than law currently prescribes.

Implication No. 4. The perception of unfair business practices by different consumer segments should be understood in the contents of the channels of distribution and promotion that specific product/service categories require and to which they might most clearly apply and also in terms of the purchase stage.

Educators should inform consumers about the particular advantages and disadvantages associated with different forms of distributing and promoting products so that more geographically isolated consumers, for example, are not compelled to be dependent on practices they consider unfair. Vendors and public policy makers should also be interested in knowing which types of media and distribution consumers are leary of and the reasons for their apprehension. The perception of unfair practices by consumers should be considered by educators, regulators, and vendors in terms of whether concerns are particularly expressed at the pre-, during, or postpurchase stages.

Implication No. 5. Within different demographic segments the more and the less aware members should be distinguished in terms of awareness of the fairness of business practices and the means of expressing complaints.

Consumer educators should enlist the aid of the more actively aware within particular demographic segments (e.g., the elderly rural poor) to develop a program to increase general awareness.

Vendors should identify the more active consumers and redress their grievances and also ensure that the less active are not being unfairly taken advantage of. Regulators should coordinate the more active into complaint channels to be able to enact new legislation or implement necessary regulation.

Implication No. 6. Programs should be concurrently developed to both increase the awareness of clearly unfair business practices and the awareness of the means of complaining.

Consumer educators should serve also as data banks on the particular people to contact to redress specific complaints and also the best manner that such complaints should take.

Vendors should participate in the design and conduct of educational programs to ensure that their industries are not unfairly maligned and also so that, if necessary, corrective measures are taken promptly.

Regulatory agencies should see that viable consumer complaints can reach them and that aggrieved consumers never feel that they are helpless when taken unfair advantage of in commercial transactions.

Implication No. 7. The social involvement of elderly consumers in society should be enhanced with a view to increasing both their awareness of fair and unfair business practices and the modes of possible redress of complaints.

Efforts should be made to encourage community groups to address consumer issues, thereby deliberately enhancing the positive impact they have on consumer perceptions of unfair practices and on consumer propensity to complain.

Vendors, public officials, and consumer educators might stimulate such activities by participating in such programs. Most importantly, particular efforts should be made to attract to these special meetings those persons who are typically uninvolved for various reasons in community groups.

A COMPREHENSIVE STUDY OF CONSUMER SATISFACTION WITH DURABLE PRODUCTS

Stephen B. Ash (student), Indiana University

Abstract

A preliminary analysis of results from the consumer durables section of a broader study directed by Professor Ralph Day of Indiana University is presented. The results reflect wide variations over the 67 durable product classifications in: (1) the sample proportion reporting a purchase; (2) the relative importance of the items to users; and (3) the patterns of reported satisfaction and dissatisfaction.¹

Introduction

The concern of consumer advocates, policy makers, and the consumer public with the apparent general rise in consumer dissatisfaction has led to a call for more and better research focusing on the products and services which seem to be responsible for the increase in the number of dissatisfied consumers. The design and implementation of "effective" consumer protection programs must overcome two basic constraints: insufficient funding and inadequate information. The first limitation suggests that since policy makers have finite resources with which to support their programs, they must attempt to discern the most useful way in which satisfaction/dissatisfaction (CS/D) research should be conducted. The central decision focuses on what kinds of data should be collected to facilitate the design of programs concerned with consumer satisfaction/dissatisfaction. Also, researchers may consider the related issue of aggregation. In assessing consumer dissatisfaction, should the unit of investigation be at the level of the individual, some particular segment of the consuming population or aggregated data on the entire population? Aggregate analysis is governed by data which may provide only very rough approximations of CS/D trends throughout society. Analysis of disaggregated data, while more costly and time-consuming, promises further understanding of the underlying determinants of consumer satisfaction/dissatisfaction. Although virtually all CS/D research to date has relied on individual measures, there have been some efforts to develop overall indexes of consumer satisfaction (Handy, 1976; Handy, 1977; Lingo and Pfaff, 1972; A. Pfaff, 1972; M. Pfaff, 1976). It is not clear to what extent, if any, the index of consumer satisfaction (ICS) facilitates the actual decision-making process of policy makers. For example, at the industry level, there appears to be some reservation about the willingness of managers to rely on ICS as a decision-making tool (Pratt, 1972).

The adequacy of volunteered complaint information as a basis for assessing consumer dissatisfaction has received recent attention (Day and Bodur, 1977). They suggest that complaint letters may be misleading since they tend not to be representative either of the types of problems confronting consumers or of the types of people experiencing consumer problems. No further elaboration on specific shortcomings of volunteered complaint data (for example, "big ticket" bias) is provided here since these issues have been discussed elsewhere (Day and Bodur, 1977).

Policy makers require a workable basis for setting priorities and planning consumer protection programs. They depend on the availability of the kinds of information which will permit them to evaluate, systematically, existing levels of dissatisfaction with products and services. A recent study (Day and Bodur, 1977) has suggested that at least four kinds of information are required for diagnostic purposes:

1. Number of users in the population.
2. Proportion of users expressing dissatisfaction with the item.
3. The degree of importance associated with the consumption of a product or service.
4. How consumers resolve their dissatisfaction with an item.

They contend that these elements may provide policy makers with a basis for assessing the "need for protection" by consumers of particular goods and services.

Purpose of the Study

The primary contribution of this study consists of reporting preliminary results of analysis on durable goods data obtained by means of a survey research instrument which was developed as a part of a larger research project (Day and Bodur, 1977; Day and Landon, 1976). The current findings may be put into perspective if assessed in relation to the underlying objectives of the parent project. The fundamental goal of the project was the design of a research method which would furnish the kinds of information essential for evaluating consumer satisfaction/dissatisfaction over a comprehensive set of products and services. The operational objective was the development of a product-by-complaints matrix based on "better quality data (than volunteered complaints or 'single incident recall' can give us) of a descriptive nature" (Day, 1977). The matrix would be used by policy makers as a tool for diagnosing consumer dissatisfaction.² At least the following issues were of interest to the designer of the research instrument:

- How and from whom should the data be collected?
- How do volunteered data provided by self-selected individuals differ from those obtained from a scientifically-designed probability sample? Which set provides more representative information about consumer problems over the entire population?
- If these data are collected from a probability sample, how free are they from "big ticket" bias and/or overpowering "demand characteristics" of the data collection procedures?

In general, the relevant information required will consist of measures: (1) of the fraction of the population using the item and (2) of the distribution of users over

¹The data for this study were provided by Professor Ralph Day, Indiana University. The author is grateful to Professor Day and to the reviewers for their comments on the original draft of this paper.

²For further details on the parent project, see reports on 1974 study, Day and Landon, 1976; Day and Bodur, 1977.

the satisfaction/dissatisfaction scale for each separate product/service category. This paper examines the possibility that certain "patterns" reflecting different levels of satisfaction/dissatisfaction may exist for consumers over the various kinds of durable goods. These patterns, if confirmed, might increase the effectiveness of consumer protection programs by enabling policy makers to focus their attention on products with the highest rates of dissatisfaction among users.

Research Design

The data for this research were obtained as part of a survey research project which utilized a set of data collection instruments designed for a larger national project currently in preparation. The actual data for the current study were acquired from self-administered questionnaires which were distributed through the "drop-off/pick-up" method to a probability sample of more than 600 dwelling units in one midwestern city during the fall of 1976. The instrument was extensively pre-tested.³

The questionnaires were quite lengthy, probing both consumer satisfaction/dissatisfaction and complaint behavior on an "aided recall" basis over approximately 200 categories of products and services. The preliminary findings which will be reported here relate exclusively to the usage rate/importance/satisfaction portion of the survey instrument which covered 67 categories of durable products. Items which were believed to be purchased and used by consumers in similar ways were grouped together into categories.

The initial task required respondents to indicate whether or not they had purchased any items from the category over a three-year recall period. Those who had made such a purchase were then asked to provide an indication of the relative importance of that category and of the relative extent of satisfaction or dissatisfaction with items contained in the category. The responses available to respondents for each item were as follows:

Purchase (?) and Importance of these products

- N = I have not bought this product (any of these products) within the past three years.
- L = This product is (these products are) of less importance to me or my family than some of the other durables we own.
- H = This product is (these products are) highly important to me or my family.

How satisfied or dissatisfied I am with them

- 1 = I am quite satisfied with this product (these products).
- 2 = I am somewhat satisfied with this product (these products).
- 3 = I am somewhat dissatisfied with this product (these products).
- 4 = I am quite dissatisfied with this product (these products).

The instrument, itself, was designed to furnish more complete information than is available from volunteered complaint data. Also, it sought to avoid or reduce the bias arising from "single incident recall" surveys which force respondents to limit their responses to one particular experience. By providing data on all products the respondent has purchased over a specified period of recall, the instrument provides a basis for assessing the extent of consumer satisfaction/dissatisfaction with items in

³For details on instrument design and pre-testing, see Day and Bodur, 1977.

each separate product/service category. Another advantage is that it enables the researcher to tap the positive as well as the negative elements of consumers' reactions to a comprehensive set of durable goods.

One familiar approach to the study of CS/D has led to operationalizing the measure of dissatisfaction as the discrepancy between performance expectations for the product or service and actual outcomes (Anderson, 1973; Cardozo, 1965; Day, 1975; Day, 1977; Miller, 1976; Olshavsky and Miller, 1973; Summers and Granbois, 1976; Swan and Combs, 1976). Concern about expectations and ultimate performance has raised important methodological issues regarding their measurement. For example, expectations may be operationalized to include: (1) expectations of product performance, (2) expectations of costs and, (3) expectations of the impact on others (Day, 1977). The relevant research question is whether all sources of expectation need to be assessed simultaneously in order to obtain a representative overall measure of the construct. If so, how is each component of overall expectation to be weighted? Unfortunately, the measurement of perceived product performance is also troublesome. For example, one approach has underscored the need to examine the influence of both physical and psychological dimensions of product performance on consumer satisfaction (Swan and Combs, 1976). The rationale for the research instrument employed in this study is that it lets the respondent define what he means by "satisfied" or "dissatisfied." The subject determines for himself what the points on the scale mean. This enables the researcher to evaluate the pattern of self-defined satisfaction/dissatisfaction over respondents for each product category.

The questionnaire also contains the usual demographics and a set of 14 Likert-type attitude/opinion scales designed to elicit subjects' impressions of business, government and marketing. The balance of the paper will be devoted to the preliminary analysis conducted on the category-by-category responses obtained from 119 usable questionnaires.

Measurement

Data on usage rate, importance, and extent of satisfaction/dissatisfaction are shown in percentages. To examine the associations between the satisfaction/dissatisfaction scores and demographic data, correlation analysis was used. Since the satisfaction/dissatisfaction scales probably should be considered ordinal in nature, use of a nonparametric correlation coefficient seems appropriate. The data consisted of a substantial number of cases classified into comparatively few categories. Since they contained a large number of tied ranks, the Kendall (tau-C) correlation coefficient was preferred to Spearman's rank order correlation coefficient (Nie, Hull, Jenkins, Steinbrenner and Bent, 1975).

During the preliminary analysis, attitude and selected demographic variables, which might be considered as interval-scaled data, were regressed, in step-wise fashion, onto the satisfaction scores. Since examination of predicted criterion scores versus residuals suggested that the data were not suitable for multiple regression analysis, the results are not presented here. Other multivariate techniques may be applied as the analysis of the results proceeds.

Preliminary Results

To demonstrate the kind of information contained by the data and its potential for use by policy makers, two sets of results are presented. First, the category-by-category responses denoting purchase, relative importance and satisfaction/dissatisfaction are summarized and briefly.

analyzed. Next the relationships between demographics and satisfaction are explored.

Product Category Analyses

Tables 1 through 4 contain percentage summaries on 67 categories of durable goods which are grouped in four sections of the durable products questionnaire: (1) housing and home furnishings; (2) appliances and personal care equipment; (3) durable items for entertainment, recreation and education; and (4) cars and other transportation durables. All four tables provide information obtained from 119 usable questionnaires. The first column in each table shows the percent of respondents who reported they had purchased the item within the three-year recall period. The next column shows the percentage of purchasers rating the item as relatively important. The rank order of percent rating the item as important is also provided. This is followed by the percentage distribution of satisfaction/dissatisfaction ratings for each category. As stated earlier, a primary objective of the research plan is to provide a basis for classifying items according to the severity of consumer problems they engender. The classification task is simplified if one relies on a combined measure of dissatisfaction for every product category under investigation. This information is covered by the final two columns of Tables 1 through 4 which show the sum of the two dissatisfaction ratings and the rank order of categories by percent dissatisfied.

In Table 1, the percentage of subjects who reported that they had purchased one or more items in any "Housing and Home Furnishings" category varies widely. Only 1.7% of the sample indicated a purchase of "swimming pool" while 88.0% said they had purchased "draperies, linens, etc." Only three other categories reveal more than 50% of respondents indicating purchase within the specified period of recall: "sofas, chairs"; "housewares, tableware, etc."; and "lamps, clocks, etc." The percentage of consumers who indicated that the various items were highly important to them or their families ranges from 35.4% for "electric blankets" to 100.0% for "single family house" and "heating installation." The percent of buyers who rated an item in one of the two dissatisfaction categories varies from 6.8% for "lamps, clocks, etc." to 37.5% for "mobile home."

A key assumption of the research plan is that the amount of dissatisfaction expressed for an item should be brought into perspective by considering it in relation to the proportion of the population using the product. For example, when a very small segment of the population indicates purchase of an item (e.g., 1.7% for "swimming pools"), reported rates of dissatisfaction probably do not have statistical reliability. It may seem intuitively logical to expect higher rates of reported dissatisfaction for widely-owned items than for products which are used by a relatively small segment of the population. The fallacy of this reasoning is exposed if one compares the rates of usage and dissatisfaction for "mobile homes" with those of "draperies, linens, etc." in Table 1. The category "draperies, linens, etc.", with a reported purchase rate of 88.0%, ranks fourteenth out of twenty according to the percentage of dissatisfied users. On the other hand, the greatest rates of dissatisfaction with "Housing and Home Furnishing" items appear to be associated with those purchased by a comparatively small percentage of the entire population. For example, "mobile homes" are ranked first by percent of dissatisfied buyers even though less than 10% of respondents reported purchase of the product. The number two item according to dissatisfaction is "swimming pools," another product characterized by limited ownership. In Table 4, 36.2% of respondents reported purchase of a used car within the recall period. It seems that approximately 41% of the used car owners were dissatisfied with the product. The apparent high rate of dissatisfaction with used cars reported in this

study is corroborated by the amount of dissatisfaction with the item expressed in conventional complaint statistics. In Table 2, the rates of dissatisfaction reported for "Appliances and Personal Care Products" may be compared to those furnished by another study (Mason and Himes, 1973). It is not surprising that higher levels of dissatisfaction were expressed by respondents in the current study. In their research, Mason and Himes (1973) defined a complaint as "any dissatisfaction with an appliance purchased and for which a consumer seeks relief from an outlet in the channel of distribution." In this study, the survey instrument enabled subjects to register dissatisfaction with an item independent of specific complaint behavior. Comparison of the results of the two studies suggests that the differences in percentage reporting dissatisfaction may be ascribed to the number of dissatisfied consumers who do not undertake any formal search for redress. Table 3 reveals a similar pattern of results and will not be discussed here. The preceding examples are meant to suggest that greater understanding of the kinds of problems which consumers experience is possible if the number of dissatisfied users is considered in relation to the total number of users.

Relationship of Satisfaction and Demographics

One premise for this study is that writers of complaint letters are probably not representative of the full range of people experiencing dissatisfaction with products and services (Day and Landon, 1976; Day and Bodur, 1977; Warland, 1975). Here, the unit of interest is any consumer who feels dissatisfied with his purchase of a durable product, not a complainer per se. The central question is: do dissatisfied users of particular items have anything in common? This question implies that it may be useful to investigate relationships between demographic variables and satisfaction scores over a comprehensive set of durable products. Tables 5 through 8 contain correlation coefficients measuring the extent and direction of the relationships between demographics and satisfaction. Since the entire sample consisted of 119 respondents, cell sizes were checked to minimize the possibility of reporting spurious results. This examination revealed that the response distributions for the education and income variables were skewed slightly to the right of normal. All coefficients reported are significant at the .05 level.

Table 5 contains the correlation coefficients for the "Housing and Home Furnishings" section of the questionnaire. All of the demographic variables are significantly correlated with at least three of the durable product categories. Examination of the table shows varying patterns of relationships between demographics and satisfaction. Although none of the coefficients are large, most of the categories exhibit some relationship between one or more demographic variables and the satisfaction scores. The category with the largest number of significant relationships is the "single family house." On the other hand, no significant relationships appear to exist between demographics and satisfaction for "mobile home" owners. The variables with the largest number of significant relationships were marital status, employment status, home ownership and income. The number of significant relationships for each demographic variable varied widely over the groups of durable products shown on Tables 5 to 8. Another study (Day and Bodur, 1977) examined the relationships between demographic variables and satisfaction scores over a broad set of consumer service categories. They reported:

1. weak associations between demographics and responses on satisfaction;
2. widely varying patterns of significant relationships over these categories;

3. situational characteristics (e.g., marital status, home ownership) were more consistently related to satisfaction scores than most personal characteristics (e.g., education and sex).

The results of the present study parallel the earlier findings of Day and Bodur, 1977.

Discussion

The sample statistics reported here are based on data which were obtained in one midwestern city during the fall of 1976. Since a scientifically-determined probability sample was obtained, the results are probably representative of the sample population. However, any generalization of these results to any other population would be inappropriate.

This study is intended to stimulate more research into the underlying determinants of consumer satisfaction/dissatisfaction with durable products. Some fruitful areas for future research on durable goods may focus on:

- (1) the role of product cost as a basis for predicting consumer satisfaction/dissatisfaction with an item;
- (2) the extent to which consumer expectations can be manipulated by manufacturers or government policy makers;
- (3) the identification and measurement of any "carry-over effect" associated with purchase satisfaction, and
- (4) the impact of contemporary advertising on the gap between consumer expectations and perceived performance for widely-used durable products.

Conclusions

This paper has reported some of the preliminary results of analysis on data collected as part of a larger research project still in progress. These findings cover the section of the questionnaire which elicited satisfaction/dissatisfaction scale responses. On the basis of these results, the discriminating power of the survey instrument as a tool for diagnosing consumer dissatisfaction seems to have been satisfactorily demonstrated. The questionnaire was designed to furnish information on rate of purchase, relative importance and satisfaction/dissatisfaction over 67 categories of durable products. The results showed widely varying relationships between the percent of a sample reporting purchase of a product and the percent of users experiencing dissatisfaction with the item. The relationship between demographic variables and satisfaction were generally weak and varied widely over product categories. On a category-by-category basis, however, interesting relationships between demographics and satisfaction scores were revealed.

The results reported here appear to have face validity. It is hoped that they will demonstrate the usefulness of the information conveyed by the data which was obtained by the survey instrument. There is room for much more research into consumer satisfaction/dissatisfaction with durable products.

CONSUMER RESPONSE TO DISSATISFACTION WITH SERVICES AND INTANGIBLES

Ralph L. Day, Indiana University
Muzaffer Bodur, George Mason University

Abstract

Although most previous research on consumer dissatisfaction has emphasized complaints and redress-seeking, dissatisfied consumers may choose a number of other options including boycotting the brand, warning friends, or doing nothing at all. This paper describes a field study of consumer dissatisfaction and reports on patterns of dissatisfaction over 73 categories of services and intangible products. Summaries of reasons for dissatisfaction and post-dissatisfaction responses are also given.

Introduction

Increases in voiced complaints and redress-seeking have been both causes and effects of the dramatic growth of consumerism over the past decade. During most of this period a major source of information for consumer advocates, consumer protection agencies, and business firms has been tabulations of volunteered complaints. The users of complaint data have gradually become aware that the writers of complaint letters are not representative of all consumers and the particular items covered in complaint letters are not representative of the full scope of consumer concerns (Stokes, 1974). During the past few years, there has been a rapid increase in efforts to provide better quality data on consumer satisfaction and dissatisfaction through survey research (Lingoes and Pfaff, 1972; Pfaff, 1972; Warland, Herrmann, and Willits, 1975; Handy and Pfaff, 1975; Day and Landon, 1975) and efforts to develop better conceptualizations of satisfaction and dissatisfaction (Hunt, 1977; Day, 1977; Day and Landon, 1977). This paper seeks to make a contribution to knowledge and understanding of this increasingly important aspect of consumer behavior and to take a step toward the development of better methods of obtaining data on the post-dissatisfaction behavior of consumers.

The results reported here were obtained as part of a survey research project which utilized a set of questionnaires developed in 1976 under a research contract with the U.S. Office of Consumer Affairs. The basic objectives and overall structure of the study were similar to those of a previous project which was begun by the senior author at the Federal Trade Commission in 1974; however, many changes in the details of execution have resulted from field experience with previous versions of the questionnaire.

The unique feature of the study design is its comprehensive scope. A single study can obtain general indications of levels of satisfaction and dissatisfaction for almost 200 different product categories spanning the full range of consumer products and services. As respondents work through the sections of related product or service categories, they are asked periodically if they have had unsatisfactory experiences with items from any of the preceding set of categories. If the answer is yes, the respondent is asked to indicate the particular product or service with which they have had the most unsatisfactory experience, answer a battery of questions which probe for the sources of dissatisfaction, and provide information on any actions which might have been taken as a result of the unsatisfactory experience.

The survey was conducted in a single midwestern city in the fall of 1976. A two-stage probability sampling plan was used to select approximately 600 dwelling units. Self-

administered questionnaires were dropped off and picked up, and the overall response rate was approximately 80%. Four different questionnaires were assigned systematically over dwelling units. Three of these questionnaires covered different major categories of products or services; durable products, nondurable products, and services. The fourth questionnaire covered the entire range of products and services. The questionnaires which cover only one of the three major classes further divide the items into four sections and contain a probe for unsatisfactory experiences at the end of each of these. The combined questionnaire contains probes only at the end of each of the three major sections. Because of a concern that the longer combined questionnaire might have a lower completion rate, it was oversampled relative to the others. As a mild surprise, it turned out to have the highest completion rate. Usable responses were obtained from 125 respondents who got the separate services and intangibles questionnaires and from 171 respondents who were given the combined questionnaire.

Space does not permit the presentation and analysis of both sets of results or a complete comparative analysis of the effects of the increased opportunity to report unsatisfactory experiences on the pattern of responses. However, Table 1 reveals some of the differences in the pattern of reported dissatisfaction for the two questionnaires. A higher percentage of the respondents who had the separate services questionnaire named one or more instances of dissatisfaction (58.5% as compared to 39.8% of the respondents who had the combined questionnaire). Also, there were reports of dissatisfaction with items from a much higher percentage of the categories of services (67.1%) than the respondents who had the combined questionnaire (34.2%). Table 2 shows that the reported instances of dissatisfaction were more evenly divided over the four sections of the separate questionnaire, as compared with the corresponding groupings of the items in the combined questionnaire. These differences tend to support the expectation that separate questionnaires will provide a more sensitive indication of the pattern of consumer dissatisfaction.

Various alternative courses of action are available to consumers who have experienced dissatisfaction, ranging from doing nothing to suing a seller or manufacturer for millions of dollars in damages. The conceptual framework utilized in this study has been described elsewhere (Day and Landon, 1977). The dissatisfied consumer's options can be classified as follows:

- A. Take no action at all--forget the experience.
- B. Take some form of private action:
 - 1) change brands or supplier
 - 2) stop using the product class
 - 3) warn family or friends
- C. Take some form of public action:
 - 1) seek redress directly from the seller or manufacturer
 - 2) take legal action against the seller or manufacturer
 - 3) register a complaint with; the seller or manufacturer, a public consumer protection agency, or a private consumer organization.

These alternatives, except for the "do nothing" response, can be utilized by consumers in various combinations. Further discussion of this framework and some results

of previous studies are available elsewhere (Day and Landon, 1975).

Results and Analysis

This section will present and discuss the major findings from the separate services questionnaire. A brief description of the questionnaire will be helpful at this point. The 73 categories of services and intangible products are organized into four sections covering: repairs and general services; professional and personal services; financial services and insurance; and rentals, public transportation, and utilities. The sections were developed by grouping together those service items which are purchased and consumed in similar ways to form four sections of approximately equal length. The sections provide convenient units for retrospective probes for unsatisfactory experiences and the consumer's responses to them.

As in the other three questionnaires used in the present research project, the respondent works through each section of the services questionnaire one category at a time, first indicating whether or not any items from the category have been purchased within a specified time (the past two years in the case of services). Respondents who have made a purchase check a two point importance scale and a four point satisfaction scale ("always satisfied" to "always dissatisfied"). After they have completed the scales for all categories in a section, respondents are asked to look back over the section and indicate if they have had one or more experiences in which they were highly dissatisfied. If the answer is yes, the respondent then reports the number of unsatisfactory experiences with items from that section during the past two years and enters the number of the specific item which was "the most unsatisfactory." The respondent then checks any of 14 to 16 possible reasons for dissatisfaction with services which have contributed to dissatisfaction with that particular item. The reasons include statements such as "the service was provided in a careless and unprofessional manner." This is followed by a list of possible actions (including no action) that a dissatisfied consumer might take, based on the classifications of responses to dissatisfaction as outlined in the previous section. Data on the frequency of use of the various items and the frequency of "always dissatisfied" response from the satisfaction scale will be presented below, along with summaries and discussion of responses to the items found to be "the most unsatisfactory." Discussion of the full satisfaction/dissatisfaction scale and the importance ratings for both the separate services questionnaire and the services section of the combined questionnaire has been presented elsewhere (Day and Bodur, 1977).

Frequency of Dissatisfaction

One of the advantages of using survey research to study the consumer's response to dissatisfaction versus relying on volunteered complaints, is that it provides data on all users of a product or service and not just the complainers. In particular, data from a sample of the entire consumer population provide a frame of reference for putting the complaints of dissatisfied consumers in perspective. At the simplest level, an estimate of the total number of consumers allows the expression of the number of dissatisfied consumers as a percentage of the user population and permits the comparison of levels of dissatisfaction among users over different products or services. If one simply used the number of complaints as an indicator of dissatisfaction, then a service used by a small segment of the population would never be recognized as a consumer problem even if practically all of its users were dissatisfied. Conversely, a very widely used service might appear to be a major consumer problem

even though the rate of dissatisfaction with it is well below the average for all services.

The number of respondents who reported purchasing each of the 73 services included in the survey are shown in the first column of Tables 3-6, which cover the four sections of services. It can be seen that there is a wide range in the fractions of the sample using the various services. The number of instances of reported dissatisfaction for each kind of service in the four sections is shown in the second column of Tables 3-6. The percentage of users who were dissatisfied also varies widely. The highest rates of reported dissatisfaction for any of the 73 items occurred with services used by relatively small fractions of the sample; 21.1% of the users of employment agencies were dissatisfied and 20.0% of the users of nursing homes reported dissatisfaction (Table 4). These services were used by 15.2% and 4.0% of the sample, respectively. Other services with high rates of dissatisfaction among users but relatively small numbers of users included furniture rental services (Table 6) and septic tank services (Table 3). The highest percentage of dissatisfied respondents in any widely used category was 18.8% for auto repairs with 80.8% of the sample reporting a purchase within the past two years (Table 2). Auto repairs has headed the list of volunteered complaints for years, but some items with substantial rates of dissatisfaction but smaller user bases have not ranked high on complaint lists.

To determine if the extreme negative responses on the satisfaction scale (always dissatisfied) are predictive of the frequency of reported dissatisfaction provided at the end of each section, the two sets of responses were compared. Column 3 in Tables 3-6 contains the number of "always dissatisfied" responses for each item in the section. Spearman rank correlation coefficients between the two sets of responses in each section were as follows: repairs and general services (Table 3), $r_s = .91$; professional and personal services (Table 4), $r_s = .83$; financial services and insurance (Table 5), $r_s = .93$; rentals, public transportation, and utilities (Table 6), $r_s = .96$. All correlations were significant beyond the .001 level, suggesting that the responses reflecting extreme dissatisfaction on satisfaction/dissatisfaction scales for particular categories are predictive of reports of dissatisfaction.

Reasons for Dissatisfaction

Respondents who indicated that they had been highly dissatisfied with a particular service considered a list of possible reasons for being dissatisfied and were instructed to check all of the reasons which they felt applied to their unsatisfactory experience. If they checked multiple reasons, respondents were asked to indicate which one of the items was the most important. The reasons varied slightly in number and content over the four sections of services to reflect differences in the nature of the services and the circumstances of purchase and use. The wording of the statements, the number of times each was checked, and the number of times each was named as most important are given for each of the four sections in Tables 7-10. The number of instances of reported dissatisfaction varies over the sections with "repairs and general services" showing considerably more causes of dissatisfaction than the other sections. The average number of reasons given in a particular instance of dissatisfaction was very consistent over the four sections, and the overall average number of reasons given was 2.62.

The great majority of the reasons given for dissatisfaction were directly related to the quality of the supplier's performance. Because of the differences in the nature of the particular service items, several different statements were related to various aspects of the performance

of the service. By far the most frequently mentioned reason for dissatisfaction was "The service was rendered in a careless, unprofessional manner." The percentage of those respondents reporting an instance of dissatisfaction who checked this item ranged from 58.3% for rentals; public transportation, and utilities to 84.6% for professional and personal services. It was also checked as the most important of the reasons for all four sections. The stronger indication of gross incompetence with harmful results was the second most frequently checked reason for dissatisfaction in the repairs and general services and the professional and personal services sections. Some reasons related to quality which were relevant for only one or two of the sections were important in those sections. For example, in the repairs and general services section, the third and fourth most frequent responses were "performance of the item was worse after the repairs than before" and "the quality of parts or materials was inferior."

The various possible reasons for dissatisfaction relating to marketing practices as opposed to "service quality" were checked very infrequently. The statements relating to misleading advertising, deceptive practices of salesmen, credit practices, and warranties were also checked infrequently. While there was some degree of concern about prices or fees, these were completely overshadowed by concerns with the quality of performance. A fraudulent practice related to the price or fee, "I was charged for work that was not done," was indicated in 19.2% of the instances in the "professional and personal services" section and in 19.4% of the instances in the "rentals, public transportation, and utilities" section. Similar reasons in the other two sections were checked somewhat less frequently.

The results shown in Tables 7-10 strongly suggest that the respondents who reported dissatisfaction with services were much more strongly concerned with performance or "service quality" issues than with marketing practices. Previous studies of tangible products have tended to show that aspects other than product quality play a more important role in voiced complaints. Although some of the data from the durable products and nondurable products sections of the present study have not been analyzed, the results of a previous study using an earlier version of the "combined" instrument used in this study suggested that marketing practices and price-related issues are somewhat more frequently mentioned for both durables and nondurables than for services (Day and Landon, 1976). This may be a reflection of the more direct and personal relationships involved in the purchase and use of many services than in the purchase and use of tangible products. Hopefully, the completion of the analysis of the present project and additional future research on the marketing of services will shed light on this and many other issues relating to services.

Post-Dissatisfaction Responses

In 29 of the 133 reported instances of dissatisfaction (21.8%), the respondent indicated that no action was taken. Although a detailed probe for reasons for these respondents' nonbehavioral response to dissatisfaction was not feasible, respondents were asked to indicate which of four possible reasons best explained why they had taken no action. These responses are shown in Table 11. None of the respondents checked the "procrastinator's response" of "I wanted to do something about it but never got around to it." The modal response was "I didn't think anything I could do would make any difference." This appears to reflect either a defeatist attitude or a pessimistic appraisal of the chances for successfully obtaining redress. With the possible exception of the "not worth it" response, it seems likely that better information and encouragement to seek redress might lead to a reduction in the number of no-action responses.

In 104 of the 133 instances, the respondent reported taking some action. A summary of reported actions is given in Table 12. A total of 250 actions were reported, an average of 2.4 actions per instance of reported dissatisfaction. These are classified as private actions, redress seeking, and complaining. The total number of actions of each of the three types are shown in the right hand column in Table 12. The distribution of the specific responses within each of the three types is shown in the body of Table 12. Private actions accounted for 46.4% of total actions and 81% of the private actions involved either changing to another supplier of the service or warning others. The remaining 19% reported that they had decided to quit using that service altogether. The public actions were equally split between redress seeking and complaining. Redress seekers primarily sought "replacement" (redoing) of the service or a financial adjustment. An overwhelming majority of the public complaints (80.6%) were directed to the company or professional person providing the service.

The results presented in Tables 10 and 11 suggest that while dissatisfied consumers take no action in connection with a substantial number of cases, approximately 80% of such instances do result in some form of action. More than 45% of the reported actions were of a "private" nature of the type that would never be brought to the attention of business firms, consumer advocates, or consumer protection agencies.

Summary and Conclusions

This paper has presented some of the results from a broader study of consumer satisfaction/dissatisfaction and post-dissatisfaction response. The focus was on the post-evaluation responses from a comprehensive study of consumer services, using the data from a probability sample of 125 households in a single midwestern city. The data include the total number of users of each of 73 categories of services as well as the number of instances of reported dissatisfaction for each category. This allows the evaluation of relative levels of expressed dissatisfaction among the various types of services. A classification of responses into nonbehavioral (no action), private actions, redress-seeking, and public complaining was applied to the results. It was found that in more than 20% of the instances of expressed dissatisfaction, no action was taken and that 46.5% of reported actions were of a private nature, such as boycotting the supplier or warning friends.

These results suggest that more complete and more readily interpretable data about levels of consumer dissatisfaction can be obtained by survey research than by keeping records of public complaints. The results also suggest that comprehensive studies of the entire range of consumer products and services are feasible and can provide useful data of a type that is not readily obtainable in any other way. The comprehensive survey shows promise as a diagnostic tool for identifying areas in which more detailed data are needed. It also offers considerable promise as a tool for consumer behavior theorists who wish to develop more complete models of the consumer's purchase, consumption, and evaluation process. Although the results reported here were from a rather small sample from a single city and cannot be freely generalized, they suggest the need for a large national study as a starting point for the development of a comprehensive data base on consumer satisfactions, dissatisfactions, and post-dissatisfaction responses.

CATASTROPHE THEORY AS A MODEL
FOR DESCRIBING CONSUMER BEHAVIOR

Terence A. Oliva, Louisiana State University
Alvin C. Burns, Louisiana State University

Abstract

Consumer behavior models do not have mechanisms to handle divergent and discontinuous behavior. Rene Thom's Catastrophe Theory seems to be a promising means for modeling such phenomena. This paper describes the cusp catastrophe and illustrates how it can describe consumer adoption and consumer complaining behavior.

function which relates various combinations of control variables (independent variables) equal to zero (Starobin, 1976). Thom has shown that only seven models are needed to describe all possible abrupt transitions in situations that are controlled by up to four independent variables (Zeeman, 1976). The mathematical formulations of these models are contained in Table 1.

Introduction

It is an understatement to contend that the behavioral scientist encounters frustration when he attempts to model the phenomena under his study. Unlike his counterparts in the physical sciences, the behavioral scientist finds his subject matter highly resistant to straightforward conceptualization. Simple models cannot possibly cope with the myriads of multiple determinants, complex interactions, non-linear relationships, discontinuities and seemingly unsystematic variations.

Consumer behaviorists have confronted these problems for some years now. While we believe we have transcended simplistic "black box" models and can portray the behavior of a consumer in the context of ladder or stairs concepts, decision trees, and elaborate flow diagrams, the behavior inevitably escapes the boundaries of the model when we attempt to describe it in appreciable detail. One possible reason for the disappointing experiences thus far may be in the implicit assumption in most consumer behavior models that behavior follows a smooth transition through and between stages in the process. As a more analytical posture is assumed, however, it soon becomes evident that such smooth transitions are rare. More commonly observed are sudden shifts, stalls, and divergent behavior. A mechanism for describing these phenomena must be included if our models are to faithfully depict the process.

Catastrophe Theory

As indicated above, a major shortcoming of consumer behavior models has been the inability to handle abrupt (catastrophic) changes in behavior. Modeling of what might be called "misbehaving phenomena" has defied mathematical analysis for a long time. The reason for this is that such analysis usually requires some form of continuum. Relatively recently, however, French mathematician Rene Thom (1972) using a branch of mathematics known as Topology developed some ideas which generate models that can handle messy phenomena.

Topology is a kind of rubber sheet geometry that allows elastic movements (Arnold, 1962). It is the branch of mathematics that deals with the fundamental properties of literally anything; and, as such, focuses on invariance through transformation (Arnold, 1962; Barr, 1964). Thom uses that part of topology that deals with multi-dimensional surfaces because of its ability to represent underlying forces in nature under different states of equilibrium (Zeeman, 1976).

Structurally, catastrophe models are topological surfaces generated by setting the first derivative of a

TABLE 1
Rene Thom's Seven Elementary Catastrophes

CATASTROPHE	CONTROL DIMENSIONS	BEHAVIOR DIMENSIONS	FUNCTION	FIRST DERIVATIVE
FOLD	1	1	$\frac{1}{3}x^3 - ax$	$x^2 - a$
CUSP	2	1	$\frac{1}{4}x^4 - ax - \frac{1}{2}bx^2$	$x^3 - a - bx$
SWALLOWTAIL	3	1	$\frac{1}{5}x^5 - ax - \frac{1}{2}bx^2 - \frac{1}{3}cx^3$	$x^4 - a - bx - cx^2$
BUTTERFLY	4	1	$\frac{1}{6}x^6 - ax - \frac{1}{2}bx^2 - \frac{1}{3}cx^3 - \frac{1}{4}dx^4$	$x^5 - a - bx - cx^2 - dx^3$
HYPERBOLIC	3	2	$x^3 + y^3 + ax + by + cxy$	$3x^2 + a + cy$ $3y^2 + b + cx$
ELLIPTIC	3	2	$x^3 - xy^2 + ax + by + cx^2 + cy^2$	$3x^2 - y^2 + a + 2cx$ $-2xy + b + 2cy$
PARABOLIC	4	2	$x^2y + y^4 + ax + by + cx^2 + dy^2$	$2xy + a + 2cx$ $x^2 + 4y^3 + b + 2dy$

SEVEN ELEMENTARY CATASTROPHES describe all possible discontinuities in phenomena controlled by no more than four factors. Each of the catastrophes is associated with a potential function in which the control parameters are represented as coefficients (a, b, c, d) and the behavior of the system is determined by the variables (x, y). The behavior surface in each catastrophe model is the graph of all the points where the first derivative of this function is equal to zero or, when there are two first derivatives, where both are equal to zero.

(From Zeeman, 1976)

The way in which catastrophe models are able to describe phenomena that diverge, are subject to sudden shifts, and are discontinuous is through folds and pleats in the surfaces that relate different equilibrium states. Love and hate, for example, represent two different states.

Transition from one to the other does not necessarily progress along a unidimensional continuum. At the same time, it would be incorrect to say that they occupy two disconnected continua such that an individual cannot go from one to the other. A catastrophe model would relate the two by means of a surface fold. (See Figure 1)

FIGURE 1
A Catastrophe Behavior Surface

The movement from hate to love or vice versa can occur a number of ways on the surface. A smooth transition develops if the process is such that the individual misses the fold. On the other hand, an abrupt transition occurs when the individual "falls off" one surface to the other by crossing the fold. Thus the theory describes equally well both the persistent suitor who slowly wins his heartthrob's affection and the wife who finds her cheating husband in bed with another woman.

Some of the situations where catastrophe models have been used are: the development of hostilities between nations, cathartic release from self-pity, aggression in dogs, behavior of the stock market, buckling of an elastic beam, anorexia nervosa, territoriality among reef fish (Zeeman, 1976), population dynamics (Starobin, 1976), and collective bargaining (Oliva and Capdevielle, 1977). All the preceding situations have conditions where abrupt transitions occur, making the use of other modeling techniques virtually impossible on anything but a trivial level.

Perhaps the best way to understand what catastrophe theory is all about is by close examination of one of its models. The model we have chosen is the cusp catastrophe since it is easily understood and has been the most widely used of the models. A Cusp Model is generated by setting the first derivative of the following function equal to zero for all combinations of the variables a, b, and x, where a and b are two control dimensions, and x represents the system's behavior dimension:

$$f(a, b, x) = 1/4x^4 - ax - 1/2 bx^2 \quad (1)$$

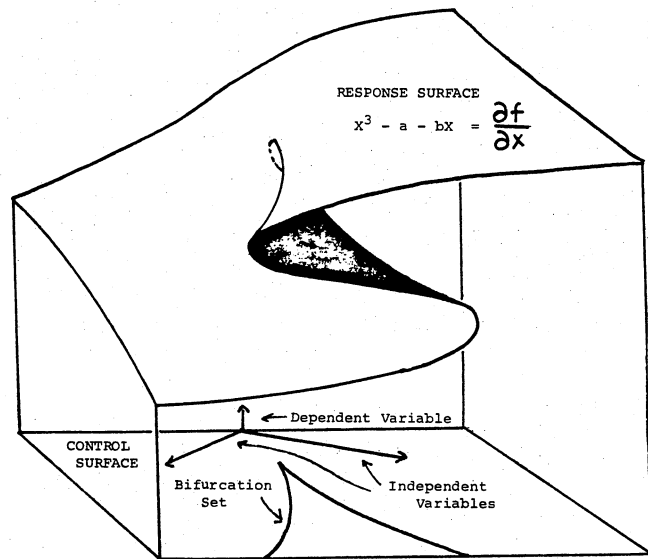

$$\frac{\partial f}{\partial x} = 0 = x^3 - a - bx \quad (2)$$

The response surface generated is peculiar (as indicated earlier) in that it has a fold in it. (See Figure 2) By projecting the fold onto the control surface, an area of overlap known as the bifurcation set is defined. It is domain where two modes of behavior are possible depending on the initial conditions.

For a situation to be suitable for description by the cusp catastrophe, five conditions are requisite:

bimodality, sudden transitions, hysteresis, unaccessibility, and divergence (Zeeman, 1976).

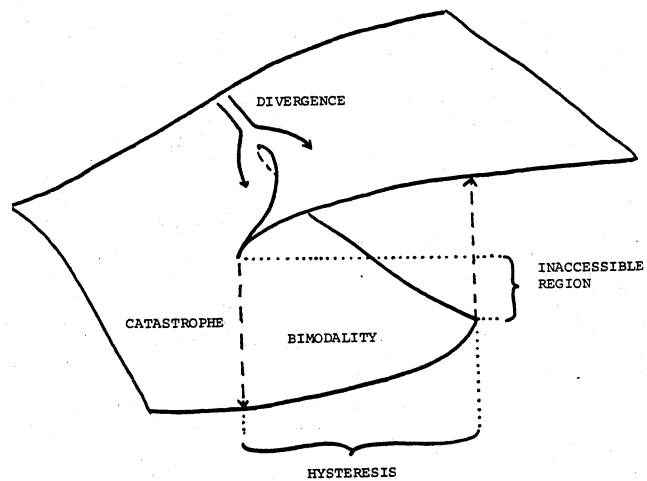

FIGURE 2
A Cusp Catastrophe

(From Zeeman, 1976)

Referring to Figure 3, we can see how the five conditions stated above are related by the model. It should be apparent from the diagram that the fold is the focal point of the model. Taking each condition in the abstract we can consider how the model operates in general.

FIGURE 3
A Cusp Catastrophe's 5 Requirements

(Zeeman, 1976)

Divergent behavior is accounted for since as one moves out from the edge toward the singularity, which is the starting point of separation between the two surfaces, the system is forced to adopt one of the two opposing behaviors (e.g., love or hate; attack or flee). The trajectory that will be followed will depend on the values of the control variables (state of the system) just prior to reaching the singularity.

Bimodality is created in the model by the top and bottom surfaces of the fold. It represents the domain where the system tends to hold equal amounts of both control variables at the same time. In a love/hate situation, the bifurcation set would represent the area of ambivalence.

The middle sheet of the fold represents the inaccessible area which is the least likely behavior. In the love/hate situation, this would be the condition of neutrality or non-emotion. To see why it is inaccessible, consider the following. If we hold control variable b constant at a value of 3 and increase the value of a , the system trajectory will proceed in a smooth fashion along the bottom surface until it reaches $(2,3,-1)$ where it will jump to $(2,3,2)$ on the upper surface and continue smoothly. Consequently, there is no means for the behavior to reach the middle sheet.

Sudden transitions (catastrophes) are accounted for as suggested in the preceding paragraph at the edges of the fold. That is, as the system moves along the surface toward the pleat at some point a small increase in the control variable will cause a sudden shift in behavior. To use Zeeman's (1976) example, if an angry dog is made more fearful, at some point his behavior will abruptly change from attack to retreat; conversely, if a fearful dog is progressively enraged, at some point he will stop retreating, turn and attack. It is the ability of the model to represent sudden shifts that gives it great advantage over other conceptualizations.

The fact that the catastrophes do not occur at the same place but depend on the prior state of the system incorporates lags into the model which match real-world phenomena. For example, if a person starts out "in love" and is made to increasingly dislike the other, the complete changeover to hate will not occur at the same point as a person who starts out hating another. That is, a person in love endures more grief from a second individual than does one who hates the second individual; at the same time, a person who hates a second will require more kindness to changeover to love than does one who already cares for the second. Simply then, movement coming from one direction precipitates a catastrophe in a different place than does movement from a different direction, and this lag is called hysteresis.

The above is not intended to be a complete examination of catastrophe theory. What has been presented is a review of one catastrophe model to help explain the application of the theory to two consumer behavior examples.

Application of the Cusp Catastrophe to Two Consumer Behavior Situations

Brief reflection reveals that the cusp catastrophe is an alternative model for several areas of study in consumer behavior. The remainder of the paper is devoted to our interpretations of two such examples. Our intent is purely illustrative, consequently, although a wealth of research and thought may exist for both of our examples, we will not endeavor to review or critique. Also, our comments will be restricted to the cusp catastrophe model. Hopefully, those who are working in the areas of our two examples will envision the value of the conceptualization and be inspired to apply it in more detailed fashion.

Example 1: Consumer Adoption

As a model of individual behavior, the cusp catastrophe offers an alternative view of the adoption decision. Its five conditions are satisfied in the following manner. Divergence exists in the form of the adopt/ no adopt decision facing the consumer. The phase of

evaluation prior to the adopt/no adopt decision satisfies the bimodality condition while inaccessibility is evident in that a consumer will resist ambivalence or half-adoption. Sudden transitions in behavior occur at the point of adoption, especially for later adopters. Finally, the hysteresis condition is evidenced by the fact that the decisions to adopt or to unadopt are unlikely to occur under the same conditions for all consumers.

To further illustrate adoption as a cusp catastrophe, Figure 4 represents the process as adoption/no adoption behavior overlaid on two control surfaces. In this interpretation, the control dimensions are: (1) conformity pressure as perhaps measured by the urgings of others or market penetration and (2) individual predispositions such as desire for novelty, recognition, acceptance, or some other relatively stable personal attribute. These are subsumed into a general attitude position ranging from liberal (acceptance of change) through moderate (deliberative and skeptical of change) to traditional (resistant to change), reminiscent of characteristics of various adopter groups. Seen this way, the cusp catastrophe model can simultaneously describe all classes of adopters (and non-adopters) across the time dimension, and it affords insight to the differences in their adoption decisions.

FIGURE 4
Cusp Catastrophe Interpretation of Consumer Adoption

Innovators progress through the adoption process by traversing the smooth surface of the cusp catastrophe defined by liberal attitudes and introduction of the innovation to the market. Their behavior is non-catastrophic in that they do not cross the bifurcation set. Adoption of new behavior is natural and uninhibited; moreover, the decision to stop adoption is a smooth transition back during this early stage. The majority of the population, however, faces a very different circumstance, for their moderate attitudes hold them at a state of no adoption until conformity pressure increases to the point at which they must evaluate the adoption decision. In the terminology of catastrophe theory, they are in the domain of the bifurcation set. Those with somewhat less moderate attitudes (e.g., the early majority) reach the edge of the no adoption behavior surface pleat and drop (up) to the adoption behavior surface. A snowball effect is seen as large segments of

the population adopt, increase conformity pressure, and cause (more skeptical) others to adopt. Ultimately, the innovation is adopted by all but a very few members of the population. At this point, the laggards or traditionalists occupy the behavior surface where the pleat is widest. Divergence for this group is greater than for any other adopter group; consequently, the change in behavior for them is literally greater than for anyone else. For this reason, they will resist change until they are forced to adopt.

Example 2: Consumer Complaining Behavior

Our illustration of the adoption cusp catastrophe utilizes a dynamic control dimension (conformity pressure) matched against a stable psychological state. The model easily handles two dynamic control dimensions, as will be demonstrated in this example. Consumer complaining behavior has received an increasing amount of attention in recent years although no widely accepted models exist in our knowledge. In our present interpretation, consumer complaining behavior can be seen as a function of consumer dissatisfaction and company promotional efforts. Dissatisfaction for the individual consumer grows and declines with product use, changes in expectations, and/or information acquisition. Company promotional efforts exist in the magnitude and quality of persuasion, education, demonstration or other such efforts. The behavior surface is comprised of complaining or not complaining (divergence). Under the same circumstances some individuals complain while others do not (bimodality); sudden changes in consumers from noncomplainers to complainers and vice versa have been observed, and complaining behavior is dependent on prior conditions (hysteresis).

Viewed as the cusp catastrophe in Figure 5, complaining behavior and even the intensity of complaints becomes clear. When a consumer's experiences engender dissatisfaction with a brand or company, he will traverse the behavior surface to the complaint mode. However, it is likely that company promotional efforts will counteract dissatisfaction to some degree early in the process. Perhaps as a consequence of personal style, some consumers will move out on the behavior surface and enter the bifurcation set on the no complain surface while others will choose the complaint surface (A). These two groups of consumers in the region outlined by the bifurcation set are undoubtedly the firm's marginal customers. One group persists in mild complaints to dealers, salesmen, or even company executives. The other group does not complain, but undoubtedly will welcome a competitor who will respond to their needs more effectively. Given that there are no satisfactory alternatives available, the situation can easily become escalated. That is, greater dissatisfaction as a result of greater product usage will draw the noncomplainers closer to the edge of complaining behavior (B). It will simultaneously push the mild complainers into a more militant posture. The reaction of the company to these symptoms is quite natural: it increases its promotional activities in an attempt to counteract the situation. Seen as a cusp catastrophe, however, the net result is to draw the consumers further out on the pleat and to thereby increase the potential of intensive complaining behavior.

At this point, the company has a tiger by the tail, even though it may not realize the situation. It cannot reduce its promotional activities; nor can it back off from its previous claims, for the model predicts an immediate and catastrophic consequence in the form of a flood of complaints to the company and probably consumer protection and other regulatory agencies as well. Moreover, when consumers change from noncomplainers to complainers under these circumstances, hysteresis dictates that massive amounts of company promotion will be

required to restore them to a noncomplaining attitude (C).

FIGURE 5
Cusp Catastrophe Interpretation of
Consumer Complaining Behavior

Fortunately, however, the model affords a prescription for the company. It must reduce dissatisfaction through product modification or restoration of damages. Actions, not words, will return consumers to the noncomplaining equilibrium state by reducing their dissatisfaction.

Conclusion

These two examples are illustrative of the ability of one catastrophe model to describe consumer behavior. It should be clear that while mathematically complex, the conceptual aspects of catastrophe theory are easy to comprehend and are sufficiently flexible to serve our needs. Given that consumer behavior is multidimensional and subject to abrupt changes, it will be to our advantage to scrutinize the applicability of the cusp and other catastrophe models in the near future.

TESTING COMPETING MODELS OF CONSUMER DECISION
MAKING IN THE PREVENTIVE HEALTH CARE MARKETPLACE

Richard L. Oliver, University of Iowa
Philip K. Berger, University of Kentucky

Abstract

Three models borrowed from social psychology, medical sociology, and communication theory which have been proposed to predict behavioral intention were compared on the basis of their conceptual strength and predictive accuracy in a study of a community swine flu vaccination program. The results suggest that models incorporating evaluative components, normative influences, and intervening summary concepts may yield a greater understanding of health care decisions. Implications of the findings were discussed.

