Step 2: For each segment, derive a product space by using Johnson's procedure (1971). In this procedure a product space is built by means of multiple discriminant analysis. This technique permits to find linear orthogonal combinations of attributes which best separate the brands, maximizing the ratio of between-brand to within-brand variances. Average scores on each discriminant function permits to position each brand in the discriminant space.

Step 3: For each individual configuration, i.e., following a micro approach, decompose the product space a posteriori according to six decision models; three non-compensatory models: Conjunctive, disjunctive, lexicographic; and three compensatory models: One linear additive and two geometric ones (centered on the ideal point or the preferred brand). Figure 1 graphically represents how each model works: The shaded area would be the evoked set zone if each model were true. For each case, the evoked set zone is defined as the smallest area containing all evoked brands. A decision rule is considered successful if that zone does not contain any brand other than the evoked ones. If not, find out to which category these "offenders" belong.

Step 4: Determine the composition of the individual evoked sets in terms of prior trial of the brands.

Findings and Interpretations

The findings will follow the four steps defined in the previous section.

Step 1: Identify segments with homogeneous perceptions. In order to identify clusters of respondents on brand perceptions, two different clustering techniques were used, that is the Howard-Harris cluster analysis, and the BMDP-2M

FIGURE 1

hierarchical cluster analysis. The Howard-Harris program uses the criterion of minimum within-group variance at each level of clustering to form groups of objects using an objects-by-variable matrix (Howard & Harris 1966). The BMDP-2M procedure is also a hierarchical method. The two cases having the shortest distance between them are amalgamated and treated as one case and then, in turn, clustered with others. The procedure continues until all cases and clusters are amalgamated into one cluster.

Both techniques led to a single cluster: The whole group of 375 respondents, and, thus, the rest of the analysis is done on the total group.

Step 2: Generate a perceptual product space. The data on brand perception is then used for a multiple discriminant analysis of scale for 375 respondents, following the method developed by Johnson (1971). This method is particularly

suited to our needs in terms of stability, uniqueness of the solution and euclidian distances (Johnson 1971). It was found that three discriminant functions are significant and explain respectively 77.8%, 17.5% and 2.3% of the total variance, for a cumulative percentage of 97.6% of total variance. The first function may be interpreted as the social dimension of beer drinking (before), the second as the strength of beer (during), and the third as another taste dimension (after) concerning physiological effects (after taste, easy to digest).

Step 3: Determine the best decision rule for evoked set formation. In order to find out the best decision for each individual, we derived individual scores on the three significant discriminant functions. For each respondent, and each decision rule, we determined whether or not a particular decision rule leads to a zone containing only evoked brands. For example, in the geometric compensatory rule centered on the ideal point (Best 1976), the evoked set zone is defined as the sphere centered on the ideal point and the radius of which is the evoked brand farthest away. We then looked to see if one or more brand(s) other than an evoked one is contained within the zone (sphere). For the cutoff models, the cutoff point is inferred by taking the evoked brand with the lowest score on that dimension. The evoked set zone is then the area represented in dark in Figure 1, and an examination of that zone reveals whether or not it contains brands other than evoked ones.

The percentage of cases for which each rule is successful is presented in Table 1 as well as the classification of the brands belonging to each set violating that rule. It is clear that the best rule is the conjunctive model for which no other brand was found within the centroid defined by the three cutoff points for 72.0% of all respondents. Most violations of the rule occurred with inert brands, with only 5.3% of the cases for which an inept brand was found within the centroid. This result can also be viewed as follows: The percentage of success increases dramatically as we move from the largest area, i.e., the disjunctive rule with 9.6% success, to a smaller area, i.e., the lexicographic rule with 46.1% success, to an even smaller area, i.e., the conjunctive rule with 72.0% success. A similar reasoning with the three compensatory models reinforces the conclusion that the process of evoked set formulation is, in our case, one of inclusion based on cutoff points for all three major dimensions of the product space. This conclusion is consistent with Myers (1979) expectations, as well as those by Pras and Summers (1977). It is also consistent with the findings of Best (1976). On the other hand, our findings do not confirm those of Parkinson and Reilly (1979) although they followed a composition approach. They do report that the questions directly measuring the conjunctive or disjunctive cutoffs were fairly difficult for the subject to complete, and that these response errors were probably magnified in their simulation procedures.

Step 4: Determine prior trial of evoked brands. A comparison was made between the brands in the evoked set on one hand, and those which the respondent had indicated as tried brands. It was found that in 95.4% of all cases, all brands in the evoked set had been previously tried. The remainder of the cases, i.e., 4.6%, may be considered as an error term if we set a level of significance of $\alpha=5\%$, in which case the critical value is $p_c=.069$. Therefore we fail to reject the null hypothesis that all brands in the evoked set have been previously tried. This is consistent with Howard's theory of concept learning in a Routinized Response Behavior Situation (Howard 1977, May 1979).

Limitations

A first limitation of the present study deals with the problem of controlling for the homogeneity of respondents since many factors may affect the choice of the decision rule as reviewed by Belonax (1979, p. 232). Our decision to limit

TABLE 1
RESULTS OF THE DECOMPOSITION APPROACH

Decision rule	Percent of cases for which the zone of evoked set brands defined by the decision rule contains		
	No other brand	At least one inept brand	At least one inert brand
Non-compensatory			
Conjunctive	72.0%	5.3%	23.5%
Disjunctive	9.6%	60.0%	69.1%
Lexicographic	46.1%	17.9%	44.0%
Compensatory			
Linear	42.9%	6.7%	29.6%
Geometric - centered on ideal point	41.9%	21.9%	48.0%
Geometric - centered on most preferred brand	53.9%	14.7%	36.8%

our research to a RRB situation, a specific scenario, regular male beer drinkers, in a relatively homogeneous metropolitan area as well as two attempts at clustering respondents provided some measure of control. But other factors may be introduced such as breadth of categorization (Pettigrew 1956) which is one dimension of cognitive style, as well as perceived risk (Bettman 1973).

A second limitation may lie in our procedure of decomposing the product space into areas based on a specific decision rule on one hand and actual brand classification on the other hand. In effect, we tested the logic of applying a specific rule more than reconstructing the rule itself as in Parkinson and Reilly (1979).

Third, the boundaries of our evoked set zones were approximated by looking at the smallest area containing all evoked brands. There may be some value in doing some sensitivity analysis by varying the cutoff points to allow for a margin of error. Finally, we only looked at minimum cutoff points, but not at maximum ones. This may apply to only our second and third dimensions since the first dimension is the social image of beer which accounted for 77.8% of total discrimination.

Finally, the study is within a static context, and not in a dynamic one as suggested by Myers (1979).

Summary and Conclusion

This research has attempted to focus on specific questions regarding Myers' phasing model, as well as May's contention that both learning theory and information processing theory are necessary to explain evoked set formation and composition.

We selected a product in the maturity stage and consumers in an RRB situation, faced with a specific scenario, and homogeneous in their perception of the available brands. For each respondent, we generated his perceptual space, and we used a decomposition approach to test three non-compensatory rules and three compensatory rules. In a perfect criterion basis, the best rule was found to be the conjunctive model, which is consistent with previous expectations and findings. Finally, all brands in the evoked set were

found to have been previously tried, which is consistent with Howard's learning theory.

The decomposition approach followed by this study allowed us to examine and compare the output at the maturity stage (RRB situation) from both information processing activities and concept learning. From an information processing viewpoint, we gathered brand perceptions on several attributes and constructed individual product spaces. From a concept learning viewpoint, all brands in the evoked set were previously tried by most respondents. Thus a comparison of brand classifications and product space configurations leads to a perfect match for 72% of all respondents for the conjunctive rule. Thus, we may see here a convergence of both theories as hoped by May (1979).

THE COMPENSATORY DIMENSION IN
SUBJECTIVE EVALUATION PROCESSES:
A MULTIMETHOD VALIDATION

Ruby Roy Dholakia, Kansas State University

Abstract

One of the characteristics of evaluation processes of multi-attributed alternatives is that of compensatoriness which defines the nature and degree of trade-offs between attributes. An empirical investigation is reported in this study that utilizes multiple methods to analyze this dimension. The objective of the paper is to represent the compensatory dimension in terms of a single quantitative measure and find qualitative support for the reported findings. Judgments of three decision makers are analyzed using these methods and the findings are then used to select representation models of the evaluation processes.

Introduction

Early attempts to describe and analyze evaluation processes revolved around the model versus process controversy (Goldberg 1968, Wright 1975). While there is ample evidence to support differences in processes, both across individuals and situations, these differences are still viewed at the model level (Park 1976). Recent approaches have been attempting to isolate these differences at specific dimension level such as the influence of time horizon on process linearity (Wright and Weitz 1977).

When multiple attributes are used by individuals to evaluate alternatives, one component of the evaluation process is that of inter-attribute compensation. Two attributes are compensatory when a decrease in the value of one is balanced by an increase in the value of the second attribute. The amount required for balancing is likely to vary and will be determined by a variety of factors. Evaluation processes will differ, therefore, in terms of compensatoriness.

In traditional economic theory, the marginal rate of substitution between two goods was an index of compensation (Henderson and Quandt 1971). Recent formulations have shown the preferences for goods to be derived from the preferences for the goods' attributes (Lancaster 1966) and the marginal rate of substitution has been extended to relationships between attributes (Lancaster 1972). Raiffa (1968) showed through isopreference curves that the rate of substitution between an unit of attribute X and an unit of attribute Y can be constant or variable. A variable substitution rate depends on the specific attribute levels while a constant rate is independent of attribute values.

The compensatory dimension can, therefore, be represented as a continuum (degree) rather than as a dichotomy (compensatory). This implies that evaluation of multi-attributed objects rather than being categorically a compensatory or a non-compensatory process, can be characterized as a process with varying degrees of compensatoriness. Raiffa's (1968) variable rate of substitution supports this view. In the utility model proposed by Keeney (1974), the different values that the multiplicative constant W can assume is based on the variable rate of substitution.

There are two important implications of viewing the compensatory dimension as a continuum. When various models are used to describe a process or predict its outcome, the current practice is to distinguish these models as being compensatory or non-compensatory. However, if the compensatory dimension is viewed as a continuum, then greater

discriminations must be made among these models and their assumptions about the degree of compensatoriness.

Second, it allows conceptualization of the influence of various situational and individual variables on the evaluation process. For example, the interaction of a specific set of variables may be to make the evaluation process more or less compensatory. If a methodology can be adopted to quantify the degree of compensatoriness, then changes in magnitude can be hypothesized and measured.

Investigation of Compensatoriness

There is limited empirical evidence pertaining to the rate of compensation among attributes. Utility theorists have used goods rather than attributes and assumed the goods to be uni-attributed. MacCrimmon and Toda (1969) used money and ballpoint pens in one study and money and pastries in the second. Similarly, Rousseaus and Hart (1951) used goods rather than attributes when obtaining trade-offs between bacon and eggs.

There are some attempts by consumer behavior researchers to assess attribute trade-offs. Johnson (1974) reported a methodology which used paired comparisons to obtain trade-offs from which utilities of individual attributes as well as overall utility were derived. Fiedler (1972) used the methodology to obtain evaluation of condominiums and found it to be a good predictor of preferences. Hauser and Urban (1979) used an alternative methodology proposed by vonNeumann-Morgenstern and found considerable individual variation in trade-offs as well as inter-attribute differences. The focus of these papers has been to assess pair-wise trade-offs directly and to derive the overall utility of alternatives from the analysis of trade-offs.

An Empirical Investigation

A research study was designed to investigate the compensatory dimension of evaluation processes. Unlike earlier studies, the attempt was not to obtain overall utility but to focus on the compensatory dimension *per se*. The objective was to represent the dimension in terms of a single quantitative measure that can be used as an indicator of the degree of compensatoriness in a process. Since the methodological issues were of primary concern, the empirical investigation was confined to a study of career opportunities by MBA candidates.

Methodology

Students from a graduating MBA class were requested to participate in a decision making study. Since career placement loomed large in their lives at that point in time, job choices were used as the subject of investigation. This ensured cooperation and involvement from the participants.

Independent Variables. A set of attributes relevant to job choice among the graduating class was identified from group responses. In a classroom setting, the students were asked to list the five most important attributes in job selection. Five attributes were identified by taking into account frequency of mention and the average importance rating assigned to each. The choice of these five attributes were validated among a second group of students. From this emerged a reduced set of three attributes which was

considered most important by majority of the students.

These three attributes (initial salary, job location and responsibility) were used to develop alternative job opportunities. Twenty-seven jobs were generated from three levels of each attribute:

- Salary: \$14,000; \$16,000; \$20,000 annually
- Location: Northeast (NE), Midwest (MW), and Farwest (FW);
- Responsibility: Low, moderate and high.

A second set of 18 (2X3X3) jobs was composed for validation purposes using a subset of the attribute values: moderate and high levels of responsibility, the same locations and \$12,000; \$15,500 and \$18,000 salaries. Each job was described in terms of these attribute values on a 3x5 card.

Dependent Variables. A series of measures were obtained for the job evaluation task:

- a) Measure of liking for each job on a 11-point scale (0-10);
- b) Measure of preference order through successive sorting into most and least preferred categories;
- c) Verbalization of thoughts underlying the sorting procedure as the sorting took place. (This was tape recorded and later transcribed).

The first set of 27 jobs was evaluated along each of these measures. The validation set of 18 jobs was evaluated only in terms of (a) above. The entire evaluation task took an average of about 80 minutes to complete.

Participants. Twelve decision makers participated in the study. They were all graduating MBA students in a mid-western university, seeking permanent placement and had volunteered for the study. A token payment of five dollars was made to each participant.

Findings

Model Performance. Since one of the objectives for identifying the compensatory dimension was to improve the selection of representational models, the first analysis performed was to predict the job preferences by the use of different models. Three different models - regression (reg), additive conjoint (con) and lexicographic (lex) - were used. The three models assume different degrees of compensatoriness: in this research they could only be ordered in terms of this assumption, with the lexicographic model being the most compensatory (rank 1) and the regression model being the least compensatory (rank 3).