Introduction

The application of behavioral concepts to health product and service marketing was a natural outgrowth of the broadened marketing concept (Kotler and Levy, 1969). Early attempts to construct comprehensive models (Zaltman and Vertinsky, 1971; Becker, 1974; Rosenstock, 1974) were followed by various applications in medical sociology (Cf. Becker and Maiman, 1975, for review) and a recent symposium on behavior in the health marketplace (Newman, 1976). Unfortunately, consumer behaviorists have been slow to apply the emerging knowledge gleaned from studies on non-health related products to the medical field.

The purpose of this paper is to compare the extent to which a model currently used by medical sociologists to explain preventative health behavior and a well accepted behavioral intention model used in the marketing community can predict intentions to receive the swine flu vaccination. In addition, a recent hybrid model focusing on drive arousal and reduction tendencies will also be contrasted with the other two models. Hopefully, these comparisons will permit medical care and public health researchers to modify their present perceptions of preventative health and health compliance behavior to include conceptual modifications suggested in the social-psychological and consumer behavior areas. Moreover, it will also be shown that many of the concepts used in health behavior models are isomorphic with the more traditional views of market behavior.

The Models

The three models to be tested include Fishbein's (Fishbein and Ajzen, 1975) Behavioral Intention Model (BIM), the Health Belief Model (HBM) as discussed by Becker and Maiman (1975), and a drive component model proposed by Wortzel (1976) to predict health care decisions. All are to some degree "instrumentality" schemata as they suggest that action is undertaken because it is perceived to result in or block various life outcomes. Each model is specified in some detail in the following sections.

The Behavioral Intention Model. Because consumer behaviorists will be most familiar with Fishbein's BIM,

This research was partially supported by grants from the University of Kentucky Graduate School and the Lexington-Fayette County Health Department.

only a brief discussion is presented here. Based on Dulany's (1968) theory of propositional control, Fishbein (1967; Fishbein and Ajzen, 1975) proposed that one's intention to perform a specific behavioral action is an additive function of two components, attitude toward the behavior and normative social influences. One's attitude toward the behavior, in turn, is a function of the sum of products of beliefs about the consequences of the behavior and one's evaluation of those consequences. In similar fashion, the summary perception of normative social influences, referred to as one's subjective norm, is believed to be a function of the sum of products of normative beliefs attributed to various referent persons and one's motivation to comply with those beliefs. Other stimulus conditions are thought to influence intention through the attitudinal and normative components.

The Health Belief Model. As summarized by Becker and Maiman (1975), the HBM predicts that people will engage in preventive health behavior if "they possess minimal levels of relevant health motivation and knowledge, perceive themselves as potentially vulnerable and the condition threatening, are convinced of the efficacy of intervention, and see few difficulties in undertaking recommended action (p. 12)." Unlike Fishbein's Behavioral Intention Model, the HBM is less formalized in its constituent components and the measurement of its variables. Based primarily upon articles by Becker (1974), Becker and Maiman (1975), Maiman and Becker (1974), and Rosenstock (1974), the version of the HBM discussed in the next section has been adopted for the purpose of this study.

Proponents of the HBM suggest that the probability of an individual engaging in a preventive health action is a function of three factors, a "benefits-barriers" analysis of the advantages and disadvantages of the health prevention activity, the "perceived threat" associated with the condition or illness, and various "cues to action" which include both mass media and interpersonal communications.¹ The perceived threat construct, in turn, is believed to have two antecedents, namely one's perceived susceptibility to the health problem and the anticipated severity of the problem if contracted. In a manner similar to that employed in the BIM model, other determinants are thought to affect the antecedents of one's intention rather than the intention itself.

In summary, an individual's perceptions of susceptibility to and severity of the focal health problem constitute the inherent threat posed by the disease. Given that a preventive health action is available, the model assumes that the person evaluates the action in terms of its perceived potential benefits to reduce this threat as well as the potential barriers or costs to taking the

¹The model described here departs in one important respect from earlier versions (e.g., Rosenstock, 1974). The cues to action component in prior formulations impacted directly on the perceived threat component and indirectly on the likelihood of behavior variable. A careful reading of the literature however, suggests that cues to action more appropriately affect the likelihood of behavior directly rather than through perceived threat. This latter interpretation is the one tested in this paper.

same action. Finally, the individual is also assumed to be further influenced by personal and impersonal recommendations. These three major components are believed to define on's subjective state of readiness to take preventive action.²

A Comparison of the BIM and HBM

A number of differences exist between Fishbein's BIM and the HBM. Some have been suggested by Jaccard (1975), others derive from exchanges between Songer-Nocks (1976) and Fishbein and Ajzen (1976) while some interpretations are novel to this paper. Each is summarized briefly in the following discussion.

First, Fishbein's BIM is designed to predict intention to act, not action itself. The original version of the HBM contains no variable similar to behavioral intention but is designed to predict actual behavior. If this difference is taken at face value, it would not be possible to compare the two models. For the purposes of this paper, however, the criterion for both models was identified as behavioral intention. If one is willing to assume a high positive correlation between intention and behavior, the data are useful for comparing the two models.³

Second, the BIM requires that beliefs concerning the consequences of the preventive health act be multiplicatively combined with one's evaluation of those consequences. In the HBM, evaluations of the consequences of the act are not explicitly called for and, as a result, may not be measured. Since the HBM is not as formally specified as the BIM, the degree of precision surrounding the explication of consequences is not known. It can be said, however, that the outcomes of taking action are assessed as perceived benefits and barriers. Moreover, it appears that all benefits are assumed to be universally evaluated as good while the barriers are assumed to be consistently evaluated as bad.

Third, social norms are a necessary component of Fishbein's model. In contrast, the analogous normative influences in the HBM are listed among many other variables in the cues to action construct. By the same line of reasoning, the BIM conceptualization does not explicitly provide for various mass media messages but rather subsumes them under the category of exogenous stimulus conditions. Thus, depending on the manner in which a particular investigator operationalizes influences external to the individual in either model, the relevant social norms or media impacts may not be included.

A fourth difference between the two models concerns the fact that the HBM maintains, as separate components, the perceived susceptibility, severity, and threat of the potential illness. Because Fishbein's model was developed in non-health related environments, the need to explicitly provide for emotional fear arousal variables was not evident. Consequently, the BIM is

²Some versions of the model suggest that demographic and personality variables affect perceptions of the major variables. These individual difference constructs have been purposely omitted in order to focus on the cognitive concepts in the HBM.

³The relationship between intention and behavior is an empirical issue which the authors intend to address at a future time when behavioral data collected by the local health department can be retrieved.

limited, to a certain extent, to the rational side of a preventive health decision. Although the HBM does not explicitly state the rules for combining susceptibility and severity to arrive at perceived threat, it does provide for their specification in the model.

To aid the reader in comparing the two instrumentality models described in the preceding discussion, the constructs in the BIM and HBM are juxtaposed on the basis of their isomorphic similarities in Table 1 along with the components of the Drive Reduction Model (DRM). Discussion of this latter model, due to its somewhat different orientation, has been reserved until this time.

Table 1

Conceptual Comparison of Three Models For the Prediction of Preventive Health Behavior Intentions

Construct	Behavioral Intention Model	Health Belief Model	Drive Reduction Model
Likelihood of Consequences	Yes	Yes (Benefits- Barriers)	Yes (Drive Reduction)
Evaluation of Consequences	Yes	No	No
Attitude Toward Behavior	Yes	No	No
Normative Beliefs	Yes	Yes (Cues to Action)	No
Motivations to Comply	Yes	No	No
Subjective Norm	Yes	No	No
Perceived Susceptibility	No	Yes	Yes } Drive Arousal
Perceived Severity	No	Yes	Yes
Perceived Threat	No	Yes	No
Exogenous Influences	No	Mass Media	No
Criterion	Behavioral Intention	Likelihood of Action Occurring	Motivation to Act

The Drive Reduction Model. A preventive health model based on the fear arousing properties of an illness and the capacity of a health action to reduce that fear has been proposed by Wortzel (1976) as adapted from earlier work by Bauer and Cox (1963) on the rational and emotional content of communication influences. Bauer and Cox originally suggested that the two critical dimensions which affect a consumer's motivation to engage in a given act are the level of emotional arousal resulting from failure to take action and the subjective probability that that same action will prevent the anticipated problem which is generating this arousal. The consumer's level of felt emotion is considered to be the drive arousal dimension while the subjective degree of success attached to a preventive action is believed to be the drive reduction mechanism.

The authors predict that, when the level of the subjective probability of success relative to arousal is sufficiently high, a person will be motivated to engage in the act; when that contrast goes below a certain (unstated) value, the person will choose not to engage in that behavior.

Wortzel (1976) later operationally redefined the Bauer and Cox (1963) drive arousal and drive reduction dimensions in term of the variables encompassed by the HBM. Specifically, the drive arousal dimension was conceptualized as the product of an individual's perception of his susceptibility to a disease and the perceived seriousness of the same disease. The drive reduction dimension, in turn, was defined as the difference between the subjective probability that a preventive health action will result in avoiding the disease and one's subjective assessment of the cost of preventive behavior. Predictions from this reoperation-alized model are identical to those of Bauer and Cox, i.e., action is a function of the level of drive reduction as related to drive arousal.

Table 1 shows how the variables suggested in the DRM compare to those discussed with regard to the BIM and HBM. Further elaboration is necessary, however, because a number of subtle differences exist in the variables used to construct the major concepts in the model.

First, the number of outcomes of the preventive behavior used in the DRM is somewhat restricted. Only one positive consequence, that of immunity from the disease, is specified while the negative outcomes are limited to "costs" which are subjectively identified. Thus, the DRM may exclude a number of positive outcomes (e.g., protecting one's family from contagion) or negative outcomes such as uncomfortable, unknown, side effects. In addition, the subject is not asked to make evaluations of the degree of immunity received or of the costs, a problem which is also inherent in the HBM.

Second, the DRM is more limited and also more explicit in its operational definition of perceived susceptibility to and perceived seriousness of the disease. While the HBM admits many diverse operational definitions of these variables (Becker and Maiman, 1975), the DRM requires a probabilistic judgment of susceptibility in the absence of the preventive health behavior. In an equally rigorous manner, seriousness is viewed as a combination of all ill effects of the disease. Also of note is the fact that the DRM specifies that the combinatorial rule for these two variables is multiplicative. Jaccard (1975) has noted that in various formulations of the HBM, both additive and multiplicative rules have been used.

Finally, the DRM appears to suffer from a greater degree of conceptual deficiency than either of the other two models. In addition to the previously discussed omissions, no measures of personal or mass media influences are specified nor is the summary construct of perceived threat. Rather, these variables appear to have been considered either redundant, exogenous, or uncontrollable.

Hypothesis

The degree to which the three models predict one's intention to receive a swine flu vaccination is the central focus of this paper. The corresponding null hypothesis specifies that no differences will be observed. The next section discusses the methodology employed to test this notion.

Method

Design

A cross-sectional field study of a community swine flu vaccination program was undertaken in October 1976. Questionnaires measuring beliefs, attitudes, and intentions concerning the swine flu inoculation campaign were mailed to residents one week before the vaccine first became available in that community. A number of other municipalities across the country had already initiated their vaccination programs.

Subjects

Two thousand residents of a medium-size midwestern community were selected from the telephone directory using a systematic random sampling procedure to receive the questionnaire used in the study. In addition, 1000 students from a major state university located in the community were also selected by the same random process from the student directory to participate in the survey.

Measures

Behavioral Intention Model. Fishbein (1975) requires that all salient consequences of the behavioral referent as well as the relevant reference persons be identified. This task was facilitated by the controversial nature of the swine flu inoculation campaign. Because of the widespread media coverage of the swine flu program, the pros and cons of immunization were fairly well documented (e.g., Boffey, 1976; Spivak, 1976). In addition, a culling of varied media presentations including local TV interviewing provided a sufficient list of consequences and referent persons and groups. The number of factors in each list was later reduced through pretesting to eight consequences of obtaining the swine flu shot, five consequences of failing to obtain the shot, and five social referents.⁴

To obtain a probabilistic measure of beliefs about the consequences, the respondents were asked to scale the possibility of occurrence of each consequence if they got (did not get) a swine flu shot on a five point scale ranging from "no chance" (0) through "50-50" (.5) to "certain" (1). The evaluative component of the model was measured by asking respondents to evaluate each consequence on a five point good-bad scale ranging from "very bad" (-2) to "very good" (+2). In a similar manner, subjects indicated their normative beliefs with regard to each social referent by responding to the question "Do the following people want you to get a swine flu shot?", on a five point scale ranging from "yes" (+2) to "no" (-2). Finally, motivation to comply was obtained from four point items asking the respondent: "Does (social referent's) opinion matter to you?" Scale points ranged from "yes" (3) to "no" (0).

Summary constructs tapping one's overall attitude toward getting a swine flu shot and one's overall subjective norm were measured on independent scales. The attitude

⁴ The consequences of obtaining the shot were a mild case of the flu, pain from the shot, immunity from the flu, protecting family and friends from the flu, being inconvenienced, side effects or allergic reactions, feeling more comfortable with people, and possible fatality due to the shot. The consequences of not getting the shot included catching swine flu and, if one caught the flu, pain and discomfort, cost of medicine and doctor's bills, lost time from one's job and/or school, and death. The social referents were one's doctor, family or spouse, local health department, company or boss, and friends and neighbors.

toward the act measure used in the study was a nine item semantic differential scale⁵ while the subjective norm variable was a one item summary measure suggested by Fishbein and Ajzen (1975, p. 314).

The Health Belief Model. Perceived susceptibility, severity, and threat were measured on five, eight, and four item Likert scales respectively. Items for these scales were suggested by Rosenstock's (1974) review of earlier studies and by media statements specific to the swine flu campaign.⁶

To obtain a measure of the benefits-barriers concept, scores from the probability of consequences scale in the BIM (i.e., the belief component) were used without the evaluative dimension. Thus, the average of the probabilities assigned to the five unfavorable outcomes (barriers) was subtracted from the mean of probabilities assigned to the three favorable outcomes (benefits) to arrive at the benefits-barriers score.

The cues to action variable was obtained in a section of the questionnaire separate from that measuring the normative influences in the BIM and included references to TV, radio, and the print media as well as one's doctor, family, and friends. Respondents were asked to specify the media and persons used as information sources and to indicate whether this information was "for swine flu shots" (+2) at the one extreme of a five item scale, to "against" flu shots (-2) at the other. The sum of these responses was used to operationalize the cues to action construct.

The Drive Reduction Model. The drive arousal component of the DRM was measured with reference to the action null set, that of failing to get a swine flu shot. According to Wortzel (1976), this variable is defined as the probability of contracting swine flu in the absence of an inoculation times the anticipated severity of the problems associated with the disease. To obtain these measures, subjects were asked to first indicate their chances of catching swine flu if they did not get a shot (perceived susceptibility) and then to estimate their chances of incurring four negative outcomes if they did get flu (perceived severity), all on five item scales ranging from "no chance" to "certain". The four outcome scores were averaged and then multiplied by the susceptibility probability.

Drive reduction has been defined by Wortzel (1976) as the subjective probability of success associated with the preventive action less an assessment of costs of that action. These measures were taken from the probability of consequences scales discussed in the BIM. The probability of success variable was operationalized as the likelihood assigned to the one outcome "immunity from swine flu" while the costs of action were estimated by the sum of probabilities attached to the negative consequences of getting a swine flu shot. Drive reduction was then operationalized as the probability of immunity minus the average of the sum of costs.

Criterion. To obtain a continuous measure of behavioral intention, subjects were asked to indicate the "chances in 10" that they would get a swine flu shot on an eleven point scale ranging from "no chance (0) to "certain" (1).

⁵The coefficient alpha reliability of this scale was .94.

⁶The scales yielded coefficient alpha reliabilities of .68, .72, and .70 respectively.

Analysis

Simple correlations were first calculated between the criterion and the antecedents suggested by the various models to test whether the predictor variables were significantly associated at the zero order level. The intention criterion was later regressed on all suggested antecedents simultaneously to determine if each variable would make a significant independent contribution to the explanation of variance in intention. Finally, the coefficients of determination generated by each model were compared in an effort to identify the model with the greatest predictive potential. These analyses were performed for the sample as a whole and then by student and resident subsamples to determine if differences in model component weights existed across the two subject groups.

Results

Of the 3000 mailed surveys, 252 student and 148 resident questionnaires were returned as undeliverable for various reasons, the most common of which was "moved, no forwarding address." Of the remaining 2600 surveys, 335 usable student replies and 515 usable resident returns were received yielding response rates of 45% and 28% respectively. Of these respondents, twelve students and 46 residents indicated that they had already received the shot and were eliminated from the study resulting in a final sample size of 792 including 323 students and 469 residents. Fifty-one percent of the student respondents and 53% of the residents in the sample were male.

Correlations between the intention criterion and all variables suggested by the three models are shown in Table 2 for the total sample and the two subsamples. It is evident that all antecedent variables were significantly correlated with the criterion. Moreover, the magnitudes of these associations were higher in the BIM than in the other two models suggesting that the Fishbein approach may have greater validity. It is also interesting to note that, in those models where concepts are linked sequentially (the BIM and the HBM), the variables posited as having a direct effect on intention produced higher correlations than those suggested as having indirect effects only, a finding which supports the conceptual structure of these models.

Table 2 also shows that marked differences across subsamples were observed only for the cues to action construct in the HBM and for the drive reduction construct in the DRM. The data suggest that intentions of the community residents were more highly related to media and word-of-mouth influences than were students' intentions and that the drive reducing properties of the inoculation were somewhat more instrumental for resident intentions than for students. For the most part, however, the correlations obtained in the two samples for all models were surprisingly similar.

When the criterion was regressed on all variables in each model simultaneously, the results shown in Table 3 were obtained. It is immediately apparent that the BIM yielded coefficients of determination much larger than those obtained with the HBM which, in turn, produced higher coefficients than the DRM. Note further that all variables hypothesized to directly affect the intention criterion generated significant coefficients while those which are posited to have indirect effects (attitudinal and normative beliefs in the BIM; perceived susceptibility and severity in the HBM) resulted in attenuated coefficients when compared to the zero-order correlations in Table 2. This finding lends support to the sequential or intervening variable influences suggested by the BIM and the HBM.

** p < .01

Table 3 shows that somewhat higher coefficients of determination were obtained when using the resident sample data. This finding was particularly evident for the HBM and DRM models and may arise from the higher zero order correlations for certain of the variables. It would be speculative, however, to attribute meaningful differences in model structure across samples to the small differences observed in the regression coefficients. Such differences may be more easily explained by multicollinearity effects or range differences in the variables.

Discussion

The results have shown that the BIM yielded much higher coefficients of determination than either of the other competitive models. As the reader may recall, Fishbein's conceptual framework differed in a number of important respects from other schemata and this may explain its predictive superiority. First, the BIM incorporates evaluative components at both the individual consequence level and at the summary attitude toward (evaluation of) the act level. This would appear to be critical because individual beliefs have little meaning unless one's affect toward a consequence or behavior is gauged (Fishbein and Ajzen, 1975). Thus, the implicit assumption in the HBM that all benefits are evaluated as equally good and all barriers or costs as equally bad is not necessarily accurate.

Second, the BIM explicitly includes the influences of referent persons and, in doing so, acknowledges that relevant others are instrumental in the formation of one's behavioral intentions. While the HBM does have a cues to action component which is somewhat isomorphic with Fishbein's normative beliefs, it does not provide for the various motivations to comply with those beliefs (which can be seen as another form of evaluation). Again, it may be inappropriate for proponents of the HBM to assume that all cues to action which support one's intention to engage in the preventive behavior are viewed as equally salient or credible by the consumer.

Finally, Fishbein's model includes two important intervening variables, attitude toward the act and subjective norm, between the summed attitudinal and normative beliefs and intention. These mediating constructs serve to "capture" the essence of the underlying beliefs and, if the results of this study are representative, suggest that individuals do, in fact, form summary judgments of positive and negative consequences and positive and negative social influences. These summary judgments, then, become the most direct influences (and therefore the best predictors) of intention. Neither the HBM nor the DRM contains these variables.

The difference in the coefficients of determination between the HBM over that of the DRM may be attributed to the greater number of variables in the former model. Specifically, the HBM explicitly recognizes external information sources on one's intention to engage in a behavior and is not as restrictive in terms of the benefits or favorable outcomes which can be considered in the model. Thus, proponents of drive models of preventive behavior may wish to add social and other influences in an effort to increase the explained variance in their criteria.

In summary, it appears that the inclusion of evaluative components, normative influences, and intervening summary measures enhance the degree to which a model aids in the explanation of preventive health intentions. The next section suggests some implications of these findings.

Implications

Profit and non-profit preventive health care marketers may find a number of the findings reported here of interest in improving their understanding of consumer health decisions. First, it is noteworthy that all three models investigated explained a statistically significant portion of the variance in behavioral intention suggesting that some of the antecedents of health intentions may be known. Consequently, practitioners and field researchers may wish to borrow from certain of the models to augment the decision making processes used by their organization.

Second, researchers concerned with the most complete determination of health care decisions (e.g., when an epidemic is imminent) may wish to combine concepts from two or more of the models. To illustrate, it appears that inclusion of one or more emotional components (e.g., perceived threat) in the BIM may increase its predictability beyond that obtained with the more rational components proposed by Fishbein.⁷ Alternatively, researchers with an HBM orientation may wish to include evaluations of the benefits and barriers as well as the individual's overall evaluation of the preventive health behavior.

Finally, it is clear that some variables in the models have more immediate impacts on one's intention decision. It follows that if a researcher or practitioner were interested primarily in prediction, a more parsimonious model consisting of direct effects only may suffice. In a similar manner, if one wished to attempt to change an existing behavioral intention, it may be more productive to work on the more immediate antecedents. For example, a person's overall subjective norm may be more amenable to influence in the BIM than would the orientations of the individual referent persons.

Limitations

The conclusions drawn here are contingent on the methodology employed to test the models. In view of this, certain readers may wish to question the authors' interpretation of model structure as well as the operationalization procedures used. To the extent that these criticisms are valid, the findings remain tentative. We would hope that others would take issue with this presentation and test alternative models and methodologies. Hopefully, a discourse of this nature will result in beneficial refinements and a more complete understanding of preventive health care decisions.

⁷ Further analysis of the data used here provides only tenuous evidence for this suggestion. When intention was regressed on the four Fishbein components and perceived susceptibility, severity, and threat simultaneously, the coefficients of determination increased by 2% for the total sample, by 4% for the student sample, and 2% for the resident sample. This is not to say, however, that greater improvements would not be obtained in other research settings.

Abstract

An argument for expanding Fishbein's Behavioral Intention Model that posits non-additivity, the introduction of a new variable, and restructuring of the model by way of explicitly identifying components as antecedent, independent, and dependent variables is put forth. Evidence providing limited support is described and a modified expansion of the model is suggested as a guideline for future research.

Introduction

The popularity of applying and investigating the Fishbein Behavioral Intention or Extended Model within the context of consumer behavior is evidenced in a recent review (Ryan and Bonfield, 1975). More recently, efforts have focused on refinements or extensions of the original model (Bennett and Harrell, 1975; Lutz, 1975; Ahtola, 1975; Glassman and Fitzhenry, 1975). This research examines a portion of a causal chain proposed by Ryan and Bonfield (1975) as a framework for identifying relationships and specifying components as antecedent, independent, moderator, and dependent variables. The major focus regards non-additivity of attitudinal and social influences and the specification of an independent variable form of social influences.

The Fishbein Behavioral Intention Model

The Fishbein behavioral intention theory states that intention to perform a behavior in a given situation and subsequent performance of that behavior is a function of (1) attitude toward the performance of a specific behavior in a particular situation and (2) social norms influencing the individual's performance of the behavior. The central equation in the theory is commonly modeled as follows:

$$BI = (Aact) \omega_0 + \left(\sum_{j=1}^k NB_j MC_j \right) \omega_1$$

Where: BI = behavioral intention

$$Aact = \sum_{i=1}^n B_i a_i \quad (\text{attitude toward the performance of the act})$$

B_i = the expectation, i.e., the probability or improbability that the performance of a behavior will lead to an i th outcome

a_i = the positive or negative evaluation of the i th outcome

n = the number of salient outcomes

NB_j = the expectation, i.e., the probability or improbability, that the performance of the act is expected by a j th referent

MC_j = the motivation to comply or not to comply with the expectation of the j th referent

k = the number of salient referents

ω_0, ω_1 = empirically determined standardized regression coefficients (beta weights)

In previous research, the operational model has taken the form of a standardized regression equation and the magnitude of the beta weights has in turn been interpreted as an indication of the relative strength of attitudinal and social influences.

By combining attitudes and social influences Fishbein attempts to overcome a probable reason for the traditional lack of empirical support for an attitude-behavior relationship. Namely, that perceived social group influence variables must be considered in conjunction with attitudes to predict and understand behavior (Triandis, 1965; Warner and DeFleur, 1969; Wicker, 1969). Although it may be useful to separate these two sources of influence in regard to understanding behavioral intention formation and change strategies, Fishbein does not provide a conceptual basis for the independence stated in the additive model. This is a crucial point since the use of beta weights to indicate the relative influence of the variables on behavioral intention rests upon the additivity assumption. Many studies (Ajzen and Fishbein, 1973; Ryan and Bonfield, 1975) have produced statistically significant ω_0 and ω_1 beta weights thus yielding empirical support for the additivity notion. However, other theorists (Banton, 1965; Krech, *et al.*, 1962; Karlins and Abelson, 1970) have argued on a conceptual basis and furnished empirical evidence (Janis and King, 1954; King and Janis, 1956; Siegal and Siegal, 1957; Newcomb, 1958; Sherif, 1958; and Janis and Gilmore, 1965) indicating that attitude and social influences are related. Although these studies did not use expectancy-value models and conceptual differences make their total assessment difficult, this evidence together with the lack of a conceptual foundation, suggests that the additivity notion be questioned.

A Reconceptualization

The research carried out by Fishbein and his associates has usually incorporated a measure of Aact as the attitudinal component instead of $\sum B_i a_i$. Since these studies (Ajzen and Fishbein, 1973) were primarily concerned with prediction of behavior and behavioral intentions, this seems appropriate from an operational standpoint. In all cases the measurement of Aact was patterned after the multi-item, bipolar adjective, evaluative dimension of the semantic differential (Osgood, Suci, and Tannenbaum, 1957; Fishbein and Raven, 1962). This technique seems appropriate for predictive purposes since it is generally considered to produce reliable and valid measures of attitude. However, the bipolar adjective set does not have much explanatory power since it merely indicates the strength and direction of attitude. It does not reveal the elements comprising the attitudinal structure and therefore does not furnish diagnostic power useful in examining attitude formation and change. In those cases where predictive power or variable associations are the sole interest this is appropriate since a determination of structural elements is not necessary, but a reliable and valid measurement is essential. Given a choice, Aact is also easier to operationalize than $\sum B_i a_i$ since there is no need to determine salient outcomes, encounter problems arising from an erroneous or incomplete list, or run the risk that correlations with multiplied non-ratio scaled scores may be invariant (Schmidt, 1973).

The major thrust of Fishbein's work has been to conceptualize the attitude formation process as the summation of beliefs times evaluations (Fishbein, 1963).

The relationship between Aact and ΣB_{1a_1} has been supported in a number of studies (Ajzen and Fishbein, 1970; Bruce, 1971; Bright and Stummers, 1971; Jaccard and Davidson, 1972; Ajzen and Fishbein, 1972) and the interaction of B_1 and a_1 manipulations has produced changes in Aact (Lutz, 1975b). Thus, ΣB_{1a_1} appears appropriate for diagnosing Aact whereas Aact seems more appropriate than ΣB_{1a_1} for predicting behavioral intention. Empirical support for this notion is found in evidence provided by Lutz (1973). When he replaced Aact scores with ΣB_{1a_1} scores the multiple correlation on BI dropped from .647 to .240 and the attitudinal beta weight dropped from .646 to .238. This evidence was strengthened when Lutz (1975a) also observed changes in BI following changes in Aact that were induced by manipulating B_1 and a_1 values. In a pilot study for the present research it was found that ΣB_{1a_1} -BI correlations disappeared when Aact was partialled out (Ryan, 1974).

Although Fishbein does not use the term, this evidence indicates that ΣB_{1a_1} fits the use prescribed to antecedent variables which in this case is attempting to discover a first cause by clarifying the influences which precede the Aact-BI relationship. Thus, ΣB_{1a_1} is recast as an antecedent and Aact as an independent variable.

Following the same reasoning used to describe the two forms of attitude as antecedent and independent variables, the formulation of the normative component appears incomplete. The ΣNB_jMC_j formulation fits the use ascribed to explanatory variables but an independent form of social influence has not been specified that avoids operational problems and is more appropriate for prediction. In fact, within the context of Fishbein's theory the present understanding of the normative component is limited (Ajzen and Fishbein, 1973; Fishbein, 1975). Consequently, it seemed useful to look elsewhere for a framework within which to develop an independent form of the normative variable. Kelman's (1961) three processes of social influence; compliance, identification, and internalization, were used for this purpose.

Compliance occurs when an individual accepts influence from another person or group because he believes it will result in a satisfying social effect which may be the attainment of rewards or avoidance of punishments under the other's control. Identification occurs when an individual adopts the role of another. It differs from compliance in that the individual is not primarily motivated to please the other but to meet the other's own role expectations since they fit the individual's self image. Internalization occurs when an individual accepts influence because it is congruent with his value system. The reward is the content of the induced behavior.

Since internalization and identification involve rewards internal to the individual, these sources of social influence seem related to attitude. On the other hand, compliance involves an external reward since the individual assumes an actor's role, that is, a role not necessarily congruent with his internal values, in order to obtain an expected reward. Consequently, compliance may well be independent of attitude. However, Kelman holds that all three processes are present and interact in a given social situation and that the nature of the situation determines which particular process predominates and the type of interaction among them. Thus, some relationship between attitude and social compliance is expected with the strength of the relationship determined by the degree to which internalization and identification are present. In the intentions model such effects would be manifested in Aact whereas the social compliance dimension by itself, hereafter referred to as SC, seems independent from Aact. Thus, SC is posited as an independent variable form of social influence that is separable yet, in contrast to the additivity notion, related to Aact.

The notion of a separable influence variable based on external rewards also has some parallel with the development of Dulany's (1968) verbal response model from which Fishbein borrowed heavily in developing the Intention's Model. Dulany manipulated his variables in laboratory experiments that employed negative and positive reinforcers administered by an experimenter after subjects verbally responded to statements that were regarded as neutral in terms of the respondent's value system.

In summary, this reconceptualization views BI as a dependent variable, Aact and SC as independent variables related to each other, and ΣB_{1a_1} and ΣNB_jMC_j as antecedent variables. Subsequent to the initial work on this reconceptualization (Ryan, 1974), Fishbein and Ajzen (1975, pp. 16, 334, 407) have put forth a similar restructured model with three primary differences. First, attitudinal and social variables continue to be viewed as independently affecting BI. Second, although positing the same general flow of effects, identification of antecedent-independent variable relationships is not made explicit. Third, a new form of social influence is introduced as a generalized social norm (SN) identified as the person's perception that most people who are important to him think he should or should not perform the behavior in question (Fishbein and Ajzen, 1975, p. 302). Evidence supporting an association between ΣNB_jMC_j and SN and between SN and BI has been furnished (Glassman and Fitzhenry, 1975) although SN has yet to be shown as separable or independent from Aact. Fishbein (1975) introduced the importance concept based on an assumption that individuals would have little or no motivation to comply with unimportant others. This notion raises questions about both the separability of SN from Aact and the need to include MC in the antecedent variable. First, importance is likely to be based on value judgments or emotional feelings thereby indicating that "important others" would be internalized and reflected in Aact. Second, if importance guarantees a strong motivation to comply, this removes the necessity for including MC in the normative structure thereby rendering the theory less general since it would exclude motivations not to comply with a perceived social influence. For example, a referent expectation would be negatively related to behavioral intention if the individual was motivated not to comply with a positive influence. In the case of social compliance, such a situation may arise if the individual places little or no value on the expected reward from the referent as a consequence of performing the behavior. This argument parallels the thinking behind the original Fishbein (1967) expectancy times evaluation approach to attitude.

Research Objectives

This research tested the proposed associations among ΣB_{1a_1} , ΣNB_jMC_j , Aact, SC, and BI. It was not possible to empirically compare SC and SN since the research was executed prior to the appearance of SN. In addition to the value of replication, attitudinal variable relationships were included since it seemed unrealistic to test social influence variables without including their relationships with all other variables in the system. More specifically, support was sought for the following relationships as specified by the reconceptualization.

In terms of the attitudinal variables, attitude toward the act (Aact) should be directly related to its underlying structure (ΣB_{1a_1}) and behavioral intention (BI) should be directly related to attitude toward the act (Aact). Behavioral intention (BI) should be indirectly associated with attitudinal underlying structure (ΣB_{1a_1}). That is, behavioral intention (BI) should be more strongly associated with attitude toward the act (Aact) than it is with attitudinal underlying structure (ΣB_{1a_1}).

In terms of social influence variables, social compliance (SC) should be directly related to its underlying

significant correlations between their respective measurement scores. Indirectly linked variable correlations should lower in magnitude and become statistically insignificant when the moderator variable score is partialled out. Variables posited to have no relationship should produce statistically insignificant correlations between their respective measurement scores.

Further testing of the antecedent-independent variable designation involved an examination of beta weight and R^2 values when the respective variables were placed in the central equation. In order to support this notion the model employing Aact and SC should produce larger R^2 s than those produced using ΣB_{iaj} and ΣNB_jMC_j as predictor variables. In addition, it was expected that the Aact attitudinal beta weights would predominate for both brands and that the SC weight would be larger in the Ultra Brite versus the Crest model. Variations from these beta weight expectations when using ΣB_{iaj} and ΣNB_jMC_j as predictors would indicate that these variables are not appropriate independent variable forms.

Findings and Discussion

The simple and partial correlations used to test the attitudinal and normative variable associations are presented in Table 2. Correlation Sets 1 through 4 test attitudinal variable associations. The positive, statistically significant correlations obtained for both brands in Sets 1 and 2 support the direct associations between the attitudinal variables ΣB_{iaj} -Aact and Aact-BI. The statistically significant correlations in Set 3 for the indirectly linked variables ΣB_{iaj} -BI became statistically insignificant (Set 4) when Aact was partialled out. This evidence supports the associations posited among the attitudinal variables.

Correlation Sets 5 through 8 tested normative variable associations. The positive, statistically significant correlations for both brands in Sets 5 and 6 support the direct associations between the social influence variables ΣNB_jMC_j -SC and SC-BI. The statistically significant correlations in Set 7 for the indirectly linked variables ΣNB_jMC_j -BI became statistically insignificant

when SC was partialled out for Ultra Brite but remained significant for Crest (Set 8). The Crest partial correlation was smaller than its indirect correlation (Set 7) indicating that the removal of SC variance did lower the BI- ΣNB_jMC_j relationship. These findings largely support the proposed associations among the social influence variables. However, the failure of the statistical test to indicate that the entire Crest indirect association was due to the moderating effects of SC mitigates these findings and renders the support tentative.

Correlations testing the relationships among social influence and attitudinal variables are presented in Table 3. Correlation Sets 1 and 4 tested hypothesized

TABLE 3
Simple Correlations

Set	Variables	Ultra Brite	Crest

* $p < .05$

** $p < .01$

associations. The positive statistically significant correlations in Set 4 support the associations between the independent variables Aact and SC. However, in Set 1 only the Crest correlation between the antecedent variables is significant and its value indicates the strength of the relationship was only moderate. This finding is unexpected, especially in view of the strong support for the independent variable relationship. It may be that the correlation of the two variable scores, each computed through the multiplication of non-ratio variable scores, may have attenuated these correlations.

Correlation Sets 2 and 3 tested hypothesized lack of associations among variables. The positive statistically significant correlations in both sets provide evidence disconfirming this hypothesis. In retrospect these findings are not surprising given the demonstrated colinearity between Aact and SC and the previous discussion concerning internalization. If certain specific sources of social influence are internalized it seems logical that these sources would become a part of attitude. This could happen, for example, if the focal person assumes a relevant other's expectation is congruent with his feelings or if a commonality of information about the product exists between the focal person and relevant others.

The findings concerning the use of the posited independent and antecedent variables in the central equation are shown in Table 4. The R^2 s were stronger for both brands and the social influence beta weight values were congruent with expectations when Aact and SC were used as independent variables whereas the weights were incongruent with expectations when ΣB_{iaj} and ΣNB_jMC_j were used as predictors. These findings lend additional support to the notion that Aact and SC are more appropriate for use as independent variables than are ΣB_{iaj} and ΣNB_jMC_j . In spite of these findings, however, the independent variable colinearity suggests that the

TABLE 4

central equation beta weight interpretations may not be straight forward. First, an assumption must be made that colinearity does not cause beta weight instability. Second, the joint contribution of the predictors (c.f., Ferber, 1949) to BI variance should be considered since this effect may be stronger than the direct effects indicated by the beta weight values.

Summary and Conclusions

The findings from this research are summarized diagrammatically in Figure 1. The clear cut findings concerning the attitudinal variables are congruent with a large

FIGURE 1
A Summary of the Findings

Solid lines represent hypothesized relationships that were supported. Dotted lines represent supported relationships that were not hypothesized. Dashed lines represent hypothesized relationships that were not supported.

body of research investigating the expectancy value approach to attitude and a smaller but growing body of knowledge regarding relationships among cognitive, attitudinal, and behavioral intention variables. However, the findings concerning social influence variables and crossover effects were not straightforward and cannot be viewed within a framework provided by a body of research. The tentative evidence reported here constitutes the only support for the SC variable. More evidence is needed regarding SC measurement validity and applications across other products, brands, and groups.

The latter suggestion is especially appropriate given the limited generalizability of the sample used in this research. Also, other independent forms of social influence have been hypothesized (Ahtola, 1975; Lutz, 1975c) in addition to SN. Empirical comparisons of these different approaches are yet to be made. Consequently, the specification of meaning for a social influence independent variable is not a settled issue.

Given the state of knowledge, the suggested relationships in Figure 1 concerning crossover and social influence variable relationships are best viewed as tentative suggestions to guide future research. It is hypothesized that the indirect paths between the antecedent and outcome variable, indicated by dotted and dashed lines, represent weaker relationships than the direct paths, indicated by solid lines. The associations in this direct and indirect network seem susceptible to empirical testing through the use of path analysis (Nygren, 1971). However, the examination of associations is considered only a starting point rather than a complete investigation of what is proposed as a possible causal chain. Additional testing of causal order and lack of spuriousness would follow before causality could be supported or disconfirmed (Popper, 1959). Causal ordering, for example, could be tested with experimental design procedures outlined by Perreault and Darden (1975) that would consider the antecedent variables as factors and attitude, social compliance, and behavioral intention as multiple criterion variables.

More evidence supporting these notions would lead to a reduced form model since there are many variables in addition to those included that have been hypothesized to explain buyer behavior (Andreason, 1965; Nicosia, 1966; Howard and Sheth, 1969). However, there are two major advantages to the reduced form model. First, the relationships among variables are explicitly structured. Second, the level of abstraction allows the development of operational definitions for all variables. Consequently, the model can be shown to fit or not fit empirical regularities, a requirement of all good theories (Kaplan, 1964).

THE MARKET FOR PERSONAL GROWTH SERVICES

Philip Kotler, Northwestern University
Lenore Borzak, Northwestern University

Abstract

Americans are enrolling in growing numbers in programs promising them "personal growth." These programs are supplied by (a) "mom-and-pop" enterprises, (b) proprietary enterprises, and (c) growth centers. Four proprietary enterprises--TM, EST, Scientology, and Silva Mind Control--attract and satisfy consumers through meeting a variety of manifest and latent needs. Underlying these services are a hierarchy of self-actualization needs that are becoming more salient in post-industrial society.

Introduction

Personal growth services, broadly defined, includes religious services, psychiatric services, psychological services, self-improvement services, inspirational services, and even occult services. It could include the Moonies, Total Woman, Alcoholics Anonymous, and even Weight Watchers. We will confine our attention to a narrower band of personal growth services that have the following characteristics:

1. The service is bought. This excludes traditional and contemporary religious movements, both Western (e.g., the Unification Church, Campus Crusade for Christ) and Eastern (e.g., Hare Krishna). Members of these religious movements do not see themselves as buying a service so much as living out a faith.
2. The service is available to anyone who wishes to buy it. The personal growth services are available to the mass market. Organizations that offer enlightenment programs only to their own members are excluded.
3. The service consists primarily of group processes rather than of individual counseling. This eliminates individual psychotherapy, religious counseling, and paid advice systems.
4. The seller is considered professionally qualified to offer the service. The founder has professional credentials and/or exemplifies to a high degree the qualities that the service offers to impart.
5. The service is trademarked and marketed. The seller creates an identity for the service and markets it.

Personal growth services are supplied to the market in three forms. A "mom-and-pop" supply system consists of a therapist or team conducting group workshops at regular intervals for a fee. They may be conducted in a home, office, or hotel. If they are not trademarked, they are at least closely identified with a particular supplier. There are hundreds of entrepreneurs running personal growth workshops on this basis.

A proprietary (or "franchised") supply system consists of an entrepreneur designing and copyrighting a particular service, developing licensed trainers to deliver this service in different cities, and taking responsibility for marketing and financing the growth of the enterprise. Scientology, Silva Mind Control, Transcendental Meditation (TM), and est (Erhard Seminar Training) are the best examples.

Finally, a growth center supply system consists of a single or multiple site center that offers a wide variety of courses on a regular basis that may run from one day to over several months. Such centers are located in urban areas (such as Esalen in San Francisco or Oasis in Chicago) and in Arcadian settings (Esalen at Big Sur, California, or Naropa Institute near Boulder, Colorado). Esalen, the earliest and best known growth center, issues a catalog every four months listing over one hundred personal growth courses, bearing such titles as "Self Acceptance--the Freedom to Be," "Psychosynthesis: Choosing to Change," and "Getting Out of Your Trap." Each course is offered either by regular Esalen staff members or well-known therapists. In recent years, Esalen has taken some of its programs on the road offering intensive training weekends in select cities.

How many Americans have taken these personal growth services? As of 1976, Scientology claims 5,000,000 registrants; Silva Mind Control, 435,000; Transcendental Meditation, 250,000; and est, 100,000. (Lande, 1976) Figures are not available for mom-and-pop enterprises and growth centers, but one can safely guess that they have serviced several million American consumers.

Though each supply system could be explored at length, we shall focus on the four proprietary services listed above, since these four have been the most conspicuous in the last few years, primarily in terms of numbers of consumers served. If, as Adam Smith has suggested in Powers of the Mind, TM is the McDonald's of the meditation business, with its relatively low fixed price, standard item, and increasing numbers of franchises or outlets, then Scientology, Silva Mind Control, and est are the McDonald's of their respective segments of the market. For highly mobile Americans who may reside in a particular area on an average of less than three years, these proprietary services insure quality control by selling a uniform item. In est, for example, the same nine trainers conduct the training throughout the United States, and there is virtually no difference between taking the training in Washington, D.C. or in San Francisco. The post-training seminars are also nearly identical in all the est centers.

Data on the characteristics of consumers are not available. However, most observers agree that the consumers are largely middle-class, college educated, and white. Younger persons predominate although all ages are represented. The various services draw both sexes in about an equal ratio. One journalist suggests that such services attract people who have "made it," because once they make it, they realize that they're still not happy, and they go looking for something else. (Preston, 1976)

Another factor contributing to the preponderance of white-collar consumers is that an increasing number of corporations are willing to pay the cost of personal development workshops for their executives. Thus, these proprietary services become part of the expense-account economy.

When did these personal growth services first appear? One could argue that they originated at the very beginning of human society. Early mankind's fears and vulnerabilities led to the need for services to counsel

and console him. Myths were created, religions built, and practitioners such as priests, shamans, and witch-doctors came forth to offer inner peace in return for allegiance or fees. Whether the incentive to seek help was prompted by the desire to exercise an evil spirit or to rid the body of an excess of one of the four "humours" that upset the temperament, people have paid attention to the working of their "inner lives." However, the practitioner in the past was called in to rectify what was wrong with the person. Attention to the inner life, which reached a new high with the emergence of psychiatry in the late nineteenth and early twentieth centuries, typically has emerged from an illness model. Freud and other physicians developed the concepts of modern psychiatry on the basis of new insights into the pathology of the human mind. They listened to patients describe their mental and emotional problems and prescribed a course of therapy to treat their symptoms and effect a cure. The focus was on disorder, on what went wrong in the past that could be corrected in the present.

Paradoxically, on the one hand, we can trace the modern roots of the human growth services to psychiatric medical practice. The patient's talking to a sympathetic and alert physician was developed into a therapeutic concept. One researcher coined the term "therapeutic man" to describe the prevalence of this healing outlook in the twentieth century. (Rieff, 1966; Hopkins, 1961)

On the other hand, the Freudian illness model can be seen as antithetical to the personal growth industry, especially if we turn to humanistic psychotherapy and all that its practitioners spawned as another and perhaps closer source of these growth services. Many of the so-called "humanistic" therapists were trained in the Freudian tradition. Yet, with few exceptions, they were clinical psychologists rather than physicians and were not committed to a medical orientation. Instead of looking at the human psyche to see what was wrong, they looked at what was right and healthy about human beings and what prevented people from realizing or actualizing their full potential.

Both Abraham Maslow and Carl Rogers, two of the most influential of the humanistic psychologists, felt that Freud and his disciples had built up theories of human nature based on the study of men and women at their worst. In the early 1940's Rogers pointed out how his client-centered approach differed from Freud's:

This newer approach differs from the older one in that it has a genuinely different goal. It aims directly toward the greater independence and integration of the individual rather than hoping that such results will accrue if the counselor assists in solving the problem. The individual and not the problem is the focus. The aim is not to solve one particular problem but to assist the individual to grow, so that he can cope ... in a better-integrated fashion ... therapy is not a matter of doing something to the individual ... it is instead a matter of freeing him for normal growth and development, of removing obstacles so that he can again move forward. (Rogers, 1942)

For Rogers "growth" is synonymous with health, and both underlie man's basic nature: the one basic tendency and striving is "to actualize, maintain, and enhance the experiencing organism." (Rogers, 1951)

This is a view of man as basically good rather than evil, a being whose nature is positive. It is a view that is explicitly contrasted with Freud's view that the id, man's basic and unconscious nature, is primar-

ily made up of instincts which would, if permitted expression, result in incest, murder, and other crimes. For Rogers the basic nature of the human being, when functioning freely, is constructive and trustworthy. He quite consciously substituted the term "client" for "patient" to depart from the Freudian illness model.

Abraham Maslow was also influential in creating what we shall henceforth call a wellness model for human services. Drawing upon his own findings both within and outside of the context of the therapeutic situation, Maslow defined what he called a viable third alternative to behavioristic psychology and to orthodox Freudianism. He labelled it a Third Force "health-and-growth psychology" grounded on the assumptions that man is basically good, and that he seeks to actualize his potentialities. Certain restraints or self-imposed barriers may prevent him from reaching his full potential, including energies directed to lower order needs such as providing food and shelter for himself. Once such barriers are removed, the person can be wholly and fully human and is able to make what Maslow calls the "growth choice" to be actualized. (Maslow, 1965, 1954, and 1962)

Both Rogers and Maslow had tremendous impact on a number of psychologists who seized on the notion of the human potential as an untapped natural resource. While there were many thinkers and practitioners from a myriad of sources, eventually this third force thrust came to be labelled the human potential or personal growth movement.

Parallel to this and consonant with the wellness model was the beginning of T-group or sensitivity training in 1946. Kurt Lewin and his co-workers had been working out the theory of using group processes to (1) train leaders; (2) develop self-insight in individuals; (3) create awareness in individuals of how groups function; (4) change attitudes; (5) resolve conflict. The National Training Laboratories (NTL) were set up in Bethel, Maine, and worked principally to train individuals to be more effective as group members, usually in business or industrial settings. The emphasis in the training was on present behavior and an analysis of it in the workshop that could be transferred to back-home settings.

The training group or T-group was the specific activity of NTL and its staff. However, their approach to group-methods became extremely popular and was carried forward into schools and growth centers around the country. Eventually the terms sensitivity training and encounter became synonymous with T-groups, although the links between them were loose. Being sensitive to one's own and others' feelings and encountering and coming to terms with such feelings in the present were practices in T-groups and in the workshops created at places like Esalen Institute. Esalen, established in California in 1962 and offering an ambitious potpourri of experiences in Eastern religion, body awareness growing out of Reichian bioenergetics, and small group processes à la Maslow, Rogers, and the gestalt therapist Fritz Perls, is clearly the grandfather of growth centers.

What is interesting about the rapid proliferation of the centers is that they seem to have been conceived as both a means of improving one's life and a leisure-time activity. Back refers to them as "psych-resorts." (Back, 1972) He notes that they provided a peculiar leisure-time experience accompanied by a feeling of accomplishment.

This latter component is the link to still another source of the personal growth industry and its success in the United States: the "self-improvement" ideology so deeply embedded in American character. Ben Franklin epitomized the American who systematically observed his own actions, evaluated them against certain standards and goals, and took a definite course of action to improve himself. In the nineteenth century, many Americans flocked to various meetings and campgrounds where they would pay a fee to hear lectures by such persons as Ralph Waldo Emerson and Mark Twain on how to think and feel better.

In the twentieth century, millions of Americans would read Dale Carnegie's How to Win Friends and Influence People and Norman Vincent Peale's The Power of Positive Thinking. Tens of thousands would sign up in follow-up courses to master these and other principles of self-improvement.

Closely allied to the concept of self-improvement is another American ideal exalted by Emerson: self-reliance. His prescription for the good life was to be "self-realizing and self-directed," (Emerson, 1946) a notion which is close to David Riesman's "autonomous" person a century later in The Lonely Crowd. While Thoreau may have epitomized the totally autonomous life in Walden, in the twentieth century millions of Americans would live it in a modified version by means of "do-it-yourself" projects.

For the outer life, doing it yourself means learning from others what are the proper tools and ways to proceed, then plunging ahead. In the business of the inner life, the process is the same. The personal growth industry appeals to the "pulling oneself up by the bootstraps" mentality: people pay for a course of training that gives them the tools to live a better life.

In the four proprietary services we are highlighting, the thrust is to give the individual more control over his or her own life. The instruction occurs in a relatively brief period of time, under the tutelage of a trainer-guide who carefully tries to establish rapport as an equal. For example, in est the trainer tells his audience more than once that he is simply a graduate who does the training and is in every way like the trainees. This is very different from the asymmetric doctor/patient relationship in the medical psychotherapeutic model where the individual is ministered to by others.

The wellness model of the humanistic therapies, along with the offshoots that have been lumped together as the human potential movement, can be viewed as consonant with the melioristic streak in American culture. These phenomena all turn on the notion of the perfectibility of human nature. Moreover, several factors seem to make proprietary services such as TM, est, and Scientology acceptable and popular to large numbers of Americans in ways that no therapy has ever achieved.

One is that there is no stigma of mental illness associated with these services. One does not have to be sick to get better. Another is the weight of the numbers of people served. Like McDonald's continually changing marquee announcing how many hamburgers have been served, each of these services takes pride in publicizing how many people have been trained. Perhaps there is a comfort in knowing that Scientology has trained five million people and in imagining that they must be getting something for their money.

Finally, there seems to be safety in numbers. Each of these services has gone far beyond the parameters of

group treatment with fewer than 20 persons that neo-Freudian therapies developed. An est workshop with 250 people in the ballroom of a hotel is really closer in origins to a nineteenth century revival meeting than to group therapy. This is mass distribution to the mass market.

While there may be religious undertones or the elitism associated with the mystique of belonging to the ever-growing throng of graduates or mediators, an important part of the appeal of these services is to a secular and science-believing generation of Americans. At introductory lectures TM distributes reprints of articles from prestigious scientific journals to document the physiological benefits of meditating. Scientology's professional aid, the "E-Meter" is a scientific-looking instrument with a moving needle, and its methodology, dianetics, is presented as a science for achieving total mental health. Silva Mind Control contains elements of alpha brain-wave training, and est draws upon Scientology and physics in its lectures.

This appeal, combined with the intensity of the group experience, is a potent combination for consumers. Perhaps, as Back suggests, such personal growth services meet many needs formerly met by religion, giving an air of scientific respectability to feelings people have previously sought in a religious experience.

Needs and Wants in the Personal Growth Services Market

What are people seeking when they sign up in personal growth programs? To answer this we will refer to the hierarchy of needs postulated by Maslow. (Maslow, 1954) He proposed that the most potent human needs are physiological -- hunger, thirst, the need to survive. When these needs are satisfied, people turn their attention to needs for safety -- saving for the future, building better shelters, practicing ordinary prudence. When their safety needs are under control, people begin to pay more attention to their needs for belongingness and love -- to have a family and friends, to love and be loved. At the next level, people strive for esteem and status -- to gain recognition, applause, and even envy in the eyes of others. Finally, when people are secure in these needs, they are free to deal with a need for self-actualization -- to improve their own capacities for thinking, feeling, and doing, experiencing fully and vividly with full concentration and total absorption.

In highly industrial societies, many citizens have achieved affluence. They have left behind their physiological and safety needs and are struggling with higher-order psychological needs. A large number are involved in searching for self-actualization. Within self-actualization, there is itself a nested hierarchy of needs.

The first need is for relaxation. The hectic pace and pressure in industrial society have strained people's nerves and created a billion dollar pain-killing industry featuring aspirin, valium, and other medicinal "calming" agents. Personal growth services represent an alternative or supplement to pharmaceutical means of detensification. Probably over eighty percent of the population would admit to an interest in learning how to relax more easily. They buy a tremendous number of books on relaxation and life simplification.

Relaxation is perhaps the simplest way to describe this need. A more active form of the need might be called reenergization, where the person wants to overcome tired feelings and regain aliveness of body and mind. Recentring is still a stronger form of the need in which the person wants to feel whole again, to be in

touch with himself or herself. This may take the form of connecting the mind and body in new ways. Rollo May, a widely-read humanistic psychologist, has stressed people's need for centering as a means of personal integration, finding a center of strength within the self particularly in the twentieth century age of anxiety. (May, 1953) TM is the primary service catering to the relaxation class of needs. The other services supply relaxation techniques but not as their primary mission.

The next self-actualization need is for awareness expansion. Many people sense a condition of not being fully aware of their own feelings, either denying, avoiding, or suppressing them. They also sense barriers to "being" with other people in the "here and now," that is, being empathic. Thus awareness expansion takes the form of wishing to enhance one's self-awareness and other-awareness, and such human growth services as est and Scientology are tuned in to this need.

A more active need is for enhanced interpersonal effectiveness. Many people would like more mastery and impact in social situations. They envy those who come on strong and who know how to get what they want. Dale Carnegie training and assertiveness training are among the services offered to this market segment.

The next need is for personality change. Many people are unhappy about their emotional makeup. They cry too much, are angry too much, are too hostile, or have no feelings at all. Some want to achieve more spontaneity; others, deeper feelings; still others, evenness of temper. They are in the market for Gestalt therapy, rational therapy, and primal scream therapy, all promising to recondition their emotional makeup.

A need that is emerging in recent years is a desire for self-transcendence. Instead of investing more in their ego, some people are trying to reduce or renounce their ego as the key to becoming tranquil, compassionate, and satisfied with their lives. They seek to attain higher levels of consciousness and enlightenment. They respond to gurus and join ashrams, camps, and monasteries in their search for self-transcendence.

Finally, some people seek to transcend their ordinary state of consciousness through occultism. They want to believe in levels of reality beyond those obvious to the senses. They are in the market for extrasensory perception, levitation, clairvoyance, communication with the dead, materializations, astral-projection, ghosts, and other occult occurrences.

Entrepreneurial Characteristics of Personal Growth Service Firms

The majority of human growth service enterprises are created by a charismatic individual rather than by a group of individuals whose identities remain vague. This is especially true of the proprietary services. Scientology centers around Ron Hubbard, TM around the Maharishi Mahesh Yogi, Silva Mind Control around Joseph Silva, and est around Werner Erhard. The leader is usually very bright, highly articulate, dedicated, very visionary. He attracts enthusiastic supporters who give their time and energy at little or no pay. The leader formulates the core service package and it goes through additional refinements in the process of being presented to different groups. The current form of the service represents the accumulated experience of the leader and several licensed trainers as to what works and what doesn't work.

To date, most personal growth firms have gone after the middle majority market because of its high discretionary income and high interest in self-actualization. These enterprises have typically sought both sexes, although a few new services are aimed specifically at the women's market (e.g., Total Woman, Applied Potential). Most services are geared to adult consumers, although some firms have designed segmented services for teens or senior citizens. Most services are available to people regardless of occupation, although some firms have designed segmented versions for special groups such as professors, executives, or prisoners. As the market evolves, undoubtedly firms will start targeting their services to mini-markets of certain social classes, races, and occupations.

Several of the proprietary services address themselves to meeting one particular need in the self-actualization hierarchy. TM, for example, positions its service primarily in the relaxation market. Here is a recent statement (from a TM poster on a college bulletin board):

Transcendental Meditation is natural, effective, systematic, refreshing, simple, effortless, spontaneous, easily learned, scientifically verifiable, practiced twenty minutes morning and evening to develop the full potential of the individual. It isn't a lifestyle, self-hypnosis, concentration, contemplation, mind control, a philosophy, a yoga exercise, an intellectual practice, a religion, a diet, a special way of dressing, or difficult to learn.

On the other hand, Silva Mind Control promises the consumer a host of benefits (from a brochure distributed by Silva Mind Control):

Control of your own mind--are you ready for it? Are you ready to do whatever you do, better? Are you ready to be a better person? Student, housewife, gardener, businessman, teacher, parent, doctor, salesman, politician, or even free spirit? Do you want to understand your self and others better? Are you ready to listen to your intuition when it tries to tell you something? Are you ready to remove those limits you keep placing on yourself? Are you ready to reach for your inner strengths and talents and make them work for you? Are you ready to control the way you think about your problems? And solve them better? Are you ready for an incredible trip into your own mind?

Scientology is also quite broad in the range of needs it alleges serving. It offers a succession of courses to help the person advance to higher grades of ability:

- Grade I. A person acquires the ability to recognize source of problems and make them vanish.
- Grade II. A person acquires the ability to achieve relief from the hostilities and suffering of life.
- Grade III. A person acquires freedom from the upsets of the past and ability to face the future.
- Grade IV. A person learns how to move out of fixed conditions and gain ability to do new things.

Grades V, VI, etc.

The personal growth service founder designs a program consisting of a mix of manifest and latent services. Manifest services are the stated benefits that the supplier promises to deliver to the target market. TM offers to teach a method that can produce relaxation and inner peace. Est offers a training that will "transform your ability to experience living so that the situations you have been trying to change or have been putting up with clear up just in the process of life itself."

Latent services are the unstated benefits that participants may seek or expect to find in the program. Most personal growth entrepreneurs are acutely aware of the "hidden agenda" of latent needs that their services might cater to, including:

1. Need to relieve boredom. Many people find their life situation drab and see a personal growth program as a way to spend their time in a more interesting manner.
2. Need for sociability. Many people are seeking an opportunity to be with other people, make new friends, and possibly develop romantic relationships, all in a socially acceptable context.
3. Need to be interesting to others. Many people want to be regarded as having done something interesting and different. They may see the service as a way to become more interesting to other people.
4. Need to find community. Many people do not enjoy their current group affiliations and want to become part of a new family or community with which they could share their energy, time, and love. The human potential group provides opportunities for volunteering services and deepening friendships.
5. Need to find meaning in life. Many people who sign up for these services have abandoned traditional religion and are looking for something new in which to believe.

Because of the multiple motives that personal growth programs satisfy, participants come away with quite different ways of describing what they got. It is common for est graduates, for example, to emphasize quite different benefits and insights that they gained from their training. Each gets "It" differently. One cynic has suggested that it really does not matter what the content of these programs is in most cases. Just putting people together to share an intensified weekend will produce a "high."

The Future of Personal Growth Services

Personal growth service firms are presently operating in a boom market. The growth of this market will attract more suppliers. Growing competition will lead firms into increased market segmentation and specialization. Eventually the rate of market growth will slow down, forcing firms to undertake more intense marketing. This will express itself in the accelerated development of new services, the intensified use of advertising and personal selling, and the cultivation of more publicity. Some suppliers will be forced out of the market. Eventually the market will stabilize at a certain size and with a certain well-known set of leading suppliers.

Some observers expect the whole size of the market to shrink as people get overexposed or lose their interest in ego services. They see the human potential movement as faddish. Our belief, on the contrary, is

that personal growth services meet a permanent need in the marketplace. They will be around as long as no other means, such as new mind drugs or psycho-technical products, are found to be more effective.

SPARKS AND TUCKER REVISITED: A REANALYSIS
AND REPLICATION

Charles M. Schaninger, University of Massachusetts
V. Parker Lessig, University of Kansas

Abstract

The personality and product usage measures employed in the Sparks and Tucker (1971) study were replicated on a sample of 142 male college students at a large midwestern university. A comparison of the simple correlation matrices between the two sets of data revealed only limited similarity. Both sets of data revealed canonical roots of similar magnitude and significance, although only limited similarity of canonical loadings among the canonical functions was demonstrated.

Introduction

Within the field of personality and product usage, most of the research appearing since the late 1960's has been strongly influenced by Sparks and Tucker's (1971) study. Prior to this and Kernan's (1968) study, most of the work in this area had focused on either simple univariate analyses, or on single criterion, multiple predictor studies. Canonical correlation analyses, cluster analyses, and multiple discriminant analyses have been used in a large number of studies (Alpert, 1972; Greeno, Sommers, and Kernan, 1973; Darden and Reynolds, 1974; Villani, 1975). Essentially, these studies suggest the existence of "molar personality types" -- i.e., patterns of product usage across product classes associated with corresponding personality profiles. Personality is viewed in a gestalt sense, with various combined multivariate approaches used to identify the different molar types. Many studies have utilized similar multivariate-statistical approaches with AIO/lifestyle/psychographic data, to identify "molar types" or segments in the market. Books by King and Tigert (1971), and Wells (1974), as well as papers by Wells (1975) and Kassarjian and Sheffett (1975), describe this vein of research.

The Sparks and Tucker paper had a strong impact because it took a broadened conceptual approach toward the area of personality and product usage, and because it's conclusions suggested the existence of much stronger and more meaningful relationships than had been found in previous investigations.

A number of authors (Kollatt, Blackwell and Engel, 1972; Engel, Kollatt and Blackwell, 1973; and Robertson and Ward, 1973) have stressed the need for replication of consumer behavior studies, particularly for studies which have a significant impact and which used limited samples. Our objective was to replicate (using new data) and to reexamine (using Sparks and Tucker's original data) the Sparks and Tucker study. We were specifically interested in examining the degree to which the original and the replicated studies yield comparable results.

Methods

The subjects for the replication were 155 male undergraduate college students enrolled in introductory marketing courses at a large midwestern university. Data were collected for the same eight personality variables and seventeen product-usage variables used by

Sparks and Tucker. Of the 155 subjects comprising our total sample, 142 accurately completed all questions. This sample is roughly comparable to that of Sparks and Tucker's original study -- although the samples do come from universities located in different geographical areas and from different time periods.

We obtained and reanalyzed the raw data for the 173 subjects completing all questions for the original Sparks and Tucker study.¹ We found a number of minor discrepancies between the correlations based upon reanalyzing their data and those reported in the original article. Evidently their calculations were based on pairwise deletions of missing data on their entire sample of 190 subjects, rather than on the reduced sample of fully completed forms for the 173 subjects serving as our reanalysis sample.

The relationships between personality and product usage were examined using the two approaches presented by Sparks and Tucker: an examination of the simple correlations between each personality trait and product usage score, and an examination of the canonical correlation analysis which focused on the overall association between the two sets of variables (product usage and personality). For both the original and replication samples, the overall strength of association between the two sets of variables was examined by Bartlett's test of canonical correlation significance, by Veldman's test of canonical correlation significance, and by Stuart and Love's (1968) redundancy measure.

Finally, the nature of the relationships found between the personality and product usage measures for the two samples was compared by examining the factor loadings associated with each set of linear canonical functions.

Results

Simple Correlations

From an examination of their correlation matrix, Sparks and Tucker reported "some weak and spotty relationships between personality traits and particular product use." They found 18 of the 136 cross correlations to be significant at the 0.05 level. Our reanalysis of Sparks and Tucker's data (n = 173) also produced 18 significant correlations; 13 of these were the same as Sparks and Tucker found. Only 12 correlations were significant on the replication sample; of these only five were the same as those of the original study. These five were between the following pairs: ascendancy and use of alcoholic beverages, ascendancy and fashion adoption, sociability and use of alcoholic beverages, sociability and fashion adoption, and between cautiousness and use of alcoholic beverages.

¹These data were made available through the courtesy of Professor Sparks.

Multivariate Relationships

Table 1 presents the first three canonical roots for our reanalysis of Sparks and Tucker's data (n = 173), for the replication study (n = 142), and those reported in Sparks and Tucker's article. We note that in both the original Sparks and Tucker study and the reanalysis of their data by Lambert and Durand (1975), it was concluded that the first three roots are significant. However, the third root in both studies was significant at the 0.01 level and not at the 0.05 level. Based upon their observations, Sparks and Tucker interpreted the first three sets of linear canonical functions. It should be noted that the studies by Sparks and Tucker and by Lambert and Durand applied the significance test developed by Veldman (1967), rather than Bartlett's (1941) test. When Veldman's test was applied to Sparks and Tucker's data (n = 173, not 190) and to our replication data, only the first two roots were significant. Examination of the Bartlett's test revealed only the first canonical root to be significant for each set of data. (These chi-square values and their corresponding degrees of freedom are also reported in Table 1.)

The discrepancy between the Veldman and the Bartlett procedures concerning the number of significant canonical roots should be noted. The correspondence between these two tests has been presented by Alpert, Peterson, and Martin (1975). Essentially, Veldman's test

partitions the first Bartlett test chi-square value (of the significance of the first and remaining sets of canonical functions) to calculate the relative chi-square contribution attributable to each of the roots. Disregarding the significance testing procedure employed, both sets of data were comparable with regard to the number of significant canonical roots.

Although both Bartlett's test and Veldman's test provide tests of the statistical significance of the association between two sets of variables, little additional information is provided. Stewart and Love's redundancy test was therefore applied to measure the amount of variation in the set of personality scores. Table 1 also shows the redundancy scores obtained on the Sparks and Tucker data and on the replication data. These scores indicate that 7.37 percent of the variation of product usage is associated with variation in personality for the Sparks and Tucker data, and 8.28 percent for the replication data. The reader is referred to Lambert and Durand (1975) and to Alpert, Peterson, and Martin (1975) for a discussion of this multivariate squared multiple correlation measure. It should be noted that the more complex mathematical form for its calculation simplifies to the mathematical average of the multiple R² for each criterion variable with the set of predictors.

TABLE 1
First Three Canonical Roots

Sparks and Tucker Reanalysis (n = 173)

^aSignificant at the 0.05 level.

^bSignificant at the 0.01 level.

Nature of the Relationships

Table 2 presents the factor loadings for the first and the second set of canonical functions for our reanalysis of Sparks and Tucker's data and for our replication sample. It should be noted that loadings represent correlations between the original variables and the canonical variate scores, and not the canonical weights (coefficients) used to multiply standardized variable scores calculating canonical variate scores. In several instances, both the direction and magnitude of the weights were different from the loadings for the reanalysis and for the replication data. When collinearity existed, the weights tended to be lower than the loadings in magnitude and when a given variable had a suppressor effect, its weight was opposite in direction to the loading.

An examination of the first set of canonical loadings for the two samples demonstrated that the contributions made by the original variables in explaining the first set of canonical relationships differ. An interpretation of these loadings for the Sparks and Tucker data suggests a pattern of heavy usage of cologne and alcohol, and high fashion adoption associated with high sociability and ascendancy, and with low responsibility and cautiousness. The comparable first set of canonical functions for the replication sample suggested a pattern of low shampoo usage and high coffee usage associated with higher scores on original thinking, cautiousness, and personal relations. Both conclusions

may be viewed as intuitively appealing, but neither could be described as representing the same basic underlying relationship.

The second set of linear functions from the Sparks and Tucker data demonstrated a product usage pattern consisting of heavy usage of mouthwash, headache remedies, and coffee associated with lower emotional stability, vigor, and original thinking, and higher cautiousness scores. This interpretation, based on loadings, is basically consistent with that given by Sparks and Tucker, based upon their examination of their canonical coefficients (weights). It should be noted that the test of emotional stability, from the Gordon Personal Profile, tends to load highly on items related to nervousness, rather than to those which would indicate emotional instability in a clinical sense.

The pattern of loadings for the second set of canonical functions for the replication data was also dissimilar to the second function for the Sparks and Tucker data, although relatively similar to the first function for their data. A product usage pattern of heavier consumption of alcoholic beverages, chewing gum, and fashion adoption was associated with lower cautiousness and higher sociability and ascendancy. Although there are differences between the second canonical function in the replication data and the first for the Sparks and Tucker data, a similar underlying pattern tends to emerge.

TABLE 2
A Comparison of the Variable Loadings of the First Two Canonical Functions
for the Sparks and Tucker and the Replication Data

Variables	First Canonical Function		Second Canonical Function	
	Sparks & Tucker Data (n = 173) Loadings	Replication Data (n = 142) Loadings	Sparks & Tucker Data (n = 173) Loadings	Replication Data (n = 142) Loadings
<u>Product Usage</u>				
Headache Remedy	.269	-.015	.440	-.285
Mouthwash	.240	.093	.507	.014
Men's Cologne	.473	.128	.012	.122
Hair Spray	.167	-.284	.127	.087
Shampoo	.324	-.509	-.112	-.273

Complexion Aids	.181	-.244	.055	.048
Vitamin Capsules	.330	.198	.058	.005
Haircut	-.144	.056	-.241	-.214
Cigarettes	.308	.057	-.051	-.097
Coffee	-.012	.599	.397	.057
Chewing Gum	.300	-.265	.130	.331
After-Shave Lotion	.067	.164	-.113	.120
<u>Personality Traits</u>				
Ascendancy	.688	.112	-.129	.610
Responsibility	-.520	.222	-.292	.006
Emotional Stability	-.295	.320	-.602	-.037
Sociability	.844	-.169	.059	.663
Cautiousness	-.433	.446	.368	-.688
Original Thinking	.287	.839	-.373	.273
Personal Relations	-.016	.403	.027	.122
Vigor	.049	.023	-.400	.093

Although the roots were not statistically significant, there was also some degree of similarity between the third root of the replication data and Sparks and Tucker's second root; however, the similarities were not as clearcut as those between the second and first (respectively) roots. Cross loadings were also calculated (the correlation between the individual predictor variables and the criterion canonical variate scores and vice versa). These were, as expected, generally lower, yet basically comparable to the original loadings for both data sets. All of the variables mentioned demonstrated significant loadings (correlations) at the .05 level, and the great majority of the cross loadings were also significant at this level. Although the significance tests of the loadings and cross loadings cannot be interpreted as significant correlations between independent variables, their relative significance levels merit examination in lieu of any other significance measures.

Summary

A comparison of the findings obtained from the reanalysis of Sparks and Tucker's data and the same analysis on the replication data reveals several similarities worth noting. First, as shown in Table 1, the magnitude of the first three canonical roots associated with the two sets of data is very similar. Second, for both sets of data, according to Bartlett's test only the first set of canonical functions is statistically significant. However, using Veldman's approach, the first two sets of canonical functions are shown to be significant for both sets of data. Finally, strong similarities are noted in the redundancy scores obtained between product usage measures and personality traits. The redundancies measured from the reanalysis of Sparks and Tucker's data and from the replication data were 7.37 and 8.28, respectively. These figures compare favorably to the redundancy of 6.2 found by Lambert and Durand.

A comparison of the matrices of simple correlations between product usage scores and personality measures for the two sets of data revealed a similar number of significant correlations, although less than half of these significant correlations were for the same pairs of variables. Direct similarities were not noted between the two sets of data when the factor loadings for the first two canonical functions were compared, although the second canonical function for the replication data revealed a pattern similar to that demonstrated in the first function of the Sparks and Tucker data.

The differences in the simple correlations between those reported in Sparks and Tucker's article, based on the full sample of 190 and those found by reanalyzing the data for the 173 with complete data, as well as the evidence of instability of canonical weights found by Lambert and Durand, suggest that the differences in the findings are due more to violation of the statistical assumptions underlying canonical analysis and to random error in the relatively weak relationships found for these small sample steps than to differences between the two samples.

Based upon the consistency of results across a number of different studies, it does appear that a statistically significant relationship exists between product usage and personality traits when these measures are treated as a whole, i.e., multivariately. Given the magnitude of the redundancy indices, ranging from 6.2 to 8.28 percent, it cannot be concluded that this relationship is significant in a practical sense.

Although the relationships demonstrated by Sparks and Tucker's first canonical function do appear to be supported by the loadings of the second function of the replication data, there were still many inconsistencies between the loadings and percentages across the different canonical functions for the two sets of data. Generalizations as to the specific nature of relationships between personality traits and product usage are questionable, and probably should not be made without stronger evidence than that which has been obtained from an unreplicated study.

PERCEPTION OF MARITAL ROLES IN DECISION PROCESSES:
REPLICATION AND EXTENSION

E. H. Bonfield, Temple University

Abstract

A study by Davis and Rigaux (1974) was replicated with two changes: greater specificity in describing decision items and use of a nonconvenience, random (cluster) sample. The earlier research was extended by checking for differences between traditional couples (masculine husband with feminine wife) and all couples. With some exceptions, generally attributable to greater item specificity, the Davis and Rigaux results were supported. Differences between traditional and all couples were found.

Introduction

In a recent study, Davis and Rigaux (1974) explored the self-reported influence exerted at three general phases of the consumer decision process. The general theoretical and methodological notions were useful, but two, recognized, shortcomings reduced the overall value of the study. First, the researchers utilized a convenience sample, making questionable any generalizations. Secondly, the 25 economic decisions were, for the most part, general in nature, leading to a possible masking of role specialization at a more "micro" level. For example, Davis and Rigaux defined housing as a single item with "location, purchase price, or rent" in parentheses. However, previous research (e.g., Hempel, 1972) has shown husband dominance, wife dominance, and joint decisions for various aspects of the housing decision. The present replication attempts to correct for these two potential contaminants, thus adding generalizability to the results.

A related question deals with sex roles. In an environment increasingly subject to changes in the perception of sex roles, it is possible traditional couples—masculine husband with feminine wife—have different perceived marital roles in the decision process than couples, for example, in which both mates are androgynous in sex role orientation.

This study was thus addressed to the same two questions as was the research by Davis and Rigaux (p. 51):

1. Do marital roles in consumer decision-making differ by phase of the process?
2. To what extent do husbands and wives agree in their perception of roles at various phases of the decision process?

In addition, this study was also addressed to the question:

3. Do marital roles and husband-wife perception agreements differ among traditional (masculine husband/feminine wife) households as compared to the more general population.

Methodology

Consistent with the replication-extension nature of this study, the methodology closely follows that of Davis and Rigaux (1974).

The Sample

Separately administered questionnaires were successfully completed by both spouses in 60 households selected by means of a cluster sample (Sudman, 1976). Clusters of respondent households were drawn from census blocks in a southeastern SMSA, the blocks and households having been drawn randomly. Only high income, high home value blocks were included in the population. Thus, while the generalizability of the following results is limited to relatively upper social class couples in a single region, the population is specifiable. The relatively high class status of the sample was reflected in the reported occupations of husbands, 61% professional and 25% white collar. While 65% of the wives reported they were homemakers, 16% reported they were professionals while an equal proportion reported they were white collar workers. Nearly half the sample reported annual family incomes of \$30,000 or more. Almost 75% of the husbands and 47% of the wives had earned at least one college degree and an additional 40% of the wives had some college education. The median age of couples of approximately 34 years was apparently greater than in the Davis and Rigaux study since only 12% (compared to 36%) were in their twenties. This age difference was reflected in the family sizes in that fewer had no children, 14% to 25%, and more had at least three children, 33% to 28%.

The Questionnaire

As in the Davis and Rigaux study, each respondent gave information about who was the first to recognize a need, who collected the information about possible choices, and who made the final decision to buy, for 20 decisions in this case. The answer categories in each of the resulting 60 questions were Husband, Wife, and Joint; latter scored 1, 3, and 2 respectively. While the decision items were in most cases the same or similar to those selected by Davis and Rigaux, an effort was made to describe each item as specifically as possible without making the task too tedious for the respondents. Thus, while Davis and Rigaux asked about living-room furniture, for example, respondents in the present study were asked about a sofa for the living room or family room. The complete list of items is included in Table 2, and a comparison of item names between the two studies is included in the Appendix. Use of more specific items limits the generalizability of the results to those items, but increases the degree of generalizability about those items.

The BSRI

Bem (1974) developed the Bem Sex Role Inventory (BSRI) in such a way as to preclude "an inverse relationship between masculinity and femininity (p. 155)." The BSRI contains 20-item masculinity and femininity scales "selected on the basis of sex typed social desirability (Bem, 1975, p. 635)." With the BSRI, then, individuals can be classified as masculine, feminine, or androgynous. Androgyny is the preferred state since, according to Bem, an individual's behavior is limited if he or she can only perform behavior conforming to his or her perception of the masculine or feminine sex role.

While it was an original hope for this study to compare households with androgynous spouses with households with masculine husbands and feminine wives, the number of

total androgynous households was too small (3) for such analysis. Surprisingly perhaps, less than half the households (28) were "traditional" in having masculine husbands and feminine wives.

Findings

These analyses follow the same pattern as Davis and Rigaux (1974), but differences in results as well as traditional-total population differences are noted.

A Framework for Classifying Decisions

Davis and Rigaux utilized a diagram, originally suggested by Wolf (1959), which displays all decisions simultaneously. The vertical axis represents the scale of relative influence between husband and wife and results from the average of scores. The horizontal axis represents the degree of role specialization operationalized in terms of proportion of respondents reporting the decision was joint. Since the axes are not independent, the area of feasible coordinates is limited by a triangle (see Figure 1). While the definitions of the regions of the triangle as husband dominant and wife dominant are self explanatory--although wife specialization and husband specialization might be more appropriate terms--syncratic and autonomic decisions require further explanation. Most simply, syncratic decisions are those in which more than half the respondents reported the decision was joint, while, in the autonomic case, less than half the respondents indicated the decision was joint, but there was not consensus among respondents as to whether the decision was husband dominant or wife dominant. Thus, autonomic decisions, as well as husband and wife dominant decisions, represent role specialization.

Differences in Roles by Decision Phase

Table 1 includes a classification of the 20 decisions at each of the three phases in the decision process. Phase

TABLE I
Patterns of Influence at Three
Stages of the Decision Process
(Percentages)

Pattern of Influence	Phases								
	Problem Recognition			Search for Information			Final Decision		
	D/R ^a	60 ^b	28 ^c	D/R	60	28	D/R	60	28
Husband dominant	8	25	25	12	25	25	8	20	20
Autonomic	40	8	5	36	15	15	20	15	20
Syncratic	28	15	15	24	10	10	52	30	25
Wife dominant	24	52	55	28	50	50	20	35	35

^aDavis and Rigaux (1974) shown in percentages, 73 couples and 25 decisions.

^b60 couples selected by means of a cluster sample.

^c28 of the 60 couples classified as "traditional," that is, masculine husband and feminine wife.

1 is problem recognition, Phase 2 is search and evaluation, and Phase 3 is final decision. Percentages are shown so the results may be compared with those of Davis and Rigaux. The earlier results tend to be supported in that there was little difference between problem recognition and search for information, in terms of proportion in each influence pattern, and there was a marked increase in proportion of syncratic final decisions. However, these differences were not so pronounced as in the Davis and Rigaux study, perhaps because of much higher wife dominance throughout the decision process.

A large proportion of the decisions remained in the same influence pattern through all three phases of the decision process (70% in the present study, 64% in the Davis and Rigaux study). There were no differences between traditional couples and all couples among same pattern processes.

Similar to the Davis and Rigaux findings, husband dominance in the three phases was found for insurance on the husband's life (life insurance in Davis and Rigaux), homeowner's or renter's insurance (other insurance), and lawnmower (garden tools) as well as replacement tires for the primary family car which was not included by Davis and Rigaux. Seven decisions remained wife dominant in all stages, including five which support the Davis and Rigaux findings. The supportive, wife dominant decision patterns included replacement or additional pots and pans for the kitchen (kitchenware), beef roast (food and nonalcoholic beverages), slacks for the wife (wife's clothes), and household cleaning products (described the same in both studies). Also, tooth paste and adhesive bandages decisions were found to be wife dominant while the patterns across the three decision phases for the corresponding, more general items, cosmetics and toiletries and nonprescription drugs and first-aid items in the Davis and Rigaux study, were autonomic-wife dominant-autonomic and all autonomic respectively. Only neck tie for the husband was found to have an autonomic pattern over all three phases in the present study. While it might be argued the corresponding, husband's clothes pattern found by Davis and Rigaux was similar in that the third (decision) phase was only barely syncratic, at no stage, and for neither traditional nor total couples, did the percentage of joint decisions reach 15 for neck ties in the present study, while the percentage of joint decisions may have been as low as 30 only in the first (recognition) phase for husband's clothes in the earlier study. The syncratic pattern characterized decisions about movies (concerts, movies, theater) and family vacation (same) in all phases, thus supporting the earlier findings.

The remaining 6 decisions, which changed patterns across phases, were individually at least qualitatively different. In two cases, Davis and Rigaux results were supported. That is, the patterns for living or family room (other furnishings--rugs, drapes) had wife dominant recognition and search phases and autonomic decision phase, and the pattern for TV for living or family room (TV, Hi-Fi, tape recorder) had syncratic-autonomic-syncratic phases in both studies. Washing machine (household appliances excluding TV) decision processes were similar in both studies being autonomic and syncratic in phases 2 and 3 in both studies, but washing machine need recognition appeared to be wife dominant in the present sample compared to autonomic for the more general appliance category of the earlier study. The remaining 3 cases were quite different. While living room furniture and child(ren)'s toys for birthdays and holidays decision processes were characterized as syncratic at all phases in the Davis and Rigaux study, sofa for living room or family room and children's toys for birthdays were found to be wife dominant in both recognition and search in the present study. Further, in the present study, the sofa decision phase was found to be syncratic

while the children's toys decision phase was found to be autonomic. Finally, car decisions, which went from autonomic to husband dominant to syncratic in the earlier study, were husband dominant, as primary family car, in the recognition as well as search phases in the present study. For the total present sample, the decision phase was syncratic for primary family car, corresponding to the earlier findings, but among traditional couples the decision phase was autonomic.

Davis and Rigaux pointed out, correctly, (p.55):

While an analysis based upon the pattern of influence gives a general impression of the change in marital roles throughout the decision process, the criterion is such that much information is lost. A decision's position could change rather dramatically along the dimension of relative influence as well as in terms of joint decision making and still remain within the same pattern of influence. A much smaller change along either dimension, on the other hand, can produce a shift in patterns if the decision happens to lie close to the boundaries.

The authors next discussed changes in relative influence and joint decisions using averages over all item decisions for each phase. The averaging may have been misleading, however, because the averages were likely to have been biased by the sample of decision items selected for the study. Davis and Rigaux did effectively utilize the figures described earlier to graphically summarize changes between phases 1 and 2 and between phases 2 and 3. Figures 1 and 2 provide the same information for the present data on the total sample and Figures 3 and 4 provide this information for the 28 traditional couples.

The Davis and Rigaux findings of right-facing arrows, indicating greater specialization during phase 2, search for information, was not strongly supported since only half the cases in the present study had arrows pointing in the direction of greater role specialization (see Figure 1) compared to 80% in the earlier study. In two cases, replacement or additional pots and pans for the kitchen (kitchenware) and adhesive bandages (nonprescription drugs and first-aid items), nonspecialization movement between phases 1 and 2 found by Davis and Rigaux was supported. Interestingly, the present study supported nonspecialization for neck tie for the husband (husband's clothes), but the direction was toward specialization among traditional couples. While the direction with respect to children's shoes (children's clothes) were opposite in the two studies, the search phase was strongly wife dominant in both, which does support specialization.

In 5 cases, traditional couples differed from the total sample in terms of direction of the arrows in Figures 1 and 3. Traditional couples moved toward nonspecialization in search for drapes for the living room or family room, tooth paste, and insurance on the husband's life, while the total sample moved toward specialization. The opposite was found for beef roast and movies.

The Davis and Rigaux finding of movement toward joint final decisions--left-facing arrows--was supported as shown in Figures 2 and 4.

Similarity of Roles Perceived by Husbands and Wives

In discussing the analytical advantages of the fact their data were collected from both spouses within the same family, Davis and Rigaux pointed out (p. 55):

SEE TABLE 2

FIGURE 1
Changes in Marital Roles Between Phase 1 and Phase 2
60 Couples (N=120)

. . . it will lead to insights about the more practical issue of which spouse to interview in family research studies . . . Previous research has shown few consistent differences between responses of husbands as a group compared with wives (Wilkening and Morrison, 1963; Davis, 1970; Granbois and Willett, 1970). On the other hand, when intrafamily comparisons of direct questions are made, considerable disagreement is often evident (Scanzoni, 1965; Davis, 1970). While the level of agreement is generally greater than chance, a common finding is that from 10 percent to 50 percent of couples disagree about the influence of one spouse relative to the other for any given decision. The size of this percentage seems to vary with the specificity of questions and, not surprisingly, with the number of response categories.

Changes in Marital Roles Between Phase 2 and Phase 3
60 Couples (N=120)

in which husbands perceived recognition to be syncratic while wives perceived recognition to be autonomic; and in the cases of phase 2 and phase 3 for primary family car, husbands perceived both search and final decision to be husband dominant while wives perceived these activities to be autonomic. Similarly, in only 4 cases among the traditional couples was there not aggregate agreement between husbands and wives. Among traditionalists, husbands perceived syncratic recognition of need for TV for living or family room while wives perceived recognition as autonomic (syncratic agreement among all couples), husbands perceived autonomic recognition for children's toys for birthdays and holidays while wives perceived wife dominance (wife dominance agreement among all couples), husbands perceived wife dominant search for information on adhesive bandages while wives viewed this activity as autonomic (autonomic agreement among all couples), and husbands viewed the decision about children's toys as autonomic while wives viewed the final decision about children's toys as auto-

FIGURE 3

Changes in Marital Roles Between Phase 1 and Phase 2
28 Traditional Couples (N=56)

nomie while wives viewed the final decision as wife dominant (autonomic agreement among all couples).

Table 2 provides information about intrafamily agreement in role perceptions. While inspecting average consensus, Davis and Rigaux said their results supported the previous research because, in averaging each decision item across the 3 decision process phases, only 3 of the 25 decisions were classified according to different influence patterns when comparing aggregate husband and wife responses. Without averaging over the 3 phases, similar results were found in the present study. In only 3 of the 60 cases in the present study was there not aggregate husband-wife agreement. Nonagreement was found in the case of family vacation in the first phase or agreement, among couples would not normally be meaningful since such summary statistics may be biased by the selection of decision items, averages were useful in this case because they provided a means of obtaining implications about item specifications and sample types.

FIGURE 4

Changes in Marital Roles Between Phase 2 and Phase 3
28 Traditional Couples (N=56)

The results paralleled those of Davis and Rigaux in that the percentage of all couples who agreed about their perceived role--consensus--was relatively stable from phase to phase (72, 73, and 68%). However, the average proportion of agreement was slightly, but consistently, higher in each phase than found by Davis and Rigaux (69, 69, and 66%), thus suggesting very slightly greater consensus for more specifically defined consumer decision items. In the aggregate sense, no real difference existed between the 28 traditional couples and the total sample of 60 couples, although the relatively sharper decline in average consensus found at the final decision phase (65% for traditionalists) may be noteworthy. In general, the previous finding that high consensus decisions were those in which relative influence was very skewed (e.g., children's shoes, household cleaning products) was supported.

In order to determine whether systematic bias in perception of roles existed among couples who did not agree, Davis and Rigaux defined two types of nonconsensus, resulting from modesty or vanity (p. 58):

modesty--either or both spouses overestimating the other's influence in a decision or understanding their own influence.

vanity--either or both spouses overestimating their own influence in a decision or understanding the other's influence.

Davis and Rigaux utilized a 5 percentage point differential between aggregate modesty and vanity as an operational criterion for systematic bias in nonconsensus. They found a majority of cases indicating vanity. Among the 19 decision items common to both studies, 6 of 9 nonconsensus items in the problem recognition phase were vanity biased, all 10 in the search for information phase, and 7 of 9 in the final decision phase.

The vanity bias results were not supported in the present study. At the problem recognition phase, there was no particular bias for either the total sample (5 modesty and 6 vanity) or the traditional couples (5 each). While the total sample was in line with the earlier results at the search phase (8 of 9 vanity biased), traditional couples were more evenly divided (4 modesty and 5 vanity). Finally, at the final decision phase, the total sample was marked by more systematic bias cases (13 to 9) than the previous study as well as having much greater modesty bias (11 of the 13 cases) than was previously found. Since no consistent bias difference pattern emerged through inspection of the 3 decision items described the same in both studies (household cleaning products, children's toys for birthdays and holidays, and family vacation), it can be suggested these between-study differences in systematic nonconsensus bias were a result of differences in item specification.

There were also some differences between traditional couples and all couples with respect to nonconsensus bias. At the recognition phase, systematic bias in the modesty direction among traditional couples was found for washing machine and primary family car when there was no systematic bias among all couples for these items. Again, while there was no systematic bias among all couples for children's toys for birthdays and holidays and, to a lesser extent, household cleaning products, there was a vanity bias among traditional couples. Among all couples, a modesty bias was found for movies while a vanity bias was found among traditional couples.

At the second, search for information, phase, traditional couples were modesty biased with respect to primary family car and neck tie for the husband, while all couples were vanity biased in the former case and not systematically biased in the latter. Traditional couples, on the other hand, were vanity biased with respect to washing machine and children's toys for birthdays and holidays, while there was no systematic nonconsensus bias for the total sample for those decision items at this phase.

At the decision phase, the all couples group was found to be modesty biased with respect to sofa for living room or family room and replacement or additional pots and pans for the kitchen while the traditional couples exhibited no systematic nonconsensus bias. While there was no systematic nonconsensus bias for the total sample with respect to lawnmower, traditional couples exhibited a modesty bias.

Product Classes and Systematic Nonconsensus
Perceptual Bias of Roles

It may be possible to generalize about perceptual bias in marital roles in terms of product classes. The classes used were convenience goods, shopping goods, specialty goods, and preference goods; a scheme suggested by Holbrook and Howard (1977) as cited by Frankel (undated). The standard definitions were utilized for the first three goods classifications, with preference goods defined as "those for which there is a strong brand preference, but low shopping effort is made (Frankel, p. 18)." It was recognized, of course, that the classification of any product is open to question since it would be a result of perceptions about how the consumer purchasing agents in question shop for those goods.

The convenience goods appeared to be beef roast and, somewhat surprisingly perhaps, adhesive bandages. These products were characterized by modesty bias at all phases. The preference goods appeared to be tooth paste, lawnmower, children's shoes, and replacement tires for the primary family car. Preference goods appear to be characterized by vanity bias, either in all 3 phases or a number of combinations of 2 phases, but not modesty biased in the recognition or final decision phase. The shopping goods appeared to be sofa for living room or family room, replacement of additional pots and pans for the kitchen, primary family car, insurance on husband's life, homeowner's or renter's insurance, movies, and family vacation. All these items were characterized by a modesty bias in the decision phase. Children's toys for birthdays and holidays appeared to be specialty goods with no systematic bias in the first 2 phases and a vanity bias in the final decision phase. Not all items were classifiable in this manner. Household cleaning products, neck tie for the husband, slacks for the wife, and washing machine were not characterized by systematic bias at any stage. These items could well have been inadequately specified as it was expected that individual household cleaning products would be preference goods while the remaining 3 would be shopping or specialty goods.

Among the traditional couples, children's toys for birthdays and holidays appeared to be a preference rather than a specialty item, while washing machine appeared to be a shopping good, and there was no clear pattern for replacement or additional pots and pans for the kitchen.

Conclusions and Implications

As in the Davis and Rigaux (1974) study, these results are based on rather intensive analysis of a small data base. These results are useful, however, in that a non-convenience sample was utilized permitting generalization to a specifiable population.

The general movement toward role specialization in search for information about alternatives found by Davis and Rigaux was not supported, as such, in this study. A major reason was due to the fact that problem recognition specialization was more prominent in this study than was true previously. Specialization at the problem recognition phase, in turn, was likely to be a result of the specific nature of the decision items rather than a difference in sample populations or methods.

Role specialization obviously does exist in household decision processes and the implications discussed by Davis and Rigaux (pp. 59, 60) have clearly not been mitigated by these results. These results strongly support, however, clearly specifying decision items in research. In fact, item attributes (e.g., color of

car) should be specified, although this information may be impossible to obtain for all decision process phases. Previous research (e.g., Davis, 1970; Hempel, 1972) has specified item attribute specialization, but not across decision process phases.

Davis and Rigaux held that one implication of high non-consensus in role perceptions was a need to word questions more specifically (p. 60) as was done in the present study. Interestingly enough, however, high item specificity appeared to have little effect on total consensus, 68% for the items common to both studies in the present study at the decision phase compared to 66% in the Davis and Rigaux study. Evidently communicators must take note of the degree and direction of nonconsensus rather than hoping to eliminate it through question wording. Nonetheless, the position taken throughout this analysis has been in favor of high specificity of items.

Decision makers should want to be knowledgeable about whether or not there is a vanity bias in perception of marital roles during the household decision process. It stands to reason that individual spouses with a vanity bias would get involved in the decision process regardless of role specialization, possibly in the phase not covered in these studies: evaluation of the final decision. These cases would thus require communication to both spouses.

Finally, while some differences were apparent between traditional couples and all couples in terms of role specialization at different phases of the decision process and level of role consensus, the number of these differences, while large enough to be significant, was also small enough to be, at least potentially, a result of random error. Thus, it would be difficult to make any generalizations with confidence. Nonetheless, the potential for differences appears established enough to be further studied in future research.

Appendix

Comparison of Economic Decision Items Utilized
In Present Study And Davis and Rigaux²

Key Number	Present Study	Davis and Rigaux
1	Sofa for living room or family room	Living room furniture
2	Drapes for living room	Other furnishings (rugs, drapes)
3	Replacement or additional pots and pans for the kitchen	Kitchenware
4	Washing machine	Household appliances excluding TV
5	Lawnmower	Garden tools
6	TV for living or family room	TV, Hi-Fi, tape recorder
7	Family car (primary)	Car
8	Beef roast	Food and nonalcoholic beverages
9	Neck tie for husband	Husband's clothes

Key Number	Present Study	Davis and Rigaux
10	Slacks for the wife	Wife's clothes
11	Children's shoes	Child(ren)'s clothes
12	Household cleaning products	Household cleaning products
13	Children's toys for birthdays and holidays	Child(ren)'s toys for birthdays and holidays
14	Tooth paste	Cosmetics and toiletries
15	Insurance on the husband's life	Life insurance
16	Homeowner's or renter's insurance	Other insurance
17	Adhesive bandages	Nonprescription drugs and first-aid items
18	Movies	Concerts, movies, theater
19	Family vacation	Family vacation
20	Replacement tires for the family car (primary)	No comparable item

AN EXAMINATION OF
INNOVATIVE COMMUNICATORS, OPINION LEADERS AND INNOVATORS
FOR MEN'S FASHION APPAREL

Elizabeth C. Hirschman, University of Pittsburgh
William O. Adcock, Georgia State University

Abstract

Recent theoretical and empirical papers have suggested a need for more meaningful and useful adopter categories. The findings in this study provide support for the construct validity and pragmatic utility of an adopter category composed of individuals who are above average in both innovativeness and opinion leadership. A comparison of survey results from two socioeconomically diverse markets points to the potential danger of generalizing from research results obtained within a limited social environment.

Introduction

Diffusion of innovations is one of the most widely researched topics in the behavioral sciences. Rogers and Shoemaker (1971) compiled a bibliography of over 1,000 diffusion research studies which had been conducted in thirteen separate disciplines. Major diffusion research traditions exist in seven of these disciplines: anthropology, early sociology, rural sociology, education, medical sociology, communication, and marketing.

Despite the massive, combined research effort represented by the existing body of diffusion research, many observers are critical of the methodology, assumptions, and concepts associated with such studies, and many doubt that results are meaningful or useful. Rogers (1976) states that most diffusion research is lacking in originality and that contributions to more effective social programs have been few.

Taylor (1977) discusses the frustration felt by many consumer researchers that no meaningful set of relationships has yet been identified to characterize early triers of new products. Kotler and Zaltman (1976) note that research into early adopter characteristics has produced many contradictory results, and that few studies have proven useful in marketing planning. They also state that little information has been generated with regard to the sociological and psychological variables influencing the adoption decision.

Recently, Rogers (1976) has commented on the need for improved research designs, including network analysis and longitudinal research studies. He also stresses that scholars have accepted the diffusion paradigm so completely that they may be unable to recognize or to overcome possible conceptual biases.

The authors of this study concur with these scholars that diffusion research results have often been confusing and of limited usefulness, particularly in the marketing discipline. Improved research designs may lead to more meaningful results in the future. However, it appears that some of the basic concepts that have been widely accepted in diffusion research also need to be reexamined as a prelude to further analysis. This paper is intended to enlarge upon several recent theoretical and empirical efforts in determining relevant adopter categories.

Categories in Diffusion Theory

Two categorizations are generally accepted as valid in diffusion theory. First, adoption patterns are assumed to follow a normal, bell-shaped distribution. Within this distribution five basic adopter categories are posited to exist: innovators (first 2.5 percent of population to adopt), early adopters (12.5 percent), early majority (34 percent), late majority (34 percent) and laggards (final 16 percent). The proportion of the population to be allocated to each adopter category reflects standard deviations within the normal distribution.

A number of marketing scholars have questioned the preciseness of this set of assumptions within a marketing context. Peterson (1973) states that a distribution in a marketing situation would probably be highly skewed, not normally distributed, because of the effects of increased numbers of producers and increased promotion as a new product began to win consumer acceptance. Peterson also proposes the use of algorithms to identify categories in specific product classes in such a way as to minimize variance within groups. The use of such an algorithm could result in more or less than five categories in any given situation. Other marketing researchers have questioned the percentage distributions within categories. Robertson (1971) favors a ten percent allocation to the innovator category in marketing studies, while King (1963) classified 35 percent of his sample as "early buyers."

The second major categorization paradigm used in adoption theory concerns personal influence. A basic assumption of diffusion theory is that some individuals within a given social structure are influential in persuading others to adopt products. Attempts to identify the characteristics of these opinion leaders, however, have produced contradictory and inconclusive results (Zaltman and Stiff, 1973).

Overlap Between Innovativeness and Opinion Leadership

The overlap between these two sets of diffusion categories, innovativeness and opinion leadership, would intuitively appear to hold a great deal of potential for increasing understanding of the diffusion process. Yet surprisingly little empirical research has been specifically addressed to this issue. Robertson (1971) tabulated results from twenty-one marketing studies which had been conducted between 1954 and 1969, and reported that thirteen attempted to study relationships between innovativeness and opinion leadership. He determined that ten found a positive relationship, while three found no relationship. In no study was a negative relationship found.

Several recent studies of women's fashion adoption have reported disappointing results relative to correlation between innovativeness and opinion leadership. King (1963) reported that early and late buyers were not significantly different with respect to influence. Studies by Robertson and Myers (1969) and by Myers and Robertson (1972) found overlap between innovativeness and opinion leadership; but in each instance the over-

lap was described as moderate or small.

In a study of male fashion adoption Darden and Reynolds (1974) identified six adopter groups, as opposed to the five groups in classic diffusion theory. Discriminant analysis showed that opinion leadership was strongly associated with the most innovative adopter groups.

The authors were able to locate only two studies within the marketing discipline which were designed specifically to look at individuals who were above average in both innovativeness and opinion leadership. The first study was conducted by Summers (1971). He examined the overlap between innovativeness and opinion leadership found in generalized change agents for women's fashion apparel. He concluded that the relationship was not strong, although it was statistically significant. Baumgarten (1975) coined the term for these generalized change agents in a study he conducted on adoption processes for men's fashion apparel. Calling this adopter category, innovative communicators, Baumgarten concluded that they were differentiable from the general population and developed a psychographic profile of their characteristics.

The following year Midgley (1976) made an important theoretical contribution to the diffusion theory paradigm by formulating a three dimensional set of adopter categories. The three dimensions he proposes are: trial, acceptance/rejection and opinion leadership. His model incorporates four categories. Active adopters are individuals who have tried an innovation and will provide favorable information on it. Active rejectors are individuals who have tried an innovation, found it unsatisfactory, and will provide unfavorable information on it. Passives are those who have tried the innovation, but who will not provide information on it. The fourth group is termed potential adopters and includes those who have not yet tried the innovation.

Kotler and Zaltman (1976) added further sophistication to the issue of innovator-opinion leader overlap, when they formulated a theory of the best prospect. Noting that early adopters may not necessarily be the best target market segment for a new product, they provide a cost-benefit equation for determining the value of a prospect. The four factors that enter into this equation include (1) propensity to innovate, (2) amount the prospect is likely to purchase, (3) additional purchases that the prospect is likely to stimulate through interpersonal influence, and (4) the cost of communicating with the prospect.

The Kotler-Zaltman model does not require that the "best prospect" be high in both innovativeness and opinion leadership. Instead, the key is the nature of the interaction between the two characteristics, with purchase probabilities and communication costs also important to the economics of a target market strategy.

In summary, some empirical research has been conducted on the overlap between innovativeness and opinion leadership. Generally, these studies have identified relationships possessing statistical significance, but lacking in pragmatic utility. The theoretical work by Midgley and Kotler and Zaltman and the empirical work of Summers and Baumgarten, however, appear to provide a basis for defining a new, and pragmatically valuable, early adopter category - the innovative communicator.

Purpose

The study reported here attempts to enlarge upon the earlier findings of Baumgarten (1975), with regard to male fashion "innovative communicators." These findings are certainly indicative of the possible existence and

potential utility of the innovative communicator construct. However, some methodological limitations of Baumgarten's study prohibit the development of a generalized theory concerning the role of innovative communicators in the fashion apparel adoption process. Specifically, his data were limited to a sample of 389 unmarried male undergraduates at Purdue University. Thus, there is the potential for a restriction of range for the findings. Further, because data were gathered in only one setting, there can be no assurance as to their external validity. The necessity of assessing the external validity of findings from a study of this type is of central importance to the development of consumer behavior theory. As Shocker and Zaltman (1976) state:

In the marketing literature on consumer research, one still finds relatively little explicit concern with the internal and external validity attending the research itself...Issues of validation are very central to the development of theory and to the progression of research from mere ad hoc responses to specific inquiries toward the cohesive bodies of knowledge characteristic of disciplines.

A further limitation of Baumgarten's study was its failure to examine other possible adopter categories; all respondents who were not categorized as innovative communicators were combined into an "others" category. The study reported here uses adoption/influence patterns to specify four adopter categories. Innovative communicators, as defined in this study and in the Baumgarten study, are individuals who rank high on both innovativeness and opinion leadership. A second group in this study, opinion leaders, includes respondents who score high on opinion leadership, but not on innovativeness. A third group, innovators includes individuals who score high on innovativeness, but not on opinion leadership. Finally, the general population includes those who do not score high on either construct.

The study reported here will also attempt to provide some preliminary examination of the four elements of the Kotler-Zaltman theory of the best prospect choice. In addition to measuring the interaction effect of overlapping innovativeness and opinion leadership, some data were gathered concerning media selection, store attribute evaluations and purchasing patterns.

Data Collection

Sampling Sites

Data for the research were gathered in two Southeastern cities during Spring, 1977. The cities and their respective sample sizes are given below:

Atlanta, Georgia	400
Augusta, Georgia	239
Total	639

The cities and sample sizes were specified by the retail firm sponsoring the research. In Table 1 are given a set of statistics comparing the two cities on a variety of attributes.

TABLE 1

	A Statistical Comparison of the Two Sample Cities	
	Atlanta	Augusta
Population	1,841,200	278,700
Average household income	\$15,162	\$12,201
Annual retail sales (000's)	\$4,791,964	\$752,957
1975-1980 pop. growth rates	10.1%	5.3%

SOURCE: 1976 Survey of Buying Power, Sales & Marketing Management Magazine.