Table 1 provides the predictive validity of the three models using two criteria - recovery of the rank ordering of the entire job set and the accuracy in predicting the first choice.

TABLE I
PREDICTIVE VALIDITY OF THREE REPRESENTATION MODELS

Decisionmaker	Correlation Between Actual and Predicted Rank Order ^a			Prediction of First Choice ^b		
	Reg	Con	Lex	Reg	Con	Lex
1	0.54	0.81	0.78	—	✓	✓
2	0.98	0.99	0.99	✓	✓	✓
3	0.56	0.96	0.81	—	✓	✓
4	0.50	0.71	0.71	—	—	—
5	0.89	0.99	0.84	✓	✓	✓
6 DM A	0.75	0.94	0.78	—	✓	—
7	0.95	0.97	0.96	—	✓	✓
8	0.88	0.95	0.91	✓	✓	✓
9	0.83	0.89	0.68	✓	✓	✓
10 DM B	0.94	0.99	1.00	✓	✓	✓
11	0.82	0.93	0.69	✓	✓	✓
12 DM C	0.96	0.88	0.64	—	—	✓

^a Spearman rank order correlation coefficient

^b ✓ indicates first choice accurately predicted

As we can see there are some interesting differences in the validity of these models as representations of the process. Using both criteria of predicting the rank order and the most preferred job, four categories of model performances may be observed. In the first category, all the three models do equally well in predicting the rank orders and first choices for some decision makers (DM 2, 5, 8, 10 and 11). For DM 7, the competition is between two models - the conjoint and lexicographic. This category represents the maximum ambiguity since the models perform similarly although making different assumptions about the degree of compensatoriness in the underlying process.

Category two, represented by DM 12, generates some amount of ambiguity because the three models differ in their predictive validity - the regression model recovers the rank order the best but fails to predict the first choice while the lexicographic model predicts the first choice successfully but performs the worst in recovering the rank order.

The third category appears to be unambiguous because it is possible to select a model based on both criteria. For DMs 1, 3, 6 and 9, the model that predicts the rank order the best is also able to predict the first choice. Finally, the fourth category (which only includes DM 4) represents a situation where none of the three models perform satisfactorily on both criteria. To allow detailed exploration of the problem, further analysis and discussion is limited to three decision makers (labelled A, B, C) conveniently chosen as representatives of the three categories. Category four has been excluded because none of the models performed satisfactorily.

The Compensatory Dimension. Given the observed differences in model performances and the ambiguity in selecting a representational model, the objective of further analysis was to directly use the compensatory dimension in evaluating alternative models. To achieve this objective it is necessary to represent each decision maker on this dimension and a composite index of compensatoriness was devised for this purpose. (Technical details are given in the Appendix).

The values of the composite index are reported in Table 2 for the three selected decision makers. Higher the value, the more noncompensatory the process since it implies larger units of an attribute being required to compensate for another attribute. A perfectly compensatory process would be represented by a zero value in terms of the composite index of compensatoriness.

TABLE 2
A COMPOSITE INDEX OF COMPENSATORINESS

Decision maker	Composite Index	Interpretation
A	12.94	Moderately compensatory
B	49.25	Highly noncompensatory
C	3.53	Highly compensatory
Perfect Compensation	0	

According to Table 2, DM C exhibits the most compensatoriness in the job evaluation process while DM B is the least compensatory. Given this information, it would appear that the lexicographic model is a better representation of DM B's evaluation process but is not appropriate for DM C's process. On the other hand, the regression model which assumes a high degree of compensatoriness may be used to characterize DM C's process. By similar logic, the conjoint (additive) model, which allows for somewhat less compensatoriness in the process than the regression model, may be used to characterize DM A's process. Thus by using the compensatory dimension directly, it is possible to select representational models that are more appropriate for a decision maker based on both predictive criteria and the assumption about the level of compensatoriness in an

evaluation process.

Convergence. To validate the findings on the level of compensatoriness, one other analysis was performed. This was done to ensure that the values of the composite index was not an artifact of the computation process. Verbal protocols were analyzed to see if trade-offs were considered by the decision makers in evaluating the alternative jobs. The verbalizations took place while the first set of 27 jobs were being successively sorted into preference categories. They were taperecorded and later transcribed. Excerpts from the protocols are reported in Exhibit 1.

EXHIBIT I
EXCERPTS FROM VERBAL PROTOCOLS

Decisionmaker A

Job S (NE, LO, 20): Just don't think I can give in to the low responsibility. Salary is attractive and it is in northwest; but what I am doing is important; how much I am allowed to move within the job. I like it the least.

Job O (MW, MOD, 14): Moderate responsibility, in midwest, 14,000 - an attractive opportunity in the midwest even though salary is low. Salary at this point not as crucial as location and responsibility. I feel if I like something - you will be good at it and will want to work it; even though salary is low, I think I can work my way up.

Decisionmaker B

JOB M (MW, MOD, 20): Prefer Q; I would rather...FW sounds better than MW and the extra salary is not enough to compensate.

JOB Y (FW, LO, 20): Poor opportunity due to low responsibility...despite high salary and good location

Decisionmaker C

JOB J (NE, MOD, 20): Like somewhat - moderate responsibility but good salary, with a NE location.

JOB I (FW, HI, 14): Like somewhat - high responsibility but low starting salary with a good location.

Analysis of the verbal protocols support the quantitative descriptions of the evaluation process in terms of compensatoriness. As we can see from the excerpts, DM A allows some amount of compensation; for instance, between a midwest location and a low salary but not a lot, since low responsibility is not being balanced by a higher salary or an attractive location. On the other hand, DM B is quite strict about attributes desired in a job and is unwilling to like a job unless it meets the attribute preferences; even a \$4,000 extra in initial salary cannot compensate for a less desirable midwest location. Much greater balancing of attributes takes place in DM C's process, for instance, when a better salary is accepted even if the responsibility is not desirable.

Model Selection. To the extent that the three models - regression, conjoint and lexicographic - can be ordered in terms of their assumption regarding process compensatoriness, these models may then be used to represent the process of the three job candidates. The lexicographic model which assumes the highest level of noncompensatoriness is therefore selected as the best representational model for

DM B even though the other two models predict the job choice and rank order.

The predictive validity of the conjoint model is supported by the level of compensatoriness found in DM A's process. This level validates the conjoint (additive) model's assumption of a limited degree of compensatoriness. For DM C, the regression model is found to be the best representation because it assumes a high degree of compensatoriness which was found to characterize DM C's process.

Selection Validity. The descriptive and predictive validity of each model selected to be representative of the three processes are reported in Table 3. The correlations may be compared to those of the conveniently accessible regression model.

TABLE 3
DESCRIPTIVE AND PREDICTIVE VALIDITY OF SELECTED MODELS

Decisionmaker	Descriptive Validity*			Predictive Validity*		
	Con	Lex	Reg	Con	Lex	Reg
A	0.96	--	0.82	0.94	--	0.75
B	--	0.99	0.96	--	1.00	0.94
C	--	--	0.88	--	--	0.96

* Spearman rank order correlation

There is an improvement in both descriptive and predictive validity by the use of a specific model even though the improvement may not be statistically significant. However, the justifications for selecting a model to represent the process are built on different grounds. A valuable illustration of the limitation of statistical considerations is made by DM B; despite high predictive validity of the regression model, it makes a totally inaccurate assumption about the compensatory dimension of the underlying subjective process.

Discussion and Conclusion

It appears that focusing on the compensatory dimension of the evaluation process provides a specific criterion for discriminating and selecting among representational models. Despite the very high predictive validity of all the models, there is support for the noncompensatory assumption of the lexicographic model which makes it more valid for representing DM B. Similarly, the conflict created by the overall predictive validity of the regression model and the first choice accuracy of the lexicographic model for DM C's process could be resolved by an analysis of the compensatory dimension. The regression model is found to be a better representation of the underlying process because of the degree of compensatoriness. Superior predictive validity of the conjoint (additive) model for DM A is supported by the findings on process compensatoriness.

Even the use of multiple measures of predictive validity (overall order and the first choice) is seen to be insufficient for determining the nature of evaluation processes implied in the job preferences. Identifying and measuring the compensatory dimension of the evaluation process is found to contribute to its understanding and representation by models. The attempt to represent the magnitude of the compensatory dimension appears also to be fruitful.

There are substantial methodological differences in this paper as compared to other studies of process compensatoriness. Past studies that have focused on this dimension have used it to derive overall utility. While that objective has been successfully achieved, it often involves use of a methodology that is quite restrictive in its usefulness (Hauser and Urban 1979). It required a high degree of conceptual ability for the respondents to understand the procedure by which trade-offs were measured. In contrast,

this study has focused on the compensatory dimension without requiring the decisionmakers to undertake any task that is difficult or not normal. Instead, it has adopted a reverse route — moving from overall measures of evaluation to a specific measure of process compensatoriness.

The approach adopted in this paper for investigating subjective evaluation processes appears to have several other merits. By focusing on a specific dimension and by viewing the dimension on a continuum, it is possible to relate the effects of individual and situational variables on the evaluation process. Instead of just saying that these variables are likely to create differences, it is possible to say where the difference is likely to exist and the nature of the difference (i.e. more or less compensatory). One can hypothesize that increased involvement with a product or issue will reduce the compensatoriness of a process and can test the hypothesis. Such an approach is likely to be more productive in creating an understanding of subjective evaluation processes.

By restricting the study to three decisionmakers, the validity of the approach is open to question. However the rationale of the approach cannot be tested by numbers alone. The objective of the approach was to understand the subjective evaluation process in terms of a single dimension — compensatoriness. It is therefore necessary to directly portray evaluation processes on this dimension and to select models as representations when they satisfied the assumption on this dimension and predictive criteria. The approach offers an alternative to the model vs. process controversy by selecting models based on an understanding of underlying process dimensions.

To fully benefit from this approach, it is necessary to explore another implication, viz to generate other dimensions of the evaluation process and to determine their relationships to the compensatory dimension. The compensatory dimension is only one component of the evaluation process.

While there is some literature on other dimensions (e.g. linearity, configularity, etc.) of the evaluation process, there is a lack of concepts and theories that link these together and create an integrative framework for the conceptualization and understanding of subjective evaluation processes. There exists a need for developing such a framework that can put past research in perspective and identify future research issues. This need is strengthened by recent findings that individual evaluation processes are likely to be constructive and not rule or model applications (Bettman and Zins 1977).

Even though the investigation reported in this paper deals with job choice, it focuses on the compensatory dimension which is likely to be of even greater relevance to study of traditional consumer goods. In the present context of shortages and inflation when significant changes are likely in consumer processes, the impact on the compensatory dimension requires major attention.

Appendix

The compensatory dimension was represented by a set of values computed from the attribute utility scores obtained from conjoint analysis. In order to reach the overall index of compensatoriness, the following calculations were performed.

1. Compensation between pairs of attributes:
 - a. Responsibility and salary,
 - b. Location and salary,
 - c. Location and responsibility.

The rate of compensation is obtained for each change in the level of a pair of attribute, e.g. the change in utility associated with an increase in salary from \$14,000 to \$16,000 and from \$16,000 to \$20,000 as compared to change in utility with an increase in responsibility from low to

moderate and moderate to high. The ratio of this change $U(16)-(14)/U(\text{Mod})-U(\text{Lo})$, is taken as a measure of attribute compensation. Similarly, for the other two pairs.

2. Perfect rate of compensation is assumed to exist when the ratio equals one. An assumption here is that the unit of change in the attribute is same across different levels (e.g. moderate - low = high - moderate). For salary, an adjustment has been made to incorporate the different levels of change ($20-16=2(16-14)$) which leads to a perfect rate of 0.5)
3. The composite index of process compensatoriness is obtained by the following:

$$\sum |X_{ij} - X_j|$$

where X_{ij} = compensation between a pair of attribute level
 X_j = rate of perfect compensation for the same pair.

For example, the composite index for DM A is found by incorporating the following values:

$$12.94 = |(3.92-0.5)+(1.88-1.0)+(5.27-0.5) + (1.14-1.0)+(0.61-1.0)+(-1.34-1.0)|$$

The detailed values are given below:

COMPENSATORINESS IN JOB EVALUATION

Decision-maker	Compensation between Attribute Pairs						Composite Index of Compensatoriness
	Responsibility & Salary		Location & Salary		Location & Responsibility		
	1	2	1	2	1	2	
A	-3.92	1.88	5.27	1.14	0.61	-1.34	12.94
B	24.18	23.09	1.38	1.73	0.07	0.06	49.25
C	1.02	1.0	0.22	0.03	0.03	0.21	3.53
Rate of Perfect Compensation	0.50	1.0	0.5	1.0	1.0	1.0	0

DEVELOPING AN INSTRUMENT TO IDENTIFY INDIVIDUAL DIFFERENCES IN
THE PROCESSING OF PICTORIAL AND OTHER NON-VERBAL INFORMATION¹

Flemming Hansen, The Copenhagen School of Business Administration & Economics
Niels Erik Lundsgaard, Frederiksberg Hospital²

Abstract

The present paper discuss recent findings regarding brain lateralization and its implications for the study of consumer behaviour. This research suggests a new view on the way in which consumers react to different media and creative solutions. It should be possible to identify individual differences in the extent to which people rely upon left or right brain informational processing.

Background

Hemispherical lateralization implies that individuals use the left and the right brain differently. This has been studied for the last two decades. The work by psychiatrists (Wexler 1980), by psychologists (Gazzaniga 1977, Kimura 1973, and Deglin 1979) and by brain researchers (Witrock 1977) has improved our understanding of the way in which the right and the left brain differ in their handling of incoming information and in controlling behaviour.

Several aspects of this specialization of the brain halves are now generally agreed upon. Whereas the left hemisphere is primarily responsible for traditional cognitive activities relying upon verbal information, symbolic representation, sequential analysis, and with the ability to report consciously of what is going on; the right brain - without the individual being able to report verbally about it - is more concerned with pictorial, geometric, timeless, musical and other non-verbal information.³

Even though the differences often can be difficult to identify because of the intensive interaction going on between the right and the left brain half, it is well-established that some tasks lead to left brain activity, whereas others generate right brain processing. It is to be expected that particularly pictorial, musical and other non-verbal forms of communication give rise to right brain processing.