Although the two cities are geographically adjacent, approximately 120 miles apart, they exhibit some large economic and demographic dissimilarities. The cities may be dichotomized using the statistics given in Table 1. At one end would be placed Atlanta, which is the larger, wealthier and more rapidly growing of the two cities. At the other end is Augusta with the smaller population, lower income per household and the slower rate of growth. This diversity between the cities comprising the sample should help provide a rich ground for assessing the external validity of the findings from this research.

Sampling Procedure

To obtain the sample, a list of all telephone exchanges within each city's S.M.S.A. was compiled. By working closely with telephone company executives in each city, a recent (within the past two weeks) estimate was obtained of the number of telephone-equipped households within each exchange. The overall sample collected from each city was then apportioned according to the number of telephone households falling within a particular exchange.

A random digit dialing technique was used to gather the sample, which eliminated possible bias against new arrivals and unlisted numbers which can be caused by using the telephone directory. All interviewing was conducted from 6:00 PM to 9:30 PM weeknights to help insure an adequate representation of working persons. Trained interviewers employed by commercial field survey research firms were used to conduct the interviews. In Table 2 are given the dates of interviewing for each city, the response rates, and the percentage of questionnaires which were validated.

Criterion Operationalization

One of the problems inherent in past diffusion research is that innovativeness and opinion leadership have been operationalized inconsistently. Rogers (1976), Kotler and Zaltman (1976), and Zaltman and Stiff (1973), among others, have criticized the measurement techniques used in most studies. These authors have advocated the use of network analysis to more accurately measure the constructs under study. The authors of this paper agree that such research designs are most desirable. As a practical matter, however, the resources needed for such studies may be unavailable for many researchers. As in the case of the study reported here, more limited measurement and operational schemes will continue to be used, but researchers should attempt to select designs that offer reasonable hope of construct, as well as face, validity.

The study reported in this paper utilized sets of self-designating questions to measure both fashion innovativeness and opinion leadership. The two sets of questions, three for each construct, are listed in Table 3. Responses to the question set for each construct were summed to create a composite score.

TABLE 3

Measurement of Innovativeness and Opinion Leadership	
Fashion Innovativeness = Question A + Question B - Question C. Fashion Opinion Leadership = Question D + Question E + Question F.	
A. Are you willing to try new ideas about clothing fashions? How often?	4. Often 3. Sometimes 2. Seldom 1. Never 0. Don't Know
B. Do you try something new in the next season's fashions? How often?	4. Often 3. Sometimes 2. Seldom 1. Never 0. Don't Know
C. Are you usually among the last to try new clothing fashions? How often?	4. Often 3. Sometimes 2. Seldom 1. Never 0. Don't Know
D. How often do you influence the types of clothing fashions your friends buy?	4. Often 3. Sometimes 2. Seldom 1. Never 0. Don't Know
E. How often do others turn to you for advice on fashion and clothing?	4. Often 3. Sometimes 2. Seldom 1. Never 0. Don't Know
F. How many of your friends and neighbors regard you as a good source of advice on clothing fashions?	4. Almost everyone I know 3. More than half 2. Less than half 1. Almost no one 0. Don't Know

Male Fashion Innovative Communicators were operationally defined in this research as men who scored one standard deviation above the mean on both fashion innovativeness and fashion opinion leadership. These persons composed 6.8% of the sample (n = 16) in Augusta and 7.8% of the sample (n = 31) in Atlanta.

To describe the differentiating characteristics of the Male Fashion Innovative Communicator, consideration must be given to the groups against which it is appropriate to make comparisons. It was felt that for the purposes of assessing construct validity three relevant groups would be required. These three groups consisted of (1) Fashion Innovators - operationalized as persons scoring one standard deviation above the mean on fashion opinion leadership. (2) Fashion Opinion Leaders - operationalized as persons scoring one standard deviation above the mean on fashion opinion leadership but below one standard deviation above the mean on fashion innovativeness and (3) the General Population operationalized as persons scoring below one standard deviation above the mean on both fashion innovativeness and fashion opinion leadership.

The distributions obtained for the four groups are given in Table 4.

TABLE 4

	Construct Distributions			
	Atlanta		Augusta	
	n	%	n	%
Innovative Communicators	31	7.8	16	6.8
Innovators	30	7.5	19	8.1
Opinion Leaders	42	10.5	27	11.4
General Population	297	74.3	174	73.7

Findings

The variables used to compare male fashion innovative communicators with the three other groups of interest fell into five categories: (1) socioeconomic characteristics; (2) sociographic influences; (3) evaluations of retail store attributes; (4) media usage; and (5) store patronage.

The Atlanta sample received primary attention in the analysis reported here, rather than Augusta, because fashion interest was expected to be greater in the more cosmopolitan of the two cities. The analysis for each

category of variables involved three major steps:

1. First, the data were examined to identify differences between the general population and the three construct groups (male fashion innovative communicators, male fashion opinion leaders, and male fashion innovators).
2. Next, the data were further examined to determine if differences existed among the three construct groups. Identification of significant differences would provide some indication of construct validity for the innovative communicator adopter category.
3. Finally, results from the Atlanta sample were compared with those in Augusta to test their external validity.

In each instance, the Chi Square statistic was used to test the significance of differences among groups (cut off at .10 level).

Socioeconomic Characteristics

The variables examined included income, age, education, and length of residence in present city. Data reported in Table 5 shows that significant differences exist between the general population and the three construct groups only with respect to age. All three construct groups tend to include higher proportions of younger persons. This finding was also reflected in data from Augusta (Table 9). However, in neither Atlanta or Augusta were any significant differences found among the three construct groups with respect to age or any other socioeconomic variables.

Sociographic Influences

Variables relating to participation in social activities and to memberships in groups were expected to provide valuable insights into the life styles and information transfer characteristics of male fashion adopters.

Social Activities. As shown in Table 6, all three construct groups are significantly different from the general population with regard to participation in a diverse group of activities. The construct groups are more likely than the general population to include individuals who entertain at home, attend movies, and attend concerts. Similar results were reflected by data from the Augusta sample.

The data in Table 6 also suggest a systematic and consistent pattern of differences among innovative communicators and other two construct groups. Although statistically significant differences exist for only four of the eight activities (attending concerts, gardening, golfing, and camping), the innovative communicator group contains the smallest proportion of non-participants for each of the activities reported here. This is true even though other groups contain higher proportions of very active participants for some activities. Thus, it appears that innovative communicators participate in a wide range of social activities, although levels of commitment to some activities may not be high. The Augusta data, however, do not reflect similar patterns of differences among the construct groups.

This finding may be attributed to three possible factors: (1) the small size of the Augusta sample introduces sampling error; (2) the pattern of correlations found in the Atlanta data are spurious, or (3) the three constructs manifest themselves differently in various social settings. Atlanta is a large, wealthy and highly transient city relative to Augusta; it is possible that the great variance in social structure

between these two cities may act to influence the form and function of social phenomena such as innovative communication, innovativeness and opinion leadership. Further, the types of and functions served by social activities and group memberships in the two cities may also be radically different.

If this third factor is indeed the most accurate rationale for the differences observed in the data, a strong argument could be made for greater attention being given to the impact of sociological variables on the adoption process, rather than limiting focus only to psychological correlates.

Group Membership. Respondents were asked to name groups and organizations to which they belong. The results indicate that unexpected behavior exists on the part of opinion leaders. Members of this group are significantly less likely than members of the other two construct groups to belong to social and recreational groups or organizations. Apparently, these individuals exercise personal influence within a less formalized or structured environment than might have been anticipated. Similar membership patterns are suggested by the Augusta data, but the results do not achieve statistical significance. Again, the impact of the social environment upon the manifestation of the construct is strongly suggested by the data.

Store Attribute Evaluations

Respondents were asked if each of ten store attributes was of much concern, moderate concern, or little concern to them in deciding where to shop. A comparison of evaluations of store attributes among the three construct groups and the general population is felt to have potential value for the development of more effective retail marketing strategies. One of the central criticisms of past diffusion research is that it has failed to demonstrate pragmatic utility (Kotler and Zaltman, 1976).

One finding in this area may be of value to both retail strategists and to consumer behavior theorists. As shown in Table 7, significant differences (.10 level) exist among the three construct groups for only one attribute, the store's guarantee, exchange and adjustment policies. The groups that exhibit innovative tendencies (innovative communicators and innovators) express more concern for guarantee, exchange and adjustment policies than do opinion leaders. Similar results, also significant at the .10 level, were found in Augusta.

This finding may indicate that an emphasis on guarantees or adjustment policies represents a form of risk reduction behavior on the part of male fashion innovators and innovative communicators. This would appear quite logical from the point of view of the fashion innovative consumer. Purchasing an unusually styled garment or one constructed from out-of-the-ordinary materials (for example, feather, fur or sequins) may activate both the social and economic components of perceived risk. Thus, if the store has a well-thought-of policy for merchandise return, exchange or repair, this may be an especially valuable attribute to the innovator.

Media Usage

Data were gathered only about newspaper subscriptions and radio station listenership, since these two media are of most pragmatic relevance from a retailing standpoint.

Data about newspaper readership included overall sub-

scription rates and preferences for morning versus afternoon newspapers. In Atlanta, neither set of data identified differential tendencies toward newspaper readership among the four groups of interest in this study, (Table 8). However, in Augusta there were significant differences (.05) in subscription rates to the morning versus afternoon newspapers. These differences existed for both the three construct groups and the general population and among the three construct groups themselves. In Augusta the innovative communicators and opinion leaders were much more likely to subscribe to the afternoon newspaper than were innovators or the general population.

There are also significant and intuitively appealing differences among the four groups in terms of radio station preference. In both Atlanta and Augusta, the three construct groups display a distinct preference for stations featuring a progressive rock or jazz format, while the general population tends to be more partial to stations with classical or easy-listening type music. Differences among the four groups were significant at the .01 level in both Atlanta and Augusta. However, the Atlanta data do not reflect any significant differences among the three construct groups; while the Augusta data do.

Store Patronage

It was expected that the four groups in question would display differential patronage patterns for the purchase of apparel. Respondents were asked where their last purchase had been made for mens suits and mens sportswear. Their responses were categorized into specialty and traditional department stores, national chain department stores, and discount stores.

Contrary to expectations, no significant differences among groups were found. It is possible that the "last purchase" specification was inadequate as an operationalization for patronage and that "usual store" would have provided somewhat different results. It is also possible that the store categories were inappropriate. In any event, survey data provide no basis for concluding that adopter groups prefer different types of stores.

Summary of Findings

The data discussed here identify significant patterns of differences at three levels of analysis: between the general population and construct groups; among construct groups; and between two socio-economically diverse markets.

Data show that Innovative Communicators, Opinion Leaders and Innovators tend to be younger than the general population, more likely to participate in several social activities, and prefer jazz/rock-oriented radio stations.

More importantly, significant differences were identified among the three construct groups. Innovative communicators are least likely to be non-participants in a wide range of activities. Opinion leaders are least likely to be members of social or recreational groups. Innovative communicators and innovators are more likely to express concern about guarantees and store adjustment policies than are opinion leaders. Findings of significant differences indicate that each group is unique and that the constructs possess more than face validity. It is also important to recognize that some findings in Atlanta were not replicated in Augusta. Differences in results may reflect the differences in the social structures and economic environments of the two cities. These differences suggest that it may be an error to attempt to generalize too widely from a single study

pertaining to a limited social environment. Unless results are tested for external validity, generalizations are probably not justified.

This study provides empirical support for the Kotler-Zaltman theory of the best prospect choice. Since male fashion innovative communicators are above average in both opinion leadership and innovativeness and also express differential patterns of media preference, it should be possible to develop communications strategies directed toward these potential best prospects. However, further research will be needed to determine if shopping patterns and purchase propensities differentiate this group from other consumers.

Implications

The study reported here is intended to be transitional. The diffusion paradigm clearly needs to be examined from fresh perspectives and reformulated in a way that will be more useful to scholars in various disciplines as well as to marketing practitioners. Any new formulation of diffusion theory should involve a redefinition of adopter categories.

Findings that two unique groups of individuals, innovative communicators and innovators, exhibit innovative behavior help to explain the failure of earlier research to identify meaningful correlates of such behavior. A single set of predictor variables would be unlikely to describe members of both groups. For the same reason, findings that two unique groups of individuals, innovative communicators and opinion leaders, exercise personal influence explain the inconsistent results of studies intended to identify correlates for opinion leadership.

Findings from this study also suggest that failure to take sociological factors into account and failure to test for external validity have caused much of the previous research into innovation and opinion leadership to be of limited usefulness.

This study is not intended to be a definitive statement as to the nature of the adopter categories which will eventually prove to be most useful. The value of the findings reported here may simply be to suggest reasons why other studies have produced few useful insights and to demonstrate that new categories can be specified. Additional research involving network analysis and longitudinal designs may be needed to go beyond the two-dimensional scheme illustrated here, but such efforts are desirable if diffusion theory is to be made more meaningful.

INDIVIDUAL TIME ORIENTATION AND CONSUMER LIFE STYLE

Robert B. Settle
Pamela L. Alreck
John W. Glasheen
San Diego State University

Abstract

F-A-S-T, a four-dimensional, trait-specific personality test was used to measure the time orientations of 599 adult subjects. These were compared to their responses to 406 Activity, Interest and Opinion items. The study reveals clearly discernible translations of individual time orientation into differing life style patterns.

Introduction

Of the wide variety of concepts and variables used by researchers to explain consumer behavior, personality factors have provided some of the most disappointing results. Yet despite the negative findings, we continue to pursue these illusive relationships because the concepts of personality have great intuitive appeal. Common observations of everyday life reveal persistent individual differences, earmarking specific personality types or traits, in both ourselves and in others. Judging from the literature on personality and buyer behavior, however, the role of personality in determining behavior in this area must be miniscule, indeed. Kassarian (1971) cites four possible causes for the failure of personality studies to explain variation in buyer behavior: (1) Few studies have been designed to test specific hypotheses obtained from a theoretical base, (2) we often expect the influence of personality variables to explain too large a portion of the variance in consumer behavior, (3) the instruments used are seldom designed to measure traits that could be expected to directly influence consumer decisions, and (4) the tests used are often standardized on special groups, rather than consumers in general. We agree.

This study has been designed to assess the role of one aspect of personality in influencing consumer behavior, while avoiding the pitfalls cited above. A point by point consideration, without extraneous detail, may clarify the intent of the project. First, the theoretical justification for the study arose from the belief that a holistic approach to the understanding of consumer behavior is ultimately more productive than a reductive-functional view (Markin, 1974, pp. 62-76). We were, then, more interested in discovering the relationship between a set of personality traits and consumer behavior patterns, rather than the selection of Brand X as opposed to Brand Y.

The typical general model of consumer behavior comprehends buyer influences that can be divided into three basic groups: Those relating to the various stimulus factors, those which affect the situation, setting or circumstances in which the behavior is performed, and those that fall under the rubric of personal factors. Among the latter, "personality" is but one of many very potent variables. Beyond this fact, personality, itself, can be divided into a myriad of traits and dimensions. Consequently, we sought traits that might be major influences, but were determined to be satisfied with broad patterns of relationships and relatively small proportions of explained variance.

The instruments used in the study were designed to measure traits that can very definitely be expected to

directly affect consumer decisions. Both of the instruments were designed by consumer psychologists, and focus directly on personality attributes and behavior characteristics directly relevant to purchase and consumption of goods and services. Lastly, the instrument used to measure personality traits was standardized and validated on large numbers of adult consumers, rather than groups such as patients, students, or convicts.

Time Orientation

The individual consumer is faced with a world that is often described in terms of three factors: time, space, and possessions. An extensive literature in the areas of economics and anthropology is devoted to the concepts of property, utility, and the artifacts of man. Geographers and psychologists in the areas of proxemics and kinesics treat human experience in and behavior toward space. The theoretical development and empirical research are less often focused on human existence, experience, and behavior in *time*. The lack of standard measure of time orientation may have inconvenienced, if not inhibited an abundant literature in this area. The requirement for such an instrument was satisfied by the construction of the F-A-S-T Time Orientation Test (Alreck, 1976). The test includes four dimensions of time orientation: *Focus*, *Activity*, *Structure*, and *Tenacity*. The name of the test is an acronym formed from the initials of each scale, and henceforth each will be identified by its initial letter.

Focus. We know from both personal observation of others and from psychological research (Seiden, 1969) that some people tend to direct their consciousness toward the past. They often recall previous experience and relive past occurrences. Others are immersed in the present moment, completely engaged in the here and the now. Still other people can be identified as projecting their thoughts and images to the future and living for what will be. There are also those who see human experience in terms of a span of time, considering the antecedents and consequences, over time, of any present phenomenon. The F scale of the time orientation test was designed to tap this tendency to recollect, to sense, to project, or to spread human consciousness across the time spectrum. It yields a continuous measure of the trait, rather than a typological assignment.

Activity. People differ widely in their perceptions of the supply of time. Some perceive time as passing very slowly, and in effect they have an "over supply" of time, relative to the activities they have available to fill it. At the other end of this spectrum are those who feel that time passes all too quickly, that there are not enough hours in the day. And of course, there are those between these extremes who feel that the supply of time is appropriate to the amount of activity in which they engage themselves. The A scale of the time orientation test measures the degree to which an individual is over- or under-active, relative to the fixed supply of time common to all of us.

Structure. Some people view time as a continuous, smooth, flowing substance; a never ending river flowing from past to present to future. They "take it as it comes," engaging in one activity after another without much regard for the particular time it is or the time it takes to complete a task. Others perceive time as a discrete commodity, neatly packaged in boxes called "noon hours, Wednesday, the 60's," or "the 17th century." Each of these discrete structures is then regarded as appropriate to some particular activity, experience, or phenomenon. Those between the extremes find planning, scheduling, and accounting for time to be acceptable when necessary, but also enjoy a certain amount of spontaneity and freedom from regulated periodicity. The S scale of the time orientation test identifies the location of an individual on this dimension of time experience.

Tenacity. There are those who can engage in an activity almost as though they regarded time as irrelevant so far as external rewards are concerned. These people are able to delay gratification for long periods of time, while pursuing some far-distant goal. Their mirror images are persons who demand rewards almost continuously as their efforts are exerted. Unwilling to wait for the outcomes of their endeavors, they shy away from those tasks or processes that require long delays between sacrifice and receipt of extrinsic reinforcement. Between the extremes are those who find it acceptable to delay gratification for a short period of time, but not for prolonged periods. The T scale provides an indication of each person's willingness to "hang in there" when there is a delay between exertion of effort and receipt of rewards.

Statistical characteristics of F-A-S-T. The test was originally standardized on 930 adult consumers and current norms are based on approximately 2,500 similar subjects. Reliability coefficients for the scales range in the 70's and 80's, while item redundancy and correlations with scale scores are well within acceptable ranges. The scales were validated against spouse observations of time-relevant behavior, job satisfaction with time-related characteristics, and several standardized psychological measures of relevant constructs (Hix, 1976). Focus was reported to be related to Jungian typology (Mann, Siegler and Osmond, 1968) but did not prove to be so when correlated with Myers-Briggs Type Indicator scores (Myers, 1962). Activity was significantly correlated with the time attitude scales of Calabresi and Cohen (1968) while structure was associated with other generalized control constructs (Budner, 1962; Moresko, Schontz and Marrow, 1954). Tenacity proved to be significantly related to the need for achievement measures of Hermans (1970) and Mehrabian (1968). Based on these characteristics of the test and on the constructs measured by the various scales, the test appeared to be an appropriate measure of consumer time orientation. The test had been standardized on consumers, and the traits might be hypothesized to influence consumer behavior.

Consumer Life Style

Before focusing on the relationship between time orientation and more specific aspects of consumer behavior, it seemed appropriate to first determine if time orientation traits influenced the more general patterns of consumer behavior. These patterns could be measured by a library of items relating to consumer Activities, Interests and Opinions (Plummer, 1971; Wells and Tigert, 1971; Plummer, 1974). The emphasis was not on identification of individual activities, interests and opinions that significantly relate to time orientation, but rather on identification of patterns of response that would point to a life style more typical of one type of

time orientation than another. Thus, we hypothesized that each of the four time orientation dimensions would be indicative of a particular life style pattern, as revealed by the activities, interests and opinions.

Methodology

The data to measure the relationships between time orientation and life style patterns were obtained in a field survey of 599 adult consumers in December of 1976. The sample was selected on a convenience basis, with quotas on the distributions of sex, age, and occupational group. As a result, 54 percent of the respondents were male, 64 percent were married, 63 percent were in white collar occupations, and 65 percent indicated they were in the middle class.

The self-administered questionnaire consisted of a cover letter explaining the nature of the project, the F-A-S-T Time Orientation Test, a section containing 406 activity, interest and opinion items, and a final set of questions to obtain the demographic status of the respondents. The questionnaire booklet was twenty pages in length, and was completely self-administered. The field worker contacted the potential respondent, explained the nature of the project, and solicited the person's cooperation. As an inducement to respond, the individual was offered a complete, six-page, computer-generated interpretation of his or her own time orientation. Field workers briefly displayed a copy of the print-out and assured the respondent that most people found it both interesting and informative. If the person decided to participate, he or she was provided with a booklet and given a few days to complete the task. The field worker called back and subsequently picked up the completed questionnaire. To avoid fatigue effects, respondents were encouraged to complete only one or two sections at a sitting, and to set the instrument aside if interrupted or tired.

Each respondent, was, of course, provided with the test interpretations, which proved to be a very potent inducement. The procedure also provided an opportunity for 100 percent validation of the field data collection, since every respondent was contacted a second time. A total of 668 questionnaires were given to potential respondents, with a completion rate of 94 percent. After elimination of those responses which were unacceptable, the final sample size was 599.

The 64 items of the time orientation test were scaled from one to five, with extremes labeled "Exactly like me" and "Not at all like me." After reflecting and con-gregating items, the scoring provided summated scores. Activity, interest and opinion items were scaled from one to six, with extremes labeled "Definitely agree" and "Definitely disagree," or were simply the number of times the individual had engaged in the activity. The relationships between time orientation and AIO items were measured by correlation analysis.

Results

The results of the study are depicted in Tables 1 through 4. Each table is devoted to a single scale of the F-A-S-T Time Orientation Test: *Focus*, *Activity*, *Structure*, or *Tenacity*, respectively. The first column of each table contains the number of AIO items that were significantly correlated with the time orientation test scale at the .01 level and were indicative of a particular aspect or dimension of life style, based on similarity of item content. These life style dimensions are listed in the body of the table in descending order, beginning with the ones that contained the greatest number of items with systematic associations with time orientation.

Focus

The summary of life style dimensions related to time focus is shown in Table 1. Of the total of 406 items, 81 were significantly correlated to the F scale. The AIO items were not highly correlated to the scale, since the largest coefficient was only .32; however, the number of items, together with the fact that the signs of the coefficients were consistently in the appropriate direction, indicates that there is a very clearly discernable relationship between consumer life style and individual time orientation.

Past oriented consumers tend to be the more cautious shoppers. They more often agreed with items such as: *I often worry that something I buy will turn out to be a mistake. I tend to do things pretty much the way my mother did. Grocery shopping for my family means sticking to a strict budget.* On the other hand, the future oriented consumer more often agreed that: *The new styles turn me on. I would like to own the most expensive things.* The past oriented consumer was also less secure, in general, tending more often to agree that: *I dread the future. Things are changing too fast. Modern life is anxiety ridden.* Some items relating to other dimensions were: *I work very hard most of the time.*

TABLE 1
TIME FOCUS AND CONSUMER LIFE STYLE

Items ^a	Past Orientation	Future Orientation
15	Cautious shopper	Consumption oriented
10	Insecure	Secure
9	Negative about work	Positive about work
8	Opinion follower	Opinion leader
6	Homebody	Cosmopolitan
5	Morally rigid	Morally flexible
5	Indifferent to cars	Car conscious
5	Conservative	Innovative
4	Financially pessimistic	Financially optimistic
4	Content	Ambitious
4	Detached	Involved
3	Cautious	Adventurous
3	Stationary	Mobile

^aNumber of AIO items correlated with Focus scale, P less than .01.

I would not work if I did not have to. Future oriented people tended more to agree to the first of these, and past oriented leaned toward the second. So, too, future oriented persons saw themselves as opinion leaders, were generally more cosmopolitan, flexible, and innovative than their past oriented counterparts. They were more ambitious, involved, adventurous, and mobile, while the typical past oriented person was more pessimistic about financial matters and more indifferent to cars, leaning more toward the home.

Activity

The consumer life style dimensions related to activity level are depicted in Table 2. Highly active consumers indicated their involvement on such items as: *I do more things socially than do most people. I am active in community projects.* Low activity people tended to agree: *The old ways are the best ways.* They also more often agreed: *When I retire, I want to sit and take it easy.* Highly active people, on the other hand, had more positive attitudes toward work: *I take pride in my job.* These people were also more family centered, they were

more confident shoppers, and they demonstrated a greater satisfaction with life in general. Low active respondents expressed conservative attitudes toward innovations, indicated more insecurity and uncertainty, and were more often the homebodies. It is also interesting to note that they were more often in agreement with maintenance of sex roles and more indifferent to appearances.

Correlation coefficients between AIO items and the A scale ranged to a high of -.33 for an opinion leadership item: *Nobody cares what I think.* Signs on coefficients were consistently in the predicted direction. In all, there were 89 items from the 406 AIO items that provided a significant correlation with the A scale. Of the four dimensions of time orientation, the activity scale scores were correlated with more items than any of the other three.

TABLE 2
ACTIVITY LEVEL AND CONSUMER LIFE STYLE

Items ^a	Low Activity	High Activity
11	Detached	Involved
10	Opinion follower	Opinion leader
10	Negative about work	Positive about work
10	Self centered	Family centered
9	Apprehensive shopper	Confident shopper
9	Dissatisfied with life	Satisfied with life
7	Conservative	Innovative
5	Insecure	Secure
5	Uncertain	Confident
5	Homebody	Cosmopolitan
5	Past oriented	Future oriented
5	Reluctant to volunteer	Willing to volunteer
4	Sex biased	Unbiased toward sexes
4	Indifferent to appearance	Appearance conscious

^aNumber of AIO items correlated with Activity scale, P less than .01.

Structure

The 10 dimensions of consumer life style defined by 58 AIO items significantly correlated with time structure are shown in Table 3. The dimension containing the largest number of items was related to shopping, with those who were time structured also tending to be careful shoppers and those low on structure leaning toward more casual shopping habits and attitudes. Examples of items positively correlated with structure are: *Before going shopping, I sit down and prepare a complete shopping list. I would not shop in a store that looked dirty, even if the prices were very low. When I get a price off coupon, I save it and use it if I can. I watch the advertisements for announcements of sales. I rely on facts, not emotions when I make decisions.* The AIO items with the highest correlation with the S scale, +.24, was: *My days seem to follow a definite routine, e.g., eating meals at a regular time, etc.* Those high on time structure also tended to agree that: *Visitors often comment on how nice our home or apartment looks. I keep my house very neat and clean.* On the other hand, those who tended not to structure time also agreed: *I don't spend very much time cleaning my house. I find cleaning my house an unpleasant task.*

On the whole, highly structured consumers also tended to be work oriented, principled, and risk averse. They also exhibited more propensity to be financially optimistic and car conscious, while those low on structure

TABLE 3
TIME STRUCTURE AND CONSUMER LIFE STYLE

Items ^a	Low Structure	High Structure
11	Casual shopper	Careful shopper
9	Deemphasis of house-keeping	Emphasis on house-keeping
7	Leisure oriented	Work oriented
5	Flexible	Principled
5	Risk indifferent	Risk aversion
5	Night oriented	Day oriented
5	Follower	Leader
4	Opinion follower	Opinion leader
4	Financially pessimistic	Financially optimistic
3	Car indifferent	Car conscious

^aNumber of AIO items correlated with Structure scale, P less than .01.

were more pessimistic about their financial condition and future and relatively indifferent to cars. Opinion leadership and leadership in general were more typical of highly structured people than those low on structure. Another interesting characteristic of low structure respondents was their preference for activity at night, rather than during the day. Highly structured persons also preferred, to a greater degree, to get up and get going in the morning. They were more often "day" people.

Tenacity

The T scale of the time orientation test provided the weakest systematic relationship to consumer life style. Only 33 of the 406 AIO items were significantly correlated with tenacity scores, and these were grouped into six life style dimensions. Of the six, shopping activities, interests and opinions were the most numerous. The more tenacious the individual, the more likely the person would agree: *I do most of my grocery shopping in one store. When I start to shop for furniture, I usually know exactly what I want. I always buy quality brands.* Those who were less tenacious also less often: *Shopped for household articles. Went shopping for clothes. Returned an unsatisfactory product.*

Other life style differences between low and high tenacious consumers related to housekeeping and attitudes toward the past. Tenacious people also tended to express more compulsive tendencies toward housekeeping: *I think dirty dishes should be washed promptly after each meal. I can usually work for long periods of time around the house without tiring.* Those low on tenacity more often tended to agree: *I dread the future. I dread the unknown. Things are changing too fast.* The tenacious consumer is more assertive: *I am more independent than most people. They agreed less often that: I have never been really outstanding at anything.*

TABLE 4
TENACITY LEVEL AND CONSUMER LIFE STYLE

Items ^a	Low Tenacity	High Tenacity
12	Casual shopper	Structured shopper
6	Unassertive	Assertive
5	Flexible	Conservative
4	Past oriented	Future oriented
3	Self centered	Family centered
3	Casual housekeeper	Compulsive housekeeper

^aNumber of AIO items correlated with Tenacity scale, P less than .01.

Highly tenacious individuals also exhibited more conservatism in: *I am in favor of very strict enforcement of all laws.* More typical of low tenacity was the item: *I like to think I am a bit of a swinger.* The more tenacious, the more family oriented the respondent: *My major hobby is my family.* Even though this dimension of time orientation was less related to the activities, interests and opinions of consumers, the differences in life style are still evident.

Conclusions

The results of the study indicate that individual time orientation is translated into measurable differences in consumer life style. In summary, the following relationships were manifest:

1. The more the individual tends to habitually direct his or her consciousness toward the future, the more consumption oriented the person will be. Such people are also more secure and positive about their work. They tend to be opinion leaders with more cosmopolitan interests. Those who direct their thoughts and fantasies toward the past also tend to be more rigid in their moral outlook, more conservative, cautious, and detached. They exhibit less ambition. They are less mobile than their future oriented counterparts and they are also less car conscious than the future oriented consumer.
2. The highly active person, who perceives time to be in short supply, also tends to be more involved, family centered, and positive about the future. This is the more confident person and that confidence is also manifested in the marketplace. The active person tends to be more secure and satisfied with life than the less active, who tend to be homebodies, less satisfied with their work, and reluctant to volunteer. These less active folks are also more conservative in their views, tend to trust traditional sex roles, and to be more indifferent about their appearance.
3. The greater the consumer's propensity to see time as a continuous, flowing substance, the more likely the person is to display casual shopping patterns, to be leisure oriented, flexible, and indifferent to risk. On the other hand, those who tend to structure time into discrete segments also seem to emphasize house-keeping, regard day for working and night for sleeping, and be more car conscious. Structured consumers value both opinion leadership and leadership in general to a greater degree than those who are less structured.
4. The tenacious individual is more of a structured shopper, assertive and future oriented. The person with less tenacity is also the one who is more likely to be a casual shopper and less compulsive about house-keeping. Tenacity is directly related to family-centered activity and interests and inversely related to flexibility in attitudes and habits.

Obviously, the summary presented above provides more of a caricature of life styles for various time orientations than classifications or typologies. The relationships discovered represent only persistent tendencies and there is a great deal of "overlap" in the life styles of individuals on opposing extremes of any of the time orientation dimensions or scales.

Aside from the more specific findings cited above, the results taken as a whole indicate that "personality" can be related to variations in consumption patterns. This study used a trait-specific personality test that was designed to measure the characteristics of normally functioning people. The test was standardized on the general public, and the "dependent" variables consisted of molar behavior patterns, rather than molecular units,

such as the selection of one brand over another. As expected, the proportions of variance explained were not large in magnitude; however, the associations between time orientation, on the one hand, and life style, on the other, were unmistakably visible. An optimistic interpretation of these results is that personality does influence the behavior of consumers in measurable ways. Further investigations of the role of personality may yet prove fruitful.

BELIEF SYSTEMS AND THE DIFFERENTIAL ROLE OF THE SELF-CONCEPT

George E. Belch (student), University of California, Los Angeles

Abstract

This study investigates the relationship between belief systems and the differential role of self and ideal self-image in determining purchase intention. The results indicate that the level of conceptual functioning at which an individual operates appears to influence the differential role of the self-concept on purchase intentions. The findings also show that the purchase intention of individuals who are characterized by a high need for cognitive consistency are more influenced by product ownership than those individuals who are more tolerant of cognitive dissonance and inconsistency.

Introduction

Relationships of product image and self-image have been given much attention in consumer research. The idea that consumers prefer products or brands that are congruent with their self-concept has been investigated by many researchers including Birdwell (1968), Grubb and Hupp (1968), Dolich (1969), Ross (1971), and Landon (1974).¹ The basic assumption of these studies has been that the self-concept is related to the manner in which consumers perceive and purchase products. To the extent that the self-concept is of importance to the individual, he will direct his behavior towards maintenance and enhancement of his self-concept.

Evidence supporting a congruence relationship between self-image and purchase behavior has been reported by Birdwell (1968) and Grubb and Hupp (1968). These studies dealt with the consumers matching of product-image with self-image. However, the consumer might be attempting to express and "ideal" self-image through his purchase of a particular product or brand rather than his "actual" self-image. Hamm and Cundiff (1969) found that individuals with a large discrepancy between actual and ideal self-image describe themselves differently in terms of products and have different product perceptions from those individuals with a small discrepancy between the two.

Several studies have examined the congruence between self and ideal self-concept and products or brands. Dolich (1969) found that there was a greater congruence between self-concept and brand most preferred than brand least preferred. He also found that both self- and ideal self-image were almost equally congruent with most preferred brand.

Ross (1971) also investigated the role of self-image and ideal self-image in consumer purchase behavior. He hypothesized that individuals would prefer products which they perceived to be similar to their self-concept. Ross also predicted that in some cases self-image would best describe brand preference. He hypothesized that ideal self-image would be more related to brand preference when the product was more, rather than less, conspicuous to others, and conversely, self-image would be more closely related to brand preference for less conspicuous products.

¹Self-concept, as used in this article, refers to both the "self-image" and "ideal self-image" of the consumer. The latter two terms are viewed as the two components of the self-concept and will generally be given specific reference.

The results of his study strongly supported the prediction concerning subject's preference for brands which were similar to their self-concept. However, little support was found for the predictions regarding the role of self- versus ideal self-image and brand preference. Ross concluded that these results were supportive of a simple congruity relationship between self-concept and brand preference.

Landon (1974) examined the differential role of the self- and ideal self-image and purchase intentions. In this study he was interested in consumer tendencies to match product image with self-image and/or ideal self-image. Landon hypothesized that some individuals would show a dominant influence of self-image/purchase intention correlation over all products, or an actualizing tendency, while some individuals would show a dominant influence of ideal self-image, a perfection tendency. The actualization model views the individual as striving to achieve harmony between his environment and his self-concept by coming to know and accept his self-concept, while the perfection model states that the individual is constantly trying to improve on his self-concept, i.e., achieve his ideal self-concept (Landon, 1974).

The results of Landon's investigation showed that factors related to products and to the individual are important determinants of the relative impact of self-image and ideal self-image on purchase intentions. Over all subjects, purchase intention for some products tends to be more correlated with ideal self-image while for some products purchase intention tends to be more correlated with self-image. Over all products, some subjects were characterized by a higher self-image/purchase intention correlation (actualizers) while some tended to be characterized by a higher ideal self-image/purchase intention correlation (perfectionists). However, neither the actualization nor the perfection hypothesis explained all of the data and Landon concluded that further research is needed to focus on conditions which might explain when each model is likely to be operative.

These studies give some indication that the self-concept is related to product perception. However, it is evident that there is still a great deal of uncertainty concerning the relative roles of the self- and ideal self-image. The findings thus far indicate that self- and ideal self-image are related and may be equally congruent with brand preference, or in some cases brand preference may be more related to one than the other.

The questions of why either self-image or ideal self-image is more related to purchase behavior and why there is a high correlation between the two self-concepts are still unanswered. One possible explanation for the relationship between self-concept and purchase behavior, as well as the degree of real-ideal self-discrepancy, lies in the level of conceptual functioning at which an individual operates. Harvey, Hunt, and Schroder (1961) have developed four belief systems, each representing a different level of conceptual functioning along a concreteness-abstractness dimension. Given the varying characteristics of these four belief systems, each group might behave differently in respect to using either their self-image or ideal self-image as a guide to their purchase behavior for certain products. The purpose of this paper is to examine the possible relationships between belief systems and the differential role of the self-concept in consumer behavior. First, however, it is necessary to examine the general nature

and function of belief systems and how they serve as different systems of motivation.

Belief Systems

A belief system represents a set of predispositions within an individual to perceive, construe, and interpret stimuli or events in a consistent manner. Each individual has certain central or core concepts which guide him in his efforts at making his world consistent. Individuals have conceptual systems which are ways of construing or dimensionalizing relevant aspects of one's world. These systems are characterized by some form of structure or relation among the various parts of the system.

Individuals are believed to develop conceptually through stages, from the undifferentiated and concrete to the more integrated and abstract. The more concrete end of the dimension represents a state of minimal differentiation while abstractness is represented by high differentiation and integration. Individuals will vary according to the degree of differentiation and relativism they attain and will tend to structure their environment according to their own particular conceptual belief system. The variation in differentiation and relativism determines the openness and closedness of the system, its receptivity to deviant elements and its capacity to admit impingements from the outside. Greater abstractness can be viewed as greater openness and greater tolerance of the different and novel (Harvey, 1966).

Harvey, Hunt and Schroder (1961) presented extensive theoretical and empirical bases from which four basic levels of concreteness-abstractness were deduced. The four basic levels were treated as different conceptual systems, each representing a different level of functioning between the hypothetical end points of greater concreteness and abstractness. A brief review of the four belief systems is given before turning to the relationship of conceptual systems to self-concept.

General Characteristics of the Four Systems

System 1. System 1 functioning represents the most concrete mode of dimensionalizing and construing the world. There is a simple cognitive structure with regard to domains of high involvement and this structure is fairly undifferentiated and poorly integrated. Representatives of System 1 show a greater tendency towards extreme and polarized judgments. This system is assumed to have evolved from situations in which individuals have been restricted in the exploration of their environment.

System 1 representatives tend to manifest such characteristics as high absolutism and closedness of beliefs, high evaluativeness, strong adherence to rules, high ethnocentrism, dogmatism and authoritarianism (Harvey, 1966). They also have a tendency to hold beliefs in accordance with clear cut definitions. Representatives of this system have a low tolerance for ambiguity and are negatively aroused by cognitive inconsistencies. This level of functioning is disposed towards system maintenance by excluding potentially conflicting stimuli from the system.

System 2. System 2 functioning is somewhat more differentiated and abstract than System 1. This level of functioning is characterized by negativism and an anti-rule, anti-authority orientation. Members of System 2 tend to be low in self-esteem and high in alienation and cynicism. This system is assumed to result from experiences with an authority who acts omnisciently and is capricious in the control of rewards and punishment. The arbitrary and unpredictable manner in which these sanctions are administered renders the individual unsure of whether courses of action will be reinforced or punished. This results in higher differentiation than System 1,

but also produces a feeling of uncertainty, distrust of authority, and rejection of social norms and guidelines. Representatives of System 2, like those of System 1, have a high need for structure and their tolerance for ambiguity is low. They are also high in dogmatism and absolutism.

System 3. System 3 functioning represents the next to highest level of abstractness treated by Harvey et. al. This system is assumed to result from an environment of over-protection. One or both of the parents act as a buffer between the developing child and his environment, thus preventing him from exploration of his physical and social world. System 3 individuals are fairly proficient in affecting desired outcomes in their environment by having others do things for them.

System 3 individuals have a great need for interaction with others and are concerned with establishing friendships, intragroup consensus, and developing dependency relations in order to avoid the feeling of helplessness and social isolation that would result from their being on their own. They need constant feedback from meaningful people in their environment in order to guide their behavior and attain the acceptance they need. System 3 representatives also develop more positive ties to prevailing social norms than representatives of the other three systems.

System 4. System 4 individuals represent the most abstract and open-minded of the four belief systems. This system is viewed as evolving from an environment in which the child is encouraged to explore his physical and social worlds and to establish and rely on values derived from his own experiences and thought. Members of this system are characterized by a high task orientation, risk taking, creativity, and relativism. They are more tolerant of ambiguity and cognitive inconsistency or conflict and are more flexible and contextual in thought and action.

System 4 individuals have a highly differentiated and integrated cognitive structure. Their set of internal standards are independent of external criteria, in some cases coinciding with social definitions, and in others not.

Belief Systems and Self-Concept

An individual's belief system will have an effect on his perceptions, cognitions, and actions and will affect his psychological processing and behavior. It is likely that the acts of individuals involved in some type of decision process will be affected by their system of beliefs and concepts. Thus, individuals of each system should manifest variations relative to their perceptions, beliefs, and actions.

Considering the varying characteristics of each system, there should be differences in the manner in which self-concept operates for each level of conceptual functioning. Specifically, this investigation is concerned with the differential role of the self-concept (i.e., self- and ideal self-image) in determining purchase intention for the four systems.

The relative importance of self- and ideal self-image to purchase intention and the discrepancy between the two components of self-concept may in part be due to the level of conceptual functioning of the individuals. For example, members of the first two systems are characterized by concrete functioning. They have a difficult time acting "as if" and role playing. These individuals might fail to see any real discrepancy between how they are (self-image) and how they would like to be (ideal self-image). Moreover, any discrepancy between the two self-concepts might tend to create a state of cognitive inconsistency for System 1 and 2 individuals. Thus,

people in these systems would have a small discrepancy between self- and ideal self-image. Members of Systems 3 and 4 should also show congruence between the two self-concepts. However, the discrepancy between self- and ideal self-image for these groups should be larger than for the first two systems.

The purchase intentions of System 3 individuals should be strongly influenced by their ideal self-image. Members of this system have a strong need for affiliation and friendship and will be constantly striving for the attainment of an ideal self-image that will enhance their position among their peers. Members of this system are concerned with social group consensus and peer group influences and may see a certain product and its attributes as a manifestation of the image they hope to project.

System 4 representatives represent the most abstract functioning of the four belief systems. The developing environment of these persons, having been free and open, has offered them an opportunity to explore and possibly discover their self-concept. This group may be more cognizant of their self-image and would no longer feel a need to seek an ideal self-image. Considering the ability of System 4 individuals to be contextual in their thinking, they may be more capable of relating the attributes and image offered by a product to their self-image.

Of primary interest in this study are the relationships between self-image and ideal self-image for the four systems and the role of each in determining purchase intentions for each group. The following research hypotheses were formulated based on the different characteristics of the four conceptual systems.

- H₁: The discrepancy between self- and ideal self-image will be smaller for Systems 1 and 2 than Systems 3 and 4.
- H₂: System 3 representatives will show the greatest influence of ideal self-image on purchase intentions of the four belief systems.
- H₃: System 4 representatives will show the greatest influence of self-image on purchase intentions of the four belief systems.

Also of interest in this study is the manner in which product ownership will affect the four systems. Belch and Landon (1977) found that product ownership affects the self-concept ratings for a product, increasing the likelihood of a product being rated as congruent with both self- and ideal self-image. If a true assessment of the role of self-concept in determining purchase intention is to be made, it is necessary to account for the effect of product ownership.

Considering the variations in the systems, particularly with respect to the need to maintain cognitive consistency, they might be affected differently by product ownership. Previous ownership of a product might influence the self-concept scores for that product or affect the purchase intentions of the individual for that product. As noted by Evans (1968) congruity between ownership and purchase intentions might result from a post-purchase process such as dissonance reduction. Individuals who are less tolerant of cognitive inconsistencies, such as members of System 1 and 2, may be influenced more by product ownership than those who can handle the cognitive conflict. The following hypothesis was formulated to test the effect of product ownership across the four systems:

- H₄: Product ownership will have a greater

influence on purchase intentions for Systems 1 and 2 than for the other two systems.

Method

Measurement of Belief Systems

The instrument used in this study has been developed by Harvey et. al. specifically as a measure of belief systems. The "This I Believe Test" (TIB) is a semi-projective sentence completion test. The TIB requests the individual to indicate his beliefs about a number of socially and personally significant concept referents by completing in two or three sentences the phrase, "This I Believe About _____", the blank being replaced by such referents as religion, friendship, people, or the American way of life among others.

By evaluating subject's responses with regard to several dimensions, including structure and content, subjects can be classified into one of the four belief systems discussed earlier or into an admixture of two or more systems. Test-retest reliabilities for the TIB within one week and after six months have been in the .80's while the interjudge reliability for trained judges in classifying subjects into one of the four systems has been .90 or greater (Harvey, 1966). For this study, subject's responses on the TIB were read and scored by professional readers in the department of Psychology at the University of Colorado. Subjects were classified as being representative of one of the four systems or as admixtures. Only those subjects whose responses classified them as being representative of a pure system were used in this study.

Measurement of Product Perception and Purchase Intentions

This study measured product perception relative to self-image and ideal self-image using a product anchored self-concept measure. This measure yields a congruence relationship between self-image and product-image. Subjects are asked to rate each product on a nine point scale ranging from "very much unlike me" to "very much like me". Ideal self-image for each product was then measured on a scale ranging from "very much unlike I want to be" to very much like I want to be". A similar measure was used by Landon (1971, 1974) for measurement of product perception relative to the self-concept.

Purchase intentions for each product were measured using a five point scale. The first four points on the scale divided a reasonable time range into four intervals. The time dimension for each product varied according to the type of product. The fifth scale point was used to indicate an intention never to buy the product. Product ownership was determined by having the subjects indicate which of the products they owned at the time of the study.

Subjects and Procedure

Subjects for the study were male students enrolled in undergraduate marketing courses at the University of Colorado. The TIB and questionnaire were administered during the regular class periods of each course. After everyone completed the TIB, the questionnaire was administered. Subjects were given twenty minutes to complete the questionnaire. When everyone was finished, the TIBs and questionnaires were collected and the class was given an explanation of the study.

The twelve products used in this study included coffee, after-shave lotion, adult games, imported wine, snow skis, mouthwash, country club membership, sun tan lotion, beer, TV dinners, and deodorant. These products were chosen

from a larger list of products used by Landon (1971). Only those products which had a test-retest correlation of .60 or greater on all three measures were used in this study. Two forms of the questionnaire were given, the first presenting the products in a randomized order, and the second a reverse of the original set.

Four questionnaires were eliminated due to homogeneity of responses by the subjects over all items in the questionnaire. After eliminating these subjects and the 36 admixtures, 124 subjects remained in the sample. The number of subjects in each system was as follows:

System 1 = 53, System 2 = 29, System 3 = 18,
and System 4 = 24.

Results

The primary interest in this study is the variation in the differential role of the self-concept among the four systems. Therefore, the analyses were designed to focus on the individuals comprising each system. The approach taken in some studies (e.g. Ross, 1970) has been to use the averaged scores of the sample over each product. This method is not as useful for revealing group differences since these variations may be confounded or even lost in the aggregation process. The analyses for this investigation were performed by treating an individual's scores on each product as single data points. By focusing on the scores of individual's comprising each system over the twelve products, it is possible to determine whether any differences are, in fact, due to the various systems rather than the products.

In order to test the hypothesis concerning the discrepancy between the two components of self-concept, difference scores between self- and ideal self-image were computed for each subject for each of the twelve products. The discrepancy scores were used as criterion variables in a multivariate Hotelling's T^2 test which is appropriate for testing the significance of the differences between the two self-concept ratings.² This test uses a sample mean difference vector and tests whether the population mean difference vector is significantly different from zero.

This statistic was computed separately for each of the four systems. Table 1 shows the T^2 , F statistics and significance level for each system. The F ratios exceed the .05 level of significance for Systems 1, 2 and 4 indicating that for these three systems the difference between self- and ideal self-image is significant. For System 3, however, the discrepancy between the two components of self-concept is not significant. These results are not supportive of the first hypothesis. In fact, the difference between self- and ideal self-image appears to be greater for Systems 1 and 2 rather than Systems 3 and 4.

TABLE 1
Results of Hotelling T^2 Test for Each System

	System 1 (n=53)	System 2 (n=29)	System 3 (n=18)	System 4 (n=24)
T^2	98.86	78.41	40.88	71.06
F	6.50**	3.97**	1.20	3.09*
Degrees of Freedom	12	12	12	12
	41	17	6	12

* Significant at the .05 level
** Significant at the .01 level

²For a description of Hotelling's T^2 test, see Tatsuoka (1971), p. 81.

To test the hypotheses concerning the differential role of self- and ideal self-image and the effect of product ownership, multiple regressions were run for each system with purchase intention as the dependent variable and self-image, ideal self-image and product ownership as independent variables. Subjects' scores for each product on the four measures were used in the regression equations. Thus, for each system the number of observations is equal to the number of subjects in that group times twelve, the number of products.

By examining the regression coefficients of the three variables it is possible to test the hypotheses concerning the differential role of self-concept and the effect of product ownership on purchase intentions across the different systems. The use of regression analysis in this study is not designed to imply causality but only to determine if there are differences between the systems relative to the association of self- and ideal self-image and purchase intentions. This analysis also allows for a better description of this relationship since it takes into account the effect of product ownership.

Table 2 shows the results of the regression run for each system. The regression coefficients, adjusted R^2 , and the significance level of each variable are presented in this table.³

TABLE 2
REGRESSION COEFFICIENTS FOR SELF-IMAGE, IDEAL SELF-IMAGE AND PRODUCT OWNERSHIP FOR EACH SYSTEM
b values and (Beta)

Variable	System 1	System 2	System 3	System 4
Self-image	.156**	.195**	.185**	.232**
Beta	(.279)	(.338)	(.318)	(.376)

* Significant at .05 level
** Significant at .01 level

Hypotheses 2 and 3 dealt with the role of self- and ideal self-image in determining purchase intention. More specifically, these hypotheses stated that System 3 representatives will show the greatest relationship between ideal self-image and purchase intention among the four systems, while System 4 will have the strongest relationship between self-image and purchase intention of the four groups. As can be seen in Table 2, the regression coefficient for ideal self-image is the highest for System 3 while the coefficient for self-image is the greatest for System 4. These results are consistent with the hypotheses concerning the differential role of the self-concept across the four systems.

The final hypothesis predicted that product ownership will have a greater influence on purchase intentions for Systems 1 and 2 than the other two groups. Examination of the regression coefficients for product ownership across the four systems (Table 2) supports this hypothesis. Product ownership has large regression weights in Systems 1 and 2 while for Systems 3 and 4 these regression coefficients are smaller in magnitude.

³Both b values (non-standardized) and Betas (standardized) are shown in Table 2. However, the discussion uses b values since this coefficient is required for a subsequent analysis reported below.

The findings discussed thus far are supportive of the hypotheses concerning the differential role of self- and ideal self-image and the effect of product ownership among the four systems. However, to determine whether or not these results are statistically meaningful, all of the data were pooled in an overall regression equation designed to test for the significance of the differences in these specific regression coefficients. The results of this test are shown in Table 3.⁴

TABLE 3
REGRESSION COEFFICIENTS FOR SELF-IMAGE,
IDEAL SELF-IMAGE AND PRODUCT OWNERSHIP
ALL SYSTEMS COMBINED

Variable	b value	Beta	F-ratio
SC	.170	.295	80.62**
SCD4	.064	.094	10.89**
ISC	.124	.226	54.70**
ISCD3	.068	.094	11.96**
OWN	.200	.066	2.83
OWND5	.403	.124	7.55**
Constant	4.64		
Adjusted R ²	.370		

**Significant at the .01 level

In this analysis dummy variables representing specific systems are multiplied with the original variables and included in the regression analysis. The variables SCD4, ISCD3, and OWND5 are cross products between variables SC (self-image), ISC (ideal self-image), and OWN (product ownership) and dummy variables D4, D3, and D5, respectively. Dummy variable D3 represents System 3, D4 System 4, and D5 systems 1 and 2. If the coefficients for the cross product variables are statistically significant, this means that the difference in the value of the regression coefficient for a specific system from the other systems is significant.