On this background, it has been proposed that even when attention - in the sense it is normally referred to in advertising research - is not present, it is still possible for the individual to receive some information, and to store this (Krugman 1977). Moreover, it is proposed that this process is particularly efficient with pictorial material and that the information is stored in a holistic unedited, non-verbal fashion very different from the way we normally store verbal and similar information, and is not recallable, but is easily triggered by recognition.

¹Sponsored by the Danish Social Science Research Council.

³These conclusions do not apply to approximately 25% of all left-handed individuals who have the functioning of the left and right brain reversed. All subjects known to be left-handed are excluded from the study to be reported on the following pages.

Individual Differences

Various authors have pointed at the possibility of individual differences in the extent to which people rely upon the left or the right brain in coping with their environment. Bogen (1977) has suggested that such differences may depend upon the nature of the stimulation the child receives, while it grows up. Children growing up in a heavy verbally dominated culture, are more likely to rely more heavily upon left brain processing. Lindzay & Norman (1977) suggest that whereas intelligence as measured by existing IQ-testing procedures mostly reflect left brain activity, some aspects of creativity may imply important right brain processing. In line with this psychiatrists (Wexler 1980) are convinced that several psychiatric disorders are explainable in terms of unbalanced functioning of the brain halves. For example, schizophrenia is believed to imply reduced left brain activity.

Even consumer psychologists have touched upon the possibility of individual differences in hemispherical lateralization. Appel, Weinstein, and Weinstein (1979), in an attempt to find hemispherical specialization in handling various informational inputs from television commercials, accidentally find significant individual differences in the way in which the test material is being handled. (for a detailed discussion of their findings see Krugman 1980).

To the extent that such individual differences exist it would imply that the right brain dominated individuals would rely more on pictorial non-verbal information and that they handle information very differently from left brain dominated people.

Purpose

It is the purpose of the project being reported here to establish whether such differences exist among normal consumers in their use of left and right hemisphere. Moreover, the attempt is made to learn what implications these differences have for communication planning, segmentation, etc. The project attempts:

1. To establish the existence of individual differences in the extent to which different consumers rely upon left and/or right hemispherical processing.
2. To develop an operational procedure for measuring such differences.
3. To examine the implication of such differences in terms of differences in consumer's receiving, handling, storing, and reacting to different kinds of information.

The present paper concerns itself with tentative findings regarding the first two questions.

Measurements

Most studies of hemispherical lateralization have used complicated measurement procedures. Measurements have been carried out in a clinical setting and often advanced instruments have been used.

Some of the earliest findings came from studies of patients with various kinds of brain damages (Sperry 1973). Other studies have used the EEG (Electroencephalogram) technique. Here the pattern of α - and β -waves in the left and in the right brain half has been studied while the respondent is carrying out different tasks.

Also special tachistoscope procedures have been developed. Here the purpose has been to control to what side of the brain visual information is transmitted. Similarly, dichotic listening techniques have been used. Here different words, pieces of music, and other auditory stimulation are presented simultaneously to the left and to the right ear. By asking respondents about what they hear, it is possible to learn in what brain half information is being processed. Finally, psychological tests normally used for diagnostic purposes have been applied in an attempt to identify individual differences in lateralization.

All of these measurement techniques are, however, complicated, and almost impossible to apply in larger scale studies of consumer behaviour. Therefore, to be able to deal with individual differences in hemispherical lateralization in larger samples of consumers, it is necessary to develop a simpler measurement device.

Since the extent to which the individual relies on right vs. left brain informational processing can be expected to influence, his overall behaviour and possibly also his beliefs and values, it might be possible to have the individual himself reporting on the extent to which right or left brain functioning dominate. Of course, direct reporting cannot be expected to be valid, but the tendency of the individual may be revealed by his responses to constructively selected questions.

For example, one can speculate that a person relying more heavily upon information stored in the right brain tend to recognize faces better than a person relying more upon left brain information processing and storing. The latter on the other hand, might be expected to recall names better than faces. Replies to items reflecting the extent to which the individual find himself relying more or less upon the one or the other kind of information could be used for identifying individual differences. It is an important part of the present project to identify and validate such statements which could be used to identify individual differences.

Validation of such statements can be approached in two ways. It is possible to test the same items on two or more groups of individuals known to differ in the extent to which they rely upon left vs. right brain processing. Such a procedure is employed in a later stage of the present project, where measurements obtained with normal individuals are compared with similar measurements obtained from people who through clinical testing have been identified to be relatively right brain dominated. The present paper, however, reports findings alone based upon the second possible validation procedure.

With a sufficiently large number of test items developed, it is possible to validate these internally by comparing the response pattern among the items themselves. For this task factor analysis is a commonly used procedure. In addition to this, it is possible to validate the test items against various psychological tests supposed to reveal left and right brain specialization. In the present study, a selection of such tests are used against which the potential test items are validated.

Procedure

The validating experiment reported here has been carried out with 50 male and female subjects recruited at a student housing complex in Copenhagen. Each respondent has been paid approx. 20 \$ for his/hers participation. Since some of the tests employed are quite time-consuming each respondent went through a procedure lasting approx. 3 hours. Basically, the following three types of measures were used.

1. Reactions to 10 clinical psychological tests
2. Dichotic listening
3. Answer to 80 selected test items presented on a self-administered questionnaire.

Clinical Psychological Tests

A total of 10 clinical psychological tests were selected from different sources.

To make the administration easy and to facilitate the registration of the response to the tests in a quantitatively operational way, both the procedure and the scoring was transformed⁴, so that each respondent answered all 10 tests within reasonable amount of time, and so that the scores could be registered in a form prepared for computer processing.

In the order to which the tests were administered, the standardized forms are described below:

1. Word-Pair Learning (Theilgaard 1979)

10 different word-pairs, 5 logical such as street/car, see/fish, window/curtain, and 5 non-logical such as cap/hotdog, church/cotton, apple/pencil, were presented with each pair typed on a paper card. The respondents were instructed to try to learn all 10 word-pairs by running through the pile two times in a moderate to fast tempo. Hereafter the interviewer named the "first" word on each card, registered the number of right answers out of the 10 possible. This test was believed to measure left brain activity.

2. Copy Recall (Freeman 1965)

A meaningful story of 44 words was read aloud to the respondent, who was asked immediately to retell the story with the use of the same words and sentences. The copy was divided into 18 units, and the number of correct answers was registered as a measure of left brain activity.

3. Face Recognition (Theilgaard 1979)

The material for this test consists of 28 photos of 14 men and 14 young women. The young men are all dressed in a white shirt with a black tie and the women in white gowns. All were portraits. All pictures looked very much alike. All 28 portraits are shown as 4 rows each with 7 portraits. In the test 12 of the persons were chosen and first shown in individual presentation to the respondent. Each portrait was presented to the respondent in exactly 5 seconds, and immediately after the presentation of all 12 portraits, the 28 portraits were presented.

⁴Details of the transformation procedure can be obtained from the authors.

The respondents were now asked within approx. 60 seconds to identify the 12 persons they had previously seen among the 28 portraits. The interviewer registered the number of correctly identified persons, as a measure of right brain capacity.

4. Visual Gestalts (Andersen 1976)

The material for this test consists of 4 pieces of paper with 4 different geometrical figures: A circle, a rectangle, a triangle, and a half-circle. Four different cards each with four different gestalts printed in the geometrical figures are then presented to the respondent. Each presentation lasts 10 seconds. After each presentation the respondent is asked to draw as many of the gestalts as possible. The number of correctly drawn gestalts is taken as a measure of right brain capacity.

5. Subtraction (Theilgaard 1979)

The respondent is asked to subtract 7 from 100 and name his result, and then to continue by subtracting 7 from the result and to go on down to zero. This is done with a fixed time-limit of 30 seconds. Subsequently the interviewer registers the number of correct subtractions completed. The subtraction test reflects left brain capacity.

6. Cube Test (after Goldstein-Sheerer, Freeman 1965)

The material for this test consists of four cubes. They are all identical, and they have the following side colours:

1. blue
2. red
3. yellow
4. white
5. diagonally cut in white and red
6. diagonally cut in yellow and blue.

Figure VII, VIII, and IX from the original test are presented to the respondent in 10 seconds each. Thereafter the respondent is asked to reproduce the figures as fast as possible. The total number of seconds it takes to reproduce the three figures is registered and subtracted from 180. The resulting number is supposed to reflect right brain capacity.

7.-8. Word Mobilization Test I. & II. (Theilgaard 1979)

I: The respondent is asked within 60 seconds to name as many things as possible that one can see in the street. The interviewer registers how many things there are.

II: The respondent is asked to name as many animals he can think of within 60 seconds. The interviewer registers the number of animals named.

Both measures are taken as indicators of left brain activity.

9. Incomplete Pictures (Freeman 1965)

The 21 incomplete drawings from Wechsler's Adult Intelligence Scale are presented one by one. Because of the relative high intellectual standard of the respondents they were only permitted a few seconds to look at each drawing. As a measure of right brain capacity the interviewer registers how many errors the respondent correctly identified.

10. Face Identification (Benton 1978)

For this test map number 7 to map number 13 from the "Benton Test" are used. Each map consists of one portrait on the top and 6 at the bottom. Out of the latter 6, 3 are portraits of the same person, as the one on the top.

On each map the respondent is asked to identify those portraits at the bottom representing the same person as the one on the top. Each map is presented for a max. of 20 seconds and the interviewer registers how many correct identification the respondent makes. This is supposed to reflect right brain capacity.

Dichotic Listening

For the dichotic listening task 78 word-pairs were selected. Examples are: RUF/BOF, STA/GJO, etc.

These word-pairs were presented to respondents simultaneously with one word to the left ear and the other to the right ear. For this purpose a stereo recorder with normal head phones was used.

In line with Frumkin (1978) the dichotic listening score was computed as the number of correct items recalled among those heard with the right ear, less the number of items recalled from those heard with the left ear divided by the total number of items recalled.

The instrument was first tested with two groups. One comprising 10 business students, and the other 10 musical students. It was believed (Sperry 1973) that the musical students would show a higher right brain score than the business students. This also was found. Most of the 10 music students scored lower than any of the business students, and the average for the two groups differ significantly. In a later test/retest reliability check the correlation between the first and second measurement for a group of business students was .76.

In the subsequent application of the dichotic listening procedure some of the test items were left out to reduce the total time spent on the listening task. This was done by deleting those items from the original version which discriminated the least between the business, and the music students. An attempt was subsequently made to validate the dichotic listening tests with two other existing tests. The first of these is normally used for psychological testing at the Copenhagen State Hospital (Heshe, et.al 1978). This attempt was not successful. Neither of the three tests correlated very well with each other. Faced with this dilemma it was decided to use the original test, since this had performed well in the first test with music and business students. This version was also technically superior.

80 Self-Administered Test Items

80 items were formulated. All of these could be answered by expressing ones view on a 5 point scale, ranging from agrees completely to disagrees completely. Some of the statements were formulated departing in what is known about lateral specialization. Examples of statements are: "I enjoy listening to music", (supposed to reflect right brain activity), "I am very good at calculating", (supposed to reflect left brain activity), "I enjoy very much watching landscape painting" (right brain), "I plan carefully how to spend my time", (left brain), etc.

In addition, items were selected from existing psychological tests. These were included based upon the assumption that the mental disorders they were supposed to measure could be related to left vs. right brain dominance. For example, a number of items used in tests of neurotic fear tendencies were included. Examples are: "I like to be told what to do", "I feel uncertain when being together with people I have not met before", etc. A total of 41 items supposed to reflect right brain dominance and 39 items reflecting left brain dominance were selected. Scoring was carried out by adding the scores on the 41 right brain items separately, and on the 39 left brain items separately. Additionally, the items were treated individually in the subsequent analysis.

Finally, for each respondent age, sex, and a couple of other demographic variables were collected.

The Data Matrix

The initial data matrix can be described as a 50 respondents by 98 items large matrix. The 98 items being:

- . 10 test scores on the psychological clinical test
- . 1 dichotic listening score computed as described
- . 80 test items
- . 1 sum-score representing the 41 right brain items
- . 1 sum-score representing the 39 left brain items, and
- . 5 demographic variables (sex, age, etc.)

In the course of the data analysis additional variables were generated. Those variables are described subsequently.

Results

Clinical Psychological Tests

As it will be recalled the clinical tests were selected with five of them supposed to reflect right brain dominance, and five supposed to reflect left brain dominance. To test the interrelationship among the scores of the 10 variables, a principal component factor analysis was carried out with a subsequent vari-max rotation of the two first factors. These two factors explain 45% of the total variance. (A third factor explains additionally 10%). The results of the factor analysis is shown in table 1. It appears that 4 of the 5 test items supposed to reflect left brain dominance are associated with the first factor. Similarly, on the second factor, 4 of the right brain tests load significantly high, though 1 of them is also associated with the first factor. Neither of the remaining two tests correlate with either of the two factors.

TABLE 1.

Two factors, vari-max principal component solution for 10 clinical psychological tests of left vs. right brain dominance. (N = 50, explained variance = 45%)

	Factor I.	Factor II.
Word mobilization II. (left)774	.076
Word mobilization I. (left)660	-.214
Copy recall (left)563	.221
Subtraction (left)487	.153
Word-pair learning (left)082	.045
Face identification (right)178	.243
Visual gestalts (right)	-.097	.512
Face recognition (right)	-.089	.419
Cube Test (right)167	.632
Incomplete pictures (right)537	.589

The failure of the face identification test to correlate with any of the factors is ascribable to the fact that this test turned out to be so easy that practically all of the participants scored maximum points. Thereby, the test becomes highly insensitive. With regard to the poor performance of the word-pair learning test, one possible explanation is that this test measures general intelligence, rather than anything else.

Based upon these results, it was decided in the subsequent analysis to combine the 4 tests scoring high on the first factor into a single score reflecting each individual's tendency to rely upon left brain processing. Similarly, four tests loading high on the second factor are used to compute a combined score for each respondent. This score reflect the individual's tendency to rely upon right brain processing. Since the intervals, within which the test results vary, differ between the tests, each test score was standardized and normalized before computing the combined score.