For example, self-image (SC) in general has a regression coefficient of .170. However, the coefficient of self-image for System 4 is somewhat greater than the other systems, specifically by .064 which is the value for the coefficient of SCD4. Moreover, this difference is significant beyond the .01 level. The difference in the value of the regression coefficient for ideal self-image between System 3 and the other systems (ISCD3) is .068. This difference is also significant beyond the .01 level.

These results offer statistical support for hypotheses 2 and 3. The influence of self-image on purchase intentions across the four systems is the greatest for System 4 while ideal self-image has the strongest influence for members of System 3.

The differences in the influence of product ownership across the four systems are also tested in this final equation. Overall, the effect of product ownership (shown by OWN in Table 3) is not significant. However, the difference in the influence of ownership for Systems 1 and 2, represented by OWND5 in Table 3, is quite large

⁴The b values are used in this analysis since the differences in the standard deviation of the variable in Table 3 (e.g., SC and SCD4) makes the Betas non-additive.

(.403). This difference is also significant beyond the .01 level. Clearly, product ownership influences purchase intention for Systems 1 and 2 much more than Systems 3 and 4.

Discussion

The results of the present study are interesting in several respects. The findings suggest that predispositional factors related to the level of conceptual functioning of an individual are related to the differential influence of self- and ideal self-image on purchase intentions. It also appears that the impact of product ownership on purchase intentions is mediated by an individual's level of conceptual functioning.

The evidence shows that for Systems 1, 2 and 4 the difference between self- and ideal self-image is significant. However, for System 3 this discrepancy is smaller and not statistically significant. Concreteness of conceptual functioning does not appear to be an explanation for any congruence between the two components of the self-concept.

One possible explanation for the unpredicted large discrepancy between the components of self-concept for Systems 1 and 2 may be that these two groups are void of a well-developed, ideal self-image. Their concrete level of functioning might dispose them towards viewing the "self-image" as the relevant and meaningful component of their self-concept. However, given the nature of the task, which requires subjects to rate each product first with respect to self-image then ideal self-image, representatives of these two systems are confronted with the problem of defining their ideal self-image. If it is not initially well defined, the ideal self-image for these two systems might be more susceptible to a "contrasting effect", wherein the more well-defined self-image serves as an anchor against which the less well-defined ideal self-image is contrasted. This would result in a large discrepancy between self- and ideal self-image for System 1 and 2.

There are, however, differences among the four systems with respect to the influence of either self- or ideal self-image on purchase intentions. Across the four groups, ideal self-image has the greatest impact on purchase intentions for System 3. The conceptual functioning for System 3 representatives predisposes them to be more concerned with such factors as social group consensus and peer group influence. They also have a strong need for affiliation and friendship and tend to develop more positive ties to prevailing social norms. These characteristics might motivate the System 3 individual to attempt to enhance his self-concept through reliance on an image that he feels is consistent with his idealized self. The ideal self-image will be the source of direction for such persons as they search for approval and guidance from others. This suggests that factors such as other-directedness, social desirability of product or brand, and reference group influence might be important determinants of the role of the ideal self-image in guiding purchase behavior.

The results also indicated that System 4 individuals show the strongest influence of self-image on purchase intentions of the four systems. This domination of self-image for System 4 suggests that persons who have had the opportunity to explore and become aware of their self-concept might tend to rely on a relevant self-image as a guide to their purchase intentions. The conceptual functioning of the System 4 individual may be more in line with the actualization model of personality discussed by Landon (1974). As mentioned previously, this model views the individual as striving to achieve harmony between his environment and his self-concept by coming to know and accept his self-concept.

The finding that product ownership had the greatest influence on Systems 1 and 2 is particularly interesting. The possible confounding effects of post-purchase measures is an important issue in self-concept research. The congruity principle of Birdwell (1968) was challenged by Evans (1968) on the grounds that it did not test causality since congruence was measured after the purchase decision was made. Evans argued that post-purchase data does not necessarily reflect purchase motivations due to self-image/product-image congruity. After purchase congruity or indication of future purchase intentions might result from a process such as dissonance reduction.

The concreteness of conceptual functioning of System 1 and 2, which disposes them toward a lower tolerance for dissonance, may motivate them to give more consideration to the fact that they presently own the product under consideration. The greater influence of product ownership for these two systems might reflect a way of maintaining cognitive consistency between past and future purchase behavior. Other empirical evidence (Harvey, 1965; Ware and Harvey, 1967; Harvey and Ware, 1967) has shown that dissonance and consistency theories have greater validity for concretely functioning than abstractly functioning individuals. These results appear to be consistent with this evidence.

The purpose of this paper was to determine if belief systems can offer insight into the differential role of the self-concept in determining purchase intentions. The present study has shown that factors related to an individual's level of conceptual functioning are correlates of the differential influence of self- and ideal self-image on purchase intentions. The conceptual system of the individual appears to mediate the relationship between self-concept and purchase behavior.

This study also indicates that product ownership may affect the self-concept/purchase behavior relationship. The significant influence of ownership on the first two systems suggests that further research might examine the effect of dissonance or other consistency theories on the self-product-image congruity of consumers.

Future research on the role of the self-concept may find it fruitful to concentrate on individual differences such as those suggested in this study and their relationship to the differential role of the self-concept. Finally, this study has shown that belief systems can provide some interesting insights into the behavior of the consumer. The conceptual systems approach of Harvey et. al. may have potential for other areas of research in consumer behavior.

MASCULINITY AND FEMININITY FACTORS
IN PRODUCT PERCEPTION AND SELF IMAGE¹

James W. Gentry, Mildred Doering, Terrence V. O'Brien
Kansas State University

Abstract

Sex roles are changing in the United States and it has been hypothesized that such changes will be evidenced in new patterns of consumer behavior. This study investigates self image regarding masculinity and femininity, sex identifications of representative products and life style elements, and usage rates of products.

Introduction

Tucker (1976, p. 353) has pointed out the impact of changing sex roles on marketing: "During most of the rest of the century marketers will increasingly miss the center of their markets because they will not understand them. And the change in the relations of the sexes will be the primary cause." This trend was also noted by Stuteville (1971), Hawkins and Coney (1976), and Dickens and Chappell (1977). Stuteville (1971) discusses the cases of two products, one of which (cigarettes) was once used almost solely by males but is now used as frequently by females (Gentry and Doering, 1977), and the other (hair spray) was once used almost solely by females but is now used almost as frequently by males (Gentry and Doering, 1977).

That sex roles are changing in our society should be sufficient for the marketer to become less interested in the male-female dichotomy and more interested in the level of masculinity or femininity. As Sechrest (1976) states, "That a respondent is male is in itself of little psychological impact. What is of consequence are the patterns of attitudes or abilities or problems or interests that are presumed to go along with being male." Aiken (1963) was one of the first to relate masculinity-femininity to purchasing behavior. He found that more feminine women were more likely to belong to the "Decoration," "Interest," and "Conformity" clusters of female dress buyers. Masculinity-femininity was not related to membership in the "Comfort" and "Economy" clusters. Vitz and Johnston (1965) found that, within each sex, a person's masculinity (femininity) is positively related to the masculine (feminine) image of the cigarette smoked. Fry (1971) found that more feminine men were more likely to smoke cigarettes that were identified as being less masculine. Morris and Cundiff (1971) found that masculinity-femininity was not related to the rating of hair spray by males; however, a strong interaction between manifest anxiety and masculinity-femininity was found.

Thus Aiken (1973), Vitz and Johnston (1965), and Fry (1971) found that their subjects' behavior was consistent with their masculine-feminine self image. On the other hand, Morris and Cundiff (1971) found that males with a relatively high feminine identification and a high anxiety level expressed strongly unfavorable attitudes toward the use of hair spray, which was viewed as being relatively feminine.

Stuteville (1971) hypothesized that the consistency of purchase behavior with one's masculine-feminine self image may vary across sexes. He stated that it is easier for a male-oriented product to attract female buyers than the reverse situation, since our culture labels the boy who acts like a girl a "sissy," but the girl who acts like a boy is called a "tomboy." The latter is much easier for a girl to accept than the former is for a boy.

The purpose of this study is to explore male and female perceptions of a wide variety of products and leisure activities and to explore whether one's masculinity-femininity self image within each sex is related to the individual's product perceptions. Given the convergence of sex roles in our society, we hypothesize that purchase behavior will be consistent with the masculine-feminine self image for 1) sexually neutral items and for 2) items associated with the opposite sex, but that inconsistency will occur for 3) items identified with the respondent's own sex due to the less threatening nature of those items.

Methodology

The population chosen for study was college students. One reason was, of course, convenience; more important was the belief that changing sex roles in our society (and corresponding changes in purchasing behavior) might be more evident in college students than in their elders.

The selection of specific leisure activities and products to be evaluated was done through a three-stage process. First, a list was compiled of activities and products that were thought to be related to the life-styles of the college student subjects. Second, a pretest was run concerning attitudes toward the stimuli and frequency of usage of them. A second pretest was run to establish the perceived masculinity-femininity of the stimuli. Stimuli were deleted if they were used very infrequently by most of the respondents. The third stage consisted of a final pretest of the instrument after the deletions were made. Then, additional stimuli were deleted because of similarity to other stimuli and because of the need to shorten the instrument. The specific leisure activities and products used in the study are listed in Tables 1 and 2.

Two hundred college students at Kansas State University (100 males and 100 females) were recruited through an advertisement in the student newspaper. While there was no attempt to randomly select subjects, the procedure did result in a representative mix of curricula. Further, the subjects' scores on a standardized personality instrument (the California Psychological Inventory Fe-scale) were nearly identical with results published for college students in Gough (1975). The mean and standard deviation for the females (23.22 and 2.85, respectively) and males (16.35 and 3.82, respectively) in our study closely approximate the CPI norms (23.16, 3.27; and 16.65, 3.73; respectively). Consequently, there is some evidence that the sample was fairly representative of college students.

Each subject was paid four dollars for completing the series of questionnaires dealing with their ratings of different consumer products and leisure-time activities.

¹The authors would like to thank Rene Klassen for his help in the data collection, Gail Holtman for her help in the data analysis, and the Bureau of General Research, Kansas State University, for financial support of the study.

The subjects also completed two masculinity-femininity scales, the CPI Fe-scale (Gough, 1975) and the Personal Attributes Scale (PAQ: Spence, et al., 1974). The last section of the instrument included demographic questions, usage measures of various media (not analyzed here), and ratings of the products and activities as to their perceived masculinity or femininity. Each subject was told to complete all forms, and each of the 56 sheets of information per subject was checked by a monitor before the subject was paid.

TABLE 1
USE OF PRODUCTS BY SEX OF RESPONDENT AND BY PERCEPTIONS OF PRODUCTS AS MASCULINE OR FEMININE

Product	Use of product, by sex		Use of product, by perception	
	Male	Female	Mas.	Fem.
Beer	4.0 ^a	3.5 ^b	3.4	3.6
Boots	4.8	3.5 ^b	4.2	4.2
Cigarettes	.9	.4	.5	.3
Cologne	4.0	5.2 ^b	4.9	4.4 ^c
Deodorant	4.6	5.3 ^b	4.9	5.0
Hair spray	1.3	1.5	1.6	1.7
Jeans	6.0	6.3	6.2	6.1
Mouthwash	2.5	2.5	2.4	2.6
Razor blades	3.8	3.3	3.5	3.7
Sandals	2.7	6.5 ^b	4.8	4.4
Shampoo	4.2	4.5	4.2	4.4
Soap	5.1	5.6 ^b	5.4	5.4
Tennis shoes	4.6	4.0 ^b	4.2	4.6

^a Entries are group means and are scaled differently for different variables; these include seven point bipolar adjective scales, rate of consumption of the product, and others.

^b The difference between male and female use is significant at the .10 level or better.

^c The difference in usage between masculine and feminine product perception is significant at the .10 level or better.

Discussion of Scales

Gough's (1975) CPI Fe-scale consists of 38 true-false items. This procedure views "masculinity-femininity" as a continuum, and a low score indicates masculinity while a high score indicates femininity. This scale was chosen because of its long tradition, being published first in 1952 (Gough, 1952), and because it has been commonly used in marketing studies (Aiken, 1963; Fry, 1971; Morris and Cundiff, 1971; Vitz and Johnson, 1965).

The PAQ views masculinity and femininity as two distinct dimensions, which permits individuals to be identified as being "androgynous," or masculine and feminine. The androgynous classification is applied to those who are both independent and tender, assertive and yielding, tough but sweet. The first androgyny scale was developed by Bem (1974), but we preferred the PAQ because of the way "androgyny" is defined operationally. The Bem Sex Role Inventory (BSRI) identifies someone as "androgynous" if his/her score on the masculine and feminine scales are comparable. Thus the BSRI identifies respondents as masculine, feminine, or androgynous. The PAQ is

more restrictive in the identification of androgynous individuals; only those who score high on both the masculine and feminine dimensions are identified as being androgynous. Those ranking low on both dimensions are grouped in a fourth category, labeled low-masculine, low-feminine. The only marketing study that we have seen that used the concept of androgyny was that by Tucker (1976), and he also used the PAQ rather than the BSRI.

TABLE 2
PARTICIPATION IN LEISURE ACTIVITIES, BY SEX OF RESPONDENT AND BY PERCEPTIONS OF LEISURE ACTIVITIES AS MASCULINE OR FEMININE

Activity	Participation in activity, by sex		Participation in activity, by perception	
	Male	Female	Mas.	Fem.
Ballet	.7 ^a	2.1 ^b	1.2	.4
Basketball	10.5	9.7	11.9	7.9 ^c
Bicycling	30.5	16.3	22.6	24.3
Car races	2.6	1.5 ^b	1.9	2.4
Fishing	6.4	2.0 ^b	3.6	3.4
Hunting	4.8	.4 ^b	2.2	1.5
Ice skating	2.8	1.0	1.4	.3
Knitting	.4	15.3 ^b	6.0	7.9
Swimming	20.6	24.2	22.2	15.2
Movies, G rated	2.1	3.0 ^b	2.8	2.2 ^c
Movies, PG rated	3.5	4.6 ^b	3.9	3.9
Movies, R rated	2.7	2.7	3.8	4.4 ^c
Movies, X rated	2.4	1.1 ^b	2.1	1.7

^a Entries are group means and are scaled differently for different variables; these include seven point bipolar adjective scales, rate of participation in the activity, and others.

^b The difference between male and female participation is significant at the .10 level or better.

^c The difference in usage between masculine and feminine product perception is significant at the .10 level or better.

The attitude measures consisted, in part, of the four seven-point, bipolar scales used in the Morris and Cundiff study (1971): valuable-worthless, sociable-unsociable, nice-awful, and useless-useful. In addition, an overall product or activity attitude was obtained using a seven-point bipolar scale with very unfavorable attitude and very favorable attitude as the end points. Numerical frequencies were used where applicable, usually with the leisure activities. Most of the product usage questions required the subject to select a response such as "once a month" or "once a day."

Analysis

The respondents were grouped in different masculinity-femininity categories based upon their scores on the two scales. For the CPI Fe-scale, boundaries were established at approximately the 33rd and 66th percentiles. The groups are labeled Masculine (60 males, 2 females), Neither (33 males, 39 females) and Feminine

(7 males, 59 females). For the PAQ, the subject population was split at the median on both the male-valued and female-valued scales (59 and 50, respectively). The four resulting PAQ groups are low masculine and low feminine (32 females, 25 males), low masculine and high feminine (32 females, 13 males), high masculine and low feminine (10 females, 34 males), and high masculine, high feminine (26 females, 28 males).

Each respondent's ratings of the masculinity-femininity of the leisure activities and of the products were normalized to remove differential response-scale tendencies before aggregating over subject. Then each respondent was categorized as viewing the product or activity as being more feminine or more masculine than average. The respondents' usage of the stimuli were then related to their sex, their masculinity-femininity, and how masculine or feminine they viewed the stimuli through a series of analyses of variance. The particular approach used was the Least Squares program written by Kemp (1976), which is designed to handle unequal cell sizes.

The categorization of the groups as being consistent or inconsistent with their self images was based on the mean usages for the different items. The differences in the cells (for example, the difference between the mean usage for those males who viewed the stimulus as being more masculine and the mean usage for the males who viewed the stimulus as being more feminine) were tested using t-statistics.

Results

Product stimuli are shown on the left side of Table 1. Note that only one product (cologne) has a statistically significant difference in the usage rate between masculine-feminine product perceptions. Those who view cologne as being masculine use the product more than those who view it as being feminine. One reason for the lack of statistical significance in usage by those with different masculine-feminine product perceptions may be that the products are essentially unisexual in nature. Another reason is the high variance in the usage rates of the different stimuli. Much greater differences exist, however, in product use by sex of respondent, with seven out of thirteen items showing marked differences. Beer, boots, and tennis tend to be used more by males, while cigarettes, deodorant, sandals, and soap are used more by females.

Similar findings (Table 2) resulted for leisure activities, in that only a few were engaged in differentially by those with different masculine-feminine product perceptions but most were, in fact, engaged in differentially by sex. Reported participation was higher for women in watching ballet, knitting, and attending G-rated and PG-rated movies; it was higher for men for car races, fishing, hunting, and attending X-rated movies. Neutral activities were basketball games, bicycling, ice skating, swimming, and attending R-rated movies. However, for only three items were usage rates different for those with different masculine-feminine product perceptions. Those who viewed basketball games and G-rated movies as being more masculine attended these activities more often. More frequent attendees of R-rated movies tended to view them as being more feminine. It may be that sex role guidelines are not relevant or usually salient for many activities or products, or there may be suppression of their perceived impact.

Table 3 shows product usage frequencies broken down by sex and by whether the product was viewed as being masculine or feminine. The interactions between sex and the perception of the product were significant for boots, shampoo, and soap. For boots and shampoo, the

significant interaction indicated that both sexes were consistent with their self image; that is, males were heavier users if they viewed the product as being more masculine, while females were heavier users if they viewed the product as being more feminine. On the other hand, the interaction for bar soap finds that both sexes are inconsistent with their self-image.

TABLE 3
PRODUCT USAGE FREQUENCIES, BY SEX OF RESPONDENT
AND BY MASCULINITY-FEMININITY PERCEPTION

Product	Perception of Product	Sex of respondent	
		Male	Female
Beer	Masculine	3.3 ^a	3.5
	Feminine	3.7	3.6
Boots ^b	Masculine	5.1	3.2
	Feminine	4.5	3.8
Cigarettes	Masculine	1.3	1.1
	Feminine	1.2	1.2
Cologne	Masculine	4.4 ^c	5.3
	Feminine	3.6	5.1
Deodorant	Masculine	4.6	5.2
	Feminine	4.6	5.3
Hair Spray	Masculine	1.3	1.9
	Feminine	1.5	2.0
Jeans	Masculine	5.9	6.5
	Feminine	6.1	6.1
Mouthwash	Masculine	2.6	2.1
	Feminine	2.4	2.9
Razor Blades	Masculine	3.5	3.5
	Feminine	3.2	4.0
Sandals	Masculine	3.0	6.6
	Feminine	2.5	6.3
Shampoo ^b	Masculine	4.3	4.1 ^c
	Feminine	4.1	4.8
Soap ^b	Masculine	5.0	5.8
	Feminine	5.3	5.5
Tennis Shoes	Masculine	4.3	4.1
	Feminine	4.6	4.6

^aEntries are group means and are scaled differently for different variables; these include seven point bipolar adjective scales, rate of consumption of the product, and others.

^bSignificant at the .10 level or better by analysis of variance.

^cFor this sex of respondent, the difference in usage between masculine and feminine product perceptions is significant at the .10 level or better, by t-test.

The interaction term is most likely to be significant if both sexes are very consistent or if they are both inconsistent. If one sex is consistent while the other one is not, the interaction term is less likely to be significant. To investigate these situations more closely, the differences in the cell means were tested using t-tests. Males were found to be significantly consistent in their use of cologne, and females were found to be significantly consistent in their use of shampoo.

Table 4 shows the usage frequencies of the leisure activities, broken down by sex and by the masculinity-femininity perception of the activity. Attendance of G-rated movies yielded the only significant inter-

action; females were more likely to attend G-rated movies if they viewed them as being more masculine; males attendance did not depend on their sex-role perceptions. On the other hand, females were significantly more likely to attend R-rated movies if they viewed them as being more feminine.

TABLE 4
LEISURE ACTIVITY USAGE, BY SEX OF RESPONDENT
AND BY MASCULINITY-FEMININITY PERCEPTION

Product	Perception of activity	Sex of respondent	
		Male	Female
Ballet	Masculine	.6 ^a	1.8
	Feminine	.3	.6
Basketball	Masculine	12.1	8.7
	Feminine	8.9	6.3

	Feminine	2.6	1.7
Movies, PG Rated	Masculine	3.7	4.2
	Feminine	3.6	4.1
Movies, R Rated	Masculine	3.7	4.0 ^c
	Feminine	3.9	5.0
Movies, X Rated	Masculine	2.6	1.6
	Feminine	2.1	1.4

^a Entries are group means and are scaled differently for different variables; these include seven point bipolar adjective scales, rate of participation in the activity, and others.

^b Significant at the .10 level or better of analysis of variance.

^c For this sex of respondent, the difference in usage between masculine and feminine activity perceptions is significant at the .10 level or better, by t-test.

Usage patterns were investigated as to self image differences by a standardized personality inventory. Table 5, results are shown from the California Psychological Inventory's Fe-scale for our product set and in Table 6 for the leisure activities. Again, usage pattern differences are not striking.

The ANOVA results indicate that the respondents were consistent with their self-image in the usage of bar soap and attendance of G-rated movies; for example, masculine respondents used bar soap more if they perceived it as being more masculine and feminine respondents used bar soap more if they perceived it as being more feminine. On the other hand, the respondents were

inconsistent with their self-image in the usage of mouthwash. When the different CPI masculinity-femininity categories were analyzed by themselves, the statistically significant findings were that the masculine respondents attend G-rated movies more if they view them to be more masculine (consistent) while feminine respondents attend basketball games more if they view them to be more masculine (inconsistent).

TABLE 5
PRODUCT USAGE, BY RESPONDENT MASCULINITY-FEMININITY
PERSONALITY SCORE AND PRODUCT PERCEPTION

Product	Perception of Product	Personality Orientation of respondent		
		Masculine	Neither	Feminine
Beer	Masculine	3.9 ^a	3.7	2.6
	Feminine	4.2	3.6	3.1
Boots	Masculine	5.6	3.6	3.6
	Feminine	4.7	3.9	3.9
Cigarettes	Masculine	.3	.8	.5
	Feminine	.4	.3	.3

	Feminine	5.1	4.5	4.1

^a Entries are group means and are scaled differently for different variable; these include seven point bipolar adjective scales, rate of consumption of the product, and others.

^b Significant at the .10 level or better by analysis of variance.

Based on use and participation rates reported in Tables 1 and 2, products and activities were classified as masculine, feminine, or neutral, as shown in Table 7. In addition, two redefinitions of previous variables were also included to better measure their effects. In Table 7, quantity of beer consumed per time period is added to the frequency of consumption measure used thus far; also, a dichotomous smoking variable is added to the previous quantity measure. In addition, the results for two of the four PAQ categories are added: the group that scored low on the masculinity scale and high on the femininity scale (the feminine group) and the group that scored high on the masculinity scale and low on the femininity scale (the masculine group). A summary of the other two groups (low masculine-low feminine and high masculine-high feminine) is not provided as their self-images can not be classified as either masculine

or feminine.

TABLE 6

LEISURE ACTIVITY USAGE, BY RESPONDENT MASCULINITY-FEMININITY PERSONALITY SCORE AND PRODUCT PERCEPTION

Product	Perception of Product	Personality Orientation of respondent		
		Masculine	Neither	Feminine
Ballet	Masculine	.2 ^a	.7	2.7
	Feminine	.3	1.1	.1
Basketball	Masculine	7.8	10.1	13.1 ^c
	Feminine	6.6	9.1	7.2
Bicycling	Masculine	21.7	30.6	15.7
	Feminine	12.0	40.3	20.7
Car Races	Masculine	3.6	1.1	1.1
	Feminine	3.8	2.3	1.1
Fishing	Masculine	6.8	2.1	1.9
	Feminine	5.8	2.8	1.7
Hunting	Masculine	5.6	.7	.2
	Feminine	3.2	1.1	.2
Ice Skating	Masculine	3.5	.8	.1
	Feminine	.1	.5	1.3
Knitting	Masculine	.04	8.2	9.5
	Feminine	1.1	.9	21.4
Swimming	Masculine	18.9	23.3	24.3
	Feminine	16.7	16.2	12.9
Movies, G Rated ^b	Masculine	2.6 ^c	2.5	3.3
	Feminine	.7	2.1	3.8
Movies, PG Rated	Masculine	3.5	3.9	4.5
	Feminine	3.6	3.8	4.2
Movies, R Rated	Masculine	4.5	4.0	3.0
	Feminine	5.1	4.4	3.8
Movies, X Rated	Masculine	3.0	1.4	1.9
	Feminine	2.2	1.6	1.5

^a Entries are group means and are scaled differently for different variable; these include seven point bipolar adjective scales, rate of participation in the activity, and others.

^b Significant at the .10 level or better by analysis of variance.

^c For this personality orientation of respondent, the difference in usage between masculine and feminine activity perceptions is significant at the .10 level or better, by t-test.

Entries in Table 7 refer to the consistency of the masculinity-femininity product or activity perception with sex of the respondent and with the respondent's masculinity-femininity personality disposition as measured by two different personality inventories. Again, our hypotheses were that consistency would exist for neutral items and when the product is associated with the opposite sex, but that inconsistency would occur for products and activities identified with the respondent's own sex--the latter because of a pull toward the center as sex roles loosen up and because of the less threatening nature of these items than of those identified with the opposite sex.

Findings for males in Table 7 tend to support expectations for sex of respondent and for the PAQ measure, but not for the CPI. For example, males were more likely to be inconsistent for masculine items (3 out of

7) than for feminine items (1 out of 6) and females were more likely to be inconsistent for feminine items (6 out of 8) than for masculine items (3 out of 8). The feminine groups as categorized by both the CPI and PAQ scales tend to support the hypothesis; they were inconsistent for more feminine items (4 out of 8 for the CPI and 6 out of 8 for the PAQ) than for masculine items (2 out of 7 for the CPI and 3 out of 8 for the PAQ). The masculine group for the PAQ was inconsistent for 5 of the 8 masculine items, but only for 1 of the 8 feminine items. On the other hand, the CPI masculine group was more inconsistent for feminine items (4 of 8) than for masculine items (3 of 7).

^a Designation of items as masculine, neutral, or feminine is based on product use and activity participation results from Tables 1 and 2.

^b "+" means that heavier users of this type (male, masculine, etc.) view the item as being consistent with their orientation, "-" means that heavier users of this type view the item as being inconsistent with their orientation, and "0" means that there is no difference in usage between those who view items as being masculine and those who view it as being feminine.

In general, the expectations do have some support when the items categorized as masculine or feminine are considered. However, we hypothesized that the respondents would be consistent with their self-images in the usage of neutral items; no such general pattern can be observed in Table 7. The only group for which this appears to have support is for males; the other groups are apparently just as likely or even more likely to be inconsistent with their self-concepts in their usage of the neutral items. Aggregating over items, it seems that males tend to be more consistent with their self-image (17 of 25 cases) than do females (14 of 28 cases). We would have to conclude that the evidence is perhaps suggestive as to general trends but well short of persuasive, especially when the scarcity of statistically significant results is considered.

Finally, a comparison can be derived from Table 7 for the personality measures, which shows little correspondence between the two. For example, there are ten instances of consistency registering on both the CPI and PAQ scales, five of inconsistency, but eleven mismatches (plus on one and minus on the other) occur. It is not uncommon to find both the masculine and feminine groups from one scale to be classified as being consistent, while the counterparts from the other scale are both classified as being inconsistent. The two scales are measuring somewhat different phenomena and the differences are evident here.

Conclusion

This study looked at a demographic variable (sex) and two measures of masculinity-femininity self image, the California Psychological Inventory Fe-scale and the Personal Attributes Questionnaire, as these related to representative marketing stimuli. It was hypothesized that consumers will use products with neutral orientations or orientations opposite from theirs (for example, feminine products for males) as long as they perceive the products to be consistent with their self-image. It was further hypothesized that heavier users of products with similar orientations to their own (for example, feminine products and females) will perceive the product to be inconsistent with their self image. The results provide very weak support for the directions predicted by the hypotheses.

Implications

It may well be that the marketing stimuli and the leisure activities selected for this research were too "unisexual" in nature, the result being not very striking findings on sex role differences. More extreme stimuli might have more strongly supported our hypotheses. We would expect, however, that a trend toward less stereotypic sex roles still could be identified, although the ideal research design for this purpose would consist of a demonstrably representative set of stimuli along with a longitudinal measurement structure. Future work in this area will hopefully include some of these features.

Our findings do lend weak support to the convergence of sex roles in consumer behavior. The lack of signifi-

cant differences in the usages of products that were formerly sex-stereotyped (cigarettes, jeans, hair spray, and shampoo) lends support to the claims of developing unisexuality of many products. Also, the weak support for our hypothesis that consumer behavior will be inconsistent with the masculine-feminine self image when the stimulus is associated with the same sex and consistent when associated with the opposite sex lends support for the convergence of sex roles. However, as noted in Gentry and Doering (1977), the male-female dichotomy still explains more of the variability in consumer behavior than does masculinity-femininity.

ATTITUDE MATURATION: CHANGES IN RELATED
BELIEF STRUCTURES OVER TIME¹

Jerry C. Olson, Pennsylvania State University
Philip A. Dover, Dartmouth College²

Abstract

This paper presents some initial ideas about the dynamic changes which may occur within the belief structure associated with a stimulus concept. In particular, we focus on a phenomenon termed attitude maturation -- the observed tendency for the belief structure and overall attitude associated with a product to become increasingly related and consistent over time as knowledge about the product accumulates. An initial conceptualization of the attitude maturation phenomenon is offered along with several alternative explanations and these ideas are illustrated with data from a five-wave longitudinal experiment. The paper concludes with suggested theoretical perspectives derived from cognitive psychology.

Introduction

How are attitudes acquired? Are crystallized, stable attitudes formed "instantly" upon learning something of an object's existence and its characteristics? Or, do our attitudes develop (evolve or mature) more slowly as we accumulate information and cognitively consider that information? How long (how many experiences, how much information) does it take to form a stable, mature attitude -- and an associated stable, mature belief structure? Does the formation of beliefs through the acquisition of information directly and automatically lead to the formation of a stable (reliable) attitude that possesses clearly defined, stable relationships with associated salient beliefs and with other attitudes? Or, does this process take time and some degree of conscious, cognitive processing effort? This paper presents our initial thinking, accompanied by some illustrative data, regarding these and other questions involved with attitude formation, attitude change, and the dynamics of the relationship between attitude and belief structure.

The theoretical literature on attitude formation typically does not address such issues. Fishbein's attitude theory presents perhaps the clearest account of the attitude acquisition process (cf. Fishbein, 1963, 1967; Fishbein and Ajzen, 1975) and has been adopted or advocated by many consumer researchers (Ahtola, 1975; Cohen, Fishbein and Ahtola, 1972; Lutz, 1975; Olson and Mitchell, 1975). In this view, attitude, defined as unidimensional evaluation or affect, is a direct causal function of one's beliefs about associated concepts and one's evaluations of those perceived associations. Beliefs and their evaluative aspects are developed through learning principles of classical and instrumental conditioning and mediated generalization (Fishbein, 1967; Olson and Mitchell, 1975). Fishbein quantified the relationship between attitude (A) and belief structure (indicated by belief strength, b_i and evaluation, e_i) via the now familiar additive compensatory model:

¹This research was funded by a Research Initiation grant to the first author from the Pennsylvania State University. We are grateful to Rajesh Kanwar for his assistance with the data analysis and to James Bettman, Joel Cohen and Richard Lutz for helpful comments on a draft version of the paper.

²Associate and Assistant Professor of Marketing, respectively. This study and paper were completed while the second author was a doctoral candidate in Marketing at the Pennsylvania State University.

$$A = \sum_{i=1}^n b_i e_i \quad (1)$$

Implicit in most attitude research which takes this perspective is the assumption that a completely formed and internally consistent cognitive structure (here consisting of an attitude and its related belief structure) is formed essentially immediately upon processing whatever information is involved (cf. Lutz, 1975, 1977). However, the questions posed above challenge this assumption. To provide answers to these questions a dynamic, longitudinal research approach is required in which changes in attitude, belief structure, and their interrelationships are monitored over time for a given group of subjects. Unfortunately, the vast majority of consumer attitude studies are static and cross-sectional and thus do not address these issues. And, the relatively few longitudinal experiments that do exist (cf. Ginter, 1974; Winter, 1974) typically do not report the types of data analyses required for a study of cognitive dynamics and thus neglect the issues identified above.

Our purposes in writing this paper are several. First, we wish to present and briefly discuss some interesting conceptual issues regarding the dynamics of cognitive structure--from an attitude perspective. Where appropriate, specific issues will be illustrated with data from our own research. It should be noted that the data reported here are intended to be only heuristic and illustrative--not conclusive--as they are derived from a longitudinal experiment originally designed for another purpose. Second, we wish to identify critical theoretical issues that seem to warrant future research attention. Broadly speaking, our goals are to arouse interest in issues of attitude structure dynamics and to encourage research specifically directed at such issues.

Background

Definitions

The common tendency in attitude/cognitive structure research to use concepts and terms somewhat loosely suggests that specific, explicit definitions of the major concepts used in this paper would minimize semantic misunderstandings.

Attitude. Consumer researchers appear to be gradually reaching a consensus that the construct of attitude is best considered as the unidimensional evaluation or affect (favorable-unfavorable, good-bad, like-dislike) associated with an object, event, action, or concept. This simple definition was adopted for the present study as the most easily justified theoretically and the most useful definition from a measurement standpoint.

Cognitive Elements. The term cognitive elements as used in this paper refers to several major cognitive variables, including beliefs (b_i), the evaluative aspects of each belief (e_i), attitude toward the concept of interest (attitude toward the object, A_o , or act, A_{act}), and behavioral intention (BI, in consumer research usually operationalized as purchase intention).

Cognitive Structure. An implicit assumption in most cognitive research is that all of the cognitive elements associated with a stimulus object or event are organized together in a more or less consistent (in some sense) way and this organized set of cognitions may be

viewed as a structure. The most basic cognitive elements in a structure are the encoded representations of the stimulus object and its characteristics. These learned concepts are represented cognitively by symbolic codes assigned to the concept during the encoding process. Beliefs refer to the cognitive link between two concepts and belief strength is the perceived degree of probabilistic association between any two concept symbols (e.g., brand X and attribute A). Taken as a whole, the associations between these concepts may be considered to represent a belief structure as discussed below. The belief structure that is salient for a particular object/concept is thought to be related in a causal way to the overall attitude toward the concept of interest (see equation 1; Fishbein, 1967). In turn, attitudes (and perhaps other factors such as social norms) influence intentions to behave, which in turn are thought to exert a causal effect on overt behavior (see Ryan and Bonfield, 1975). Since concepts or codes, linking beliefs, evaluation/attitudes, and intentions are all cognitive elements, the overall pattern of their interrelationships may be considered as partially representing the cognitive structure for a particular concept such as a brand. However, because this paper is primarily concerned with attitudes, we shall deal mainly with belief structure interrelationships and belief-attitude relationships.

Belief Structure. The various salient and non-salient beliefs associated with an attitude concept can be considered as a structure of interrelated beliefs. That is, each belief concept is associated with the attitude concept and may also be "interconnected" with other belief concepts. The overall evaluation associated with a belief structure may be quantified by summing the cross products of belief strength and belief evaluation, $\sum b_i e_i$ (cf. Lutz, 1975; Olson and Dover, in press). This belief structure evaluation should influence (perhaps cause) the evaluation or attitude associated with the overall concept.

Method

The study which produced the data used here for illustrative purposes was designed to investigate another phenomenon--disconfirmation of expectations. The relevant methodology has been reported in sufficient detail elsewhere (Dover and Olson, 1977; Olson and Dover, 1976) and therefore is only briefly reviewed below.

Two treatment groups were randomly created from among 38 adult housewives. Group A (n = 20) received five exposures to information about a new, unfamiliar (actual) brand of ground coffee. The first three informational stimuli were three written, ad-like messages each of which stated (in different ways) that the coffee had absolutely no bitterness. No information about other coffee attributes were contained in any of the ads. Following the third message, consumers actually tasted a coffee sample intentionally prepared to be bitter and thus to disconfirm pretrial expectations. Then, to provide an extended period of product experience (and extensive product information) consumers received a free one-pound can of the coffee to try in their homes for about 10 days. The first four stages were each separated by approximately four days. Following each of the five stages, the major cognitive elements (associated with this brand of coffee) were measured. In sum, the five experimental stages for Group A can be seen as five opportunities for consumers to acquire information about a previously unknown product, with at least some of the information likely to be inconsistent with the remainder.

Consumers in Group B (n = 18) received no pretrial information regarding the coffee or its level of bitterness. These consumers merely tasted the purposefully bitter coffee and then took a one-pound sample home for

an extended trial period. Thus, the cognitive structures of group B subjects were measured twice. Consumers in this group had two opportunities to acquire information about the unfamiliar brand--both involving direct trial experiences with the brand.

For purposes of the present paper, this longitudinal experiment allows a close examination of (a) the dynamics of the belief structure-attitude relationship and (b) changes in the interrelationships within belief structure, as a function of multiple, sometimes inconsistent product information. The relationship between beliefs and attitude was modeled by the Ahtola (1975) adaptation of the Fishbeinian expectancy-value model (see Dover and Olson, 1977).³

Issues and Data

Magnitude of Experimental Effects

The experimental treatments, as expected, had significant effects on several cognitive elements, particularly on beliefs about the degree of coffee bitterness (see Olson & Dover, 1976, 1977). A substantial amount of "movement" over time was produced in the various cognitive variables by the exposures to the experimentally controlled information (see Figure 1, Dover and Olson, 1977). Our present interest, however, is with the dynamics (trends, shifts, or fluctuations) involved in the interrelationships between cognitive variables.

Major Interrelationships Among Cognitive Elements

One relationship of major interest to an attitude theorist involves the degree of correspondence between beliefs and overall attitude. As discussed previously, belief structure evaluation can be operationalized by the simple model, $\sum b_i e_i$. Column 1 in Table 1 contains the results pertaining to the validity of the basic Fishbein/Ahtola notion that belief structure is strongly and causally related to attitude ($\sum b_i e_i = A_0$).⁴ A steady increase⁵ in the strength of relationship between the belief structure index and attitude was obtained for Group A, increasing from an r^2 of .14 upon first learning something about the product to .61 after three weeks of varying experiences with the product. It is this effect that we have termed the attitude maturation phenomenon. The change in the attitude-intention relationship was even more dramatic, steadily increasing to a correlation of .95 ($r^2 = .90$) by the study's end. Group B

³This study adopted Ahtola's vector model, which separates belief strength from belief content, in order to more precisely monitor belief structure changes. In this model, a specific product attribute is reduced to a vector of discriminable levels or amounts of the attribute. Measures of belief strength and evaluation are taken for each attribute level. Summing the belief strength-evaluation cross products ($\sum b_i e_i$) within a vector yields an index of evaluation for that attribute. Summing across vector scores ($\sum \sum b_i e_i$) yields the composite evaluative index for the entire belief structure.

⁴Attitude toward the object (the coffee brand) was measured by the mean of three measures of evaluation -- good-bad, like-dislike, and high quality-low quality--each measured on 5-point bi-polar scales.

⁵We were unable to find a procedure for statistically testing differences between correlations of the same variables measured at different points in time for the same subjects.

TABLE 1
CORRELATIONS RELEVANT TO MAJOR THEORETICAL
RELATIONSHIPS BETWEEN COGNITIVE VARIABLES

Groups, and Experimental Stages	Theoretical Relationships	
	$\sum \sum b_i e_i = A_0$	$A_0 \approx BI$
<u>Group A (n = 20)</u>		
1. Ad A	.37	.54
2. Ad B	.39	.70
3. Ad C	.59	.76
4. Initial trial	.64	.93
5. Extended trial	.78	.95
<u>Group B (n = 18)</u>		
1. Initial trial	.48	.49
2. Extended Trial	.68	.63

Note: All correlations are significantly greater than zero ($p < .05$, one-tailed test).

also evidenced increases (although less dramatic) in the strengths of both relationships over the extended trial period (see Dover and Olson, 1977, for a more complete analysis and discussion of these results from an Expectancy value model perspective).

Interpretation. Despite the relatively small samples involved, at least compared to most correlational studies, increases of this magnitude and consistency in theoretically predicted relationships aroused our interest. A number of rather simple explanations for these dynamic effects were considered and tentatively judged unable to account for the effect (see Dover and Olson, 1977). For instance, increasing model correlations were not caused by a steady monotonic increase in the magnitude of the individual cognitive elements which might in turn produce increasing consistency between the cognitions. In fact, the variables fluctuated in magnitude across the experimental stages as would be expected given the conflicting information at stage 4 (see figures in Dover and Olson, 1977; Olson and Dover, 1976). However, the observed variations of the manipulated bit-terness belief, belief structure, attitudes, and intentions were relatively consistently related (see figure 1, Dover and Olson, 1977). That is, although cognitive changes were not monotonic over time, the change patterns for individual cognitive elements were similar.

An alternative explanation for the attitude maturation effect is that the observed increases in correlations were due to the repeated measurement of consumer subjects. However, this simple statement does not explicate precisely how the multiple measurements could have caused the correlation increases. For instance, it seems unlikely that subjects remembered their previous responses and/or consciously modified their responses to create a more consistent cognitive structure over time. The number and complexity of the measures and the relatively long intertrial time (at least four days) argue against this explanation. However, repeated, indeed any, measurements of cognitive variables certainly affect the measured cognitive structure and presumably also influence the relationships between cognitive elements. Thus, questions remain as to exactly what these measurement effects are and how they operate.

Belief Structure Dynamics

A more conceptually intriguing explanation for the observed attitude maturation effect concerns the dynamic changes that may have occurred within the belief structure underlying the product attitude. Using terms somewhat loosely at this point, the belief structure may become "clearer" (to the subject), more stable and reliable, more internally consistent--in other words, increasingly mature--and, as a consequence, more strongly associated with overall attitude. Such changes would not necessarily be evidenced in the absolute magnitudes or levels of specific cognitive variables, such as increasing belief strength, but rather might be more subtly represented by changes in the interrelationships between cognitive variables. In the following sections we discuss these possibilities and propose specific, theoretically based explanations regarding the belief structure changes, and illustrate their viability with data from the experiment described above.

How is Information Structured and Stored?

It has been common in cognitive psychology and to a lesser extent in consumer research to discuss cognitive structure in terms of specific memory stores; e.g., sensory, short-term, intermediate, and long-term memories (see Chestnut and Jacoby, 1977 or Olson, 1977, for overviews). This approach led to rather mechanistic theories of information transfer between these structural "warehouses" via the "forklift trucks" of rehearsal or various retrieval processes. Currently these notions are being rejected for a less rigid concept of memory structure. In this view, memory or cognitive structure takes form as information is encoded and organized (cf. Estes, 1975; Hayes-Roth, 1977; Restle, 1974). That is, information enters memory and becomes a part of cognitive structure simply by having been encoded during initial processing activity.

From this view, cognitive structure involves the content and organization of knowledge as stored in memory. Because of the focus on the meaning assigned to processed informational stimuli and the relations between that meaning and other, previously acquired knowledge, this aspect of cognitive structure or memory has been termed semantic memory (see Tulving, 1972). In sum, semantic memory concerns not the structural aspects of the storage system, but the structural characteristics of the knowledge that is represented in memory.

The traditional theoretical paradigm to explain knowledge representation in cognitive structure has been associationist theory (e.g., Anderson and Bower, 1973). Associative models of memory typically assume that knowledge is represented as networks of nodes and connecting arcs, where the nodes encode specific discriminable concepts and the arcs between nodes encode the perceived relationships between concepts (see Figure 1-a). Thus, cognitive structures can be modified by changing arcs (modifying the perceived association between two concepts) or by adding new concepts (and, of course, connecting arcs) to the cognitive structure.

Consumer attitude researchers will note the distinct similarity of these notions to their typical conceptualization of belief structures (Figure 1-b). Lutz (1975), for example, discussed strategies for modifying belief structures (and subsequently, attitude) in analogous terms. In their ubiquitous measurement of consumers' belief structures for products and brands, consumer researchers have in fact been investigating aspects of consumers' knowledge structure in semantic memory. However, the usual focus in consumer behavior/marketing has been on predicting attitudes from such belief structures rather than on describing the structural characteristics of the knowledge representations associated with a

a. Cognitive Structure in Associationist Terms

b. Cognitive Structure in Attitude-Belief Terms

FIGURE 1. ALTERNATIVE VIEWS OF COGNITIVE STRUCTURE

product concept.

Given this perspective, this paper can be seen as an initial, exploratory attempt to examine consumers' semantic structure per se, particularly focusing on the belief structure and the dynamics of its relationship with attitude. Following are several possible (and probably only partial) explanations for the attitude maturation effect. These ideas focus on changes within the structure of salient beliefs regarding the attitude object. Where possible, each notion is illustrated by data analyses from the study described above.

Belief Stability

One explanation for the observed maturation effects is that beliefs may not be well-formed or stable or "held with conviction" until several "experiences" with the belief object have occurred. There may be some problem in developing measures of this "stability" or "conviction" construct, since belief strength scores may not adequately assess such changes. That is, it seems possible that one could have a stable, clear belief that a particular concept is only weakly (or occasionally) related to another concept. In fact, belief strength scores for Group A did not increase (or decrease) consistently over the multiple stages (see Figures 1, 3, and 4 in Olson and Dover, 1976).

In the social and cognitive psychology literatures, researchers have taken independent measures of subjects' confidence in their belief ratings (cf. Wyer, 1973, 1974). Such confidence scores could be treated as direct evidence for the "clarity," stability, or degree of conviction of one's beliefs. In the present study, subjects were asked to rate their degree of confidence in the belief strength allocations for each of the five attribute

vectors.⁶ Table 2 presents the resulting five sets of confidence scores for each experimental stage. Confidence in beliefs about each attribute increased over the five stages for group A (all p 's < .10).⁷ Similarly, confidence increased over the two stages for group B for all belief vectors except bitterness (p 's < .10). However, group A's confidence after five exposures to product information was stronger than group B's confidence after two such exposures, for all attributes except the bitterness vector (p 's < .10). Thus, it would seem that a relatively steady increase in belief clarity, stability, or certainty occurred with successive exposures to information about the belief object. The confidence data, therefore, support the notion that an increasingly well-developed, stable belief structure develops over time as one becomes more knowledgeable or familiar with the relevant object.

Structural Relationships Between Beliefs

Another perspective to belief structure dynamics is provided by the notion that the interrelationships between the beliefs associated with an object/concept develop rather slowly and require time and experience before they become clearly defined and stable. This idea reflects the commonly-accepted tendency toward consistency among cognitive elements, but suggests that consistency may evolve over time with successive experiences which "activate" the belief structure. It seems logically reasonable that a well-formed, internally-consistent belief structure is more strongly related to overall attitude toward the belief object than a less well-developed structure.

Note, however, that the basis for consistency among beliefs has not been specified. Broadly speaking, two types of cognitive consistency have been investigated in past research -- consistency in terms of evaluative reactions and consistency based on perceived logical, meaningful, or semantic linkages between cognitive concepts (a review of this area is provided by Fishbein and Ajzen, 1975, pp. 143-156). For example, we may develop belief structures composed of beliefs that are increasingly similar in evaluative content--e.g., all or most of a consumer's beliefs about this coffee become more positive (or more negative). Alternatively, beliefs may be consistent in a meaningful, semantic sense; for example, one belief connotatively implies another belief. Stated differently, beliefs may be consistently related because they "fit together" on a logical basis--their meanings are consistent with one's previously learned expectations. For example, if one learns that a winter jacket is filled with goose down, one might also logically develop beliefs that the jacket is lightweight, expensive, and casual in style. In this case the consistency within the belief structure would be measured by the probabilistic relationships between belief concepts (belief strength) and not necessarily by increasing evaluative consistency. In summary, one might postulate a "need" or tendency to acquire internally-consistent cognitive structures, the evolution of which could occur over time as a function of processes "driven" by goals of evaluative or semantic consistency, or both.

⁶ Confidence in the 10-point belief strength allocation to the levels along each belief vector was measured on a 5-point scale with bi-polar labels not-at-all confident and very confident.

⁷ Due to the relatively small sample sizes (which decrease the power of statistical tests) and our greater tolerance for Type 1 errors and reluctance to commit Type 2 errors at this early state in our research, an alpha level of .10 was adopted for these analyses.

TABLE 2
MEAN CONFIDENCE IN BELIEF STRENGTH JUDGMENTS
FOR EACH ATTRIBUTE VECTOR

Groups and Experimental Stages	Product Attributes/Belief Vectors				
	Bitterness	Caffeine	Expense	Strength of Flavor	Consistency
Group A (n = 20):					
1. Ad A	3.70	3.35	3.65	3.70	3.45
2. Ad B	3.95	3.70	4.25	4.05	3.50
3. Ad C	4.15	3.75	4.10	4.05	3.80
4. Initial trial	4.40	3.40	3.95	4.35	4.05
5. Extended trial	4.55	3.95	4.10	4.60	4.20
Group B (n = 18):					
1. Initial trial	4.44	2.50	2.55	3.88	2.72
2. Extended trial	4.05	3.05	3.22	3.89	3.55

Evaluative Consistency. The following analyses concentrate on the relative changes in evaluative consistency among the belief elements in cognitive structure. Two indices of the evaluative consistency among the beliefs about the five product attributes were derived from the belief vector scores ($\sum b_{ie_1}$). These scores reflect the overall direction and degree of evaluation associated with each attribute. Estimates of internal consistency among these product attribute evaluation scores are provided by the coefficient alpha (α) index (see Nunnally, 1967, for a thorough discussion) and the average zero-order correlation between the five vector scores. Table 3 presents these two indices of evaluative consistency for both groups over the experimental stages. On both measures, group A evidenced a fairly dramatic increase in evaluative consistency after the second informational exposure, with relatively little increase in evaluative consistency thereafter. The evaluative consistency of belief structure for group B increased to a relatively low level over the two trial experiences.

TABLE 3
EVALUATIVE CONSISTENCY OF BELIEF STRUCTURE, BASED ON
CORRELATIONS BETWEEN BELIEF VECTOR SCORES ($\sum b_{ie_1}$)

Groups and Experimental Stages	Internal Consistency (coeffic. α)	Average Inter-item Correlation
Group A (n = 20):		
1. Ad A	.33	.09
2. Ad B	.57	.21
3. Ad C	.66	.28
4. Initial trial	.62	.25
5. Extended trial	.56	.20
Group B (n = 18):		
1. Initial trial	.03	.01
2. Extended trial	.29	.07

Yet another perspective on the evaluative consistency within a belief structure is provided by examining the relationship of each attribute vector ($\sum b_{ie_1}$) with the independent, direct measure of product attitude. Changes in these relations over time provide additional evidence for dynamic shifts in evaluative consistency within the belief structure. Table 4 presents the correlations between each belief vector evaluation score ($\sum b_{ie_1}$) and the direct rating of overall product attitude (A_0) for group A (recall that "no bitterness" was the product attribute belief most directly manipulated by the experimental treatments). By the study's end for group A, the evaluation associated with bitterness beliefs was the most strongly related to A_0 , $r = .78$ ($r^2 = .61$), followed by that associated with the amount-of-caffeine beliefs, $r = .50$ ($r^2 = .25$), and beliefs about the coffee's strength of flavor, $r = .47$ ($r^2 = .22$). The expensiveness and consistency vectors were only weakly related to overall attitude ($r^2 = .08$). A basically similar pattern of relationships was found for group B.

In sum, changes in evaluative consistency among salient beliefs seem to be somewhat related to the attitude maturation effect. It should be noted, however, that the present study probably attenuated the degree of evaluative consistency because the product information was not consistent over the course of the experiment. However, it does seem reasonable that as one's attitude structure "matures," one tends to acquire beliefs relatively consistent in terms of evaluation. A major problem with this explanation is in identifying sufficient and/or necessary amounts or degrees of evaluative consistency for a strong belief structure-attitude relationship. Threshold effects seem a distinct possibility. Such issues could be relatively easily explored in longitudinal correlational studies with larger samples.

Semantic Consistency. It is of interest to note that the three belief attributes most closely related to overall product attitude also seem closely related in a connotative or semantic sense as well. That is, an experienced coffee drinker might be expected to draw logical inferences about caffeine content and flavor strength after learning about a coffee's level of bitterness. There are probably relatively clear, semantically-based, expected linkages between these three attributes for experienced, knowledgeable consumers. In numerous studies, Wyer (cf. 1974, 1976) has quantified such semantic "connections" by asking subjects to rate the probability of one concept (or attribute level) given knowledge about the likelihood of another concept (or attribute level).

TABLE 4
CORRELATIONS OF BELIEF VECTOR SCORES (Σb_{ie_i}) WITH
DIRECT MEASURE OF OVERALL ATTITUDE (A_0)

Groups and Experimental Stages	Belief/Attribute Vectors				
	Bitterness	Caffeine	Expense	Strength of Flavor	Consis- tency
Group A (n = 20):					
1. Ad A	.26	.00	.45	.00	.26
2. Ad B	.15	.05	.19	.47	.36
3. Ad C	.28	.45	.47	.39	.39
4. Initial trial	.70	.30	.06	.60	.20
5. Extended trial	.69	.50	.29	.47	.29
Group B (n = 18):					
1. Initial trial	.43	.06	-.44	.48	.29
2. Extended trial	.29	.36	.17	.69	.15

Although such data was not collected in the present research, similar types of analyses could be done in consumer product judgments research, in effect yielding predictions of inferential belief formation, based upon conditional probability theory and analyses (see Olson, in press).

Summary. The confidence data (Table 2) and evaluative consistency data (Tables 3 and 4) support the inference that changes occurred within the product belief structure over the experimental stages. It seems logical that such changes in belief structure may cause (or at least partially influence) the increasing predictive validity for the Fishbein/Ahtola attitude model (see Table 1). Thus, the present analyses provide post-hoc support for the notion that the attitude maturation effect is due at least partially to changes occurring within the associated structure of salient beliefs. Clearly, however, before much confidence can be placed in these relationships and interpretations, similar measures and analyses must be included in subsequent research so that these initial findings can be replicated, or not.

Mediators of the Attitude Maturation Effect

To provide additional insight into the dynamics of the belief structure-attitude relationship as a function of multiple exposures to information, a final set of analyses was conducted to investigate possible mediators of such changes. This approach coincides with Chronbach's (1957, especially 1975) contentions that individual difference factors (variable characteristics of research subjects) tend to interact with experimental treatment variables in determining their effect on the dependent variable of interest, and thus should be explicitly examined. Similarly, Underwood (1975) has argued convincingly that researchers should make and test specific predictions of the mediating effects of individual difference variables in order to provide more rigorous tests of the theory of interest.

In anticipation of such use, several characteristics of the consumer subjects were measured in the study reported here (e.g., perceived product risk, coffee purchase volume). Because of their intuitive implications for belief structure dynamics, two of these variables were selected

TABLE 5
MEDIATING EFFECTS OF PRODUCT EGO-INVOLVEMENT AND SELF-CONFIDENCE ON THE ATTITUDE MATURATION
EFFECT AND ON THE INTERNAL EVALUATIVE CONSISTENCY OF BELIEF STRUCTURE

Group A Experimental Stages	Ego-involvement with Product						Product Specific Self-Confidence

* Correlation significantly greater than zero ($p < .05$, one-tailed test)

for presentation in this paper: (a) ego-involvement with the ground coffee product class, and (b) product specific self-confidence in evaluating and choosing alternative brands of ground coffee.

Ego-involvement. Consumers in group A were categorized either "higher" or "lower" in product ego-involvement based upon the relative number of coffee brands they sorted into the acceptable and neutral (noncommitment) regions for possible purchase.⁸ The 10 subjects who placed one-third or less of the familiar brands into the acceptance and noncommitment latitudes (or, alternatively, who rejected two-thirds or more of the brands) were deemed higher in product class involvement than the other 10 subjects.

Table 5 presents the relevant cognitive states and cognitive interrelationships for these "high" and "low" involvement subjects. Of greatest interest are the correlations between belief structure and attitude. Although the "high" and "low" involvement subjects yielded essentially the same belief structure-attitude relationship at the study's conclusion (r 's = .81 and .79, respectively), the more highly involved subjects reached that level of evaluative consistency more slowly. In fact, only after trial did the belief structures of the higher involvement group begin to become strongly related to overall attitude.

The explanation advocated for the lack of consistency between belief structure and attitude is that belief structures which are not well-formed, stable, or internally consistent may not be highly related to overall attitude. General support for this notion may be found by comparing the pattern of attitude model correlations for the "high" and "low" involvement subjects with the respective indices of evaluative consistency (see Table 5). Except for the data for the second stage (ad B), the evaluative consistency of belief structures is relatively low for those subjects with lower attitude-belief structure relationships, and vice versa for subjects with higher model correlations.

Product Specific Self-Confidence. A similar internal analysis was conducted by dividing group A subjects into two categories (n = 10 each) based on their relative self-confidence in making quality judgments of ground coffee.⁹ The product self-confidence variable also mediated dramatic differences in belief structure-attitude relationships (see Table 5). "Higher" confidence consumers had much greater consistency of belief structure and attitude than did subjects lower in confidence (r = .73 versus .25, respectively). However, the "internal evaluative consistency explanation" for this pattern of relationships was supported for only three of the five stages (2, 3 and 5).

Summary

The basic phenomenon of interest in this paper involves the cognitive structure changes termed attitude maturation--namely, the tendency for the salient belief structure associated with a stimulus concept to become in-

⁸This procedure is an adaptation of Sherif's ordered alternatives procedure for establishing involvement with an attitude issue. See Jacoby and Olson (1976) or Olson and Dover (1977) for detailed descriptions of the task and analysis.

⁹Self-confidence was assessed by a simple question which asked subjects to rate on a 5-point bipolar scale the degree to which they were "confident" in their ability to evaluate the quality of alternative brands of ground coffee.

creasingly predictive of the overall attitude towards that concept. Unfortunately, the present research design does not allow analysis of the unique effects of multiple measurement of cognitive structure (measurement and exposure to information were confounded), nor is it possible to completely eliminate the alternative explanation that the effect is caused by increasingly strong halo effects.¹⁰ Rather, this paper focuses on the heuristic and more interesting (to us) idea that cognitive structures, including the interrelationships among cognitive elements, develop and evolve toward evaluative and/or semantic consistency as one accumulates knowledge about the stimulus concept of interest. The illustrative data were generally consistent with this explanation, although there were exceptions. However, these analyses provide no explanations of the processes that cause such changes to occur.

The concluding section identifies three theoretical ideas derived from the cognitive psychology literature that may provide useful perspectives regarding the causal processes underlying cognitive structure dynamics. It is suggested that these theories can be combined to form an initial conceptual framework for explaining changes in cognitive structure, and can generate a number of interesting hypotheses to guide future research.

Evolution of Cognitive Structure

Very little has been written in the basic cognitive psychology literature regarding dynamic changes in cognitive structure. Recently, however, Hayes-Roth (1977) presented a clear theoretical description of the evolution or maturation of cognitive structure from initial formation to a well-formed state. Her theory is essentially consistent with our interpretations above. Briefly, Hayes-Roth stated that an organized cognitive structure begins with the establishment of encoded representations of elementary knowledge (cogits), which become stronger (more stable?) as experience accumulates. Basically this is the concept formation process (see Olson and Mitchell, 1975). As experience increases, these simple representations become cognitively linked to other representations and these associations become stronger. This is analogous to the belief formation process described by Fishbein (1967) and an attitude theorist might operationalize such changes as increases in either belief strength or confidence in belief ratings. Through repeated activations of these cognitions (caused by multiple exposures to the controlling stimulus), configurations of associated representations develop and become stronger. At some point a configuration may become so well-learned that it becomes "unitized," after which the entire cognitive structure may be treated as a single discrete memory representation or cogit (or perhaps a chunk, cf. Miller, 1956; Simon, 1974). Hayes-Roth emphasized that the development process for a cognitive structure proceeds "slowly," requiring repeated "activations" of the evolving structure.

Memory Schemata

The ideas regarding the evolution of highly organized cognitive structures are basically consistent with the heuristic concept of memory schemata (Olson, 1977). Norman and Bobrow (1975; Bobrow and Norman, 1975) based their conceptualization of memory schemata on the idea

¹⁰Note, however, that the two internal analyses yielded data that do not support the explanation of a steadily increasing halo effect. For example, the "high" involvement group produced strong belief structure-attitude relationships only after initial trial. And, the "high" confidence group produced relatively strong model correlations immediately upon the first informational exposure.

that the central goal of cognitive processing is the formation of a meaningful interpretation of the world; therefore, the sensory information available to a person must be encoded and organized relative to and in terms of some coherent framework of previously acquired knowledge (Norman and Bobrow, 1975, p. 119). Schemata are the large number of such structural frameworks of knowledge that a person has learned (developed or evolved) as his/her experiences have accumulated. A schema consists of the knowledge or encoded information about a concept as organized into a meaningful set of structural relationships. Thus, schemata not only contain representations of knowledge, but also "rules" of relationship between cognitive elements and even, for well-developed schemata, evaluation or decision rules for overtly responding to the schema concept. From a memory schemata perspective, conscious perception of a stimulus first involves the activation of the appropriate schema and then the interpretation or encoding of the stimulus "in light of" that schema. Thus, schemata may be considered to provide the framework of basic knowledge regarding a concept within which (and from which) initial encoding of incoming information (from ads or trial) relevant to that concept take place.

A number of interesting ideas and hypotheses regarding the attitude maturation effect can be derived from the schemata concept (see Olson, 1977). For instance, one might postulate that the development of a stable, internally consistent belief structure with a strong relationship to overall attitude is essentially equivalent to the formation of a well-developed schema. Following this reasoning, the belief structure encodes the interrelationships between knowledge concepts related to the attitude object. As the schema "matures," the "rule" for relating the knowledge structure to overall attitude toward the object concept develops and presumably gets stronger and more stable. One would expect a general expectancy-value model (if it is roughly similar to the true "rule") to show increasing correlations over time in such a situation. The present results are consistent with this line of reasoning. As one more example, one might expect consumers who are high in product self-confidence to possess more stable and well-developed schemata for that product. Such consumers, upon learning something about a new brand, should be able to quickly form a stable, well-developed belief structure for that brand, which in turn should be more strongly related to brand attitude. The internal analysis for self-confidence presented in Table 5 produced data consistent with this scenario. The belief structures for "higher" self-confidence consumers were much more strongly related to attitude than were those of the "lower" self-confidence consumers.

Depth or Level of Processing. A final notion from cognitive theory that appears relevant to the attitude maturation issue is "depth of processing." Craik and Lockhart (1974) introduced this concept to account for the common finding that memory performance (typically recall ability) is substantially enhanced when subjects perform cognitive "analyses" or tasks on the incoming stimuli that require their consideration of the meaning of the stimuli (cf. Jenkins, 1973). These results suggest that the encoding processes--that is, the specific cognitive operations carried out during initial processing of incoming information--are critical determinants of later memory performance. In particular, it seems that the degree of conscious attention focused on the meaning or semantic aspects of the stimulus is the critical type of encoding operation for improved memory performance.

Craik and Lockhart's basic notion, later modified somewhat (see Craik and Tulving, 1975), is that certain types or domains of encoding operations exist that can be characterized in terms of "depth," from less semantic to "deeper" levels of semantic processing. "Shallow" processing might concentrate on encoding physical characteris-

tics of the stimulus, while semantic processing would focus on various aspects of the meaning of the stimulus. The encoding operations applied to a stimulus do not necessarily proceed from sensory, shallow levels to deeper, more semantic domains. Rather, encoding processes may be elaborated at a particular level or domain, as indicated by the term "spread of processing."

Several implications for the attitude maturation phenomenon can be derived from the levels-of-processing concept. Perhaps most broadly, it would seem that the development of a well-developed, internally consistent belief structure (or schema) would require relatively "deep" conscious attention to the semantic meaning of incoming product information, over a series of exposures. That is, consumers would have to consciously consider the meaning of product information (e.g., the function of an attribute) and determine for themselves the value of that characteristic. Perhaps in the real world this degree of "semantic involvement" with product information, derived either from advertising or direct experience, is not common, especially at the time of exposure. But, in the present study, this level of conscious processing was essentially "forced" upon the subjects via the process of completing the extensive questionnaire regarding their beliefs, attitudes, and intentions about the product. That is, a subject had to engage in rather "deep" semantic encoding processes in order to answer the detailed belief questions regarding the various product attributes. By this reasoning, one would expect, *ceteris paribus*, that successive exposures to information and forced semantic processing should lead to the development of relatively consistent, stable, mature attitudes and associated belief structures.

Note that this predicted relationship between "depth of processing" and the formation of well-developed belief structures or schemata provides a theoretically-based and more satisfying account of the measurement effect explanation discussed previously. In one sense, the extensive postinformation measurements can be seen as manipulations of relatively deep levels of processing which, over time should create well-developed, stable schemata (belief structures). Future research could test this explanation (a) by including treatment conditions which receive the information of interest in the experiment, but receive no measurement of cognitive structure until the final stage, or (b) by forcing semantic analysis of the product information in ways other than responding to a questionnaire (e.g., tell someone else about the product).

Summary

The theoretical ideas presented here suggest that attitudes and associated belief structures evolve or mature over time as a function of repeated activations involving "deep" processing. The illustrative data cited were generally consistent with this hypothesis. The concept of attitude/cognitive structure maturation is theoretically interesting and, if verified, has clear practical implications for marketing research. For example, one should not be dismayed to find weak correlations for an expectancy-value attitude model applied to a new or unfamiliar product. Second, these ideas suggest that communication research might be focused on developing methods of enhancing cognitive structure "maturity." Finally, the maturation phenomenon is highly relevant to major marketing issues such as repetition effects of advertising (Mitchell and Olson, 1977) and the development of brand loyalty (Jacoby and Olson, 1976), among many others.

Many problems, of course, remain to be solved. Foremost among these are the clear conceptualization and development of valid measures of structure "stability/consistency/maturity." This paper presents several measure candidates, but future work must carefully examine the con-

vergent and divergent validities of these measures in a variety of situations. In contrast to the empirical problems, theoretical accounts of the maturation phenomenon are more easily provided. Several concepts from the cognitive theory seem useful in explaining these dynamic phenomena and in formulating future research questions. These include the Hayes-Roth (1977) theory of evolving cognitive structures, the Norman and Bobrow (1975) concept of memory as composed of numerous structural frameworks of organized knowledge called schemata, and Craik and Lockhart's (1972) notions of various types of encoding operations and their effects on information storage and memory.

As mentioned at the outset, our major goal was to stimulate interest in issues regarding changes in cognitive structure over time and as a function of specific informational manipulations. We hope this paper is an additional stimulus to the emerging interest among consumer researchers in cognitive structure dynamics.

CARRYOVER EFFECTS OF CORRECTIVE ADVERTISING

Alan G. Sawyer, The Ohio State University
Richard J. Semenik, University of Utah

Abstract

A laboratory experiment tested based on communication theory and empirical research, about the delayed or carryover effects of corrective advertising. The results of the tested corrective advertisements present evidence that one exposure of a corrective advertisement may not influence brand beliefs as would be hoped by public policy makers. Problems with the employed longitudinal design are discussed and suggestions for future research are offered.

Introduction

The effects of corrective advertising have been examined in several published laboratory experiments by consumer researchers. The general conclusion that may be gained from this literature is that one exposure of a corrective advertisement can, under certain circumstances, have the desired negative effect on target beliefs and attitudes. This paper examines the persistence of effects of corrective advertising over time. The thesis of this paper is that any obtained immediate effects of a corrective ad are likely to rapidly dissipate over time. The experiment described in this paper tests this proposition by including measures delayed up to eight weeks after the exposure of a corrective ad. In addition, it includes several factors which provide a communication situation for the tested corrective advertising more externally valid than some past research in this area.

After first discussing the theoretical and empirical rationale for the predictions about the carryover effects of corrective advertising, this paper will review four past experiments about corrective advertising. Following that review, the methodology of this experiment will be described and contrasted with the methodology of the previous research in this area. Although the described results fail to support the predictions about the immediate and delayed effects of corrective advertising, it is hoped that this paper will encourage other researchers to examine delayed as well as immediate effects of advertisements and other marketing communications.

Hypothesized Decay of Corrective Advertising Effects¹

Figure 1 shows the hypothesized results of an experiment which measures beliefs toward an established product both immediately before and after exposure to a corrective advertisement for the product and also several weeks after exposure. Although the effects of the corrective ad (point 2) might immediately neutralize or even reverse the previous cumulative effects of the deceptive advertising campaign (point 1), the belief based on deceptive prior information would reassert itself with time (point 3). Although no previous corrective advertising research has examined carryover effects, several other areas of research about the effects of attitudes over time lend strength to the above prediction. Especially relevant are two areas of investigation of carryover effects: 1) the general nature of attitude decay and 2) the relative

¹Space prevents a full discussion of the literature discussed in this section. For more details, see Sawyer (1976) and Sawyer and Ward (1976).

persistence effects of discounted or qualified messages.

Attitude Decay

If, as some researchers believe (e.g., Miller and Campbell, 1959), decay of attitude change resembles the negatively accelerated forgetting curve, a prediction of Jost's Second Law of Learning (Jost, 1897) is very relevant to the corrective advertising situation. Figure 2A illustrates the prediction that, for two stimuli equal in strength but of different age at a given point in time (t_1), the effect of the older of the two will decay less rapidly - reaching some asymptotic level higher than that of the newer campaign. Figure 2B shows the same curves as in Figure 2A except that curve D shows the hypothesized "positive decay" of any negative effects of corrective advertising. A major assumption in Figure 2B is that, whereas a brand belief rated highly probable will decay over time "down" toward some neutral point or mean probability for all competing brands; a belief rated highly improbable will decay "up" towards the same point of neutrality or mean probability for all brands. A copy test may misleadingly indicate at time t_1 that a corrective ad (C) is effective at reversing the effects of a deceptive campaign (D). Over time, however, the effects of the much newer and less often exposed corrective ad is likely to decay more rapidly and result in a belief much more positive than the immediate effect.

Discounted Messages

The "discounting cue hypothesis" theorizes that, if there is some aspect of a message that causes the message to be initially discounted or resisted, the passage of time may lead to a dissociation of the inhibiting cue from the original message so that the potential attitude change impact of the persuasive content may gradually take effect (see Gruder, et al., 1974). The combined impact of a positive (deceptive) message followed by a negative (corrective) message can be viewed as a discounted cue situation where the corrective ad discounts the previous positive advertising claim(s). The results of each of the three discounting cue experiments, which examined the delayed effects of messages highly analogous to corrective advertisements, are consistent with the prediction graphed in Figure 1.

FIGURE 1
HYPOTHESIZED IMMEDIATE AND DELAYED
EFFECTS OF CORRECTIVE ADVERTISING

Weiss (1953) presented four exposures of a list of eight statements about the effects of smoking on health. Each statement was followed by the words "true" or "false" (e.g., "Studies have shown that smoking is an important factor in producing cancer of the lungs and throat. True"). Immediately after these four learning trials which were designed to produce anti-smoking beliefs, subjects in the discounted message group were also presented with a brief countercommunication in which they were told that more recent smoking experiments conclusively contradicted the findings of the research studies on which the statements were based and that they should be very skeptical about the truth of the original statements. Belief was then measured either immediately, three weeks, or six weeks after the messages.

FIGURE 2A
RELATIVE EFFECTS OF OLDER, MORE REPEATED
ADVERTISEMENT (A) COMPARED TO NEWER COMPETITOR AD
(B) WITH NEGATIVELY ACCELERATED ATTITUDE DECAY

FIGURE 2B
RELATIVE EFFECT OF DECEPTIVE ADVERTISING CAMPAIGN
(D) AND NEW CORRECTIVE AD (C) WITH NEGATIVELY
ACCELERATED ATTITUDE DECAY

Figure 3 shows the effects of the discounted message condition which is directly analogous to a situation of a repeatedly exposed, deceptive advertising campaign advocating that smoking is unhealthy followed by a corrective advertisement to the contrary viewpoint. As would be desired by public policy makers, the discounted message produced initially lower beliefs about the unhealthy effects of smoking than the non-discounted message. After six weeks, however, the relative effectiveness of the discounted (corrective) message condition was

reversed from the immediate situation and produced significantly higher beliefs that smoking was unhealthy than the non-discounted condition. Ironically, the condition directly analogous to corrective advertising was even less effective in maintaining "correct" beliefs than the "uncorrected" messages when the effects were measured over time.

FIGURE 3
THE EFFECTS OF DISCOUNTED AND NON
DISCOUNTED MESSAGES ON BELIEFS
(from Weiss (1953))

A recent experiment by Gruder, *et al.* (1974) found not only significantly less negative attitude decay in the discounted condition compared to a non-discounted message but also found a significant positive slope of attitude over time for the discounted message. Subjects were exposed to two exposures of either one of two messages - one arguing against a new law allowing right turns on red lights and the other arguing that a four-day work week decreases worker satisfaction. The discounted message condition also included a following message that cautioned the subject that, since the selection of the previous message for the experiment, it had been learned that the message's arguments were not true and had positively been refuted as "inaccurate and, frankly, wrong." Attitude change was measured both immediately and five weeks after the messages.

Not only were the slopes different as predicted, but the attitudes produced by the discounted (corrective) messages actually became more positive over the five week period. Although this increased attitude did not exceed the attitude produced by the message only condition, the large differences in slopes add further support to the prediction that a corrective ad is likely to be ineffective in producing enduring negative effects to eradicate the residual attitude based on deceptive information.

In the corrective advertising used in the Profile and Ocean Spray cases, the employed format was essentially that of a qualified argument where the messages were positive in overall nature but contained corrections of misimpressions that might have been formed by past advertisements. Bartlett (1932) predicted that, for a message arguing for one side of an issue but also presenting some qualifications and reservations against the main arguments, the qualifying details would be forgotten more quickly than the main conclusion. Because of this

difference in forgetting, the qualified message would show a delayed action effect on beliefs with more change after a passage of time than immediately following the message.

Papageorgis (1963) tested Bartlett's hypothesis about the relative persistence of belief change of qualified and unqualified messages. Two messages low in ego involvement--one advocating that life expectancy was longer in cities than in rural areas, and the other arguing that there had been few technological advances in oil deposit location practices--were presented. A subject received the unqualified message for one topic and the qualified version for the other. The qualified message conditions contained the same arguments but stated much more equivocally with many reservations about the validity and generality of the contained arguments. Content recall and beliefs were measured immediately, two days, fourteen days, and forty-one days after the message.

The recall results were nearly exactly as predicted. For the qualified messages, recall of the main conclusions barely declined over forty-one days whereas there was substantial decay in the recall of the qualifications. As predicted, the decay in belief produced by the qualified messages was less than that of the unqualified messages. Although this difference averaged across both message topics was not statistically significant, the predicted relative advantage for delayed belief for the qualified message was statistically significant for the life expectancy issue. In other words, the qualified messages, which were quite similar in format to corrective advertisements, produced beliefs that, although initially lower as would be hoped by public policy makers, tended over time to revert toward the position held by subjects who viewed only unqualified messages.

Immediate Effects of Corrective Advertising

Four laboratory experiments on the attitudinal effects of corrective advertising have all indicated that the effects of deceptive ads tended to be at least partially neutralized by one corrective ad. Hunt (1973) found that a print form of a corrective ad about allegedly false claims by Standard Oil of California produced a more negative attitude about Chevron than a group which viewed only the deceptive ad. Similar negative effects of a corrective ad resulted whether the copy was a detailed, research-based refutation of the truthfulness of the original claims or a general statement that the original ad was false and deceptive, and whether the source of the ad was Standard Oil, a government agency, or an independent consumer organization. The explicit, detailed corrective ad appeared to be especially effective.

Kassargian, Carlson, and Rosin (1975) examined the effects on product image of a corrective print ad for a motorcycle safety helmet. This corrective advertisement, which was sponsored by a retailer, was effective in reversing the positive effects of the original deceptive ad on several general dimensions of product image. However, the negative effects of corrective advertising did not generalize to the retailer.

Dyer and Kuehl (1974) reported slightly more equivocal results of fictitious corrective advertisements for nationally advertised products. One corrective ad was a print ad about a diet soft drink and the other was a radio ad about a suntan lotion. Only when the F.T.C. was indicated as the source of the corrective message was the corrective ad for the suntan lotion effective in decreasing intentions to buy the product. When the source was the manufacturer of the product, the suntan lotion corrective ad was ineffective. Neither source was effective in decreasing purchase intention in the

radio corrective ad for a diet soft drink.

Mazis and Adkinson (1976) tested four advertising conditions for a well-known mouthwash brand currently negotiating with the F.T.C. about a corrective advertising order. Two corrective ads stressed that the brand was ineffective at preventing colds or sore throats but helped to kill germs. In addition, one of the corrective ads mentioned that the admission about the cold prevention ineffectiveness had been required by the F.T.C. One positive, non-corrective ad stressed the germ-killing effectiveness, and the other positive-only ad emphasized only the breath freshening qualities without making any germicidal claims. The results showed that aided recall of the corrective ads was higher than of the non-corrective ads. Analysis of variance, controlled for brand usage, found that the target belief about the probability that the brand was effective at preventing colds or sore throats was significantly lower after exposure to the corrective ads. A similar decrease was found for the non-target belief about germ-killing effectiveness. Not only was the target belief strength lowered, but the evaluation of the goodness of that product attribute was also lowered by corrective advertising. No effect of corrective advertising on overall attitude toward the brand was found.

Methodology

Table 1 classifies the four past research studies according to several important methodological dimensions. These areas include the research method, advertised brand, corrective advertising conditions, and measurement details. In addition to including the time factor, this experiment differed from the previous ones in several important respects.

Advertised Brand

The product which was the focus of the corrective advertising in this study was Listerine mouthwash, which is currently under negotiation for corrective advertising with the F.T.C. This product met several important criteria presented by Sawyer (1977). First, the product was a real brand familiar to the subject population. Although research using fictitious or unknown brands as stimuli is "clean", it is also irrelevant to the problem of whether and how corrective advertising can accomplish its goal of erasing the residual of a deceptive campaign. It is highly unlikely to have a strong residual belief about a fictitious or unfamiliar brand. Thus, it is not surprising that, in the studies which showed merely one exposure of a "deceptive" ad to subjects who had never seen that ad before, one exposure of the "corrective" ad was able to negate its effects (Hunt, 1973; Kassargian *et al.*, 1975).² Such a design can be viewed as a primacy-recency experiment which is not appropriate to the research question of whether corrective advertising can overcome and reverse the residual of a familiar, highly repeated deceptive campaign. In the study reported here, the use of a well-established ad campaign as the "deceptive" advertising permitted a natural experimental design (Campbell, 1969) in which the deception was already established or, at least, easily reestablished with a reminder exposure of the deceptive advertisement. Also, the fact that subjects may have been previously exposed to the publicity of the court case involving the mouthwash product and the F.T.C. added to the external validity of the research.

²The Chevron F-310 ad in Hunt (1973) was not familiar to the Iowa college student subjects in Hunt (1973). The motorcycle helmet ad which was sponsored by a New York City retailer had not been exposed to the Maryland residents who were subjects in the Kassargian, *et al.* (1975) study.

TABLE 1

Summary of Past Research on Corrective Advertising

	Research Method	Advertised Brand	Brand advertised and sold in local area?	Corrective Advertising Copy Conditions	Advertising Medium	Subjects	Beliefs on Deceptive Dimension Measured?	Measurement over time?	Other Independent Variables	Major Results
Hunt (1973)	Lab	Chevron F-310 gasoline	No	1) explicit--point-by-point corrections of deceptive claims 2) general--statement that past ads were "misleading, deceptive, and untrue" 3) control	Print	College students	No (affect toward brand)	No	Type of inoculation by advertiser in deceptive ad (supportive, refutational, none)	Corrective ads led to significant negative effect; explicit ad most effective--especially with refutational inoculation defense
Dyer and Kuehl (1974)	Lab	Diet soft drink; Suntan lotion	Yes	1) high strength explicit corrective language and disclosure of past deceptive advertising 2) low strength explicit corrective language but vague reference to "past misleading impressions" 3) control	Radio; Print	College students	No (aided brand recall; other brand beliefs; purchase intention; perceptions of both advertisement and company image)	No	Source of corrective ad (F.T.C.; offending company)	Purchase intention decreased by corrective ad only in high strength message; F.T.C. source condition led to less trustworthy corporate image
Kassarjian, Carlson, and Rosin (1975)	Lab	Motorcycle safety helmet	No	1) weak corrective ad sponsored by retailer admitting lack of accredited research substantiation 2) control	Newspaper	College students	No (ad recall; 15 general beliefs about both brand and retailer)	No	Ad exposure; natural (ad unobtrusively placed in five page newspaper) and forced (focused attention)	Corrective ad led to more negative image profile of brand but not of retailer; profiles did not differ between ad exposure conditions
Mazis and Adkinson (1976)	Lab	Mouthwash	Yes	1) corrective copy about cold prevention capability plus positive germ-killing appeal (F.T.C. source) 2) same corrective copy as condition 1 (company source) 3) non-corrective copy--only positive germ-killing appeal 4) non-corrective copy--only positive, non-germ killing appeal	Radio	College students	Yes (also evaluation of goodness of rated product dimensions; overall brand attitudes; brand usage; ad recall)	No	Control for whether subjects used test brand	Corrective ads decreased target belief about "cold prevention" capability and also belief about germ-killing capacity; evaluation of cold prevention also lower for corrective ads; no effect of ad source or brand usage on beliefs
This study	Lab	Listerine Mouthwash	Yes	1) non-corrective, positive only 2) negative only 3) two-sided, positive first 4) two-sided, negative first	T.V.	Adults	Yes (also importance of each of eight belief dimensions)	Yes	whether one exposure of deceptive ad was exposed prior to corrective ad	

Second, the brand advertised an explicit claim which was believed by the general population. Such believability was ascertained by a pretest--using belief measures described below. Listerine was rated as significantly ($p < .05$) more probable than Scope, Lavioris, or Cepacol to possess the attributes of "prevents colds", "relieves nasal congestion", and "reduces colds severity"; more likely than Scope or Lavioris to "kill germs"; and less probable than the other competitors to "have appealing taste."

Finally, the advertising claim refuted in the corrective advertising was not telecast after the initial laboratory exposure to the corrective advertising. After early May of 1976 when this experiment was begun, Listerine did not use its campaign which stressed the (allegedly false and deceptive) claim of preventing colds and reducing the severity of their side effects. The former campaign was replaced by a new campaign which stressed an appeal based on germ killing and breath freshening effectiveness.

Ad Copy and Medium

Five 30-second TV commercials comprised the treatment stimuli. These ads, including one deceptive message, three versions of a corrective message, and one non-deceptive positive message, featured a professional actress and were filmed in color by the Photography and Cinema Department of Ohio State University. The advertisements were buried within a half-hour video tape of a television program. The copy for the advertisements employed the recommended corrective copy offered by the Federal Trade Commission for the brand (FTC vs. Warner-Lambert, 1974, p. 102), as well as copy devised by the researchers. It should be noted that the advertisements were of such quality that none of the subjects doubted the authenticity of the advertisements.

Subjects

Unlike past studies, subjects were not confined to a

college student population. Of the 142 total subjects (122 experimental and 20 control), 50 were obtained from random mail solicitation and 113 subjects from a commercial marketing research firm. To give a general profile of the laboratory subjects, the average age of the participants was 43.1 years and they had an average household income of between \$12,500 and \$15,000. The sample included 29% males and 71% females; 32.7% of the subjects had college degrees; and only 15.6% were currently students.

Communication Measures

There have been two major problems with the cited past research on corrective advertising. It has, in our opinion, sometimes employed improper measures of effectiveness, and, as mentioned previously, it has measured only the immediate effectiveness.

If the FTC's goal for corrective advertising is to eliminate the residual of deception, then that residual must be defined. Advertising can attempt to achieve several communication goals including awareness, beliefs, attitudes, and intended or actual behavior. Concerning attitudes, an advertiser can try to influence either consumers' beliefs about some attribute(s) of its brand or competing brands or the evaluation consumers place on various attributes of brands in the product class in question. (Boyd, et al., 1972). It is very important to distinguish among a belief about how a particular brand rates on a particular attribute or dimension, an evaluation of that attribute, and a general affective attitude toward that brand (see Fishbein and Ajzen, 1975).

If an advertiser makes a deceptive claim about a particular attribute, the most direct effect would be to change consumers' beliefs about that attribute (e.g., Lutz, 1977). Of course, the ad may also have secondary effects on other beliefs or, through the changed beliefs, affect attitudes, purchase intention, or behavior. However, in the opinion of the authors, the prime criterion of impact of the deceptive claim is the change in the belief about that dimension and not anything else (see also Olson and Dover, 1978, Wilkie and Gardner, 1974). If belief is the prime residual of deceptive advertising, corrective advertising must focus on the particular dimension in question and change that belief to coincide with the ascertained facts.

In this study, informal interviews and pretests prompted the use of eight attribute dimensions of the mouthwash product category. Thus, the questionnaire measured eight beliefs about the advertised brand as well as three other competing brands and the perceived importance of those attributes. Most critical to the goals of this experiment, these measures were taken not only immediately following exposure of the corrective advertising but also two, four and eight weeks later.

Experimental Procedure and Design

Upon arrival at the laboratory, all participants were informed they would be participating in a study regarding advertising and general social issues and were asked to complete a questionnaire concerning attitudes toward advertising in general, attitudes toward government regulatory activities, product usage, and demographics.

The practice of some past experiments (e.g., Hunt, 1973, Kassarjian, et al., 1975) which included one exposure of the deceptive ad shortly prior to the exposure of the corrective ad seems low on external validity when, in an actual campaign, these ads would be widely separated. On the other hand, inclusion of an exposure of the deceptive ad might be necessary to trigger the deceptively-based belief. In order to test the impact of this factor, exposure to a deceptive ad closely preceding exposure to a corrective ad was experimentally manipulated. Half the

experimental participants were exposed to a deceptive advertisement, which argued that the product was effective in reducing colds and sore throats; the other half viewed an ad for an entirely different product. Following this exposure, half of each of these experimental groups was given a questionnaire assessing attitudes toward the firm, attitudes toward several mouthwash brands, and product performance beliefs. The other half was given a "bogus" questionnaire measuring attitudes toward social issues. This procedure was followed to determine whether any learning effects were present for subjects using the same rating scales both before and after the corrective messages. (Subsequent analysis (Semenik, 1976) revealed no effects of this pretest, so all subjects were combined into one analysis).

During the next phase of the procedure, all subjects were informed that they were to view a program aired on network television concerning the solid waste disposal problem. On a video tape monitor and playback unit, subjects watched a seventeen minute program on this topic with the appropriate treatment stimuli contained as part of the program.

Depending upon the treatment group to which they had been randomly assigned, experimental participants viewed one of the four corrective advertisements contained in the program (see Semenik (1976) for the exact copy of each): Corrective Version 1: One-sided positive appeal only. Since only favorable product attributes were communicated (deleting the deception in the previous advertising for the firm), this was not a corrective ad. This ad emphasized the breath freshening qualities. This version represents a possible outcome of a "cease-and-desist" order issued by the FTC. Corrective Version 2: One-sided negative only. This ad explicitly stated that the product was not effective at reducing colds and sore throats. A firm might be required to run such an advertisement in which only the previous deception is explained and the firm is not able to present favorable product attributes. Corrective Version 3: Two-sided, positive first. This communication related positive product attributes first and then revealed the deception of previous advertising. Corrective Version 4: Two-sided, negative first. The firm first presented unfavorable information (disclosure of deception) and then presented positive product attributes.

Following exposure to one of the four corrective advertisements, subjects rated, as a diversion from the true purpose of the experiment, several open ended questions about the effectiveness of the television program. Subjects were then asked to complete another questionnaire regarding attitudes toward the brand, attitudes toward the firm, and product performance beliefs. Upon completion, they were each paid \$2.00 and were told that they might be contacted again as part of their paid participation.

The experimental design was a 2 x 3 x 2 x 4 mixed, factorial design with order of measurement (immediately after ad exposure or delayed) as a within-subjects factor and length of delay (two, four, or eight weeks), prior exposure to original deceptive commercial or not, and corrective ad copy (positive-only; negative-only; two-sided, positive side first; and two-sided, negative side first) as between-subjects factors. Whereas all subjects were measured immediately, subjects in each ad copy-exposure condition were randomly assigned to one of the three delay conditions. Either two, four, or eight weeks later, they received a mail questionnaire which, after reminding them of their earlier participation, asked them to answer a "few last questions." These questions included belief and importance ratings identical to the previous immediate-past measures. Return rates were remarkably (and quite uniformly) high over the three delay conditions with 90.9%, 89.5% and 81.3%, respectively.

In addition to the experimental groups, another group (n=20) acted as an immediate post-measure control group. This latter group saw the same television show and filled out the same questionnaire but did not see any experimental ads. Regretably, a clerical error caused an omission of delayed questionnaires sent to the control group. Table 2 presents the experimental design and sample sizes.

TABLE 2
Experimental Design and Cell Sample Size

Also Exposed to Deceptive Ad				
Corrective Ad Copy Condition	Positive Only	Negative Only	Two-sided Positive First	Two-sided Negative First
Order of Measurement	Imm/Delay	Imm/Delay	Imm/Delay	Imm/Delay
Delay Condition:				
Two Weeks	5	5	6	5
Four Weeks	4	4	6	4
Eight Weeks	6	3	5	4
Not Also Exposed to Deceptive Ad				
Corrective Ad Copy Condition	Positive Only	Negative Only	Two-sided Positive First	Two-sided Negative First
Order of Measurement	Imm/Delay	Imm/Delay	Imm/Delay	Imm/Delay
Delay Condition:				
Two Weeks	4	6	6	3
Four Weeks	7	7	3	4
Eight Weeks	8	7	5	5

Results

Two experimental hypotheses were tested in an analysis of variance.³

H1: The corrective ads would have an immediate negative effect on brand beliefs about the prevention/reduction of colds and sore throats. However, this immediate effect would dissipate over the eight week test period in a manner graphed in Figure 1.

H2: The positive-only copy (non-corrective) condition would have an immediate positive effect on brand beliefs. This immediate effect would decrease over the eight week post period (in a fashion directly opposite to the corrective ads).

To support the first hypothesis of initial lowering of beliefs by the corrective ads and a gradual increase over the eight week period, the order of measurement by length of delay interaction term of the ANOVA should have been statistically significant for attributes relating to colds and cold symptoms prevention. A significant main effect of length of delay by itself would not be a sufficient test of hypothesis one since differences among subjects were expected only when measured after a delayed period. There was no reason to expect differences among these groups when they were each measured immediately after exposure to the corrective ad. The second hypothesis concerning the positive (non-corrective) ad would be supported by a significant main effect of the ad term and a significant three-way interaction of ad and length of delay with order of measurement. The ad copy main effect term would test whether the positive and negative (corrective) ads had, as hypothesized, opposite effects, and the third-order interaction term would test whether these opposite effects had opposite decay effects over time.

Table 3 presents the results of the ANOVA for the sixteen measures. In addition, the analysis of the sum of the products of the importance and beliefs of each of the eight dimensions is shown. For convenience of presenta-

³For the description and results of several hypotheses about the immediate effects of the three corrective advertisements, see Semenik (1976).

tion, only the statistical significance levels of .10 or lower are reported. Two separate ANOVA are reported; the first figure in each column is the results of an ANOVA with four levels of ad copy, and the second figure (in parentheses) is the results of a second ANOVA in which only two levels of ad copy are considered - corrective (negative only or two-sided) and non-corrective (positive-only).

A look at the results reveals several interesting findings not directly salient to the research hypotheses. First, the second ANOVA with ad copy collapsed into two levels seems more statistically powerful. This is probably due to the fact that the ad copy factor in both ANOVAs had very little effect and there was a smaller error term in the second analysis. Second, it seems that being exposed to the deceptive ad shortly before one of the four versions of the test Listerine ad consistently had an effect on both the importance and belief perception on the various attributes (see the column entitled "Exposure" in the table). A check of cell means revealed that the effect of such exposure was always to decrease importance or to decrease the perceived probability that the brand possessed the attribute in question. It appeared that this condition artificially increased the impact of the subsequent corrective ad. Perhaps the first ad sensitized subjects to pay more attention to the later exposure.

As stated earlier, the ANOVA term relevant to the hypotheses about the carryover effects of the corrective ad was the length of delay by order of measurement interaction. Table 3 shows that there was no support for this hypothesis; in no instance was this interaction term statistically significant at the .05 level. The main effect of time was significant for several attributes. However, the absence of a significant interaction term testifies to the fact that, in no case, was the predicted increase in importance or belief probability significantly greater in the delayed conditions (where the increases were predicted) than in the immediate conditions (where there was no reason to expect differences among groups who differed only in that, subsequently, they were to be measured after different delays). For most attributes, there were equal increases for those in the immediate measure condition and those in the delayed condition.

The only result that resembled the hypothesized effects was the importance of "long lasting" which was not explicitly addressed in any of the rested Listerine ads. The time of delay by measurement order interacting term was nearly significant in the first ANOVA ($F = 2.88, 2$ and 98 df, $p = .07$). Table 4 presents the cell means which show no changes in ratings in the immediate conditions and an increase in the delayed conditions. This was the result that was predicted and not found for beliefs relating to the prevention of colds and cold symptoms addressed in the corrective advertising copy. As an example typical of most of the other ratings, Table 5 presents the mean ratings of the target belief "prevents colds/sore throats". It can be seen that an overall increase was found ($F=3.17, 2$ and 110 df, $p=.05$) but very little difference was found between the three immediately measured groups and these same three groups measured, respectively, two, four and eight weeks later.

Given the lack of overall support for the predictions about the decay of beliefs, the question arises as to whether the ads had any effect at all. As previously noted, the ad copy variable showed no significant effects. To test the immediate effects of the ad copy, the positive only (non-corrective) and negative only (corrective) copy appeals were compared to the immediate control group with Dunnett's Comparison test (see Kirk, 1968). These two conditions were chosen because of the conceptual non-ambiguity of the direction of their likely effects.

Table 3

SUMMARY OF ANALYSES OF VARIANCE OF IMPORTANCE OF EIGHT DIMENSIONS AND LISTERINE BELIEFS ON THOSE DIMENSIONS

	Measurement Order	Length of Delay	Exposure to Positive Ad	Ad Copy	Order By Delay
Evaluation of:	df: (1,98)/(1,110) ^a	(2,98)/(2,110)	(1,98)/(1,110)	(3,98)/(1,110)	(2,98)/(2,110)
Appealing taste				(.09)	
Kill germs		(.02)			
Long lasting					.67
Prevents colds/sore throats		.01 (.01)			
Relieves nasal congestion		.07			
Reduce severity of cold/sore throat		.02 (.01)	(.05)		
Reduces coughs/sneezing		.09 (.07)			
Prevents bad breath		(.04)	.05 (.17)		
Beliefs about Listerine:					
Appealing taste	.01 (.01)				
Kills germs		(.04)			
Long lasting			.01 (.01)	.05 (.09)	
Prevents colds/sore throats	.03	(.05)	.05 (.01)		
Relieves nasal congestion			.01 (.01)		
Reduce severity of cold/sore throat	.04		.01 (.01)		
Reduces coughs/sneezing			(.05)		
Prevents bad breath			.05		
$\sum_{i=1}^8 I_i B_i$.01 (.01)	(.04)		

^aIn each main column, the first significant sum and degrees of freedom are for the ANOVA with four levels of the ad copy factor and the second column details the ANOVA with only two levels of the ad factor.

Table 4

MEAN IMPORTANCE OF "LONG LASTING" AS A FUNCTION OF ORDER AND TIME OF DELAY OF MEASUREMENT^a

Group	Order	
	Immediate Post	Delayed Post
Two Weeks Delay	1.91 ^b	2.59
Four Weeks Delay	1.98	1.96
Eight Weeks Delay	1.65	1.35
Immediate Control	1.15	

^aThe lower the number, the more important.

^bFor all three groups, the immediate post measurement followed exposure to the ad. The delayed post followed by the number of weeks indicated in the group label.

Table 5

MEAN RATINGS OF "PREVENTS COLDS/SORE THROATS" AS A FUNCTION OF ORDER AND TIME OF DELAY OF MEASUREMENT^a

Group	Order	
	Immediate Post	Delayed Post
Two Weeks Delay	4.94	4.84
Four Weeks Delay	4.65	4.64
Eight Weeks Delay	4.13	3.86
Immediate Control	4.35	

^aThe lower the number, the higher the rating.

Table 6 shows only a limited number of immediate effects. There was little difference between the positive and negative copy. The main area of immediate impact was the effect of the negative, corrective ad on the importance of four attributes - "appealing taste" and "long lasting" (decrease) and "relieves nasal congestion" and "reduces coughing/sneezing" (increase). Because, as noted earlier, control groups were unfortunately not remeasured in the delayed conditions, Table 6 presents comparisons of de-

layed measures with the immediate control group. Although the validity of these comparisons is tenuous at best, it is interesting to note that, in comparison to the immediate control group, both the importance and Listerine belief on the dimension of "prevents colds/sore throats" went from significantly negative two weeks after the negative copy (corrective ad) exposure to significantly positive at eight weeks. A similar reversal can be noted for the importance of "reduces severity of colds/sore throat" and "prevents bad breath".

Summary and Discussion

The goals of this experiment were to test, for the first time, the carryover effects of corrective advertising and to add to the external validity of past research about corrective advertising. Unfortunately, the results are accompanied by more questions than answers. Although the tested television commercials were explicitly worded, they showed little immediate effects on target beliefs. This non-effect contrasts with the effects found by others including Mazis and Akdinson (1976) with the same advertised mouthwash product. Moreover, no differences between corrective and non-corrective (positive only) ads were found. Finally, no support for the hypotheses about the carryover effects of the corrective ads was found.

Of course, the limited immediate effects made the tests of delayed effects somewhat moot. The hypotheses of rapidly decaying immediate effects assumed that the ads would, as in past research, have the desired initial impact. It might be concluded that the changes adding to external validity in this study also served to limit the effectiveness of the corrective advertisements. Some of the cited past research which resulted in immediate effects of corrective advertising did not focus on a product with familiar claims as the target of the corrective advertising, and thus made it easier for the corrective advertising to be effective. However, the Mazis and Akdinson (1976) experiment, which used the same product, similar beliefs measures, and somewhat similar advertising copy (although a different medium) as this study, did find significant immediate effects on beliefs. Thus, a

Table 6

RESULTS OF BULWELT'S COMPARISON OF POSITIVE AND NEGATIVE AD COPY WITH CONTROL GROUP

Importance of:	Positive vs. Control				Negative vs. Control			
	Imm.	2w	4w	8w	Imm.	2w	4w	8w
Appealing taste					-a	-b		-b
Kills germs		-b	-b			-b	-b

Prevents bad breath		-b						

a = p < .10

b = p < .05

conclusion that a "stiffer test" of corrective advertising in this study limited the effects of corrective advertising does not seem to be a valid excuse for the non-effects in this experiment.

Although it is conceptually appealing that the proper measures of corrective advertising be belief specific, the few observed effects of the tested corrective ads on rated beliefs and importances were neither intuitively nor theoretically sensible. It seemed that the major impact of the negative corrective copy was to affect importances and not the target ratings. Although the idea that consumers' importances are altered by corrective advertising is not surprising (see Mazis and Adkinson, 1976) it is odd that such effects would be in lieu of effects on beliefs.

If the target beliefs about cold prevention had been immediately lowered as hypothesized, then it would seem that the importance of those beliefs would also decrease since that attribute would be perceived as less of a discriminator among competing brands. Instead, the observed results in Table 6 showed an increase in the importance of the cold and cold symptoms prevention beliefs ("relieves nasal congestion" and "reduces coughing/sneezing") and a decreased importance of (what, conceptually, should be more important) other beliefs ("appealing taste" and "long lasting").

The fact that parallel differences were found in both the immediate and delayed measures is simply baffling. A demand artifact explanation makes no sense since subjects were randomly assigned to a delay condition after they had been immediately measured.

The fairly consistent patterns over two, four and eight weeks suggest the strong possibility that some uncontrolled external force influenced subjects' ratings. It may be that what was thought to be a major strength of the research design - the use of a naturally occurring advertising campaign - proved to be a major problem. Although the mouthwash product did not use the (allegedly deceptive) "colds" campaign during May and June of 1976 when the data were collected, other positive advertising for the product was being telecast. Perhaps this con-

tinued advertising increased all ratings over the period of time in question. If so, the observed increases may not represent, as originally hypothesized, a reversion to former beliefs, but may rather represent the positive effects of Listerine's spring advertising campaign. Alternative speculation would suggest a "ceiling effect" to explain the lack of immediate effects. It could be that the FTC publicity and other available information about the Listerine case in combination with the fact that Listerine had recently ceased its "colds campaign" had already, to some degree, lowered the target beliefs of the corrective advertising. If so, merely one exposure of the corrective ads could not be expected to further decrease beliefs very much. Perhaps the observed increase over time was a decay of the effects of the negative publicity surrounding the case and not, as originally hypothesized, the single corrective ad exposure. Of course, the regrettable lack of delayed control groups becomes a crucial void because of the corresponding lack of ability to answer questions about the effects of any brand advertising during the experimental period. It is also possible that the slightly lower return rate at eight weeks delay represented a lower number of negatively oriented subjects.

The authors plan to re-examine the persistence of effects of corrective advertising. Planned improvements include a strengthening of the power of the experimental design by focusing on the negative-only corrective copy condition with no reminder exposure of the deceptive ad and having a greater sample size per cell. Also, repetition of the corrective ad will be experimentally manipulated to (hopefully) increase its initial impact. Inclusion of proper control groups for the delayed measure conditions (which were planned but not implemented in this experiment) should allow a separation of immediate and delayed effects of the experimental ads from ads exposed outside the laboratory in the period following exposure to the test ads. Finally, improved measurement of cognitive structure following the suggestions of Ahtola (1975) will be incorporated. The questions and problems raised in this study deserve answers and renewed attempts at improved solutions. Despite the methodological challenges, attitude research that goes beyond a static perspective is sorely needed in consumer research.

Abstract

A social identity approach is described which treats attitude expressions as interpersonal communications that present a particular image of the respondent to self and others. The approach predicts when people will associate themselves with particular symbols, and when attitude change will follow pro and counter-attitudinal behaviors. These predictions often differ from those advanced by dissonance and self-perception theories.

The concept of attitude has occupied a central and almost hallowed place in the explanatory systems of theorists interested in human behavior. The field of social psychology was once defined as the study of attitudes (Thomas & Znaniecki, 1918), and the utility of the concept for the field of consumer behavior has hardly gone unrecognized: "No other single psychological construct has permeated consumer research as has the construct of attitudes" (Jacoby, 1976, p. 337).

Attitudes and Social Identity

Attitude is an intrapersonal construct designed to account for different individuals' consistent favorable or unfavorable response patterns vis-a-vis particular social objects and/or events. Attitude is usually defined as the amount of positive or negative affect held toward a particular object and/or event. However, all expressions of attitudes, whether given through gross overt behaviors, verbal statements, or questionnaire responses, are interpersonal communications. Like other actions, attitude expressions present a particular image of the respondent to himself and to others. Attitude responses carry diagnostic value, since they can associate the person with particular groups of people (e.g., liberals vs. conservatives), reveal aspects of the person's personality (e.g., simple vs. complex; stable vs. unstable; optimistic vs. pessimistic), reveal the person's positive or negative orientation toward the social interaction and social setting (e.g., friendly vs. hostile), reveal the person's desired role in the interaction (e.g., dominant vs. submissive), and can be used to gain approval and avoid disapproval (e.g., conformity vs. nonconformity). In short, attitude expressions communicate aspects of the person's social identity and world view and set the tone for interactions. Even "private" attitudes, expressed only to oneself, occur in the context of imaginary social settings and serve the same functions in our private worlds. Every response used to infer our own and others' attitudes (except for physiological measures, which are notoriously unreliable) exists in a matrix of real or imagined social interaction, and can be used to influence the opinions and actions of others.