The interrelationship between the two scores is studied in figure A. It appears that the two scores - although slightly positively related (R = 0.301)- do measure two different dimensions.

FIGURE A.
The Relationship between Right and Left Brain Scores.

Since the purpose of the project is to differentiate between relative left and relative right brain dominance regardless of the absolute scores, a ratio was computed:

$$(I); \quad \frac{\text{Left brain score} \div \text{right brain score}}{\text{Left} + \text{right brain score}}$$

It will be seen that this is the same ratio as the one being used for the dichotic listening scores.

Dichotic Listening

The correlation between the dichotic listening score and the combined left brain activity score is .167 and only approaching significance.

The correlation between the dichotic listening score and the right brain score is -.328 and significant with $p \leq 0.01$. The resulting correlation with the ratio (I) is small and insignificant.

Even though there is some relationship between the dichotic score and the right brain score, the correlations are far below what was expected. Several reasons may be suggested for the almost complete failure of the dichotic score to validate the clinical test scores.

Basically, the dichotic listening score tests a left vs. right brain dominance. The data in figure A, however, suggested a four-way grouping rather than a two-way grouping.

A second reason for the problem may be the extreme difficulties encountered in presenting stimuli simultaneously. The same problem existed with the two other dichotic listening versions against which we originally tried to validate our own instrument. In conversations after the test, several respondents reported to have been able to hear with one ear before the other.

A third problem, of which we are aware, is more complicated. Even though information sent to the left ear is transmitted to the right brain and initially processed there, in normal individuals there is some information immediately being transmitted back to the left brain half. Moreover, it is possible that some information is picked up in the left brain, while the signals are being sent from the ear to the opposing right brain hemisphere. These complex interactions make it difficult to interpret the meaning of the dichotic listening scores. This is even more so since the disturbing processes may be more or less important depending upon whether verbal material, musical material, or nonsense words are used.

These experiences with the dichotic listening have not discouraged the research group completely, however. Further work with the dichotic listening procedure is being done in co-operation with the Frederiksberg Hospital in Copenhagen, where work is now going on in an attempt to develop more accurate procedures for the presentation of the stimuli.

The 80 Test Items

The 2 sum-scores did only correlate poorly with the clinical tests. Presumably too many irrelevant items were included. Therefore, a different analysis was carried out.

Like it was done with the clinical test the 80 test items were factor analyzed using a principal component procedure with the two first factors vari-max rotated. These two factors accounted for 18.3% of the total variance in the data. Out of the 80 items, 34 significantly correlated with the first factor, and of those 28 came from that subset of 41 which originally were believed to test left brain activity.

Similarly, among those 22 items significantly correlated with the second factor, 16 came from those 39 items originally believed to reflect right brain activity. Thus, there is some evidence that the first factor parallel the first factor of the clinical test analysis, and that the second factor reflect the same dimension as the one being measured with the second factor in the clinical test analysis. However, the low amount of variance accounted for, and the many questions not loading with any of the two factors again suggests, considerable noise in the data. Particularly, a number of items originally selected from tests of mental insecurity came out in contrast with the original hypothesis. For this reason it was decided to carry out a second analysis of the 80 scores. For this purpose the ratio (I) was used and a Pearson-moment correlation between each of the 80 tests and the score was computed.

In table 2 those 24 statements are reproduced which have significantly correlated with the ratio (I) with a probability of .85 or more. In the table the exact probabilities are reproduced.

TABLE 2.

24 out of 80 statements correlating with the combined left dominance score from the psychological clinical test. Positive correlations suggest left brain association, and negative suggest right brain dominance.

<u>Statements:</u>	<u>Correlation</u>	<u>Item No.</u>	<u>Exact probability</u>
I have a large vocabulary	0.26	3	.033
I read a lot	0.30	4	.017

Further Work

The findings reported so far are positive in the sense that they suggest that it may be possible to develop a test battery which will throw light on the extent to which an individual is relying more or less upon left and/or right brain information processing. There are also some suggestive findings that it may be possible to develop self-administered test items which will do the same job.

There are, however, also problems with the present results. The self-administered measurement instrument has not found its final form, and elements to go into it need further validation. Within the framework of the present project several attempts are being made to this effect.

A test is being carried out with patients from a major Copenhagen Hospital's psychological ward. For these patients other evidence suggest retarded left - relatively right brain dominated information processing. Along the same lines a test is being planned with a group matching the group of university students with respect to age, and sex, but not with regard to school training, verbal experience, etc. Both of these tests are hoped to show the ability of the revised self-administered test, as well as of the 8 clinical tests to discriminate among groups with supposed different hemispherical lateralization.

Also further work is being done with the dichotic listening instrument, and it is planned to develop a tachistoscope similar to that used by Kimura (1973). Also the possibilities for using EEG-measurements for validating the presently used tests are explored.

Finally, work is going on developing new statements based upon the experience gained with the present battery and based upon renewed screening of existing findings regarding the nature of specialized left and right brain processing.

If these activities result in an improved self-administered questionnaire, it becomes possible, with this in hand, to study a number of derived hypotheses regarding the nature of left and right brain information processing. For example, it will be possible to study the extent to which pictorial information communicates better with people with a tendency to use right brain dominated information processing. Similarly, various executions of verbal material can be tested in an attempt to identify sensitivity of the information processing procedures to variations in complexity of the material.

Also with a self-administered questionnaire available, it is possible to identify segments in society with more or less left vs. right brain dominated information processing.

Similarly, it is possible to carry out choice experiments with people known to differ in their hemispherical lateralization, whereby it becomes possible to study to what an extent different choice criteria influence choices for different individuals.

CONSUMER INFORMATION AND WORKABILITY OF COMPETITION:
A THEORETICAL FRAMEWORK

Gunter Schoppe, University of Frankfurt/Main
Christine Czerwonka, University of Frankfurt/Main

Abstract

This paper deals with the question, whether the usual division of labor between competition and consumer information policy generates but positive effects, by using examples of price surveys and product tests that practice consumer information causes or intensify developments which counteract the common goal of supporting workable competition and improving the consumer's position. Consideration is also given to guidelines for the development of consumer information policy which are compatible with the aims of workable competition.

The "Ignorant" Consumer and his Godfathers

At the time the consumer was declared sovereign, the prevailing opinion was that he himself would best be able to rule his destiny without special assistance. Furthermore, it was felt that treating the consumer as primary would best serve social welfare. No further external interventions seemed to be necessary aside from establishing free markets and guaranteeing far-reaching personal liberty and equal rights for all members of society. Competition was not only expected to ensure consumer interest in better and reasonably priced goods, but it was also expected to achieve a compromise between conflicting consumer and seller interests.

The implementation of these ideas has resulted in consumer technological progress and a considerable increase in consumer welfare. However, in contrast to its promises, this development was accompanied by a concentration of economic power, by self-abolition of competition, by a partly disadvantageous technological evolution, and, last but not least, by a growing imbalance between producers and consumers. Search for the causes of these obvious insufficiencies has led to the recognition of a fundamental conceptual weakness of the liberal paradigm, namely that the market system is a vulnerable one and therefore needs organizational management. Thus, the aim to maintain the spontaneous self-controlling mechanism of the market became the guiding principle and led to the establishment and further development of competition policy. However, maintenance of the competitive system was not an end in itself; the ultimate aim was to increase the influence of buyers' interests and to abolish or prevent the predominance of sellers. In German literature this is well documented by such metaphorical slogans as: "Consumers and cartels are contradictions like fire and water; consumers and competition should be as thick as thieves" (Bock 1958, p. 51); "An effective antitrust law is the best consumer protection" (Bock 1958, p. 52); and "A law of this kind is first of all a law for consumer protection" (Erhard 1957, p. 172).

This intervention on behalf of the consumer represents the first prominent "godfather"; that is, one who takes care of the well-being of consumers by controlling producers' behavior via prohibitive general rules. This sponsor has tended to direct all his efforts -- in the scientific sphere as well as in practice -- towards furthering the development of the existing system of competition norms and the related catalogue of sanctions.

Most characteristic of this sponsor is the fact that, in accordance with the ruling opinion, he claimed an

exclusive role and only occasionally accepted the responsibility of other policies, (which in fact had a long tradition in social policy, the predecessor to today's consumer protection). Cases in example are when the "results of unrestricted free choice may be damaging to the individuals concerned or to others" (Hildebrand 1951, p. 22) and when there was the necessity for proper "distribution of scarcity". This claim to a sole agency which was based on a broad consensus originated from the conviction that the realization of consumers' interests, as well as the direction of the economy-- would be most satisfactorily guaranteed if the principle of competition was assured by an appropriate economic order. It was well known in this context that, among other things, the degree of competition depends on buyers' information, but, as Scitovsky (referring to Marshall and his contemporaries) has emphasized, one believed that "buyers' information in turn depends on the organization of the market" (1950, p. 48) and, accordingly, would be adjustable by means of public market organization. Both of the assumptions turned out to be false as time went on. However, in spite of this knowledge, no consequences were drawn as far as an extension of the catalogue of competition policy instruments is concerned. The only reaction was to assign occurring problems to the responsibility of others.

The impulse for abandoning an exclusive claim to sponsorship, which opened an "appreciated" field to modern consumer policy, was above all to be found in the debate about "workable competition".

During this discussion, the fact was stressed that, because of increasing product differentiation and other market imperfections (supposedly necessary for the dynamics of competition) one should not expect a given or a growing expertness of consumers (cf. Clark 1968, p. 13-14). Consumer ignorance (cf. Mitchell 1912, p. 269; Clark 1968, p. 20) would be an invitation to fraud unless adequate counter-measures were taken (Clark 1968, p. 466-467). In addition, their ignorance would prevent satisfactory resources allocation and, at the same time, would bring the danger of something like Gresham's law becoming operative, whereby these markets might drop to the lowest quality levels (cf. Clark 1968, p. 483). As already mentioned, these insufficiencies were not looked upon as severe challenge by the godfather competition policy. This was probably so, because, at least implicitly, the assumption of a monocausal relationship between market structure and buyers' information was kept up even though attention was more and more directed towards the interdependences between market structure, market conduct and market performance. Thus, neither the information deficit nor changes in consumers' state of information were expected to cause negative effects. This is a possible explanation for the fact that in modern literature on competition policy considerations of the type of consumer information that would be compatible with the aims of competition policy are missing. There have only been occasional hints that "... measures such as comprehensive grade-labelling..., plus, perhaps, wide public dissemination of product information would be salutary" (Bain 1967, p. 217; Clark 1968, p. 74-77; p. 86-87). This opinion has prevailed despite Scitovsky's (1950) convincingly expressed ideas that consumer ignorance reduces the necessity for price and quality competition, enforces the process of seller concentration and raises barriers to entry

which prevent potential competition. However, these are theses which suggest an intensive engagement with questions about adequate means of compensation on the part of competition policy.

Consumer policy is the younger sponsor of the consumer. It is similar to competition policy in that it is a one-sided action-program; however, it differs in that it is not as concerned with problem definition. Consumer policy has, with the help of its advocates in science and policy, not only aimed at improving the position of the individual consumer, who is overstrained in the market, but it has also aimed at achieving social advantages for the economy as a whole. This has been tied to the hint that only intelligent use of free choice can guarantee a selection of the best goods and the most efficient firms and thus lead to optimal allocation of resources (cf. Ferguson et al. 1971, p. 72).

Even after having been accepted as a policy area of high social importance (Kennedy 1962), consumer policy has tended to orient its market-directed actions (like information, advice, and education) to problems of the individual consumer's role rather than towards requirements for the functioning of the overall system. Additionally to this point, with exception of some rudimentary attempts (cf. among others Beem & Ewing 1954; Morris & Bronson 1969; Scherhorn 1977), there has been no result-control.

In exploring these neglects (cf. corresponding criticisms by Day 1976, p. 51; Chestnut 1977, p. 195), essentially two explanations can be found. First, consumer policy is concerned with itself as well as with those problems which arise as questions along the chosen way. Half of these are questions of proving that the consumer is overstrained and thus is not able to play the expected part. The other half is concentrated on description of activities, particularly on attempts to solve problems which are connected with insufficient use of consumer information. Second, this specific way of solving the task can be explained by the interpretation of competition's aims wherein the function of static allocation is dominating, in spite of occasional appreciation of the long-term advantages of the competitive innovation process. This view is closely connected with the conviction that removing information deficits is a problem to be solved separately, and that additionally provided information would automatically increase the efficiency of the competitive system.

This is the point where consumers' "godfathers" meet each other. It is quite understandable that each group looks upon its respective action programs as non-conflicting. This customary division of labor, however, does not necessarily best serve the common task of supporting a functioning competition and of adequately strengthening consumers' positions. When considering specifically Scitovsky's (1950) theses and the fact that consumer information changes the information environment of others too, it seems possible, according to the kind of information diffused, that consumer information might create problems not only for competition policy but for consumer policy as well. This idea suggests that more efforts be directed towards the evaluation and the further development of such instruments, within the frame of consumer research. It is the purpose of the following sections to point to questions which lead in this direction. Starting with a short outline of present consumer information policy in the Federal Republic of Germany (which is similar to American practice), we will discuss possible effects of price information and product tests on competition before questioning whether and to what extent there is a need for change.

Practiced Consumer Information and its Theoretical Foundation

The conditions under which consumers make buying decisions are the starting point for considering consumer information needs. These conditions include growing diversity and complexity of products, aggressive and manipulative selling techniques, and, last but not least, consumer deficiencies such as their comparatively small resources and their inability to make reflected decisions about their needs and to achieve a good price-quality relation. Thus, there is agreement that in order to correct consumer disadvantages and the resulting misallocations, the consumer should be given additional objective information, in order "to aid and foster a self-reliant, self-actualizing consumer who can make the most of decisions and play an equal role with sellers in the marketplace" (Thorelli & Engledow 1980, p. 9).