This focus on the interpersonal nature of attitudes is similar in some respects to the functional approach of the Michigan school (Katz, 1960), which examined attitudes according to their instrumental, ego-defensive, knowledge, and value expressive uses. Ultimately, these functions can be compressed to two: an informational facet, which involves cognitively organizing information about ourselves, others, and the world in a way that can guide actions; and an instrumental, or hedonic facet, which involves acting to maximize desirable outcomes and

minimize undesirable outcomes. Expectancy-value or subjective expected utility models (e.g., Anderson, 1971; Fishbein & Ajzen, 1975; Jones & Gerard, 1967; Rosenberg, 1956) come closest to capturing these facets as they pertain to the conceptualization and measurement of attitudes. However, researchers who have worked with these positions have generally not devoted sufficient attention to the symbolic, interactional, and social identity aspects of attitudes, except indirectly through the assessment of the probability or utility components. Focusing on these aspects, though, generates hypotheses which might otherwise remain hidden and provides for the integration of seemingly disparate phenomena (e.g., Freudian defense mechanisms, reactions to inequity, dissonance) into a common framework. Thus, while accepting the basic usefulness of such models, it becomes worthwhile to explore avenues opened by a focus on social identity and attitudes.

Social Identity and Self-Presentation

The presentation of self is the activity of constructing and maintaining particular identities in social life. Identity is the composite of the social attributes associated with an individual.² Each attribute creates a particular image of the person. Everyone--business person, politician, housewife, student, professor--develops an identity through and for social interaction and projects various aspects of that identity to particular audiences. Through impression management strategies people control how they see themselves and how they expect to be seen and treated by others. People respond to others on the basis of the identities those others create, so everyone finds it to his or her advantage to control the image of self presented for public and private consumption (Goffman, 1959; Jones & Wortman, 1973; Schlenker, 1975a).

The social identity approach derives in part from symbolic interactionism, a model of people which views them as symbol users and interpreters. According to the position, personality develops from and is inseparable from real or imagined social interactions (Carson, 1969). The focus is on the integral relationship between the person, others, society, and social symbols (cf. Brittan, 1973). Goffman's (1959, 1967, 1971) dramaturgical approach to social behavior developed from symbolic interactionism and views people as actors who perform roles available in society, managing the impressions they give to others in order to lay claim to specific social attributes. Although Goffman's work tends to minimize psychological factors and focuses upon interaction rituals, there is no reason to exclude internal, personal factors when studying self-presentation.

²It is worthwhile to distinguish between the self-concept and social identity. The self-concept is defined as the theory an individual has constructed about himself or herself (Epstein, 1973), and consists of perceptions of personal attributes and relationships between them. Social identity refers to "the individual's major role and social-type categorizations" (Gordon, 1968, p. 118). It describes what, who, and where the person is in social terms, and is not simply substitutable for the word self due to the more extensive social evaluation implied.

¹The present paper was facilitated by National Science Foundation grant BNS77-08182.

Constructing Identities: Attitudes and Identification

It is assumed that people manage the impressions they create to project a particular identity, both constructing it and maintaining it against actual or potential threats. Attitude expressions partially define identity and can arouse identity-maintenance concerns. Naturally, attitude topics vary in the degree to which they are relevant to identity concerns; the social judgment theory concept of ego-involvement is one way of conceptualizing such a continuum (Sherif & Hovland, 1961; Sherif et al., 1965).

Products similarly vary in the degree to which they have identity relevance. Some products can capitalize on their identity value; e.g., a Cadillac is a symbol of affluence and status, a Porsche is a symbol of a sporty life style. Other products, which initially might seem to suffer a handicap in this regard for one or another reason, can have symbolic value created for them; e.g., a Volkswagon "bug" seems at first glance to be ugly, but became a symbol of a pragmatic, environmentally-concerned life style. Even the use of products which might not appear to have any relevance for one's identity can be surprisingly revealing, at least to particular people. For example, a mother might never forgive her daughter-in-law for serving her son frozen or canned vegetables rather than fresh ones. To this particular mother, such behavior connotes laziness and indifference to her son's nutritional needs, and is an expression of the daughter-in-law's flawed personal qualities.

It often seems to be the goal of advertisers to increase the positive identity relevance of particular product lines or brands as a means of producing attitude change and ultimately affecting purchasing decisions. Desires for new products can be created by focusing on identity concerns (e.g., unless deodorants are used, doubts are raised about one's viability as a social participant) or previously neutral product brands are associated with existing relevant attributes (e.g., use of "Brut" deodorant identifies a "macho" individual). The classic techniques of testimonials and getting on the band wagon can be seen as attempts to create bonds between the consumer, some desirable image (e.g., attributes of the "star" or qualities of the symbol), and the product. "Join the Pepsi generation" (and have all the fun it entails for those who do); be like Farrah Fawcett-Majors or Joe Namath; smoke the cigarette of the rough-and-ready cowboy. Numerous studies have been devoted to specifying images associated with products (Jacoby, 1976).

From a social identity perspective, such attitude change is exemplary of a more general hypothesis: People act to increase their personal association with desirable attributes and outcomes, and act to decrease their personal association with undesirable attributes and outcomes. Personal association is defined as the probability that a particular attribute describes the individual; or in the case of outcomes, the degree to which the person is seen as responsible for producing the outcome. Desirability is defined as the worth of a particular attribute or outcome to the individual in a particular situation; it is defined idiosyncratically rather than normatively.

Research from a variety of areas provides strong support for the association hypothesis. In attributing the "causes" of particular actions, most people retrospectively report greater responsibility for successful task performances than for failing ones (e.g., Mynatt & Sherman, 1975; Schlenker, 1975b; Schlenker & Miller, 1977; Schlenker et al., 1976; Snyder et al., 1976; Wolosin et al., 1973; Wortman et al., 1973), and this is true whether the person worked on the task alone or with a group of others. People also more readily accept the implications of favorable rather than unfavorable personality information (e.g., Eagly, 1967; Jones, 1973;

Steiner, 1968). Even when a person is objectively non-responsible for producing a desirable outcome, the same proclivities are evidenced. Cialdini et al. (1976) found that more students wore school-identifying products (e.g., school sweatshirts) after their school's football team had been victorious rather than nonvictorious; and that they used the pronoun "we" more when talking about a school victory rather than a defeat. The latter effect was strongest when the students had previously suffered a personal failure that threatened their self-images. When important self-images are threatened or otherwise in doubt, people display a greater association/dissociation effect.

As the above suggests, individuals often prefer to associate themselves with attributes that are evaluated by most people as desirable, e.g., competence, attractiveness. Such findings are frequently explained as being the result of self-esteem needs, social approval needs, or cognitive consistency needs. But it seems somewhat simplistic to propose that people's identity-relevant actions are taken merely to maximize self-esteem and/or to maximize approval from others. It would then be difficult to explain why some people present themselves as incompetent, hostile, unfriendly, unworthy of responsibility for success, or even out of touch with reality and mentally ill (cf. Braginsky et al., 1969; Carson, 1969). Braginsky et al. (1969), for example, found that schizophrenics' self-presentational behaviors were affected by the identity they wished to project to particular audiences. Mental patients who were old-timers in an institution and who enjoyed open ward privileges were asked to complete mental tests or talk with a psychiatrist. These patients were assumed to prefer the freedom, with attention from the staff, provided by the open wards, and would want to avoid being seen as either healthy enough to be sent home or ill enough to be confined to restrictive closed wards. When the patients believed that the test/interview was for the purpose of diagnosing their mental health, with high scores indicating they should be sent home, they presented themselves as mentally ill. They gave frequent reports of hallucinations and showed other signs of abnormal, incompetent functioning. But when they believed that the test/interview was for the purpose of diagnosing their mental illness, with high scores indicating they should be placed in undesirable closed wards, they presented themselves as mentally healthy. They gave few reports of hallucinations and showed signs of normal, competent functioning. Thus, schizophrenics, often defined as being out of touch with reality and incapable of normal functioning, were quite adept at modifying their self-presentations to fulfill their interaction goals.

Similarly, identity-relevant actions don't seem motivated by "needs" for cognitive consistency. If they were, it would be difficult to explain the prevalence of inconsistent belief systems or belief-behavior relationships (cf. Tedeschi et al., 1971). Schlenker (1975a), for example, found that people who view themselves as "failures" will present themselves in a self-effacing manner when the failures are publicly known but will present themselves quite positively when the failures are unknown to the audience.

Such data falls into place when viewed from a social identity perspective. The desirability of an attribute or outcome can only be assessed with reference to the identity the individual is attempting to project. As Braginsky et al., (1969) demonstrated, different attributes acquire different values depending upon one's goals in a situation. Further, certain attributes can only be claimed by certain people. Most people might like to be seen as intelligent, competent, witty, attractive, respected, and so forth. But only certain individuals can successfully lay claim to such attributes; reality does impose constraints on projected identities. Inaccurate claims to social attributes produce

disruption of interactions, anxiety, guilt, and the possible censure and punishment of the offender (Goffman, 1959, 1967). Not only does an illicit identity (i.e., one the individual has no "right" to claim) produce embarrassment and anxiety for the discovered offender, it creates similar states for those who are duped into believing the misrepresentation and then realize their mistake. Schlenker (1975a) supported the hypothesis that people must believe they can successfully (without irrefutable challenge) act in accord with the identities they project before they will present themselves in a normatively positive fashion to an audience.

Claimed images or attributes can create obligations for the person. An obligation is defined as the belief that certain physical characteristics or behaviors should accompany claims to a particular image or attribute. A person who claims intellectual prowess should be able to demonstrate it; a person who claims physical beauty should possess some such recognizable features. Attributes (and products) vary in the degree to which they create obligations, and people vary in the degree to which they perceive obligations. A man might avoid a "Joe Namath" cologne if he believes wearing it would make him the object of jests about his baldness, pot belly, lack of coordination, and failures with women. A second man with a similar set of characteristics might not believe that any obligations derive from the use of the product (and thus not expect such chiding), and revel in his fantasies of himself as playboy extraordinaire.

Images or attributes also vary in the degree to which claiming them produces public (vs. only private) concerns. The personal desirability of a normatively desirable attribute will be low when the identity it implies creates public obligations which the person believes he or she cannot satisfy. But if a normatively desirable attribute only creates private obligations (e.g., those of a Walter Mitty fantasy world) and no public ones, its personal desirability will be high. The use of some products (e.g., "personal" items meant to be concealed), even if it would create obligations if publicly known, can be hidden away from public scrutiny.

In the realm of consumer behavior, this translates into the prescription that one must be careful of the type of image associated with particular products. The individual must attach a high personal desirability to the image. But this will only occur when he or she favorably evaluates the particular image in others, and either (a) believes that there are no public obligations associated with the image, or (b) believes that he or she can fulfill whatever public obligations are perceived, or (c) believes that although there might be public obligations that can't be fulfilled, he or she can "hide" public use of the product and not have to fulfill them. If public obligations exist which cannot be hidden and cannot be personally fulfilled, normatively desirable images will be rejected.

This would seem to be a particularly fruitful area for consumer research. Although worthwhile data do exist on product and brand images, to my knowledge nothing has been done with respect to (a) obligations that derive from those images, (b) consumers' abilities to fulfill whatever obligations exist, and (c) the public vs. privateness of whatever obligations may exist. Knowledge of the interrelationship between these factors relative to particular products could provide a more adequate predictor of purchasing decisions and behaviors.

Maintaining Identities: Attitudes, Accounting, and Counterattitudinal Actions

One of the more salient areas of attitude research has been on the relationship between behaviors and subsequently expressed attitudes, particularly with respect

to counterattitudinal behavior. Attitude change following counterattitudinal behavior has typically been explained via dissonance theory (Aronson, 1968; Festinger, 1957) or self-perception theory (Bem, 1967, 1972). The social identity approach offers an alternative conceptualization of the area which focuses on the interpersonal concerns raised by such actions (Riess & Schlenker, 1977; Schlenker, 1973, 1975c; Schlenker & Forsyth, 1977; Schlenker & Schlenker, 1975).

The counterattitudinal advocacy paradigms employed by psychologists typically induce subjects to lie, cheat, harm others, refrain from doing what they want to do, or otherwise make themselves appear to be immoral, unattractive, incompetent, or irrational. In other words, they place subjects in a predicament that could threaten their projected identities. Following actions which create a predicament (i.e., ones which are embarrassing, undesirable, illegal, anti-normative, or disruptive) people try to account for their behaviors. Accounting is an attempt to describe (interpret) the action and its consequences in personally desirable terms. Typically, this translates as interpretations which are socially acceptable (Lyman & Scott, 1968). People are "scientists" in the sense that they try to understand and explain the causes of events through attributions. But accounting can go beyond "logical" attribution in that a search is made to "explain" one's otherwise undesirable actions in desirable ways. Accounting involves the use of attributions and attitude expressions in the service of maintaining a particular identity.

Although there are numerous accounting tactics, two general classes of responses predominate--excuses and justifications. Excuses are attempts to remove from oneself personal responsibility for the predicament. Excuses include tactics such as (a) denying one did it, (b) stating it was an accident or the consequences were unforeseeable, (c) citing external coercive pressures (e.g., "He made me do it"), and (d) citing internal coercive pressures (e.g., "I couldn't help it, I was [starving] [drunk] [mentally ill] [possessed by demons]"). Justifications allow a person to admit responsibility for the predicament but alter the perceived negativity of the consequences of the predicament. For example, one might justify harming another by noting why the other person deserved it (and hence the act was not "bad") or by minimizing the amount of harm done ("It was only a scratch"). Thus, successful excuses allow one to escape from the predicament by minimizing personal responsibility, while successful justifications allow one to escape by minimizing the aversive consequences.

It is hypothesized that the particular type of account which is used in any situation will depend upon (a) its subjective probability of extricating the person from the predicament or minimizing the potential punishment, and (b) the utility of the perceived outcomes it generates (the degree to which it eliminates or minimizes the potential negative sanctions from observers and from self guilt). People will use that accounting tactic with the most positive (or least negative) subjective expected utility. The characteristics of the actor, situation, and audience affect these probabilities and utilities, since they affect the standards involved in judging the action and the degree to which a particular account could be challenged or refuted by the "facts." As this implies, accounts which can be obviously refuted by known information are least likely to be used because they are easiest to challenge, making the person not only still accountable for the original action but also sanctionable for the attempted deceit. Space does not permit a full exploration of accounting here, but two points are worth noting. First, predictions can be made about when particular types of accounting tactics will be used. Second, the accounting tactics mentioned above bear a striking resemblance to phenomena previously discussed under the headings of (a) modes of dissonance

reduction, (b) equity restoration techniques, and (c) defense mechanisms in psychopathology.

People frequently internalize the accounts they deliver and come to believe their own interpretation of the situation, producing relatively enduring attitude change or restructuring. It is hypothesized that people will internalize their accounting tactics when they negatively evaluate the action that created the predicament. If a person does not negatively evaluate the act, or feels the act is much less negative than does an audience, an account might be used to placate the audience but will be recognized by the actor as a "necessary lie" (cf. Schlenker & Forsyth, 1977, for an elaboration of this hypothesis). When "necessary lies" are told, it can complicate the person's existence; he or she must then keep multiple sets of books to recall which accounts were delivered to which audiences. Thus, an account which is accepted by both self and others facilitates one's effective functioning.

The amount of accounting necessary following a predicament is directly related to both personal responsibility for the predicament and the magnitude of its negative consequences. Responsibility is defined as the attribution that an individual freely and purposefully behaved to produce the primary consequences associated with the action, and did not engage in the behavior because of coercive pressures, accident, or to achieve other associated consequences. The more negative the action and the greater the responsibility of the actor, the more imperative it is to eliminate, or at least minimize, the potential guilt and punishment.

Consistent with the accounting hypothesis, it has been found that significant attitude change occurs following counterattitudinal actions only when a person appears to be personally responsible for engaging in the behavior and the behavior produces aversive consequences (Calder et al., 1973; Collins & Hoyt, 1972; Hoyt et al., 1972). Envision the typical paradigm. A subject is given either high or low choice (high vs. low responsibility, respectively) about making a speech which persuades or does not persuade (high vs. low harm, respectively) an audience. If no choice exists, the person has a ready-made visible excuse for the behavior and does not have to further account for it. If no harm is done, there is no need to account for the action. Only when responsibility and aversive consequences coexist is accounting necessary. But how can a high choice, high harm subject account for the behavior? The action can't be excused, since it was emphasized that the choice to perform it was solely his. It can be justified, though, by showing why little or no harm occurred. If the subject expresses attitudes which are roughly congruous with the position taken in the speech, then no real harm has occurred--after all, the subject personally endorses the beliefs the audience adopted. The counterattitudinal behavior becomes neither a lie nor harmful to others.

Research examining social identity theory indicates that responsibility and consequences are important not because they impact on cognitive consistency, but because they define the nature of the social identity dilemma (e.g., Forsyth et al., 1977; Riess & Schlenker, 1977; Schlenker, 1975a, 1975c; Schlenker & Forsyth, 1977; Schlenker & Schlenker, 1975). In many (though not all) counterattitudinal behavior situations, social identity theory makes the same predictions as does Aronson's (1968) revision of dissonance theory, which stresses that dissonance is produced when the implication of a behavior is inconsistent with one's self-concept. However, the two approaches differ in the hypothesized mediating mechanisms behind attitude change. Dissonance theory focuses on cognitive consistency-inconsistency, while social identity theory focuses on accounting following social predicaments. The difference is best illustrated by the fact that most counterattitudinal behaviors do two

things: (1) produce a predicament for the person since he or she has, by definition, lied and perhaps harmed others, thus being subject to sanctions and (2) produce cognitive inconsistency. This natural covariation has perhaps caused dissonance theorists to focus on the wrong variable. According to dissonance theory, motivation arises from cognitive inconsistency; according to social identity theory, motivation arises from the nature of the identity predicament. Although these variables covary in most situations, they can be separated such that a "lie" is made to produce positive rather than aversive consequences. When this is done, data indicate that inconsistency *per se* is particularly non-troublesome, and people behave according to predictions derived from social identity theory rather than dissonance or self-perception theory (Schlenker & Schlenker, 1975).

It is necessary to elaborate some of the implications of the above. The above does not imply that people do not organize attitudes and beliefs in a way that frequently gives the appearance of logical (or psychological) consistency. They do. All models of information integration (e.g., Anderson, 1971; Osgood & Tannenbaum, 1955; Wyer, 1974) are in some sense "consistency" models, since they describe how information is processed to achieve a "consistent" behavioral orientation. However, information integration models do not automatically lead to the conclusion that inconsistency has major motivational by-products that steer social behaviors in a particular direction. Only the so-called cognitive consistency theories (balance theory, dissonance theory) posit such drive-reduction needs arising from cognitive inconsistency. It is one thing to discuss the process of information integration, another to assume that cognitive inconsistency *per se* produces psychological needs which must be satisfied. The fact that people do weight and integrate information in order to make sense out of their environment and to function effectively in it is certainly compatible with (indeed, assumed by) social identity theory. Similarly, "incentive theory" (Elms, 1967; Janis & King, 1954; King & Janis, 1956) ideas about the effects of cognitive contact and biased scanning on attitude change following role-playing are quite compatible with information processing models. However, most research attention has been devoted to people's attitudinal reactions to predicaments. In such situations, motivation does not appear to arise from intrapsychic, cognitive consistency pressures, but from the nature of the predicament for social identity.

Social identity research suggests that many of the dissonance-type ideas about counterattitudinal behavior, effort justification, and so forth, might not have the marketing implications previously thought. For example, getting a consumer to reach to a higher shelf to get a product (exerting maximal effort) might not automatically lead to more favorable attitudes toward the product. It might do so only to the extent that the behavior created a predicament for the individual. Say, he was asked by another shopper why he strained to get the product when an equivalent one was in easy reach, believed so doing was somewhat irrational, believed it would harm his identity if he admitted this was irrational, and believed that an account based on product-liking would be most effective. It would be rare for a person to encounter this specific sequence of events. Or, instead of using "free giveaways" of new products, dissonance theorists might advocate making consumers pay some small amount for it or making them mail a postcard (exerting effort) rather than having it left on their doorstep. Once again, unless a predicament is generated, the strategy does not seem likely to have the most positive effects. Hedonic considerations suggest fewer people will be exposed to the products, and those that are will probably not develop any more favorable attitudes than otherwise. Marketing strategies based on "insufficient justification" do not appear to have strong data

to recommend them.

The only marketing area that does seem to yield data consistent with the "insufficient justification" idea involves the use of pricing techniques. Some dissonance researchers have recommended that products be sold for the largest amount possible (that will still get purchases) so that dissonance is aroused (Doob et al., 1969). Yet when a direct relationship is found between pricing and liking for a product, it is probably best to conceptualize it as due to economic evaluation processes; the relationship between price and perceived product quality has generated more laboratory research during the past eight years than any other topic in consumer behavior (Jacoby, 1976). Many products are simply perceived as more valuable the higher their price, at least up to some upper limit (Gabor & Granger, 1966). This is true irrespective of whether a purchase has been made.³

Maintaining Identities: Attitudes, Acclaiming, and Proattitudinal Actions

The social identity approach is built around the self-presentational nature of attitude expressions; it focuses upon the potential consequences of attitude expressions and the ways the consequences and the situation affect attributions which can be made about the person by himself and others. As was seen, many counterattitudinal actions produce consequences which are identity-threatening and which require accounting tactics. A complimentary process should occur following proattitudinal actions. Proattitudinal actions are often identity-supporting, and, depending upon the nature of the action, might produce consequences which are highly desirable. Hence, the association hypothesis indicates that people should want to appear personally responsible for relevant proattitudinal behaviors. For example, a person who contributed to a charity would prefer the attribution that the donation was made because he believed in the cause, and would want to avoid attributions such as "He did it because it is expected of those in his societal position," or "He did it because he was pressured into it by the canvasser for the charity." Responsibility implies that the person is entitled to the appropriate rewards, credit, respect, and feelings of self-worth that derive from the action. As the desirability of the consequences increases, so should the value of the accompanying image and personal association.

If an individual already appears associated with the behavior and its obviously desirable consequences, no further actions are necessary; he or she can reap the appropriate rewards. However, if the actor does not appear to be responsible for the action or if the consequences appear to be less desirable than the actor believes they should appear, acclaiming tactics will occur. Acclaiming is an attempt to describe (interpret) an action and its consequences in ways which reflect favorably on the actor. The two most salient acclaiming tactics are entitlements, which involve attempts to increase one's responsibility for an action and its consequences, and enhancements, which involve attempts to increase the apparent positivity of the consequences of the action. As with accounting, predictions can be derived about

³This is not to suggest that postdecisional distortions of the values of accepted and rejected alternatives do not occur. However, this well documented phenomenon does not follow exclusively from dissonance theory. Virtually identical predictions can be derived from conflict models, the idea of unequivocal behavior orientation (Jones & Gerard, 1967), social identity theory (based on derivations of the association hypothesis), and self-perception theory. Though the mediating processes may be debated, the end results relevant for consumer behavior seem to be comparable for each approach.

which acclaiming tactics will be used in particular situations based on the tactics' subjective expected utilities.

It is hypothesized that when environmental variables decrease the amount of responsibility that can be attributed to a person for proattitudinal actions, the more desirable the actions and their consequences, the more the person will use acclaiming tactics. Responsibility can be demonstrated by increasing the extremity of one's position on the topic or by appearing highly involved with the topic, such as by stressing its personal importance, its value to society, and one's behavioral commitment to it. Extremity and involvement are typically conceptualized as dimensions of one's attitude toward an issue (Scott, 1968). When a person already appears responsible for a desirable action, little or no additional acclaiming is required; responsibility and recognition are already theirs. But when environmental pressures decrease responsibility and dissociate the person from the positive consequences, he or she should use acclaiming tactics to increase the likelihood that responsibility is attributed.

As an example of the application of this hypothesis in role-playing situations, consider a politician who delivers a speech which coincidentally favors the popular side of some local issue. Naturally, the politician would prefer the audience to make the attribution that the speech reflected his personal attitudes (personal attribution) rather than that the speech merely reflected the desire for reelection (role attribution). To insure that the origin of the speech is attributed to personal attitudes, the politician might demonstrate increased gesticulation, hand-pounding, and voice inflection during the speech (as compared to a situation in which responsibility was not in doubt). In addition, he should evidence more favorable attitudes toward the issue at the conclusion of the speech than were held by him the previous day, at least up to some maximal point. This show of involvement with the issue would serve as a means of convincing the audience, and perhaps himself, that the behavior was desirable and was due to personal feelings rather than external role constraints.

Consistent with the above, research has found that when important positive consequences are produced by behaviors (e.g., delivering a proattitudinal speech), subjects subsequently express more favorable attitudes toward the topic when they are given no choice rather than high choice about engaging in the behavior; the effect has been found following both proattitudinal (Schlenker & Riess, 1977) and counterattitudinal (Schlenker & Schlenker, 1975) actions. These results fail to support predictions of the opposite effect (greater attitude change following high rather than low decision freedom) derived from self-perception theory.

These findings indicate that when the consequences of an action are identity-relevant and important, the type of "insufficient justification effect" which occurs will depend upon whether the consequences are desirable or undesirable. When the consequences are undesirable, insufficient justification (i.e., high responsibility) for the behavior is directly related to subsequent attitude change; as choice increases, so does attitude change. When the consequences are desirable, though, insufficient justification is inversely related to subsequent attitude change; as choice increases, attitude change decreases.

These results do not imply that self-perception principles are majorly incorrect. Self-perception theory, in conjunction with even more general ideas about attribution, has been quite successful in predicting attitudes in situations where (a) the consequences of the action are minimal and social identity concerns are not aroused (e.g., Taylor, 1975), and (b) subjects are given

false or misleading information about their internal states and must make sense out of the information available to them (e.g., Nisbett & Valins, 1972). As the desirability of an action increases, though, social identity concerns become engaged and people appear to follow a pattern of rationalization rather than "rational" information processing.

Conclusions

The social identity approach highlighted here has potential for integrating a wide variety of phenomena under a common rubric. The approach weaves together symbolic interaction (people are symbol users and interpreters), attribution theory (behaviors have social meanings which reflect on the identity of the actor with certain probabilities and consequences), hedonic principles (people act to maximize subjective expected utility), and social influence (people use impression management strategies for accounting and acclaiming purposes, which influence self and others).

In the realm of attitudes, the approach is not competitive with information processing models or with functional approaches to attitudes. Rather, it complements these by focusing on the communicative, interpersonal, social, and symbolic uses of attitude expressions. It emphasizes both rationalization and rational information processing. Rationalization is not conceptualized as an aspect of Freudian intrapsychic conflicts determined sometime during the first five years of life, or as due to needs for cognitive consistency. Instead, it is viewed as an identity protecting and enhancing tactic that arises from the nature of the social interaction process. People are "action centers" (Heider, 1958) who intend to produce certain effects and who are held accountable for what they do. The rewards and punishments (both from others and from pride or guilt) associated with accountability provide a powerful hedonic impetus for rationalization.

At one level, it has been argued that the basic motivational processes described by dissonance theory may well be in error--needs for cognitive consistency do not appear to have the omnipotent driving force that has been attributed to them. At another level, the kinds of predictions typically made by dissonance theory can be reconceptualized as a "special case" of the more general social identity approach. Such a possibility has been indirectly suggested by Zimbardo (1969, p. 15), who believes that Festinger's theories of social communication, social comparison, and dissonance, "may be subservient to more basic phenomena which characterizes this approach as a 'face-saving theory,' in which the individual is motivated to modify and distort both internal and external reality in order to make them appear consistent with having made the 'correct' decision."

Although the attribution process is salient in the social identity approach, attributions serve as the foundation for information about one's identity. These attributions can be biased by one's self-interests in order to control identity; attributions are acted on and manipulated through accounting and acclaiming tactics. From this perspective, attribution does not play the passive role it does in self-perception theory, where attributions about our attitudes are the end points of the attitude change process. There is rarely, if ever, only one attribution that can be made about an action. People exercise the opportunity to sort through the attributional possibilities until one or more can be found which best serve self-interests and establish the preferred type of social identity.

Finally, the social identity approach is most directly applicable to symbols that are (or can be made) at least somewhat identity relevant. The boundaries of identity relevance are cloudy at the moment, since relatively

little empirical work has been directed at specifying when people evaluate a symbol as relevant versus irrelevant to their identity. But it seems reasonable to suggest that many products have some identity relevance, or at least that many products can take on such relevance through particular types of advertising campaigns. Campbell's soups, for example, once stressed their relevance to the image of the stay-at-home housewife by emphasizing attributes associated with mother's good home cooking. Today, changing times have dictated another strategy; the value of the product is stressed for the image of liberated women who want to provide proper nourishment for their families while escaping the house quickly for an afternoon game of tennis. The degree of identity relevance of particular products or product brands is an empirical question, but it would seem that a large number of products already have the requisite relevance to make social identity hypotheses applicable.

A FUNCTIONAL APPROACH TO CONSUMER ATTITUDE RESEARCH

Richard J. Lutz, University of California, Los Angeles¹

Abstract

The potentials and current limitations of the so-called functional approach to the study of attitudes are delineated. In order to more fully illuminate the functional approach, the evolution of its research tradition is traced. The core of the functional approach, it is argued, can be captured by an expectancy-times-value reconceptualization of the theory. Implications for research and practice under the new conceptualization are discussed.

Introduction

It has been over fifteen years since Daniel Katz published his classic article, "The Functional Approach to the Study of Attitudes" (Katz, 1960). In this paper, which was essentially the last in a series of studies espousing the functional approach, Katz outlined the basic notion of the approach--i.e., that people hold attitudes toward objects, events, issues and behaviors for various reasons. That is, attitudes fulfill functions for the individual, such as maximizing rewards, expressing one's values, etc. He went on to specify four basic functions that an attitude may perform for an individual--utilitarian, value-expressive, ego-defensive and knowledge--and presented a summary of conditions under which the various functions might be aroused and another set of conditions conducive to the change of attitudes serving the four functions.

Katz's article was a major conceptual contribution to the attitude literature in that it made explicit the motivational underpinnings of attitudes and drew attention to the possible individual differences (in attitude function) which may be obscured by a simple affective representation of attitude. Consumer behavior scholars have been quite cognizant of Katz's contribution, as evidenced by the frequency with which the functional approach is discussed in consumer behavior texts. Virtually every major book in the field includes some treatment of the functional approach, and generally concludes that a functional approach is fundamental to understanding (1) why people hold the attitudes they do, and (2) how those attitudes might be changed.

Unfortunately, consumer researchers, and attitude researchers in general, have not shown as much interest in actually applying the functional approach. In fact, recently the functional approach has come under attack by some researchers who cite the lack of operational procedures to allow its application (Kiesler, Collins and Miller, 1969; Day, 1973; Eagly and Himmelfarb, 1974). The currently fashionable position on the functional approach, therefore, is that it is "...more important as a classificatory schema and general analytical framework than as a theory generating hypotheses for research" (Eagly and Himmelfarb, 1974. p. 598).

The purpose of the present paper is to develop a rationale for the measurement of attitude functions. To accomplish this, a review of the historical development of the functional approach will be undertaken, followed by a proposed reconceptualization. Implications of the reconceptualized functional framework for consumer attitude research will also be discussed.

¹Associate Professor of Marketing, UCLA. The present paper is an excerpt from a more comprehensive version (Lutz, 1977) which may be requested from the author.

Evolution of the Functional Approach

The functional approach to attitudes subsumes two independent schools of thought, one fostered by M. Brewster Smith and his colleagues at Harvard, and the other represented by Katz, Sarnoff and others at the University of Michigan. Though developed independently, the two approaches are remarkably similar. Each will be reviewed briefly here, in order to highlight their similarities and differences, and to provide a flavor of the functional approach.

The Harvard Study

At the close of World War II, the American people were confronted with the emergence of Russia as a major world power. Communism was a dreaded menace, and the concern among the public was great. Smith and his colleagues set out to study the nature of attitudes toward Russia and, in particular, the reasons underlying these attitudes.

Smith (1947), in the first explicit statement of functional theory, posited a relationship between attitudes and "personality." Based on the results of a survey of 250 New England males, Smith identified five functions which attitudes could serve for the personality:

- 1) the value function, wherein the attitude expresses a value of the individual;
- 2) the consistency function, which maintains the relationship between attitudes and characteristic modes of reaction (e.g., personality traits);
- 3) the gratification function, whereby the attitude indirectly satisfies some basic need;
- 4) the meaning function, which allows the person to give order and stability to his world; and
- 5) the conformity function, which is served by attitudes expressing identity with, and fostering acceptance by, important social groups.

The essential thrust of Smith's functional formulation, then, rested on the postulate that attitudinal affect is in some way based on the relationship of the attitude object to underlying psychological constructs variously labeled values, motives and needs. The partitioning into five distinct functions is perhaps best seen as an attempt to specify some qualitative differences among the underlying needs. For example, the meaning function was seen as relating to the needs for "adequacy" and "simplicity," while the conformity function centered on "need for approval" and "need for acceptance." The value function dealt with "what sorts of things people think are important in life" (Smith, 1947, p. 518) such as liberty and economic security, while the consistency and gratification functions analyzed the relationship between attitude and traditional personality variables (e.g., extroversion).

While Smith (1947) did not go into any detail regarding the mechanisms through which the various functions operate, it seems clear that the indirect satisfaction of needs as specified by the gratification function would differ qualitatively from more direct mechanisms. Thus, there would appear to be not only differences in the content of needs across the five functions, but also qualitative differences in the psychological mechanisms

implied by the functions.

In a subsequent paper, Smith amplified on the nature of the value function:

A person will tend to perceive and judge the focus of an attitude in terms of one of his personal values to the extent that (a) the value is important to him, occupying a central position in his value hierarchy; (b) the information available to him about the focus contains a basis for engaging the value; and (c) the scope of the value and of the person's interest is broad enough to extend to the focus of the attitude. (Smith, 1949, p. 486).

Thus, although the other functions were not similarly analyzed, Smith did engage in theorizing with respect to the conditions necessary (and presumably sufficient) for the value function to be an underlying mechanism in support of an attitude. This represents at least a partial rebuttal to those who contend that functional theory is not really "theory," but rather is little more than simply a taxonomy of attitude-related needs and values (Eagly and Himmelfarb, 1974; Baron, 1968).

In 1956 Smith, Bruner and White authored Opinions and Personality, which reported on the entire study of attitudes toward Russia, but focused primarily on the results of in-depth interviews with 10 men. From this study emerged a modification of Smith's earlier functional theorizing, together with an elaboration of theoretical mechanisms embodied by the functional approach.

Rather than the five functions postulated by Smith (1947), Smith *et al.* (1956), conceived of three basic functions: object appraisal, social adjustment and externalization. The latter function is closely related to Smith's earlier gratification function, while social adjustment corresponds to his conformity function. The object appraisal function has no direct analogue in Smith's earlier work, although it does appear to include his meaning function. Oddly, the value function, which was so central in Smith's earlier work, seemingly is ignored in the Smith, *et al.* (1956) statement.

The basis for the object appraisal function is "reality testing," in that an attitude serving the function is seen as classifying the attitude object for the purposes of allowing the individual to adequately cope with the object. Stated differently, "...object appraisal is the process whereby the person develops attitudes that are a creative solution to the problems posed by the existence of disparate internal demands and external or environmental demands" (Smith, *et al.*, 1956, p. 41). Again emphasizing the basic need-relatedness of attitudes, Smith, *et al.* further specify that objects are appraised in terms of their relations to the person's "motives, goals, values and interests" (p. 261). But they are careful to point out that they are not advocating "...that admirable fiction, the 'rational' man," (p. 265), but rather are postulating object appraisal as only one of the functions attitudes may serve.

Smith, *et al.*'s social adjustment function deals with "...facilitating, disrupting or simply maintaining an individual's relations with other individuals (p. 41). Such processes as identification, conformity, which represents a broadening of Smith's (1947) conformity function.

Finally, the externalization function is operating when "...an individual, often responding unconsciously, senses an analogy between a perceived environmental event and some unresolved inner problem" (Smith, *et al.*, 1956, p. 43). This externalization helps the individual

to reduce anxiety. Like the other functions the degree and importance of externalization are expected to differ greatly across both individuals and situations.

Turning to an analysis of attitude change implications of the functional approach, Smith *et al.* state that while any one function can be a "precipitating factor" in attitude change, the process of change must entail a "...shift in the balance of all factors" (p. 276). This implicitly assumes a weighting of the various functions in their relationship to attitude, and this weighting has important implications for the form that attitude change strategies might take. For instance, a predominantly object appraisal attitude would most likely be modified by the presentation of information, while an attitude serving the social adjustment function ought to be more susceptible to "prestige suggestion" (Smith, *et al.*, 1956, p. 277). Attitudes which are primarily based on externalization are expected to be more rigid and not subject to modification through either information or social manipulation (p. 277). As Smith, *et al.* conclude:

If this analysis of the conditions of attitude change is correct...it becomes important to devise rigorous and objective means of assessing the contribution of the different functional supports to people's opinions on given issues. Ways of doing so seem entirely within the range of feasible attainment." (p. 278)

But Smith, Bruner and White did not attempt to develop the measures they specify, leaving these important attitude change propositions untested and largely untestable. This lack of operational procedures remains the single most glaring weakness of functional theory, not only for Smith, *et al.*, but also for the work of Katz and his associates at Michigan.

The Michigan Group

Just as the Harvard Study had centered on an important social phenomenon--attitudes toward Russia--the University of Michigan group focused its work on the problem of understanding and changing prejudicial attitudes. The earlier work of Adorno, *et al.* (1950) on the authoritarian personality and its relationship to anti-Semitism had a significant impact on the Michigan group. However, rather than concentrate solely on the personality antecedents of prejudice, the Michigan group broadened its study to include a number of motivational bases supportive of attitude formation and change.

In the first paper in the series Sarnoff and Katz (1954) outlined three "motivational contexts" for attitudes corresponding roughly to the major psychological research traditions of Gestalt theory, learning theory, and psychoanalytic theory. These three contexts were labeled reality testing, reward and punishment, and ego-defense, respectively.

Reality testing was described in terms of the need to explore, the need to know, the quest for information, curiosity and the like. In what today might be described as an information processing view, Sarnoff and Katz (1954) stated that attitudes serving this function are "...a function of the range of information which has been accessible to the individual in regard to certain target objects" (p. 117). Further, they specified that such attitudes could be changed via a "rational" approach involving the presentation of new information within an appropriate frame of reference.

Attitudes based on reward and punishment were seen as an amalgam of two basic sorts of rewards: (1) those based on social group norms, and (2) those emanating from the individual's internal value system. Sarnoff and Katz were more interested in the former type (because of the

presumed social nature of prejudice) and therefore emphasized the use of normative group pressure in changing such attitudes. In addition, however, they noted that restructuring the value system "...through making the specific connections between the target object and a different set of values" (p. 122) was also a viable modification strategy.

Finally, attitudes based on ego-defense were viewed as serving "consciously unacceptable" motives through such ego-defense mechanisms as projection. Ego-defensive attitudes were regarded by Sarnoff and Katz as "inappropriate," in that the cognitive object...perceived contrasts with characteristics of the object" (p. 120). These distortions could only be corrected through attitude change procedures involving some form of catharsis, which would allow the individual to perceive and respond to reality in a more "appropriate" manner.

Similar to Smith, et al. (1956), Sarnoff and Katz (1954) noted that any given attitude may serve one or a combination of functions. They concluded their paper with a discussion of attitude change "programs" designed to modify attitudes serving the various functions. While they reported no empirical work, a number of studies followed in the next several years which were aimed at investigating some of Sarnoff and Katz' ideas.

Reality testing. Cohen, Stotland and Wolfe (1955) investigated the need for cognition (n-cog) as "...the individual's tendency to organize his experience meaningfully" (p. 291). This corresponds directly to Sarnoff and Katz' (1954) reality testing function. Using two independent measures of n-cog, they were able to demonstrate that students' feelings of "frustration" were greater when reading "ambiguous" stories than when reading unambiguous stories, and further, that the increment in frustration was greater for students who were high in n-cog. While they failed to support two hypotheses regarding the degree to which the students would attempt to "impose structure" on the ambiguous stories, their study was important in documenting that n-cog did exist and that affective reactions to a situation varied with both intrapersonal (i.e., n-cog) and environmental (i.e., manipulated ambiguity) factors.

In a subsequent study, Cohen (1957) investigated the relationship of n-cog to the order of presentation in persuasion. Specifically, he used two orders of presentation, one in which need-arousal was followed by information, with another which reversed the two. His hypothesis was that those subjects high in n-cog would be less affected by the order of presentation, since they would work harder to structure the situation for themselves. Using a forced-choice scale to measure n-cog, he divided a class of 35 students into high and low groups. A communication supporting "grading on the curve" was presented either before or after a "fear-arousing" discussion of the vagaries of the grading system.

Cohen (1957) found greater attitude change on an immediate posttest for the group receiving the need-arousal treatment first. He concluded:

"Need satisfaction and presumably, therefore, opinion change in this situation demanded the perception of the information as instrumental to the aroused need" (p. 94).

However, on a delayed posttest, Cohen found that the high n-cog subjects retained a significant change in attitude regardless of which group they were assigned to, while the low n-cog subjects showed no positive change, regardless of which order of communication they had received. The results of this study served to re-affirm the presence of a reality testing function and its mediating influence on attitude change.

Reward/punishment. In 1955, Helen Peak published her classic article, "Attitude and Motivation," in which she outlined an expectancy-times-value (ExV) approach to representing the motivational structure underlying attitudes. Peak was a member of the Michigan group and a part of the Attitude Change Project under Katz' direction, and she assumed directorship of the project for one year while Katz was away. During this time, a number of studies were conducted which, while closely related to the functional approach, did not explicitly position themselves within the Sarnoff-Katz functional framework.

In the first of these studies, Rosenberg (1956) investigated the "attitude structure" underlying attitudes toward free speech for Communists and the removal of Negro housing segregation. By measuring the "value importance" of each of 35 goals and values, as well as the "perceived instrumentality" of the two issues mentioned above in blocking or attaining those goals, Rosenberg was able to construct an ExV "cognitive structure index" which was closely related to overall affect. Rosenberg's work was later cited by Katz, et al. (1956) as "...a combination of the rational and reward approaches..." (p. 28). The "rational" portion derived from the measure of instrumentality, while the "reward" function was represented by the value importance hierarchy.

In a second study, Carlson (1956) built on Rosenberg's earlier work on Negro housing segregation in attempting to modify instrumentalities relating to the values of American prestige, protection of property values, equal opportunity, and being broadminded and worldly-wise. By having students write essays supporting the removal of segregation and then following this with an in-class discussion, Carlson was able to modify the individual instrumentalities, the overall ExV index, and to a somewhat lesser extent, attitude. Subjects with initially moderate attitudes changed the most while initially favorable subjects had little room to change, and initially negative subjects exhibited a "boomerang" effect. This latter finding suggests that some of Carlson's subjects were holding ego-defensive, rather than reward/punishment attitudes, but since Carlson included no measure of ego defense, the finding is only suggestive. Katz, et al. (1956) also cite Carlson's (1956) study as utilizing a combination of the reward and rational approaches, although it should be noted that neither Rosenberg (1956) nor Carlson (1956) characterized their own work in this way.

In the subsequent studies reported by Peak and her associates (Peak and Morrison, 1958; Peak, 1960; Rosenberg, 1960), the emphasis continued to be placed on the ExV representation of cognitive structure, with no explicit links being made to the functional approach.

Ego-defense. Wagman (1955) tested Sarnoff and Katz' (1954) propositions regarding the ego-defense function by attempting to modify students' anti-Negro attitudes through both authoritarian suggestion and a "non-authoritarian" cognitive restructuring technique. Splitting his sample into thirds based on their F-Scale scores, Wagman was able to show a fairly consistent pattern across four different attitude measures:

- 1) low F-Scale subjects changed more than high F-Scale subjects under conditions of cognitive restructuring;
- 2) high F-Scale subjects changed more than low F-Scale subjects under conditions of authoritarian suggestion, regardless of which direction of change was advocated (i.e., more anti-Negro prejudice or less anti-Negro prejudice).

These results are consistent with the Sarnoff and Katz' (1954) reasoning that ego-defensive (in this case, authoritarian) attitudes will be less susceptible to

change through a "rational" approach. However, Wagman's findings indicate that ego-defensive attitudes are not necessarily rigid in the face of less "rational" attitude modification strategies.

In two related studies which were aimed at directly investigating the ego-defensive function of attitude, Katz, Sarnoff and McClintock (1956) and Katz, McClintock and Sarnoff (1957) attempted to change attitudes toward Negroes. In the first study, both an informational (rational) and "interpretive" (ego-defensive) appeal were used, in order to determine their relative effectiveness in attacking a prejudicial and presumably ego-defensive attitude. In order to measure ego-defense, a TAT card was designed and codes were developed for projection, denial and extrapunitive, three ego-defense mechanisms. These were combined into a single score which was used to split the sample into thirds. It was predicted that the efficacy of the informational appeal would decrease with increasing ego-defense, while the interpretive appeal would be maximally effective for moderately defensive subjects. Neither prediction was confirmed, which led Katz *et al.* to question the ego-defense measure they had employed.

In their second study, Katz, *et al.* (1957) used four separate measures of ego-defense: a pair of TAT cards, an 18-item multiple choice sentence completion task, 45 items from the paranoia subscale of the MMPI, and six subscales from the F-Scale. The former two measures were found to be insensitive, while the latter two were judged to perform adequately. An interpretive appeal was administered to 131 college women, with the expectation that those moderate in defensiveness would exhibit more change than either the high or low defensiveness groups. This prediction was confirmed for the two standardized measures (MMPI and F-Scale), while being disconfirmed for the two more *ad hoc* approaches.

McClintock (1958) investigated the relationship between attitude change and two personality variables, ego-defensiveness and other-directedness. One hundred ninety-eight female college students were exposed to one of three forms of persuasive appeal (information, insight, ethnocentric) designed to change anti-Negro attitudes. Consistent with Katz, *et al.* (1957) McClintock found that moderately defensive subjects (as measured by a portion of the F-Scale) changed the most under the insight treatment, while no differences were observed among the groups under the informational appeal. Under the ethnocentric appeal, subjects high in ego-defense changed more than those low in defensiveness. McClintock (1958) concluded:

...the findings of this research indicated that a given influence may have little effect in moving the total population in the direction of that influence... Thus, knowing the personality structure of the individual seems necessary for... the devising of appropriate and effective methods for changing attitudes. (pp. 492-3).

In yet another study of the self-insight approach to changing ego-defensive attitudes, Stotland, Katz and Patchen (1959) attempted to manipulate racial attitudes. Contrary to the pattern of findings emerging from earlier studies, a monotonic decreasing relationship was obtained between ego-defense (as measured by the F-Scale) and attitude change. This failure to replicate the earlier findings was not readily explainable, but Stotland, *et al.* speculated that it could be due to an insensitive measure of ego-defense (even though the same measure had been used satisfactorily in a number of other studies), increased awareness by low defensive subjects of their "inappropriate" attitudes, or a greater amount of projection among those low in ego-defense than had been previously anticipated. This study serves to underscore the rather weak operational procedures characterizing the

research on the ego-defensive function, even though this function was clearly the major focus of empirical research by Katz and his associates.

In his summarization of the ego-defensive function of attitude Sarnoff (1960a) states:

It begins to appear that--insofar as consciously unacceptable motives do form the basis of an individual's disposition to agree with prevailing anti-minority stereotypes--projection plays a larger role than any of the other mechanisms of ego defense. (p. 273)

He concluded this on the basis of the results of a number of studies utilizing projection and other defense mechanisms (Katz, *et al.*, 1956, 1957; Sarnoff, 1951, 1960b; Sarnoff and Corwin, 1959; Cohen, 1956). Thus it would appear that any further attempt to investigate the ego-defense function of attitude should rely heavily on projection as a basis for assessing attitudinal function.

In the first major theoretical statement of functional theory since the Sarnoff and Katz (1954) article, Katz and Stotland (1959) outlined a theory of attitude formation and change based upon the research described above. At the heart of their theory were the motivational functions served by attitudes. These functions were classified as proximal, object-instrumental, ego-instrumental, and ego-defensive.

Proximal attitudes are those where the attitude toward the object satisfies some need of the individual directly. This is in contrast to attitudes which are held toward an object because it is instrumental in helping the individual to satisfy a need. Attitudes toward foods and sex objects are cited as possible examples of proximal attitudes, but perhaps the most important example is the attitude based on the need for understanding. This is directly analogous to Cohen's (1955, 1957) investigations of n-cog and re-asserts the notion that to understand, to explore, to search for meaning is an end in itself, and not merely a means to some other end-state. Proximal attitudes are seen as being reinforced through repeated interaction with the attitude object and are "...based on the principle that individuals put high value on objects which satisfy their needs and low value on objects which frustrate them" (Katz and Stotland, 1959, p. 437).

Object-instrumental attitudes are those based on the means-ends principle first explicitly stated by Peak (1955) and her associates. According to Katz and Stotland (1959), many social attitudes fall into this category. Positive attitudes are developed toward those social objects which are seen as a means to ultimate satisfaction of wants and needs. These sorts of attitudes may be learned through trial-and-error, but as noted by Katz and Stotland: "The concept of instrumental learning has been converted into the notion of perceived instrumentality by workers dealing with cognition, perception and attitudes" (p. 436). Thus, the characteristics of the attitude object and their relationship to need satisfaction act as the motivational underpinnings of object-instrumental attitudes.

In contrast, an ego-instrumental attitude "...arises from sources further removed from the attitude itself, from ego satisfactions" (p. 440). The key feature of this type of attitude is that it allows the person to express to others what kind of person he is. Thus, such constructs as "value" and "self concept" become relevant attitude bases. When compared with object-instrumental attitudes, the cognitions underlying ego-instrumental attitudes are "...elaborated less upon the basis of the objective characteristics of the attitudinal object than upon the individual's need to maintain his own self-image" (Katz and Stotland, 1959, p. 440).

The final category of attitudes, ego-defensive, is essentially the same as was discussed by Sarnoff and Katz (1954). Ego-defensive attitudes conform to the classic pattern of repressing consciously unacceptable sexual and aggressive impulses and subsequently projecting these impulses onto others, usually outgroups of some kind. In this sense, ego-defensive attitudes are maladaptive and leave the basic conflict within the individual unresolved. They are quite resistant to change through common forms of influence, which follows from the deep-seated nature of the motives being repressed.

Katz and Stotland viewed the motivational-attitudinal-action system as dynamic, characterized by constant interaction, such that no true distinctions can be made among independent and dependent variables. However, they did feel that certain variables would be more dominant in a causal sense:

...we would in general regard motives and environmental forces as independent variables, attitudes as intervening variables, and expression in behavior as the dependent variable (p. 468).

This view of the causal structure of the system has direct implications for the derivation of attitude change strategies; hence, Katz and Stotland recommend modifications of (1) the individual's value system; or (2) cognitions with respect to the attitude object as the most viable means of changing attitudes.

In the final major paper pertaining to functional theory, Katz (1960) offered what is perhaps the most systematic description of the proposed functions as well as the conditions conducive to their arousal and change. The four functions he outlined were similar, but not identical, to the ones described by Katz and Stotland (1959): utilitarian (also referred to as instrumental or adjustive), ego-defensive, value-expressive, and knowledge.

The utilitarian function was described by Katz as an attempt by the individual to maximize rewards and minimize punishment from the environment. Thus, attitude formation was seen as "...dependent upon present or past perceptions of the utility of the attitudinal object for the individual" (p. 171). This relates closely to the notion of object-instrumental attitudes presented by Katz and Stotland (1959).

The ego-defensive function, as conceived by Katz (1960), is essentially identical to the one originally conceived by Sarnoff and Katz (1954) and reiterated by Katz and Stotland (1959). It is through this function that the individual protects himself from either external threats or internal conflicts. In its linkage to Freudian psychology, the ego-defensive function is concerned primarily with consciously unacceptable motives.