However, a good deal of the discussion in the area of consumer research and consumer policy is focused on the question of whether and to what extent information could contribute to the solution of consumer problems. Objections to the information model and the underlying image of the rationally acting consumer overlap with arguments against the corresponding claims of practiced information policy. These arguments include (1) that the provided information is not attained by those social groups who need most assistance; (2) that consumer information hunts a spectre by trying to improve market intelligence in that certain deficiencies are inherent characteristics of the market; (3) that these instruments start at a point where decisions concerning the fulfilment of needs have already been made and, thus, they contribute to the stabilization of existing social consumption patterns; and (4) that cognitive, motivational, temporal and spatial limitations of consumers is a hopeless undertaking since consumer behavior is more guided by hereditary S-R-patterns than by cognitive processes (Kroeber-Riel 1980, pp. 588-611). All these objections lead to the conclusion that the concept of consumer information needs to be legitimized. In fact, most of the research effort in the area is directed towards a search for confirmation, whether by discovering imminent efficiencies (e.g. with the help of improved lay-out and stronger incentives for users) or by discovering possibly positive effects on the sellers side which result from the mere existence of consumer information and not from the reactions of consumers. In particular, the discovery of indirect effects, called non-use benefits (Padberg 1977), was a great relief because this made it easier "...to bear our experience that the published test information usually does not reach those groups who need our special attention as far as consumer policy is concerned." (Neumann 1977).

The perception - or the rediscovery (cf. Beem & Ewing 1954) - of these effects upon suppliers shows an attribute which is very much neglected in the entire discussion: consumer information is a public good in the popular sense and, therefore, becomes known to producers and sellers as well, so it has not only effects on sellers' behavior indirectly through anticipation of possible reactions of consumers (Day 1976, p. 50), but also affects market performance and market structure because of the circular nature of the competition process (Sosnick 1958, p. 387). Consumer information is not only a matter of reactive adaptation but, because of its public character and its predictability, it can be used as an instrument to diminish future competitive pressure and, thus, indirectly change market structure. Both these aspects contribute to the fact that consumer information finally determines conditions of future competition as well as those structures with which consumers will be confronted when they are to make use of their free choice in the future. The same statement is valid for those effects which lead to direct changes in consumers' behavior because they also change

producers' and sellers' behavior as well as market performance and indirectly market structure.

In face of these interdependencies, consumer information is likely to create direct and indirect effects on competitive processes. Thus, it seems not to be sufficient to only look for affirming "use" or "non-use" benefits. It can be expected that for an adequate development of consumer information policy the opposite way would be more helpful, namely to look for "use-" and "non-use" costs'. The latter approach would not only uncover deficiencies and "traps" but would also result in consumer information which is adapted to the claims of workable competition. This approach is developed below.

The starting points of our considerations are two information instruments which are in widespread use in the US and in the FRG: price surveys and comparative product tests. Even though these instruments are essentially alike in both countries (product-related and seller-identifying price information on the one hand; quality ratings, connected with information on price differences on the other hand), the German procedure will be dealt with since it is characterized by peculiarities.

Price surveys as well as product tests are fully or partly financed by public means in Germany. Seventy-five percent of the costs for product tests are covered by the sales of the consumer magazine "test". Regional price surveys are distributed (with a circulation of about 500 - 30,000 samples) among consumers free of charge. They serve, like the "test" - magazine, as a base of information for local consumer advisory services. The dissemination of product test information is not restricted to the 'test' - magazine (circulation in 1980: more than 620,000 samples) but in a condensed form they are published by several other media.

Price surveys are carried out in a selected number of big and medium-sized cities (1979: 35 cities) as a non-disguised survey. The product categories concerned are especially electrical household appliances, audio - and video equipment as well as photographic articles, in some cases even food, detergents, and cleansers. They tend to be well selling brands and models. The results of the surveys are presented in brochures (title: "What to buy where cheapest?") in which, for every included model, the lowest price (optically accentuated), the highest price, the medium price, and the absolute as well as the relative price differences are shown. At the core of the tables is a compilation, specified by models, where the cheapest sellers are listed by name, address, and their demanded price. There is also a notice indicating whether the product was available at the moment of inquiry.

The quality rating published in the consumer magazine "test" is made by the "Stiftung Warentest" on the basis of tests that are carried out externally. "Stiftung Warentest" is a public foundation which is bound by charter provision to "...inform the public about objectifiable characteristics of utility and use-value of goods and services".

The specific organizational structure including controlling and technical bodies (members are sellers, representatives of consumer organizations, and "neutral" persons) implies much more transparency concerning testing intentions and operations than in the case of US-organizations. This transparency is enforced by the early public announcement of tests planned as well as several intended communications with the respective manufacturers. Similar to US-conditions, the tested product samples are limited to a certain number of nation-wide sold models whose market share is more than average. The testing programs are designed by the staff of the "Stiftung Warentest" and discussed by the bodies already mentioned. The same procedure takes place as far as the fixing of rating criteria and their weights are concerned.

The results are presented in detailed tables, where the separately rated characteristics and the subsumed test rates (five ratings from "very good" to "deficient") are shown. Usually there is a notice referring to minimum "medium" and maximum prices for the model as determined from a separate representative survey. Furthermore, these very detailed results are compressed to a short "compass" where the tested products (classified from the cheapest to the most expensive) are presented together with their most important ratings. In an additional text test results, characteristics, and trends of the concerned product market are explained and hints for adequate produce usage are given.

Comparatively high importance is given (as was found by our own investigations of a two years' edition of the 'test' - magazine) to information about prices, price differences and price trends. Frequently the "Stiftung Warentest" headline stresses the benefits of price active behavior and, in this context especially, the profitability of price comparison. They do not inform however about the dispersion of prices, because it is believed that even these simple diagrams will not be understood by the average consumer (Huttenrauch 1973).

The Effects of Consumer Information on the Competitive Process: Observations and Hypotheses

Advice, Direction, and Incentive to Buy by Means of Comparative Testing

As already shown, both comparative testing and price surveys have above all two characteristics in common: information is limited to a sample of renowned, well selling models and they are hardly suited to promote the proclaimed reflection on needs in so far as they are only able to give a certain assistance after the decision about needs has already been made. Comparative tests, however, have more advisory capacity, since they do not directly focus the attention on only one product. But the underlined final test results and price data give rise to a sympathy effect which, last but not least, results in a common desire to be relieved. Therefore, consumer information receives - in contrast to the original intentions - a partly uncritical confidence and works, in connection with the fact of product selection similar to commercial advertising.

Going even further than these directing effects, particularly comparative tests are expected to give buying incentives not only for individual products but also for product classes, because these tests create an effect of attention (especially when there are good rates resulting) and in this way influence decisions for one certain purchase out of many other product alternatives.

Selective Information about Price and Quality as an Investment to Strengthen Seller's Power

The fact that product test information and price surveys report primarily on well-known and widespread trademarked goods intensifies in principle those tendencies which would occur by themselves because of consumers' ignorance (Scitovsky 1950). The sales of large firms and well-known brands - which already serve as surrogate for information signals (cf. Nelson 1976; Spence 1976; Hauser 1979) - are thus promoted (when there are good test rates), whereas small and/or only locally selling firms, as well as newcomers suffer competitive disadvantages. Transmitted by retail's screening, this can in some cases go as far as threatening existence.

In spite of a possible expansion of the evoked set, consumer information makes only insufficient use of the opportunity to stimulate competition among producers. Beyond this, there is a further effect in the field of

retail: well-rated products and/or those which are shown as being moderately priced are, so to speak, presold, a fact, which is accommodating big low-price shops and furthermore contributes to retail's concentration because of the regularity of tests and price surveys.

Promotion of Lemon Markets

As already mentioned, consumers' ignorance tends to push away good quality and instead creates so-called lemon markets (cf. Akerlof 1970), if the market mechanism itself does not produce quality discriminating signals and appropriate information is lacking¹. However, the efficiency of these kinds of signals or respective information depends in how they are perceived. In case they are noticed by only a few segments of the entire consuming public, hybrid forms of lemon - and high quality markets may develop. Both of the phenomena are especially fostered by practiced consumer information which essentially reaches an elite only (Thorelli & Thorelli 1977), by pointing out "better" alternatives to just the quality conscious user only who is able to criticize and therefore initiate his exit (Hirschman 1970). But the majority of immobile consumers might remain loyal to slack firms (the poor pay more; cf. Caplovitz 1963) and secure their existence.

The Influence of Comparative Testing on Entrepreneurial Innovation Activities

It is known at least since the empirical research of Beem & Ewing (1954) that comparative testing (especially repeated testing of the same product classes) and the awarding of discriminating test rates have an influence on entrepreneurial R&D activities, because "...manufacturers begin to act as if this information may be an element in their competition with other manufacturers' (Padberg 1977, p. 9). The test criteria act as a minimum standard: As times goes on, they lead towards quality equalization and they influence methods of and technologies for quality control. They do so, not only after a test but - because of the common early announcements of tests in the FRG - also with respect to future tests. Critical points for the competitive process of innovation are that, on the one hand, they occupy the attention of entrepreneurial R&D activities and also prevent them from looking for alternatives. On the other hand, it is not sure that the quality standards requested by the experts are congruent with those of consumers (Kroeber-Riel 1977, p. 100). Finally, these influences create no pressure for innovation as soon as qualities are standardized. Thus, comparative testing has a tendency to direct innovation, but it is stimulating innovation only within the borders of a given technology.

Promotion of Model Change

The possibility or necessity for model changes are promoted by the now practiced comparative testing, as well as by price surveys - especially for goods which attract a high degree of attention. The latter is the case when tests of a certain product class are often repeated within short intervals of time. In this manner, the personally felt aging of products is increased and therefore increases the desire for replacements. Among other things, this takes place because consumers are often not offered a choice between unchanged and changed models at a price differentiated fully reflecting the cost-saving made possible by sticking to the former, and finally there is neglect of social costs (waste of resources and environment) which are caused by frequent model change.

¹This phenomenon has been discussed in economics recently; cf. especially Akerlof 1970; Nelson 1970; Nelson 1976; Spence 1973; 1976; 1977; Rothschild 1973; Hirshleifer 1973; Darby & Karnai 1973; Salop & Salop 1976; Rothschild and Stiglitz 1976; Jaffee & Russell 1976; Hauser 1979.

Price surveys in comparison do not only promote the possibility but even increase the necessity for frequent model change especially for mature and relatively high priced goods. Usually this is true for those products where there is an intensive price competition in agglomerated areas anyhow, which leads to short term price collapses that can only be caught up by price concessions on behalf of the manufacturers. Since this cannot go on infinitely, the way out of this dilemma is a regular change of models, which usually does not mean basic technological change, but which does offer the possibility to raise prices - at least temporarily - and so to warrant "healthy" mark-ups. The predictability of periodical price surveys of many considered products induces especially modern large scale retailers (at least at the time of the inquiries) to cut prices down to a level which is attractive for advertising. So the described process of price collapses and the resulting coercion for frequent model change are even intensified. In so far as currently practiced consumer information does not only contribute to the planned obsolescence which is so much criticized by consumer policy, it even contributes to tie up resources which then are missing for beneficial innovations and a socially desirable process of R&D.

Consumer Information as Substitute or Supplement of Market Information and Open-Price Systems

There was a discussion about supplier-sided market-information and open-price systems in the US as early as at the turn of the century (cf. Eddy 1913), and about 50 years later a lively debate on their evaluation started in the FRG, in the course of which in view of the requirements of dynamic competition and especially of incentives for competitive initiatives - essentially those conditions were developed as a profile, which would not allow to come to a conclusion about suppliers' and customers' identity or about individual transactions; which must be open to the supply as well as to the demand side; which report on completed transactions only; and which need to fulfill certain requirements as far as minimum-, maximum-, or average prices are concerned.² Likewise relevant for competition as market information - and open price systems is identifying price- and quality information prepared for consumers, because they produce mutual knowledge, the importance of which must be at least looked upon ambivalently. This is immediately understandable as far as identifying price surveys are concerned. Referring to the comparative product tests, this is similarly true. But being a source of information about the quality of competing products, this parameter hardly hinders active competition (cf. Beem & Ewing 1954, p. 117) in as far as the respective information is transmitted with a delay and so the imitation lag, which is necessary for workable competition, remains.

Bias Caused by Emphasizing Price as Competitive Parameter

There is a still increasing discussion going on about competitive effects as well as distortions caused by identifying price comparisons, and about the advantages of test-caused price active behavior. In general, one can expect the permanently repeated advice (in test reports) and the information about low-price sellers which is published in the price surveys to cooperate. One of the crucial points is that for several reasons it cannot be made sure that the consumer actually makes the "best buy" because of his price knowledge. On the one hand, price comparisons usually do not include technologically homogeneous goods (i.e., actual quality information which is necessary for "intelligent buying decisions" should be

²This corresponds closely to American jurisdiction concerning the Sherman Act Sect. 1; cf. Scherer 1971, p. 450-453.

published too as a premise for "true" price transparency). Since this does not happen, it may remain veiled that the cheaper product is possibly not the one with the more favorable price-quality-relation. On the other hand, identifications directing consumers to low-price-sellers do not necessarily guarantee the realization of good bargains, and they might not even warrant a buying environment which is profitable for all consumers.

On the long run, identifying price surveys are especially advantageous for aggressive distribution systems and "submarginal" retailers, and in directing distribution structures towards concentration. Transmitted by producers' increasing dependence on retail - which is a result of this concentration - there are feedbacks on the structure of production as well as on product supply itself. In the concrete case of a purchase, they might be favorable to consumers when those skim the cream, but perhaps not when they do all their shopping there. It should be added - at least in the case of complex products - that a buyer who is guided by price surveys could be subject to persuasion in the course of sales talks. He might buy a different product which is calculated more in favor of the seller and which might be cheaper in a different store. It is well known that price information is deliberately used in ads as a flat catcher in order to attract potential buyers. In a recorded case this method was abused to divert buying decisions to more profit-bearing products by means of bonus/malusincentives for salespersons; a case which most probably is no exception.

Reduction of Services and Lowering of "Marginal Morals" in Retail as a Result of Identifying Price Comparisons

"Last week I heard one Lady ask, 'Is this book O.K. for a nine year old?' and the clerk answered, 'Look, Lady, all I know is the list price is \$3.50 and our price is \$1.98'" (The New York Times, Dec. 1, 1961, p. 58, cited by Kahn 1966), p. 34. This example illustrates drastically the effects of structural changes in retail, which are supported particularly by identifying price surveys which increase the normal desire to make good bargains. These structural changes - among other things caused by price policy - are a result both of more favorable acquisition conditions of great distributors and of their neglect of traditional services like qualified advice, free delivery etc., a behavior which can usually be found by "armchair-retailers". Frequently this causes consumers to go to a qualified specialist retailer for advice, but to buy at a low-price shop in order to make noticeable savings. In economics this phenomenon is known as external effect. It is supposed to be one of the reasons for the failure of self-control in free-enterprise systems, in as much as there is no possibility to internalize such effects, which would mean in our case to separately charge these normally cost-free services. As a matter of fact, it would be possible to bring several of these services to an extra account, services which are characteristic for specialized trade and are claimed as being very desirable (cf. Kahn 1966, p. 37). This is not valid for consultancy by specialized personnel, because it is neither possible to tie these services to a purchase, nor can they be redemanded. So they are a quasi-public-good, the provision of which is dependent on the corresponding "part of subsidy" included in the price. Whenever this subsidy can no longer be held up because of the competitive pressure of submarginal traders, the competitors are forced to adjust this marginal behavior.³ In reality this result, in consumers being left

³ Such tendencies are imminent to the competition process which is based on enforcement of egoism. On the part of neo-liberal social scientists this has been recognized as a factor which can threaten an effective and (in favor of consumers) well functioning do-ut-des-principle. This is true whenever the ruling marginal moral is exposed to a submarginal pressure. (cf. especially Briefs 1957; Ropke 1961, p. 145-255)

alone if there are no public funded or commercial institutions which offer such services. In either case, the consumer would have to pay for such services.

Status Quo-Oriented Control Effects and Undesired Structural Changes as a Consequence of the Tyranny of Small Decisions

Considering the above impressions in the context, one can find a coherent pattern: On the one hand, its origin is to be found in the perspective of consumer policy which is oriented towards compensation of deficiencies of the present economic situation of consumers and towards an improvement of allocative efficiency. Consumer policy thus intends to contribute to an increase of economic efficiency in general. But - similar to what has been shown by Leibenstein (1966) at the example of allocative efficiency vs. X-efficiency - only marginal improvements could be made in comparison to what could have been achieved by an orientation according to the needs for a dynamic development of economy and society. On the other hand, consumer policy's orientation towards the problems of today, together with the provision of only selective information, may possibly lead to structures - by way of quantitative and temporal cumulation of effects of many (though individually advantageous) "small" measures and decisions - which are less favorable than today's ones, "in the sense that consumers might disapprove of the larger results thereby produced, if they were ever given the opportunity explicitly to vote for or against it" (Kahn 1966).

Guiding Principles for Consumer Information Which is Compatible with Workable Competition

Starting from the already outlined considerations and observations, the question arises - what kind of a profile a consumer information policy can have that is compatible with the aims of workable competition and which is the starting point for an obviously necessary re-orientation of consumer information. The above referenced deficiencies and "traps" give first hints, in as much as they indicate misdevelopments and possible one-way roads. In addition to a concept of a functionally appropriate consumer policy however, it is necessary to develop positive guidelines.

A first link is the idea, common to practically every concept of workable or dynamic competition, to understand competition as a process in which corporations develop initiative - they cut prices, improve product quality, create new products or processes - and in which imitators push from behind; not immediately (in order to preserve incentives for initiatives), but with not too much of a time lag either, so that the advantage can still be caught up and all the customers benefit from cheaper and better products. This assigns a key position to the time aspect (i.e. the central problem is to create or to preserve competitive situations (cf. Clark 1954, p. 324-328) so that the effective "imitation-lag" roughly corresponds with the time necessary for initiatives, and to prevent or abolish situations, in which the effective time is either much shorter or much longer than the necessary imitation lag (cf. particularly Prahl 1969, p. 26-48). Whereas in the latter case, which is characterized primarily by dominating positions and barriers to entry, potential competition is to be initiated, the first case is marked by a competitive stalemate-situation that can be found especially in oligopolies with only a few firms, in markets with comparatively homogeneous goods, and where participants are well informed. Such stalemate-situations are not broken up by more transparency however. They are even strengthened. An encouragement for the creation of advantageous big innovations, e.g. by pointing out the respective chances for innovations, would seem to be an adequate way. Consumer organizations could act as intermediating agencies between consumers' needs and possibilities of production. From the point of view of consumer policy, this does not mean that innovative activities

should be promoted at any price, but that only innovations with a positive trade-off between an increase in benefits and social costs should be initiated.

Another important aspect for the further development of consumer-information policy results from the necessity to get on distance from the image of the consumer as a selfish permanent-calculator with an irrational passion for rationality and to accept that consumers in a series of decisive situations do not want more intellectual efforts but relief (e.g. Kroeber-Riel 1977, p. 98). This makes sense, because this way the consumer keeps the capacity to continue to develop his needs in other, subjectively more attractive fields.

By using these considerations for the further development of consumer information, at first glance, the moderate transparency stressed by most concepts of workable competition seems to be an important guiding principle which suggests a certain reserve in the provision of consumer information. This may be opportune for some (especially mature) markets, but in many other markets (especially those with high rates of innovation) this will hardly create situations which would end in competition stalemate. Anyhow, the idea of "necessary" deficiencies results from the common perspective that suppliers can only be disciplined by buyers' exit. However, considering the fact that market reality is not only marked by exit, but also by loyalty (in connection with voice as soon as quality is diminished; Hirschman 1970), transparency may be evaluated differently. Voice does not only inform firms about CD and the related reasons, but it even diminishes - loyalty provided - the danger for existence, if such a firm is willing to take the evident chance for increased efforts. Improving the possibilities for articulation and transmitting voice (may be by initiating and evaluating complaints) would be a starting base for activities of consumer organizations which would not conflict with the transparency problem.

In spite of this diminishing of the transparency problem, identifying price surveys without simultaneous quality comparisons seem to be problematic and should be omitted in the frame of consumer information and consumer advice. As long as information about "best buys" as an instrument of consumer information is continued, adequate advice should be given as far as the implications of price and quality as well as differentiating characteristics of different types of shops are concerned. Easily available and consumer-conscious information about the buying-risks, which are related to individual product classes might be of a much higher value for buyers than regular price surveys, although the information does not give a "product-survey", but it enables one to avoid possible "traps". Adequate starting points for a reorientation of the requested kind are already being developed (cf. Schoppe & Czerwonka 1980, p. 69-70). After their introduction and further development they would be able to contribute to an increase in consciousness of consumers. However, facing scarce resources, it is necessary to set priorities with which the categorization which was introduced by Nelson (1976) in "search-" and "experience qualities" might be of some help. Product classes with a high portion of "experience qualities" which are unveiled to the consumer only by the way of usage and which are reported about only insufficiently by other sources should thereby be preferred.

Considering the further development of comparative product tests, it seems to be urgent on the one hand not only to raise but to lower barriers to market entrance for small sellers and newcomers, and, on the other hand, to improve the chances for product innovation by adequate reports.

It also seems necessary to have a stronger feedback between the choice of product classes, criteria for tests and ratings, and consumers. Only in this manner could it be

assured that dynamics of competition would be promoted and that the innovative process receives adequate signals as well as new impulses.

For an improved coordination of test-criteria and their importance to consumers' needs there are two different procedures, which could be tried either alternatively or - possibly - complementarily. The first procedure follows the conception of "perceived buying-risk", whereby a non-fixed number of buyers are interviewed about buying-risks with the help of semi-standardized questionnaires. In a second run the so-won risk-catalogue is presented to a random sample of consumers once more, in order to measure the relative importance of risks. In our opinion, this starting base offers a feasible approach for the development of consumer-oriented product test criteria. Furthermore, it enables one to find out changes in the desired quality standards by way of inquiries, and to feed this information back to producers by means of subsequent comparative tests.

The second method is risk-oriented too, but in this case it is tried to make use of group-dynamic effects by not only inquiring "isolated" consumers about deficiencies and suggestions, but by gathering and inquiring small groups of consumer "experts". In this case too, perceived risks and their relative importance should be evaluated separately in a two stage process. Possibly - at least some experience lead this way - group discussions may contribute not only to summarizing perceived deficiencies, but even to detect uncovered needs (which means desirable innovation in this case) and by doing so give information which could be passed on in the frame or test reports - information which would then become public but nevertheless stimulate competing firms to even more competition about better solutions.

THE IMPACT OF NON-COMMERCIAL PRODUCT TEST INFORMATION
ON COMMERCE AND INDUSTRY
- OUTLINE OF THE STUDY AND PRELIMINARY FINDINGS -

Hans Raffée, University of Mannheim¹

Abstract

This paper presents an outline of the research program and preliminary findings of an empirical investigation, concerning the impact on the consumer-goods industry of product-test information in West Germany, published by the most important non-business test institution, the "Stiftung Warentest".

Introduction

Of the more than one dozen commercial and non-commercial product-testing bodies and institutions in the Federal Republic of Germany, the most important, in terms of consumer policy, is the non-commercial "Stiftung Warentest" in Berlin (see Meiners 1968, pp. 64-69; Thorelli and Thorelli 1974, pp. 246 - 288; Brinkmann 1976, pp. 30-43; Silberer 1979, pp. 65-87; Kandler 1980). The importance of this independent testing institution, which is sponsored by public funds, is evident due to the high degree of diffusion of its test results and its well-known status in West Germany.

Following a representative survey, the "Stiftung Warentest" was known in 1978 to 79% of the population in West Germany. Its most important publication is the monthly journal "test" which, in 1978, achieved a total edition of 786,000 per issue, reaching 15% of the population for a readership of 7 million consumers per issue. The readership, in the widest sense, taking those into account also who seldom read the journal, reached 34% of the population in 1978; this was approximately one-third of the total population of West Germany (see Stiftung Warentest 1978, pp. 5-6 and p. 49).

The fact that the "Stiftung Warentest" is so very well known is not due merely to the growth in the size of editions of the journal "test", but more especially to the increasing diffusion of the test results; these are published as short reports in other newspapers and publications and are broadcast on radio and television (see Silberer 1979, p. 67-75; Stiftung Warentest 1978, p. 5, p. 56 and pp. 69-81).

The fact that the "Stiftung Warentest" is so well known and has gained such a wide diffusion is not sufficient to evaluate the consumer-political effects of the "Stiftung Warentest". However the question must be examined, whether and how far the activities of the "Stiftung Warentest" help realize consumer-political goals (see Silberer 1979a, pp. 110 f.).

¹The authors are members of the "Forschungsgruppe Konsumenteninformation" at the University of Mannheim - a research project that belongs to the research program "Empirische Verbraucherforschung", sponsored by the Federal Department of Research and Technology, West Germany.

The "Stiftung Warentest" is, according to its constitution, bound to inform the public on the quality of widely used consumer goods which can be objectively measured. According to the aims of the federal government (the founder of the institution), the "Stiftung Warentest" is designed to augment the freedom of consumption for the consumer and to strengthen his market position vis à vis the suppliers of consumer goods, thus contributing to the maintenance and expansion of a workable competition (Friedrichs 1974, pp. 6-9; Schachtschabel 1976, p. 101; see Silberer 1979a, p. 111; Czerwonka, Schöppe and Weckbach 1977, pp. 279 f.; Biervert et al. 1977, p. 135; Scherhorn 1975, pp. 132 f. and pp. 211 ff.; Meiners 1968). Consequently the efficiency of the "Stiftung Warentest" must be judged not only by its impact on the consumer but also on the supplier, since this is the only way that one may evaluate the "non-use benefits" of the product test.

The Present State of Research

The systematic investigation of consumer test effects, as far as suppliers are concerned, has been considerably neglected both in Europe and in the United States. Only few empirical studies have been carried out in this field; these can be roughly classified into three groups:

- 1 The first group deals solely with the content analysis of the test reports and more particularly with the changes of the average quality level and/or price-quality relationship (USA: Morris and Block 1968; Morris and Bronson 1969; 1970; West Germany: Beier 1977; 1978; Diller 1977; Mensch 1975, pp. 68 f.).
- 2 Another group reports on investigations dealing specifically with single aspects of the effects of the consumer reports in the field of commerce, taking personal selling and assortment policy especially into account. Questionnaires and observation methods are used (see Beyss 1977; Eiermann 1977; IfaV 1977; Landes 1978; Landes & Specht 1979; Silberer 1980).
- 3 The last group deals with the investigation of the effects of the consumer product test on industry and commerce. Only a pilot study has been carried out in West Germany (Arnold 1978). The most comprehensive study in the US was conducted by Beem and Ewing in 1954.

None of these investigations are either systematic, comprehensive or a reliable analysis of the test effects on industry and commerce (see Silberer 1979a, p. 119). These investigations were based on insufficient samples and, therefore, often represent merely case studies. Furthermore, the studies build upon no theoretical background, and no theoretically oriented explanations were given (e. g. Arnold 1978). The methods used were often ill-suited for revealing causalities between the product-test results and certain assumed effects, eg. the changes of price-quality relationship. This applies especially to the content analysis. The investigations are therefore not generally representative, and have merely a descriptive character, possibly offering weak connections for, in our opinion, an overdue systematical analysis of product-test effects in the field of industry and commerce. The figures

indicated by the "Stiftung Warentest" concerning the changes in sales volume caused by the product tests refer to a few examples which have not been systematically investigated (see Hüttenrauch 1978; Silberer 1979a, p. 119). They thus have merely an anecdotal form (Thorelli and Thorelli 1974, p. 256).

Objectives, Theoretical Background, and Methods Implemented in the Investigation

The objective of the research project is the systematic analysis of the consumer-political effects and the deficiencies of product test results. The research project seeks to analyze the effects of product tests on industry and commerce as well as the effects on consumers. This combined observation makes it possible also to investigate the so-called non-use benefits of product tests. Such non-use benefits can be caused as a result of producers improving the quality of poorly evaluated products, these quality improvements, therefore, also benefiting the non-users of the product test. Furthermore, we have the opportunity more closely to analyze the interaction between suppliers and consumers.

This paper deals with the preliminary analysis of the effects and deficiencies of product-test information in the field of industry and commerce.