The value-expressive function involves attitudes which express the individual's own personally-held values or his self concept. This is analogous to Katz and Stotland's (1959) ego-instrumental function. It is virtually opposite to the ego-defensive function, which serves to obscure aspects of the person from himself and others. Value-expressive attitudes instead reveal the self concept and in some cases help the individual to move closer to his "ideal" self concept.

The knowledge function is served by attitudes which help the individual to find meaning, organize the environment, and in general provide clarity and consistency to the person's view of the world. This is in agreement with the proximal attitude based on n-cog as described by Katz and Stotland.

Katz' (1960) major contribution was a formal specification of the factors underlying attitude formation, and change. His was the only systematic analysis of the nature of the various functions, together with an assessment of the key elements which could be brought to bear on attitude change efforts. While some later authors have criticized the conditions he outlined as being too general to allow empirical test, nevertheless the formal statement of these conditions was at least a good first step toward building a set of testable propositions, which is a requirement for any theory.

More disappointing than the generality of the determinants of attitude arousal and change was the lack of any clues as to how the approach might be operationalized. Katz (1960) cited the need for public opinion polls measuring needs and attitudes, but beyond a few references to the F-Scale, MMPI and n-cog, he gave no indication as to how the functions could be assessed. It would appear that at least some of the difficulty that arises in the assessment of attitude functions derives from a lack of conceptual clarity with respect to the various functions. By moving toward appropriate measurement procedures, some of the somewhat vague notions regarding attitude arousal and change conditions may crystallize into more clearly testable hypotheses.

Summary

Table 1 summarizes the various functions of attitude discussed in five major theoretical papers. As is evident from the table, there are some discrepancies among the articles in terms of both the number of functions and the exact nature of these functions. The two functions which were identified with the most consistency across the various studies were (in Katz' (1960) terminology) the ego-defensive and knowledge functions, although the latter was characterized by five different labels and in one paper (Smith, et al., 1956) was combined with the equivalent to Katz' (1960) utilitarian function into a single "object appraisal" function. The consensus on the ego-defensive function is not surprising, given the involving and apparently threatening nature of the attitudes under study (i.e., attitudes toward Russia and racial and ethnic minorities).

With the exception of Smith's (1947) article, there was agreement on a utilitarian function stressing the reward/punishment notion of hedonism. Somewhat less agreement was found, however, on the existence of a value-expressive function. It appeared in the later work of the Michigan group, but was not considered by either Sarnoff and Katz (1954) or by Smith, et al. (1956). In fact, the latter authors explicitly rejected the notion of a value-expressive function (although Smith (1947) had earlier postulated one), and instead argued that value expression was not a "need" of the individual but rather just a by-product of the expression of an attitude (Smith, et al., 1956, p. 38).

The clearest difference between the Harvard and Michigan groups is apparent in their treatment of the social adjustment function. Smith, et al. (1956) strongly emphasized the social function of attitude, while Katz and his associates (1954, 1959, 1960) did not distinguish it as a function per se. To some degree, the social function of attitude was subsumed in Katz' (1959, 1960) discussion of the value-expressive function, but the discussion focused more on socialization as a source of values than on social needs as direct underpinnings of attitude.

While there was some disagreement as to the exact functions served by attitude, the theorists were unanimous in their characterization of attitudes as having multiple determinants. Although it was conceded that unifunctional attitudes may exist in some cases, the consensus was that most attitudes serve more than one function

TABLE 1

A COMPARISON OF THE FUNCTIONS OUTLINED IN MAJOR THEORETICAL PAPERS

Basic Need Syndrome	Smith (1947)	Smith, et al. (1956)	Sarnoff & Katz (1954)	Katz and Stotland (1959)	Katz (1960)
Expression of values or self concept	value	a	_____	ego-instrumental	value-expressive
Indirect gratification of consciously unacceptable motives	consistency gratification	externalization	ego-defense	ego-defensive ^c	ego-defensive
Satisfaction of social needs	conformity	social adjustment	_____	_____	_____
Search for knowledge, organization consistency	meaning		reality testing	proximal ^d	knowledge
Maximization of reward or minimization of punishment	_____	object appraisal ^e	reward and punishment	object-instrumental	utilitarian

^a not explicitly a function of attitude, but rather a by-product

^b can also relate to "consciously acceptable" personality traits

^c also can be regarded as exhibiting properties of a proximal attitude.

^d is not limited to the need for understanding

^e combined the ideas of reward/punishment and need for understanding

for the individual, and that only through an understanding of these functional bases could attitudes be diagnosed and effectively changed. Thus, the functional theorists agreed on an approach to attitude which was strongly based on individual differences; i.e., the same observed attitude (in terms of strength and direction of affect) for two different individuals may be reflecting two entirely different motivational structures in terms of the functions being served.

A Reconceptualization

The lack of operations for measuring functions of attitude has been identified as a major drawback to functional theory (e.g., Insko, 1967; Himmelfarb and Eagly, 1974). Some researchers have gone even further with this criticism suggesting that the theory is really nothing more than a broad conceptual integration and should not be viewed as a potential operational framework (Kiesler, Collins and Miller, 1969). However, the functional theorists themselves clearly regarded the theory as potentially operationalizable. Smith, et al. (1956), while offering no clues as to how to operationalize the theory, nevertheless pointed out the need to do so and voiced optimism that the measurement of attitude functions "...seem entirely within the range of feasible attainment" (p. 278). Similarly, Katz (1960) discussed the assessment of attitude functions, pointing to the need for systematic sampling of target populations and advocating increasing reliance on methods other than the depth interview.

Yet, despite the early attempts to measure ego-defensive (e.g., Katz, et al., 1956, 1957) and knowledge function

(e.g., Cohen, et al., (1955) attitudes, little systematic empirical work was devoted to the task of functional assessment. Perhaps the best explanation for this problem lies in the following quotation from Katz and Stotland (1959):

...we cannot systematically develop the conceptual properties of all our constructs, point to validated operational measures for them, or describe an appropriate mathematical model for handling the data in this field. (p. 425, italics added)

Thus, although the Katz and Stotland (1959) contribution was considered only a "preliminary" statement of functional theory, the final conceptual article was published the very next year by Katz (1960). In neither of these articles was there sufficient conceptual clarity to allow rigorous specification of operations for representing the various functions and their relationship to the expressed attitude of an individual. Yet, the kernel of a fundamental approach to solving the conceptual, and, concomitantly, the operational problems with functional theory was present in these and earlier articles. The following section attempts to explicitly draw out from the functional literature the roots of the proposed reconceptualization.

An Expectancy-Times-Value View²

Weiner (1972) describes the expectancy-times-value (ExV) approach to human motivation as the conception that "...direction and intensity of behavior is a function of the expectation [E] that certain actions will lead to the goal, and the incentive value [V] of the goal object" (p. 8). The ExV notion is central to Murray's (1938) theory of personality, Rotter's (1954) social learning theory, Atkinson's (1964) theory of achievement motivation, and Peak's (1955) theory of attitude. A careful examination of the literature on the functional theory of attitude suggests that it, too, is strongly grounded in ExV principles.

In their discussion of the relationship of attitude to personality, Smith, Bruner and White (1956) posited that personality is marked by an "...adaptive striving after goals [V]," and further that the individual becomes "...selectively aware of objects related [E] to certain goals..." (p. 32). In a similar vein, Katz (1960) states:

Knowledge of need state [V] indicates the type of goal toward which the individual is striving. But the means for reaching this goal [E] may vary considerably...(p. 203).

Thus, the general notion of goal-oriented behavior is apparent in both of the major approaches to functional representation of attitude.

The basic idea of an ExV reconceptualization of functional theory is that the cognitive "component" of attitude serving a particular function becomes elaborated around the basic needs or values salient to that attitude function. The "index of cognitive structure" (ExV) becomes an index of the particular attitude function under consideration. The exact nature of the cognitive (E) and affective (V) elements making up the index would vary with the content of the various functions. A consideration of the individual functions serves to further illuminate this ExV orientation of functional theory.

Utilitarian.

Probably the clearest expression of functional theory's implicit reliance on ExV principles is found in Katz' (1960) discussion of the utilitarian or adjustment function:

Attitudes acquired in the service of the adjustment function are either the means for reaching the desired goal or avoiding the undesirable one....In general, then, the dynamics of attitude formation with respect to the adjustment function are dependent upon present or past perceptions [E] of the utility [V] of the attitudinal object for the individual...The closer these objects are to actual need satisfaction [V] and the more they

are clearly perceived [E] as relevant to need satisfaction, the greater are the probabilities of positive attitude formation (p. 171, italics added).

According to the ExV formulation, then, the utilitarian function would be measured by expectations regarding the need-related attributes of the attitude object, weighted by the value or utility of these attributes to the individual. The degree to which the utilitarian ExV index relates to attitudinal affect is an assessment of the degree to which the attitude is serving the utilitarian function for the individual.

Value-expressive. As noted by Katz and Stotland (1959), the utilitarian function rests primarily on the properties of the attitude object and their relationship to goal attainment. On the other hand, value-expressive attitudes are seen as reflections of properties of the individual:

The cognitive component of the attitude becomes elaborated less upon the basis of the objective characteristics of the attitudinal object than upon the individual's need to maintain his own self-image (Katz and Stotland, 1959, p. 440).

Katz (1960) postulates that the expression of the self concept is rewarding to the individual. Presumably, in order for an attitude to serve the value-expressive function, then, there must be some expectation (E) on the part of the individual that holding that particular attitude gives expression to some aspect of self (V). Or, as stated by Smith (1947):

...intensity of attitudinal affect is a function of the extent to which a personal value is engaged [E] and of the importance [V] of this engaged value in the hierarchy of the person's central values (p. 519).

Whether dealing with aspects of the self concept or central values of the individual, the mechanism underlying the value-expressive function relies on the perceived relationship (E) of the attitude object to some characteristic or value, and the strength or importance (V) of that value to the individual. The strength of the relationship between an ExV index based on individual values and overall attitude serves as an indicator of the value-expressiveness of the attitude.

Knowledge. In an investigation of the knowledge function, Cohen, et al. (1955) implicitly used an ExV conceptualization in their hypotheses that:

1. An ambiguous situation [E] will be more frustrating [i.e., negative affect-producing] than a more structured one.
2. Hypothesis 1 will be more applicable to people with high need for cognition [V] than for those with low need. (p. 291)

Need for cognition was postulated as a desired end-state (V) which could be satisfied by perceptions (E) of the environment as unambiguous and structured. The assumption of multiplicative combination of the E and V terms is clearly present in Hypothesis 2. In their later discussion of the knowledge function, Katz and Stotland (1959) state:

Thus it would be expected that those objects in the environment which aid in understanding the world would be evaluated highly. Furthermore, if the object itself is clearly understood, it will be evaluated more highly than if it is understood but vaguely (p. 438).

²In the recent discussion, "expectancy" will be used to refer to any perceived relationship between an attitude object and some related attribute, property or value. No distinction is made between the level of the perceived relationship (e.g., degree of sweetness of a soft drink) and the probability that the level exists (e.g., it is very likely that the soft drink is sweet). While this distinction may be important in subsequent measurement of attitude functions, it is not critical to the conceptual development of an ExV approach.

Therefore, it is apparent that the perception of the environment as unambiguous, or as aiding in the reduction of ambiguity, is the major factor in satisfying the need for knowledge function attitudes. An ExV index based on needs for knowledge, understanding, cognition, etc., and the related environmental perceptions would form a measure of the knowledge function. The relationship between this index and attitude would indicate the degree to which the knowledge function was being served by the attitude.

Ego-defensive. The final function to be considered here, ego-defensive, is on the surface rather far-removed from an ExV formulation in its emphasis on unconscious motives. In fact, Locke (1975) criticized ExV theory as being incompatible with subconscious motives. However, there is reason to believe that this criticism may be somewhat overstated, in view of several observations made by functional theorists. For instance, in discussing their externalization function, Smith, et al. (1956) postulated that:

Covert strivings influence selectivity in the perception [E] of objects [p. 271] ...Attitudes toward objects are influenced by attitudes toward covert strivings [V] (p. 273).

Similarly, Sarnoff and Katz (1954), in discussing the distortion that is inherent in ego-defensive attitudes, noted that four types of distortion could be present:

In terms of distortion of the target object, the person with ego-defensive attitudes may:

1. Attribute to others [E] qualities which they do not possess.
2. Ignore [E] qualities which they do possess.

In terms of affect loading, he may:

1. Experience an excessive emotional reaction (either positive or negative) [V] to real or attributed qualities of the object.
2. Fail to experience an adequate emotional reaction (either positive or negative) [V] to real or attributed qualities of the target. (p. 120)

Finally, Sarnoff (1966) notes:

...a precise determination of the functional relationship between an attitude and a consciously unacceptable motive involves:

1. A postulation of which combination of consciously unacceptable motive [V] and ego defense [E] might plausibly account for the particular overt response from which the attitude is inferred.
2. After conceptualizing the most plausible combination of ego defense and consciously unacceptable motive, we must proceed to demonstrate empirically the relationship between that combination [ExV] and the attitude it is presumed to support. (p. 283).

It has been previously noted that the ego defense mechanism of projection is the only one which has been shown to consistently relate to social attitudes (Sarnoff, 1960a). To the extent that the projection of unacceptable traits and motives onto outgroup members constitutes an expectation (E), however inappropriate, then the resultant satisfaction of ego-defensive motives (V) should lead to

the formation of ego-defensive attitudes. Further, an ExV index composed of all projected traits and their associated evaluations should provide an index of the ego-defensive function. To the extent that this index is associated with a measure of overall attitude, the attitude can be regarded as serving the ego-defensive function.

The preceding references to, and quotations from, functional theory literature should point out the considerable compatibility of functional theory with an ExV formulation, although this linkage was not explicitly recognized by the functional theorists, nor by later attitude researchers. While it may be argued that the ExV notion is obvious in the writings of functional theorists, it is not so obvious as to have been carried through in systematic fashion. This is particularly evident in Katz' (1960) hypothesized conditions mediating attitude arousal and change and in the lack of operations for assessing attitude functions. It is therefore asserted that viewing functional theory from an ExV perspective constitutes a first step in reconceptualizing the theory along lines which explicitly note its compatibility with ExV theory and move it further toward the status of an empirically testable theory.

Implications

There are numerous important implications stemming from the proposed reconceptualization of functional theory. These implications can be broken down into implications for theory and implications for policy.

Theoretical Implications

Most importantly, the ExV reconceptualization of functional theory provides a means for empirical testing of functional theory propositions. Thus this conceptually rich approach to the study of attitude and attitude change can, for the first time, be thoroughly investigated to determine its usefulness as a theory.

Secondly, the ExV framework proposed here, together with appropriate operational procedures (Lutz, 1977), can perform an integrative function in at least two respects. At one level, the reconceptualization has helped to expose the basic similarity of process underlying the various functions. At another level, it can help to achieve the integration of multiattribute models of attitude (Wilkie and Pessemier, 1973), as well as self-concept research (e.g., Ross, 1971) and the Rokeach (1968) value paradigm, under the functional umbrella, an important unifying step in current research on attitudes. Self-concept research, in particular, has been a stepchild in consumer behavior research, with no broader frame of reference. Functional theory provides that frame of reference.

Policy Implications

Functional theory is a potentially powerful policy tool; until now, however, its usefulness was hampered by the lack of measurement procedures. The current approach should lead to a solution of the measurement problem, thus making the theory available for market application. Its contributions should be felt in at least three areas.

Attitude measurement. Functional theory, as reconceptualized, would provide a unified framework for the measurement of attitudes toward brands, products, social issues, etc. Depending upon the level of involvement, different weights should appear on the various functions. It should be of interest to the manager, for example, to know the functional basis of attitudes toward a particular brand in comparison with the functional basis of attitudes toward the product class in general. This

knowledge could lead to an industry-based campaign directed at one function, while brand advertising may focus on another function altogether.

Market segmentation. McClintock (1958) noted that "... knowing the personality structure of the individual seems necessary for the devising of appropriate and effective means for changing attitudes" (p. 493). Since modern segmentation theory espouses a "building up" of individuals into homogeneous market segments, functional theory is well-suited for market segmentation based on the particular attitude function(s) being served for various groups in the market. This approach to segmentation has been attempted, with some success, by Locander and Spivey (1975).

Communications strategy. Clearly, the functional approach should be quite useful in the diagnosis of consumer attitudes for the purposes of prescribing attitude change strategy. By measuring the various functional supports and determining their relative weights, the most efficient means of change can be derived. The functional framework also provides a basis for communications copy pretesting, to determine if the appropriate cognitive-motivational structure is being impacted. Finally, the proposed functional approach could be used for monitoring the effects of a persuasive campaign in the marketplace (Lutz, 1978).

Conclusion

In this paper, the origins and propositions of the functional theory of attitude have been reviewed, evaluated and reconceptualized within an expectancy-times-value framework. The proposed reconceptualization has been shown to be consistent with theoretical statements by the original functional theorists.

Functional theory is a potentially powerful managerial tool for use in advertising and segmentation decisions. Thus, adoption of the proposed ExV framework would not only enable testing of the theory, but also application of the theory to policy decisions. The potential richness of the theory for decision-making has long been noted but never attained due to lack of measurement procedures. The proposed reconceptualization does not completely ameliorate that deficiency in view of the fact that no data have been reported, but it does serve to make it clear that measurement is feasible within the reconceptualized functional framework.

NEW DIRECTIONS IN ATTITUDE RESEARCH: A CRITICAL EVALUATION

Joel B. Cohen, University of Florida

I have been asked to discuss the four papers presented at the session, "New Directions In Attitude Research." I suppose it would be appropriate to start off with the question, "So what is new?" While I'm not certain any of the authors would claim to have started us down a truly virgin path, consumer researchers can, I think, harken back to four identifiable research orientations which have been given a shot in the arm by these papers. All have been underrepresented in previous consumer research. I have labeled these four major research thrusts as: (1) an information processing approach to attitude formation and change, (2) the importance of time in studying cognitive organization and change, (3) explicit consideration of the motivational bases for attitudes and attitude change, and (4) attitudes as interpersonal communications. I'd like to discuss how each of these has been treated by the authors who have addressed these issues.

Attitudes As Interpersonal Communications

I begin with this topic because it is probably the newest of the attitude research orientations to be represented within the consumer behavior area. The notion of products as identity-relevant symbols, of course, is one of the oldest and best enduring concepts in our field. From the social class and reference group-oriented approaches of the 1950's (cf. Rainwater, et. al., 1959; Levy, 1959) through interpersonal response trait-oriented research (cf. Cohen, 1967; Cohen and Barban, 1970) to self-concept based research (cf. Dolich, 1969; Ross, 1971), consumer researchers have long recognized the importance of identity enhancing social communications to product and brand choice.

Schlenker's "social identity theory" provides a unifying conceptual structure within which to examine self-presentation strategies and behaviors. Attitude expressions and statements are viewed as interpersonal communications--thus, behaviors to be studied in their own right. According to Schlenker, "Even 'private' attitudes, expressed only to oneself, occur in the context of imaginary social settings and serve the same functions in our private worlds." Viewed within the framework of social identity theory, then, a person's attitudes and expressions of attitudes represent a deliberate attempt to create a particular identity, an impression management strategy.

Knowing Barry Schlenker as well as I do, I simply cannot believe that he is expressing favorable attitudes toward his social identity theory merely or primarily to gain respect and admiration or to otherwise stroke his self-concept. No, I am certain he believes very strongly in the worth of this orientation and, in fact, would evidence considerable enthusiasm for it were he isolated on a desert island with no praise in sight. Indeed, were Barry physically restrained from communicating about this topic to any other human being, it would probably play the same guiding and organizing role in his beliefs about human behavior.

Rich Lutz might want us to analyze Barry's attitudes toward social identity theory in terms of a "functional" approach, which I suspect might go heavy on utilitarian and particularly knowledge functions. In fact, what better example of an attitude object based on the knowledge function can be found than a theory in the hands of a dedicated scientist? Such a theory helps the scientist to find meaning out of seemingly disconnected observations, to organize relevant aspects of human behavior and thereby to provide clarity and consistency to his thought processes. We can think of this in terms

of the observations Jerry Olson and Phil Dover have made with respect to the organizing aspects of memory schemata.

The functional approach argues for balance, for a willingness to see attitudes as serving multiple and diverse needs and goals. Social identity theory promises to enrich our understanding of attitudes which, at least in part, serve value expressive needs. Such attitudes, whether expressed in the form of volunteered statements about a particular product, responses to a questionnaire or in overt purchase behavior convey an association between aspects of a desired self-image and certain product characteristics. Under what conditions (e.g., situations, types of products, the nature of the "audience") a consumer's attitudes will be most likely to reflect impression management goals would appear to be a highly relevant, and eminently researchable, topic area.

Motivational Bases For Attitudes

One of the interesting theoretical issues involved in all of the papers is the motivating role of cognitive consistency in human behavior. To what degree is the establishment and maintenance of cognitive consistency a major driving force, goal or function? Rich Lutz's paper addresses this issue by viewing knowledge, cognitive organization and consistency needs as one of the major bases underlying the existence of attitudes in the first place: to provide meaning and structure and as a guide for action. The disruption of cognitive consistency, in this sense, could produce considerable ambiguity, uncertainty and behavioral conflict. Restoration of consistency, such as through exposure to information favorable to one's initial position, should be favorably regarded and conducive to the acceptance of such material. Yet, conflicts frequently exist between one's desire for consistency and one's adjustment needs. Only by being open to new information and being willing to modify existing beliefs as well as behaviors can the individual grow and adapt successfully to a dynamic environment.

Under conditions other than those which threaten to disrupt cognitive systems which the individual is committed to maintain (e.g., central beliefs about one's self, beliefs whose disruption would so disorient the individual as to impact on his ability to act), knowledge and organization-based cognitive consistency processes, while fundamental and pervasive, are probably not dominant.

Sources of Cognitive Inconsistency

Barry's paper makes the point (which other critics have also made) that the concept of cognitive inconsistency as a drive-like state (which then "pushes" dissonance reduction processes) is not well conceptualized or defined by its advocates. Is cognitive inconsistency really all that important? This criticism is, I believe, well founded and stems in large part from the failure of dissonance theorists to come to grips with and spell out both the source and the nature of such drive-like states.

One could, I suppose, attempt to argue that critics have all too often ignored the clearly stated proposition that dissonance theory requires an assessment of the number and importance of dissonant cognitions, and thereby a determination of the magnitude of the dissonance present, before rushing off to make predictions regarding dissonance reduction processes. Clearly,

some cognitive inconsistencies appear to be trivial and others quite important. But, frankly, the theory's advocates have tended to skirt this important issue, and the critics have been left with an inviting (if imprecise and ambiguous) target. Psychological commitment to an action or position, degree of choice, choice incentives and foreseeability, while eminently researchable correlates of the magnitude of dissonance, do not provide a very satisfying conceptualization of the nature and strength of the dissonant state.

One's response to this state of affairs could be to look elsewhere, to turn to other "competing" models in the hope they will be at least as productive and a good deal more precise. Incentive theory (Elms, 1967), self-perception theory (Bem, 1972) and most recently social identity/impression management theory (Tedeschi, et. al., 1971; Schlenker, 1977) represent well-conceived efforts in this direction. While each of these (and particularly social identity theory) can be seen to offer compelling alternative explanations for dissonance-like effects, particularly in the typical counterattitudinal behavior paradigms, I do not find any of these formulations to be as fundamental theoretically as dissonance theory. The potential integrative strength of dissonance theory has not been realized, in part because of a failure to recognize and combine both information processing and self-concept related underpinnings.

What I would like to propose is that there are two major sources of dissonance, in the sense of dissonance being a drive-like state resulting from cognitive inconsistency. The first of these is clearly related to Katz's (1960) "knowledge function" which Lutz has described in his paper. There is a need for meaningful and consistent cognitive organization in order to deal effectively with the external world. Without this, the world would be a mass of disconnected stimuli. In response to such needs, we see the development of cognitive structure, which provides an interpretative and integrative function influencing all information processing activities.

Clearly, there must be an adaptive balance between openness to reality (even if it be counter to our prior beliefs and expectations) and the maintenance of an organized system of cognitive categories (which we take to be our knowledge of what is and what is not, what things go together, etc.). Experiments such as those which confront subjects with a deck of playing cards containing a black queen of hearts or a red king of spades illustrate a principle which has been termed "assimilation to the typical instance" (Jones and Gerard, 1967) and which is of considerable importance for social perception (e.g., stereotyping). Milton Rokeach has emphasized this dimension by defining resistance to change of a belief "solely in terms of connectedness: the more a given belief is functionally connected or in communication with other beliefs, the more implications and consequences it has for other beliefs and, therefore, the more central the belief" (1968, p. 5).

Very few dissonance studies have specifically examined the drive-like effects of a disruption in one of a person's central beliefs. It is not an easy matter to design a study which would seriously challenge an important personal belief. There can be no doubt, however, that the dissonance caused by strongly believing A implies B and then learning that A implies not B would be drive-like: some resolution of this cognitive dilemma must be found to restore order and meaningfulness. (See Abelson, 1959 for a discussion of denial, bolstering, differentiation and transcendence in resolving belief dilemmas.) Carried to an extreme, "It may be supposed that any inexplicable disruption of these taken-for-granted constancies, physical or social or

self, would lead one to question the validity of one's own senses, one's competency as a person who can cope with reality, or even one's sanity" (Rokeach, 1968, page 7). Field studies which have the potential to create powerful disconfirmation of beliefs (supported by behavioral commitment) as when one who is committed to a course of action is suddenly and dramatically confronted by evidence that his beliefs and course of action are wrong (see for example Festinger, et. al., 1956) may provide a more appropriate setting in which to examine the power of cognitive inconsistencies than the usual types of scenarios presented to subjects in laboratory studies.

The major source of dissonance is probably inconsistencies relating to the self-concept. Here the issue is not coping with reality and cognitive organization, per se, but rather what Katz (1960) has termed "value expressive" needs. It is quite true, of course, that self-concept related beliefs may be important anchoring points for a large number of related beliefs, and hence play an important organizing function. Such beliefs should be quite resistant to change, and behavior seen as inconsistent with them should provoke considerable dissonance. It is with self-concept related beliefs that dissonance theory and social identity theory may be inextricably linked. Whether or not social identity theory is a competitor or serves to extend and clarify may be more a matter of judgment than an empirical question.

Another reaction may be that what is proposed here is no longer quite dissonance theory or at least is a substantial modification of it (perhaps extending Aronson's, 1968, line of thinking). The basic point, though, is that the theory itself is unusually silent on such a key issue as the nature and identification of the "importance" of a cognitive element. This was acknowledged as early as 1962 (Deutsch, et. al.) when the following proposition was advanced: "Thus, we offer the hypothesis that a chooser will experience post-decisional dissonance only when he perceives his choice in a given situation to be inconsistent with the conception of some aspect of himself which he tries to maintain (for himself or for others) in that situation."

Dissonance Reduction Versus Self Enhancement

What then is the motivating force, inconsistency among cognitive elements one or both of which serve important self-defining or organizational functions, or (per Schlenker) a desire to act so as to increase personal association with desirable attributes and outcomes and to decrease such association with undesirable attributes and outcomes? Social identity theory sees the degree of fit between the identity the individual is trying to project and some action, attitude, or choice object as the key element. Dissonance theory would conceptualize this fit or association in terms of cognitions of varying importance and consistency.

Paired in this way, the commonality among these formulations may be more important than the differences. Social identity theory greatly extends, clarifies and refines the nature of attitude-behavior relationships which involve social identities and related behavior.

Schlenker and Schlenker (1975, p. 963) state, "The greater the degree of personal responsibility an individual perceives for an action which generates negative consequences, the greater his degree of personal dissatisfaction, anxiety, and attendant social punishment." The dissonance theory position proposed earlier leads to a very similar hypothesis, since negative consequences of one's behavior should be strongly inconsistent with a very important set of cognitions: those which define and proclaim one's self-concept. The Schlenkers, in an

insightful overview of the counterattitudinal behavior paradigm so often used in dissonance and self-perception theory research, point out that these "have placed individuals in positions where their self-image and public image is jeopardized..." (p. 964). While they maintain that "attitudinal discrepancy is not a necessary antecedent to attitude change," I would argue that the discrepancy between self-concept attitudes and inconsistent behavior is precisely the nature of the individual's predicament. Social identity theory, to its credit, goes on to identify tactics to be used by the individual to maintain and enhance his self-image and presentation of self. These same tactics, of course, serve to provide the individual with cognitions regarding his behavior which are more consistent with his self-concept.

The conceptualization of self-image maintenance and enhancement tactics appears to be quite similar to that adopted by Lutz in his treatment and proposed operationalization of the functional approach. By positioning the functional approach within an expectancy-value framework, Lutz develops the similar (to Schlenker) notion that attitude change attempts (whether externally or internally generated) must effect either the perceived association (i.e., perceived instrumentality) between the individual and the action (e.g., taking personal responsibility in Schlenker's system) or the value of the consequences (e.g., minimizing the amount or existence of harm in Schlenker's system). Perception of choice manipulations are a favorite device used to impact on the amount of responsibility (perceived instrumentality) the experimental subject perceives he had for whatever consequences developed. When personal responsibility is heightened, and the individual is therefore unable to excuse or justify his actions, he will frequently attempt to alter his perception of the resulting consequences (e.g., "No 'real' harm occurred; At the time I said, wrote or did X I really believed it was the good, true, or the right thing to do").

The same type of expectancy-value analysis has been applied by Schlenker and Schlenker (1975) to the situation in which positive rather than negative consequences result. Specifically, an average to dull person was told that she was quite attractive under either high or low choice (responsibility) conditions. S's subsequent scores were more positive than those of a control group only when there was low choice and S's expected future interaction during the study with the other person. A social identity theory expectancy-value analysis explains this result quite nicely in terms of S's exhibiting favorable attitudes toward the other person in order to associate themselves with and claim responsibility and credit for the positive consequences stemming from their (experimenter imposed) communications to the other person.

Schlenker and Schlenker feel that attitude change, which has the effect of establishing an internal locus of responsibility, is counter to dissonance theory predictions (i.e., S's having no choice and producing positive consequences should, they claim, experience no dissonance).

The problem, however, is that dissonance theory is ambiguous in terms of the source of the cognitive inconsistency. If, as the Schlenkers acknowledge, the dissonant cognition may relate to the self-concept (e.g., "I'm a friendly and helpful person. Yet I'm coming across as if I might not be that way at all because the experimenter wouldn't let me exhibit these qualities-- I was given no choice."), then dissonance reduction is a viable alternative explanation. The Schlenkers' unwillingness to accept this explanation seems to be more a matter of overall discontent with dissonance

theory's lack of precision (or an inability to pin it down, if you like) than the responsiveness of this particular explanation to their data.

Actually, there may be an even simpler dissonance theory interpretation: S's were merely bringing their questionnaire responses into line with their anticipated behavior. The no-choice, future interaction S's probably anticipated behaving in a positive and favorable manner toward the other experimental subject when the experimenter brings them together. Such S's will also know that the experimenter has told the other person that the favorable communication was assigned rather than chosen. These S's should have a greater reason to show both the experimenter and the other person that their attitudes and subsequent behavior are, in fact, consistent than S's whose free choice has already conveyed this.

Now, whether this preference for consistency stems primarily from a desire for cognitive order (i.e., to eliminate confusions that might interfere with one's ability to behave clearly and convincingly-- see Jones and Garard, 1967, for a discussion of the value of an "unequivocal behavioral orientation."), or a desire to appear consistent and genuine (to be otherwise would be inconsistent with important self-concept attitudes) can't be definitively resolved in this study. Even worse, it looks like it is going to be very difficult indeed to design a study in which dissonance reduction and the maintenance and enhancement of social identity (as alternative explanations) are not somehow confounded.

Concerning the need for jousting with dissonance theory, my recommendation to Barry would be to let the dragon slumber. It's been pretty quiet of late and doesn't seem to be up and about too often. There isn't really any need to take it on. The issues, settings, and most importantly the interpersonal goals which are directly addressed by social identity theory are not directly captured or represented by the more cognitively oriented dissonance theory.

Thus, even though dissonance theory may provide a somewhat more elegant and over-arching theoretical position which can incorporate virtually any set of data or conceptualization which possesses consistency-striving characteristics (whether to an actual or ideal self-image or presentation), it offers comparatively few insights into the self presentation and impression management areas when compared to social identity theory. While theoretical validity, comprehensiveness and parsimony may be ultimately satisfying to the soul of any behavioral scientist, the usefulness, adequacy and operational vitality of a conceptual framework may be a good substitute for the working social psychologist. On this score, and given the area on which Barry has chosen to focus, social identity theory appears to be off to a flying start. That one person or another may explain the same percentage of variance in one's data by some simple or "oblique" rotation of conceptual axes in and of itself does not establish the "truth" of that conceptual system.

Social identity theory is at one and the same time both less and a good deal more ambitious than any generalized consistency theory. It is less ambitious because it presents no claims on areas of inquiry which do not reside within its narrower domain (e.g., Olson and Dover's concern with information processing aspects of cognitive consistency). It is more ambitious because it does seek to provide a much more adequate and complete description and explanation of the many facets of human behavior concerned with social identity and self-presentation. This is a difficult and challenging area and one of great relevance to social psychologists and consumer behaviorists alike. There is no doubt that

we shall be hearing a great deal more about social identity theory in the near future.

Status of the Functional Approach

I'd like to turn now to a consideration of Rich Lutz's excellent review and analysis of the so-called "functional approach to the study of attitudes." There are a number of reasons for advocating a categorization scheme similar to the one Rich has been working on. First, of course, such a scheme has the potential for shaking us out of any intellectual lethargy we may have fallen into in thinking too narrowly about such things as the antecedents, support for and conditions for changing attitudes and behaviors. There is also a specificity problem inherent in theories conceptualized at a highly abstract level (e.g., learning theory, dissonance theory), especially when considering applications to an area like consumer behavior, although such theories are generally considered to be more fundamental as well as parsimonious.

The general notion of differing functional bases seems sound enough. Attitudes and behavior expressive of prejudice toward a minority group, or for that matter, of liking for a dashing new sports car, may have very different functional bases and goals. Lutz's extension and modification of Katz's (1960) categorization scheme for the consumer behavior area may well help us to keep this fact firmly in our minds.

Another reason for advocating such a categorization scheme is as a kind of motivational check list (e.g., before leaving on a long trip, stop the newspapers, call the post office, lock the doors and windows, etc.). It is here that Rich may run into some trouble. At what level of specificity should functions be stated so as to be useful, say, to those interested in changing existing attitudes? My check list of things to do before leaving on a long trip is quite specific and at an actionable level. In addition, I have some confidence that these are, in fact, the things to do and that there aren't any major omissions. Can the same be said of Lutz's listings? Kiesler, Collins and Miller (1969) had earlier leveled this type of criticism at the functional approach.

If what we are after is a check list which is both more complete and more precise, we might begin with a review of the literature pertaining to personality needs and goals, from the pioneering efforts of McDougall (1908) through Murray (1938) to the recent day factor theories (see, for example, Cattell and Scheier, 1958). Clearly, the number and diversity of human needs, motives and goals can approach staggering proportions if our goal is to be exhaustive or purely descriptive (as in psychographic research).

It seems clear that Rich must be striving for something different than an exhaustive check list, some midpoint at which the structure provided attains that happy balance between pointing and naming, on the one hand, and abstract conceptualization on the other. While researchers have never been able to reach a consensus on how many functions, or needs or goals is the "right" number, not to mention what these are, that probably should not foreclose efforts at developing the sort of categorization which Rich believes would be useful. It seems clear, however, that "merely" developing satisfactory operational measures for the functions he advocates does not address the more basic question regarding the adequacy of the conceptualization of needs and goals represented by the classification scheme.

In summary, it appears as though the jury is still out, and a verdict cannot yet be given as to the usefulness of the functional approach in consumer behavior. If it

does nothing more than alert us to the need to look beyond utilitarian product attitude in assessing consequences of using (or not using) a particular product, it will have contributed to our understanding of consumer attitudes and attitude change. We will look forward to greater operational specificity and empirical research on the part of those who advocate this approach.

Information Processing Aspects

The Olson and Dover paper is important for consumer researchers particularly because it raises a set of issues which cannot be ignored by those who would focus on the outcome of information processing and decision making activities extending over several days, weeks or even months.

Changes in Cognitive Structure Over Time

Time (that bane of a researcher's existence, because it forces us out of one-shot measurement paradigms) is the catalyst. It is inconceivable that we will be able or willing to generalize our findings regarding information processing and decision-making very far without adequately investigating changes in cognitions and cognitive organization that occur over time.

Olson and Dover go on to analyze the impact of time on cognitive structure by looking at data from a longitudinal study designed to investigate disconfirmation of expectations. Obviously, some compromise must be made whenever the data one uses are not exactly what one would have gathered for the present purpose, and the authors acknowledge this limitation.

A major result, which Olson and Dover seek to understand and explain, is the increasing consistency among elements of cognitive structure over time. One suggestion that could be made with respect to research of this kind is that cognitive structure is a property of an individual's cognitive system, and hence the degree of consistency should be studied on an individual rather than group level. I'm more than a little uncomfortable with group means and correlations as indicants of changes in an individual's cognitive structure over time.

Evaluative and Probabilistic Consistency

An important distinction with respect to inference processes has been highlighted by the authors who call attention to the parallel concepts of evaluative and probabilistic consistency. The latter refers to the degree to which two concepts seem to be logically related to one another based on a combination of learning and stimulus cues so that inferences regarding an object's possession of other attributes follow along the lines of a conditional probability statement. Inferences based on evaluative consistency, on the other hand, seem not to be as concept-driven as they are affect-driven. That is, I may attribute positive qualities such as intelligence and warmth to a person because he is portrayed positively, not because I believe there is an associative link between the two attributes. Aspects of this process have been referred to as a "halo effect." These, then, are alternative mechanisms for filling in the gaps in one's belief systems, and since all information acquisition is necessarily incomplete and leaves gaps, these are very important processes.

Olson and Dover seek to disentangle the results of these two processes by looking at the increasing consistency they observe among $b_i e_i$ elements. I would recommend looking at the b_i elements by themselves since the concept of evaluative consistency pertains to the basis for the inference process (i.e., a positively regarded object is thought to possess positive attributes), the result of the inference being the

association of the object with some attribute. Once again, though, it is hard to see how this can be done on anything other than an individual basis. In addition, disentangling these processes will require a study specifically designed for this purpose. While the authors suggest that evaluative consistency is operating in their study, this appears to be highly speculative in the absence of data specifically establishing the probabilistic linkage among the belief elements (i.e., the probability of A given B) as well as an independent evaluation of attributes.

Their group data (Figure 1) reveals wide fluctuation in attribute evaluations until people first tasted the bitter coffee, at which point four of the five attribute evaluations moved in the same direction (i.e., became more negative). Then, after an extended trial of the unadulterated coffee, four of the five attribute evaluations became more positive. The authors, looking at intercorrelations among attribute evaluations at the end of the study, concluded that the three attributes most closely related to overall product attitudes were also closely related logically (i.e., probabilistically). While these findings are quite interesting, the data used is simply not adequate to the delineation of inference mechanisms. It is simply not sufficient to estimate the degree of internal consistency among attribute evaluation scores. This sheds no light on the process that led to such a level of consistency.

Separating Out Sources of Impact

One potentially troublesome research issue suggested by the use of multiple measurements in a within-subjects longitudinal design is that our attribute-specific measures may be consistency-inducing. Wyer (1976) has referred to this not uncommon phenomenon as the "Socratic effect." That is, we may be making a person more aware of the probable existence of an attribute-based belief structure and its presumed "logical" relationship to one's overall attitude. In so doing, we may encourage him to think through any inconsistencies in his own belief structure and, particularly for insightful experimental S's, to resolve these in the direction that would allow us to perceive them as more logical.

The authors make the important observation that beliefs may not be well-formed or stable after an initial exposure to information about an object or even the object itself: it may take several such experiences with the object. They argue for the direct measurement of S's confidence in their belief ratings. Here again, a within-subjects design may cause some problems. It may be that S's will believe that they should become more confident as a result of increased information and/or experience.

Olson and Dover report that the evaluation associated with beliefs regarding bitterness was, by the end of the study, the most strongly related attribute to overall attitude. This may, of course, simply be the result of demand effects since there were three separate communications designed to convince people that the coffee was not bitter followed by a "bitter" manipulation, and S's may have gotten the idea that bitterness was somehow important, at least to the researchers.

It is interesting, however, that the correlation between the evaluation of this attribute and overall evaluation was not particularly strong nor showing any particular trend until people actually experienced the bitter coffee. Perhaps this is still another illustration of the difference in impact between communications as information and experience as information. It may be something to think about in designing experimental

manipulations, not to mention the various reasons to be interested in attitude and behavior change strategies! Perhaps one explanation for the greater impact, following the thrust of Olson and Dover, may be the greater "depth of processing" that is probably associated with the increased involvement overt behavior typically generates (See Nisbett, et. al., 1976, for a related viewpoint).

This particular piece of data also reminded me of the unique problems (e.g., long hours spent trying to communicate to respondents followed by blank stares) involved in the association between the absence of a negative state (i.e., this coffee is not bitter) and one's resulting positive evaluation. This double negative leading to a positive may not be as easily learned as a positive state leading to a positive evaluation.

There are, after all, a very large number of attributes an object doesn't possess, most of which we are not aware of to begin with or ignore. Saying that an object doesn't have something may actually communicate less information than saying it does have something, when the attribute in question is not highly salient to begin with. Thus, communications which instruct me that a particular brand of coffee does not possess an attribute I hadn't given much thought to will not produce very much cognitive work: there is nothing more I must deal with. By comparison, instructing me that the coffee does possess an attribute I hadn't given much thought to provides me with information which I need to integrate with existing information. The informational act of tasting the bitter coffee and experiencing its consequences should have given people a much better reason to link the absence of that attribute with their overall evaluation of the coffee.

Time and the Decay of Advertising Effects

Olson and Dover have enlightened us as to the substantial changes which may take place in cognitive structure over time, and Sawyer and Semenik, likewise, stress the need for researchers to examine delayed as well as immediate effects of advertising. The major thrust of the paper has to do with the decay of corrective advertising effects. Sawyer and Semenik invoke Jost's Second Law of Learning to explain why a corrective ad may appear to be more effective in reversing the effects of a deceptive campaign than it really is. According to Sawyer and Semenik, this translates to mean that "the effect of the older of the two (stimuli) will decay less rapidly - reaching some asymptotic level higher than that of the newer campaign."

The rate of decay (i.e., memory based) argument is quite similar to the explanation frequently given for observed recency effects when dependent measures are administered shortly after the second communication and some interval of time has elapsed between the first and second communications.

I have some difficulty with the higher asymptotic level of the older stimulus without knowing a great deal more about the reward and practice schedules which might so forestall further decay as to give it absolute superiority over a newer stimulus. Phrased more colloquially, Sawyer and Semenik's Figure 2A suggests to me that the older stimulus is comparable to a George Allen established performer and newer stimulus to an unproven rookie. A specific a priori determination of relative belief strength toward to the two stimuli, in my opinion, will not be derivable from any law of learning which fails to specify the exact relationships between each stimulus and other pertinent

beliefs together with the value of the respective items of information to the individual. This is a tall order!

Another compelling interpretation may be that processing of the information in the second communication may be incomplete if measures are administered immediately thereafter, with the result that a "play back" of the position advocated in this communication (assuming it has been presented in a convincing manner) is a "sensible" response to the questions we are asking. With continued processing of the message, the individual should have a much greater opportunity to compare both its conclusions and premises with related stored information. If aspects of the new information are not as consistent with previously well-supported beliefs as it appeared on first contact, it may then be treated with less than perfect certainty or otherwise qualified. In any event, both memory-based and information processing-based arguments support the taking of delayed measures.

Time and Cue-Dissociation

I have related problems with the "discounting cue hypothesis" which assumes that a dissociation of an inhibiting cue (the authors look upon a corrective ad as an inhibiting cue) over time will reinstate the effects of the original stimulus. First, I have difficulty with translating a sometimes empirical observation into an explanation. Some information had less effect over time. Why? Because people discounted it. Very enlightening!

Perhaps a closer look should be taken at the authors' descriptions of the characteristics of information that was apparently "discounted" in other research. This might provide some idea as to why people might behave in this fashion. Let me throw out just one possibility. Whereas the non-discounted information seems to combine both conclusions and supporting arguments, the discounted information appears only to have offered a summary blanket refutation. Unless this refutation succeeded in removing the previous information from memory storage, further reality and consistency testing of that information was possible, indeed likely because of the conflicting conclusions which had been transmitted. No such opportunity was apparently present for arguments underlying the refutational conclusion, because none were presented. So a much greater opportunity seems clearly present, then, for people to make a subsequent assessment as to whether the "positive" conclusion "rings true."

Additionally, I'm not sure that Sawyer and Semenik have made a very good case for applying such concepts directly to the corrective advertising area. As I tried to indicate above, we need to take a long and hard look at both the concepts advocated and how they are operationalized. A concept invariably contains surplus meaning beyond a given operationalization. Perhaps we ought to be a little more conservative and claim no more territory than we have empirically staked out. In a sense, this is another argument for the importance of construct validity in behavioral research. To the extent that the corrective advertisement operationalizations are quite different from the research paradigms on which the concepts are based, a healthy skepticism seems in order. Identification of the major differences between the two contexts and settings may be a necessary and important step.

Let's just take one more brief example which spotlights the nature of the problem. Sawyer and Semenik present some findings indicating that qualified messages (stated more equivocally and with more reservations) persist better than unqualified messages. One set of

now familiar explanations is that the qualifications and reservations are forgotten, discounted or dissociated from the main conclusions over time.

But what if this effect is due instead to the greater perceived credibility, expertise and trustfulness of a communicator who appears to be trying to be fair to both sides as well as more objective? It certainly looks like that person has been very thorough and is clearly well informed (more so that I could be on the topic). I might tend to believe his conclusions to a far greater extent than those of the communicator who has presented an unqualified message. Sawyer and Semenik seek to equate qualified messages with the format of corrective advertisements. But, if the communicator credibility notion is correct, and we assume that the credibility of an FTC-initiated conclusion is quite high, making the conclusion more equivocal and tentative may not only be unnecessary but a serious mistake.

Unfortunately, the ambitious study designed by Sawyer and Semenik appears to have misfired with respect to the stimulus materials themselves (i.e., there were no significant differences on the target belief between a control group of people who were not exposed to any message and S's exposed to either of the experimental messages). It would not appear to be particularly useful, therefore, to attempt to interpret some of the other results (a number of which are non-obvious) in the light of the difficulties and suggestions for improvement the authors have themselves raised in the paper.

SHORT AND LONG TERM COST CONSEQUENCES OF GOVERNMENT REGULATIONS TO CONSUMERS

Rachel Dardis, University of Maryland

Abstract

Government regulations in the area of textiles are categorized according to whether they are designed to protect the worker, the environment or the consumer. In most instances regulations will entail an increase in manufacturing costs which will be passed on to consumers in the long run. However, the existence of imports may serve to depress price increases in the case of regulations affecting the worker or the environment.

Introduction

It is not possible in this paper to cover all government regulations affecting the textile industry. However, most government regulations may be classified under three major headings: (a) regulations to protect the textile worker, (b) regulations to protect the environment, and (c) regulations to protect the consumer. Major regulations in each of these areas will first be discussed while the impact of such regulations on the industry and the consumer will be discussed in the second section of the paper.

Regulations to Protect the Textile Worker

Two major regulations address the exposure of the worker to cotton dust and noise. Cotton dust is believed to cause byssinosis though the specific agent in cotton dust has not yet been identified. The current OSHA regulations for cotton dust exposure are set at 1 mg/M3 of total dust (ATMI, 1975). The standard also requires that administrative or engineering controls to reduce cotton dust be implemented where feasible. If such controls are not feasible then respirators or other protection equipment must be worn by the worker. OSHA has proposed a new standard for cotton dust of 0.2 mg/M3 of total dust (Textile World, 1977). Estimated costs of meeting the standards, assuming that equipment could be developed, include initial capital expenditures of at least \$860 million, and annual energy and maintenance costs of \$35 million and \$4 million respectively (ATMI, 1975; Textile World, 1977). The feasibility of the proposed standard was also challenged by a cotton-dust expert at a recent hearing. Hocutt claimed that "anything under 0.5 would shut down spinning; anything under 1.0, weaving" (Textile World, 1977, p. 23).

Noise regulations affect most industries including the textile industry. However, they have a significant impact on the textile industry in view of the fact that textile processing is characterized by relatively high levels of noise. The present OSHA regulations specify that employees shall not be exposed to noise in excess of 90 dBA for an eight hour time period (ATMI, 1975). If noise levels are exceeded then engineering controls must be implemented or protective devices such as ear plugs and muffs must be worn by the worker. However, protective equipment is viewed as a temporary device by OSHA since there is no guarantee that it will be used by the worker. Recently the EPA has proposed an 85 dBA standard which would entail even greater costs for the textile industry. A study by OSHA estimated that it would cost \$1.1 billion to meet the present 90 dBA level and \$2.7 billion to meet the 85 dBA level (Storey, 1976).

Regulations to Protect the Environment

A major regulation in this area pertains to water pollution. Regulations for controlling the discharges of pollutants by the textile industry were promulgated in Feb-

ruary 1974 (ATMI 1975). Two levels of abatement were proposed with the lower level recommended for 1977 and the higher level for 1983. According to industry spokesmen there are few problems in meeting the 1977 level (ATMI, 1975). However, the feasibility of meeting the 1983 level has been debated. Estimated costs to the textile industry in achieving the 1977 and 1983 levels were estimated by the National Commission on Water Quality as follows:

(\$ million)	1977	1983	Total
Capital required	384-780	526-785	910-1,565
Annual Operation & Maintenance	49-68	50-81	

Regulations to Protect the Consumer

The Consumer Product Safety Commission began operation in 1973 after passage of the Consumer Product Safety Act. Four major areas of enforcement are (a) clothing textiles, (b) carpets and rugs, (c) children's sleepwear, and (d) mattresses (Lyons, 1976). Standards have also been proposed for upholstered fabrics and furniture and for wearing apparel.

Studies of the existing children's sleepwear standards concluded that they would increase consumer costs by approximately 30% (Dardis, 1977). However, the standards were also cost effective in view of the number of flammable fabric incidents involving children's sleepwear. Extension of existing sleepwear standards to children's clothing resulted in unfavorable cost-benefit ratios even under the most favorable assumption that the standards would entail no reduction in consumer choice. Cost-benefit analysis has not been applied to either of the two proposed standards. The proposed upholstery standard is estimated to result in a 10% to 30% price increase at retail as well as the elimination of certain fabrics (Storey, 1976). The proposed general wearing apparel standard combines flammability characteristics of textiles with garment style and is designed to reduce flammability treatment costs since tight fitting garments have less severe fabric flammability requirements. However, this standard may also entail a certain reduction in consumer choice since certain fabric/garment combinations will be eliminated. Testing and record keeping requirements for manufacturers will also entail costs.

Impact on Consumers

Impact on U. S. Textile Industry

In assessing the impact of government regulations on the consumer it is first necessary to take into consideration the impact of such regulations on the textile industry. The textile industry is characterized by perfect competition or monopolistic competition, both of which are competitive market structures. In addition the industry faces competition from imports from low wage countries such as Korea, Taiwan and more recently Red China.

Recognition of the textile industry's vulnerability to imports and the need for maintaining a viable domestic industry has led to trade regulations to control the flow of imports into the U. S. The most recent agreement was the MultiFiber Agreement (MFA) which is due to expire at the end of 1977. In spite of this agreement imports continue to present a problem and there has been increased

awareness of the necessity for modernization in order to meet competition from other countries. However, the textile industry's ability to modernize may be constrained by the diversion of funds from productive investment to investment to meet government regulations in the area of worker or environmental protection. According to Storey "for the abatement of cotton dust, noise and water pollution, there is a capital requirement equal to five years of the industry's earnings and equal to five years of its average annual investment in new plant and equipment" (Storey, 1976, p. 20). In addition operating and maintenance costs of meeting government regulations in these areas will reduce after tax profits of the industry and hence its earnings for capital expenditures. The reduction in productive investment by the textile industry will mean higher prices for the consumer in the long run.

Short-Term Cost Consequences to Consumers

The impact of government regulations on consumers is illustrated in Figure 1.