The first elementary objective of the study is to describe the possible effects and deficiencies of product test information, in particular in the following fields

- marketing activities (product policy, assortment policy, pricing, distribution, communication policy) of the suppliers;
- changes in sales volume;
- market structures.

It is planned to investigate whether and to what extent the product-test results lead to improvements in the product qualities, sales programs and price-quality relationships, as well as consumer-oriented product innovations. Furthermore planned is to investigate whether the diffusion of positively evaluated products is increased by the use of product tests in advertising, sales promotion and personal selling.

Another question to be examined is whether and to what extent product-test results are able to change the mobility of demand, which can be noted in changes in the sales volume.

Finally, note should also be taken of the changes in the market structure, due to product-test information. The question as to whether product-test results limit the degree of competition, or whether they influence the distribution of power between industry and commerce needs to be studied.

The second elementary objective of the investigation is to explain the described effects and deficiencies of product tests using theoretical approaches. The theoretical framework consists of two substantial principles, the gratification and capacity principle according to which individual and organizational behavior can be explained by expected or real gratifications and the restrictions of the behavior (see Silberer 1979, pp. 50-60; Schanz 1977, pp. 97-178). These principles help discover, classify, and integrate the theoretical approaches from which the workable hypotheses can be derived. In this context, approaches of communication, power and organization theory are especially important.

Product-test information influence the system of suppliers within a multi-step flow of communication. On the one hand, they influence the supplier system directly, i.e. without using information processing systems, and produce

effects, e.g. merely due to the anticipated test reaction of the buyer. On the other hand, test information actually cause changes in buyer behavior and in the behavior of other relevant persons or bodies (e.g. standardization institutes) and thus have an indirect influence on the suppliers (see Silberer 1979a; p. 112). In this context the hypothesis of communication theory, in particular dealing with multi-step flow and the efficiency of communication are of fundamental importance when explaining the test effects on the supplier system (see e.g. Specht 1979, pp. 139-155, 175-178; Silberer 1979, pp. 40-47; Kroeber-Riel 1980).

The type and extent of the test effects depend a great deal on the real or supposed distribution of power between buyers and suppliers, and this again can be altered by the test results (see e.g. Box 1977, pp. 190-196; Specht 1979, p. 159). Product-test information increases the independence of the consumers and makes it easier for the consumers to implement sanctions, such as "voice" and "exit" vis à vis the suppliers, and increase the bargaining power of the consumers (see Hirschman 1974, pp. 17-45; Scherhorn 1975, pp. 36-40, 76 f., 211-213). Product-test information improves mobility and articulation possibilities, therefore increasing the potential power that the consumer has against the suppliers (vgl. Box 1977, pp. 190-196; Specht 1979, pp. 67-74). Furthermore, the product-test information limits the power of the suppliers by increasing the degree of competition (see Müller 1965; Meiners 1968). Product-test information can alter the distribution of power between the suppliers by altering the articulation and mobility possibilities of commerce compared to those of industry. Thus not only approaches of communication theory but also those of power theory are extremely important for the explanation of the test effects.

Product test information often has merely an effect upon the supplier system if it brings about decision processes within organizations, resulting in changes in the behavior of these organizations. Behavioral theories of organization have to be taken into account when explaining the effects of tests on the supplier system; communication and power theoretical aspects also have to be considered (see Müller 1965; Schanz 1977; Kieser & Kubicek 1978; Wilpert 1980). Organizational reactions to test results depend, on the one hand, on the restrictions of behavior possibilities, e.g. the size or structure of the organization, and on the other, on the gratification expectations, e.g. perceived opportunities and risks (see Silberer 1979, pp. 148-155). Thus special note has to be taken of the so-called situational approach (see e.g. Kieser & Kubicek 1976), the behavioral theory of the firm (see e.g. Cyert & March 1963; March & Simon 1958), and the information processing approach (see e.g. Kirsch 1970-1971; Newell & Simon 1972) when explaining the effects of tests on the supplier system.

The third elementary objective is to propose practical measures for the marketing of the suppliers and especially for the product testing and consumer policy.

The investigation methods used include representative interviews using standardized questionnaires. The target is to interview at least one hundred firms, in industry and commerce. In industry, as the number of firms in specific branches to be interviewed is relatively small, complete investigations are to be carried out. Samples should also be conducted, above all among retailers.

The interviews in commerce and industry are designed to complement one another, and also to control the respective results.

The interviews are, as far as possible, to be carried out by the directors and members of the research group.

Preliminary Empirical Results

As the field work in the supplier system began only in August 1980 and is scheduled to last until the middle of 1981, we have as yet only few preliminary findings. These are based on extensive interviews lasting between 1 1/2 to 2 1/2 hours and were carried out with members of the top management of electrical appliance producers, especially those producing washing machines. Until now we have interviewed half of the producers selling washing machines in West Germany (both foreign and German makes), whose products were tested by the "Stiftung Warentest" (17 in all).

The survey method has proven to be very useful. The use of standardized questionnaires has presented no problems, nor have the interviews, which last between 1 1/2 and 2 1/2 hours. The willingness of industry to provide information has, until now, been considerable.

According to the results at present available, the marketing activities of the producers have been influenced in a number of ways by the product tests. With respect to the product policy most producers admitted taking note of the examining criteria of "Stiftung Warentest" when developing new products. Several top managers have even reported that their companies are prepared only to produce those products meeting the requirements of the "Stiftung Warentest". This means that in many cases it is not the published findings, but the anticipated inclusion of products in a test and the test requirements that influence the product policy.

The information from the sales companies of several foreign producers has been especially interesting; they stated that the test requirements of the "Stiftung Warentest" had been taken over by the foreign parent company for the development of new products for the foreign market. One of these firms is, in fact, one of the largest European companies in its field. This result can be considered to be a first indication of the international technological effects of product-test results in West Germany. Such effects can be expected especially for those foreign markets which have a large technological gap, which has to be compensated for by raising the level to that of the domestic market.

These international effects are limited not only by the different technical terms of delivery and stipulations on building that exist abroad, but also due to an obvious lack of international cooperation of the testing institutions. As several producers reported, the quality requirements of various foreign testing institutions, which differ to those of the "Stiftung Warentest", often stipulate that the production must be specifically adjusted to the quality requirements of testing institutions in foreign markets. At the same time however, the different requirements present sales possibilities abroad for those products which can no longer be sold at home due to the negative test results obtained.

Compared to the consideration of the test information within the field of product development, other product-political consequences of product-test information have hardly been mentioned. Some firms have mentioned the elimination of products and the introduction of new products, due to the test results. Very few firms have reported that product changes occurred because of the test results obtained.

In this context it is interesting to note that in some cases, the companies were of the opinion that the present product test had an inhibiting effect on innovations, above all new product ideas were either not sufficiently taken into account by the "Stiftung Warentest" or if notice was taken, this was usually too late.

An important area of test effects is, according to present results, the communication policy of the respective producers. About half the firms interviewed mentioned regular advertising and sales promoting activities, with positive test results, e.g. stickers or circulars sent to commerce. This indicates a difference in the effects of American tests, since these are not allowed to be used for advertising purposes (Thorelli & Thorelli 1974, p. 432).

Upon negative test results most firms try to ignore the results or to complain to the "Stiftung Warentest". Corrections, counter-advertising, or legal actions against the "Stiftung Warentest" have hardly ever occurred.

As far as the distribution policy is concerned, the test results above all influence the information used by the salesman. Until now all firms interviewed have admitted that they always inform their salesmen about the relevant test results. The salesmen often use these test results in sales discussions; moreover it has also been mentioned that commerce often initiates discussions based on the test results, and following negative test results special conditions or even the returning of products in question is demanded.

Nevertheless, according to the present findings, few test reactions of the producers deal with pricing. Price increases, due to positive test results, or price reductions, due to negative test results, have been carried out in only a few cases.

According to available information, most producers do not believe price reductions to be suitable to compensate for feared sales reductions due to negative test results, as these price reductions seem to "confirm" the poor test results.

The findings available to the present indicate that product-test information exerts a large influence on the sales of the firms interviewed. Most firms registered an increase in sales, following positive test results, and/or a drop in sales following negative test results.

These sales changes are, according to the producers concerned, however only of short duration, and after eight to ten months sales are back to normal. During this period a doubling of sales for products which received good results and/or a drop in sales by about 50% for products which received poor results was often the case. Spill-over effects of the positive test results on the sales of products which were not tested, however, have hardly ever been noted.

Not merely the actual, but also the anticipated reaction of sales to the test was considered particularly important by the firms interviewed. Virtually all the producers questioned took high sales risks into account following possible negative test results, and following possible positive test results, high sales chances were perceived. This is probably one of the decisive determinants of the indirect effects of the test results on industry.

To have an idea as to the relevant effects of the product-test on the market structures, we evaluated the appropriate statements made by the producers. Most of the producers interviewed were of the opinion that the product test increases quality competition, and at the same time favors large firms to such an extent that small and medium-sized firms are threatened with closure. Thus the power potential of the "Stiftung Warentest" vis à vis industry was considered to be especially large and insufficiently controlled. It was also considered to be superfluous as far as competition is concerned.

In summing up, it can be stated, that the test information of the "Stiftung Warentest" produces extensive effects within industry. These affect in particular product development, advertising, sales promotion, information of sales personnel, and above all the sales volume of the producers in question. It is important to note that many of these effects are brought about by anticipated demand behavior due to the test results and the resulting sales expectations. Thus, without a doubt the power and influence of the "Stiftung Warentest" on the market is considered very great. The proven results can confirm the assumption that the product test in the Federal Republic of Germany results in "non-use benefits" for the consumers.

These findings are, however, to be considered merely as preliminary results. The small number of interviews carried out up to now does not yet permit a determinant analysis nor hypothesis test.

All the same, due to the often mentioned statements, we can perhaps assume that the test effects are limited by - presumably - incorrect test results and above all by the low degree of topicality of the test results. In many cases, by the time the test report is published, new models or altered models of the goods tested are on the market. This can possibly have a neutralizing effect on the test results. The low degree of topicality could also possibly lead to the fact that potential opportunities to promote product innovations can often not be made use of.

If this is confirmed by the investigations still to be carried out, the current testing practice may be required to expand its testing capacities and possibly use new, time-saving media so as to alter this situation. The additional question should then be raised as to whether a test of proto-types, taking into account all the problems this involves, could contribute to increasing the innovative impulses of product-tests.

Furthermore, based on existing information, we can assume that due to a reduction of the international differences in quality requirements of the testing institutions, the international technological effects of product tests could be increased. This could be achieved by increasing the cooperation of the "Stiftung Warentest" with other foreign testing institutions.

To summarize the proven effects of the product tests on industry, it can be concluded that consumer policy should pay more attention to the supplier reactions on product test results than has to now been the case, and should not concentrate its activities solely on the consumers.

Summary

The "Stiftung Warentest" is the most important non-commercial product-testing institution in the Federal Republic of Germany. As its economic functions are directed towards maintaining and expanding a workable competition, its efficiency must be evaluated not only due to its effects on the consumers but also by its effects on the suppliers. The effects on suppliers have up until now not been empirically investigated to a satisfactory extent.

The objective of the reported research project lies in the description and explanation of the effects and deficiencies of product tests in the field of marketing activities, sales volume, and the markets of the suppliers of consumer goods, as well as in the presentation of practical suggestions.

Following the first extensive interviews with members of top management of electrical appliance producers, the preliminary results show that product tests have an especially marked influence on product development, advertising, sales promotions, information of sales personnel and sales volume. The power and influence of the "Stiftung Warentest" on the market can therefore be considered to be substantial.

SOURCES FOR PRODUCT IDEAS: A PROACTIVE
VIEW ON THE CONSUMER

Gerd Fleischmann, University of Frankfurt¹

Abstract

Normally consumers are not sources for product ideas both because for the individual consumer exit is cheaper than voice, and because producers for mass markets prefer process innovations to product innovations. But in affluent societies households are no longer constrained to be general producer units: they get the chance to specialize and to become expert partners to smaller firms which in order to survive show more interest in product innovation.

Why Consumers Are Normally Not Sources For
Product Ideas

Consumers usually feel powerless vis-à-vis firms. They believe all they can do with consumer goods, offered by a given firm, is take it or leave it. The firm too, be it a producer or a retailer, also feels pressured by the market. It believes that consumers easily switch to another supplier. Households and firms are anonymous to each other. Consumers do not suggest product changes or new products to firms, and firms do not ask households for new product ideas. This is not out of any ill feelings on either side, but, under certain conditions, the rational way to behave.

Consumers Prefer Exit to Voice: Exit Is Cheaper

If a consumer is dissatisfied with a consumer good, produced by one of several competing firms, he can choose either to induce the producer to change the good according to his preferences--this option is called "voice" by Hirschman (1970)--or to look for another supplier, i.e. to choose what Hirschman calls the exit-option.

In general the cost of exit is low. The consumer just has to find out, which are the other suppliers, to get from neighbors, retailers, consumer unions, or state agencies, some information about the qualities of the competitors' goods, and to buy next time one of these goods. Of course, there is the risk that experience with some other product is also disappointing. But even then, the difference between the expected and the experienced quality will hardly be larger, because the quality distribution of mass produced consumer goods is generally very narrow.

By contrast, the cost of effective voice is very high for the individual consumer. Admittedly, it is not expensive to write a letter to the producer. But chances are very poor that the complaints of a single consumer will induce the firm to change the good or to produce a new good. For, why should a firm with mass-produced goods follow the advice of an individual consumer? It is rational to do so only if there are indicators favoring the conjecture that the advice comes from a representative consumer. But it has to be suspected in the first place that consumers writing informed letters on how to change the quality of a product are not representative for the average consumer

of mass products. One effective way to convince the firm that it will pay to change the product is to induce a large number of other consumers to advise the firm concerning the same kind of change. But this is a very expensive endeavor, and even if a consumer tries it and succeeds, it is still uncertain, whether a firm will make the recommended change.

Seen from the point of view of the economic theory of collective action (Olson 1965), the choice of the voice option by an individual consumer is a contribution to a public good, in this case a contribution to the common goal of consumers with similar preferences regarding the kind of goods the individual consumes is complaining about. Generally, in large groups an individual has no incentives to make such contributions. A "political entrepreneur" is needed who organizes the group by preparing selective incentives for group membership, for instance in form of private goods, which are available for members only, so that free-riders can be excluded.

To sum up, if the consumer of a certain mass-product is dissatisfied with it, he will normally prefer the exit option, because it is cheaper than the voice option, if voice is to be effective. But in the case that consumers with similar tastes get organized by a political entrepreneur, the voice option may become cheaper.

Producers of Consumer Goods Prefer Process Innovations to
Product Innovations: Process Innovations Are Less Risky

My starting point is the general economic hypothesis that a firm facing alternatives with the same profit per dollar capital invested will choose the least risky. Now it is easy to see that for mass producers of consumer goods it is generally less risky to invest into a new production process than into a new product. The main reason for this is that the suppliers of investment goods, which are needed for the process innovation, have to supply their own investors with calculations and details of the know-how concerning the new process: in order to sell an investment good, one has to show that the good to be used will reduce production costs. There is no comparable activity on the side of the new consumer product. Even in cases in which the firm incurs the cost of getting informed about consumers' preferences of goods and of changes of goods, the probability that a new consumer good will be a success is relatively low.

The risk of innovation is controllable to some extent. One important way to reduce the risk is to have more communication with the main partners in the innovation process, namely the suppliers of new investment goods and the customers of new consumer goods. But here again it is more efficient for a firm with mass production of consumers goods to intensify the communication with firms supplying investment goods than with households buying the consumer goods; this is so mainly because in the case of communication between firms there are experts on both sides, but also because of the existing network of communication. Experts can easily agree, then, upon what is needed and what can be done about it, whereas households have in general no expertise on mass produced consumer goods and no easy access to the industry.

¹Professor of economics, co-ordinator of consumer research projects for the German Federal Department of Research and Technology. Address: Schumannstrasse 60, D 6000 Frankfurt/M. I thank Professor Joseph Agassi for his kind advice.

An additional reason for mass producers of consumer goods to concentrate on process innovation rather than on product innovation is that the loss of customers due to exit towards a producer of a new consumer good is usually a relatively slow process. Consumer habits usually do not change very quickly. But if a competitor succeeds in cutting down markedly production costs and thus prices, then there is the danger of a sudden loss of buyers. To put it differently, households are more accustomed to a kind of consumer good, for instance, to an automobile, a refrigerator or a washer, than to a special brand of that good.

In sum, mass producers of consumer goods generally prefer process innovations to product innovations because process innovations are easier to compute, because there is a better communication between firms than between firms and households, and because a successful process innovation by a competitor threatens the survival of the firm.

Consequences of the Dominance of the Combination of Exit and Process Innovation: More Goods and More Free Time for Everybody

The dominance of exit and of process innovations has resulted, on the positive side, in the rapid growth of productivity of labor and in rapid economic growth in general. On the negative side, the fine tuning of the qualities of consumer goods with the tastes of the consumers has been somewhat neglected. From an elitist standpoint this development may be deplored. Compared to the high standards of craftsmanship of former generations, many mass products of the present are of comparatively lower quality. But there are lots of consumer goods which even the most ardent admirers of pre-industrial craftsmanship would not miss: if not railroads, automobiles, airplanes, refrigerators, then cameras for reproductions of art work, hi-fi records, etc.

Seen from an egalitarian standpoint, the consequences of the combination of exit and process innovation seem more positive. The emphasis on process innovation resulted in transforming the luxuries of the rich of yesterday into mass consumption of the man in the street today. The most impressive example in the history of this development may be Ford's famous model T. It has not been a marked progress in automobile quality or style, but a very marked progress in automobile production. It was the breakthrough to the automobile using society. Even though it is easy to see today the negative consequences of automobilization--smog, noise, cancerous growth of suburbia, etc.--the automobile has doubtless also enhanced the freedom of action of the average household very effectively.

The emphasis on process innovations resulted not only in rapid economic growth; a part of the gain in productivity has been transformed into the acquisition of more free time for all members of the household: their role as income earners has been better accomplished by a shortening of their work day, and their roles as producers in the household was made much lighter by household investment goods which raise the productivity of household work; these are electric washers and irons, wash-and-wear clothing, vacuum cleaners, deep freezers, etc. As will be shown later on in more detail, it is just this gain in free time which hopefully will alter the relationship between firms and households, at least between some kinds of firms and households, from exit toward more voice.

Incentives and Capacities for the Development of Product Ideas in Households of Affluent Societies

Abundant free time in the household allows members to specialize within the household. This leads to a growing

demand for specialized consumer goods coupled with the required higher ability of the consumer to communicate with firms.

Households as Producers

Households are not only institutions offering the services of their work-force in the labour market and demanding products and services in consumer goods markets; they are also institutions in which market goods are transformed into final goods and services to satisfy its own members. Except for goods purchased for their function as status symbols, goods bought in the market serve as inputs into the household's own production process, where the other inputs are the (household work-) time and the human capital of its members. The output is the satisfaction of a variety of demands. Because there are many of those which have to be satisfied almost simultaneously, the household performs diverse production processes in parallel. The household can thus be characterized as a generalized producer. As long as the household has only enough income and free time to perform a multitude of the more urgent tasks, the members have little chance to develop expertise in one or a few of the household's production processes.

The scene alters as soon as the household has a growing income and free time, which enables individual members to specialize on one or few production processes.

The most important features of this specialization are the cumulative effects in knowledge and motivation. The specialized household has the chance to accumulate knowledge or--as economists say--human capital in a way similar to that of the specialized firm. In contrast to physical capital human capital has the nice property that use does not diminish it; on the contrary, use, above all intelligent and intensive use, gives the chance of growth of knowledge, through criticism, innovation, and adaptation. In this way members of the household may become experts in cooking, hiking, fly fishing, photography, even painting, etc.--with the result of ever-increasing standards of quality of the household production.

The cumulative effect of specialization is reinforced by a cumulative motivation effect. In humanistic psychology three kinds of needs are distinguished: existence needs (i.e. need for food, shelter, etc.), social needs (i.e. needs for communication and cooperation with other people) and growth needs (i.e. needs for personal development or ego growth). Whereas the satisfaction of existence needs intensifies social needs and the satisfaction of social needs further strengthens growth needs (c.f. Alderfer 1972). Thus it is to be expected that households with little income will concentrate mainly on existence needs--whereas those with income and free time at their disposal, will in the first place try to satisfy more growth needs. Specialization in households in the process of production intended to satisfy growth needs will therefore stabilize these processes. The cumulative process of the development of human capital or the growth of knowledge and the motivational cumulative process of growth needs, are thus mutually supporting.

Growing Demand for Expert Consumer Goods as Consequence of Growth of Human Capital in Household Production

An important consequence of the accumulation of human capital is that the productivity of the specialized production process in the household grows. Therefore the shadow prices of the input-goods for this production process will fall relative to the process of the other input-goods of the household production processes. *Ceteris paribus*, as prices fall the household will buy more of these input-goods (c.f.

Becker and Michael 1973). For instance, when a consumer becomes expert on baroque music, records with this music are relatively cheap considering the time invested to become an expert and the time necessary to hear the records repeatedly. The growth of knowledge in the realm of specialized household production reduces the significance of the market price of the relevant input-goods, though their quality will become more important; this is so because these goods have to fit the higher quality of human capital.

Higher Communication Ability and Interest as Consequence of Growth of Human Capital in Household Production

By specialization in a line of household production the consumer also will be an expert on those input-goods which he buys from firms. And because the quality of these goods is increasingly important to such a consumer, he is not only able, but also has increasingly greater interest in communicating with the supplying firm.

As distinguished from his interests in his role as generalized household producer, the preference of the specialized consumer is of voice over exit. The specialized consumer has as consequence of his expertise and of the minor importance of market prices generally input-goods of the highest attainable quality or input-goods which he finds best suited for his specialized production. Therefore exit is of little use for him: he has already left most of the market. All he can do in order to improve the input-goods is to convince the supplying firm to upgrade its product, or to improve his own specialization. Yet there is an important question here: is not the specialized consumer better off when he behaves as a free-rider, hoping that other consumers with the same specialization communicate with the firms in order to change the quality of the input-goods? Does the economic theory of collective action also apply here, because consumers specialized in certain kinds of household production form large (latent) interest groups? Obviously, many specialized household producers will choose the free-rider position. But there are also many consumers who want to communicate because this process is self-rewarding in the sense that exchange of information between experts has always the chance of promoting the knowledge of both sides.

Incentives for Firms to Adopt Product Ideas from Households

Communication requires at least two partners. It is not enough that specialized consumers are interested in it; also the supplying firm has to be ready for communication. It is therefore advisable to look for the consequences of household specialization for the firm, in order to find incentives for it to communicate.

Specialized Small Firms as Complements to Specialized Households

One result of household specialization is the mushrooming of new small markets for expert consumer goods in addition to the large markets of mass-produced consumer goods for the generalized part of household production. Small markets imply small series of production and therefore higher costs and higher prices. But as has been demonstrated, for expert consumers quality is more important than price. Therefore small enterprises producing expert consumer goods may be viable, whether as independent economic firms or as small activity units within larger corporations.

Small Production Series Favorable for Product Innovation

Just as large scale production is accompanied by a tendency to stress production innovations, so small scale

production induces entrepreneurs to use product innovation as main instrument of competition. This does not mean product innovation just for the sake of novelty. For an expert consumer the new is not always the better. More important for him are high standards of product quality and fit for the specialized household production process. The better the fit between qualities of the product and the requirements of the production process in the household, the better and the clearer will be the market position of the firm.

The hypothesis that mass production favors process innovation and small scale production favors product innovation could be challenged by the wave of revolutionary product innovations. The latest was caused by microelectronics in mass-produced consumer goods. Obviously, quartz watches, pocket computers, electronic programming of household appliances etc., are all instances of a large set of important product innovations of mass produced consumer goods. But all product innovations of the last century will do as examples. This is why the hypothesis says mass-production favors, not entirely insists on process innovations. The rapid diffusion of product innovations can only be explained by the fact that it resulted in even more revolutionary process innovations. Therefore if process innovation is understood in a generalized sense, the hypothesis can be stated strongly: Mass production insists on process innovation. Thus, about ten parts of an electronic watch, for instance, are cheaper to produce and to assemble than the about hundred parts of a mechanical one. Similarly, the contribution of microelectronics to large productivity gain can best be recognized by the change of the production location of pocket computers. Invented in the USA it has been first produced there. Lower wages in Japan and in other Asian countries attracted production to these countries. But with the invention of microelectronics, that is to say of the chips, the United States regained international competitiveness.

The importance of product innovation and quality adaptation to the demands of expert consumers are incentives for entrepreneurs to be responsive to suggestions of consumers. Whereas a complaining consumer in the case of mass products may be viewed as unrepresentative, in the case of specialized consumer goods the hints of a consumer are taken seriously, since his suggestions are from the start backed by the expertise that prompts them; and they depend to a much lesser degree on emotions than those of the mass-product consumer's complaint. This way newer and even higher standards of both production and consumption emerge.

Smaller Hierarchy Distances in Small Firms Facilitate Communication with Households

Not only the incentive to communicate with consumers is higher in small specialized enterprises than in large, mass producing firms, there are also higher chances that suggestions made by consumers will not be buried in the files of a large bureaucracy. In small enterprises it is easier to have a shortcut between gatekeepers in the organization, who communicate with the outside, and those persons, who initiate and support the processes of innovation. This is not to say that large firms necessarily are less innovative. They may decentralize and build small subsidiary enterprises which have in principle the same possibilities as independent small firms.

The New Combination of Voice and Product Innovation

I shall now present a brief historical case study to show how communication between households and firms in the process of product innovation may work and close with a word about consequences for the future. But first let me sum up.

Voice and Product Innovation as Consequences of Specialized Household Production

Household's disposable income and free time grows; money and time are no longer used for necessities of life only; an increasing part of the household's budget is spent on activities that satisfy personality growth needs; an important change occurs in household production. The generalized part of household production is complemented by a specialized one, characterizable by a cumulative process of human capital growth and of motivation for further growth. Consumers become experts interested and capable of influencing the process of product innovation in firms. In their role of specialized household producer, they prefer voice to exit. Consequent to specialized households small specialized enterprises evolve, at times viable in spite of small scale-high cost production processes, because the specialized households, for whom they cater prefer high quality to low price. Instruments of competition are therefore in the first place product innovations. This corresponds to the interest of the expert consumer to influence the quality of the goods, made by the firms. This way the firms become susceptible for new product ideas from consumers. A paradigmatic case is the following.

A Paradigmatic Historical Case Study: The Amateur Photographer Heinrich Kuehn, the Optical Engineer Franz Staebler, and their softlens "Imagon"

Heinrich Kuehn (1866-1944), who lived in Austria most of his life, was a famous photographer (c.f. Scholz 1980). He was an amateur photographer both because he was a person of independent means, and he objected to the professionalization of this new art. His artistic ideal was photography imitating painting. He wanted to be an artist who produces paintings not with brush and paint, but with camera and film. One of the techniques he invented is to superimpose images on one frame of film, one hard and one soft. This was effected by the use of the center of a lens, which gets a sharp image; the soft image was effected by the use of the periphery of a lens. The superimposition of a soft image on the sharp one had the result of a clear image with slight diffusion and sparkling light spots, so as to resemble a painting. This technique was very difficult and time-consuming and only fitted for immobile objects. Kuehn wanted to have a lens which at once produced the wanted result of the two images. He had the ingenious simple idea to put in front of the lens a diaphragm which has a perforated periphery. The normal small iris opening now yields the sharp core image and the marginal rays, which are reduced by the variable perforation of the periphery, form the the soft, but at once superimposed image.

In Franz Staebler Kuehn found an owner of a small optical firm who was ready to design and produce the lens he wanted. For years they communicated and cooperated. Staebler produced many models and Kuehn tested them till he had the model which met his demands. The lens first appeared on the market in the year 1928. Ambitious photographers still seek the "imagon", produced today nearly unchanged and never outperformed by any other softlens producer.

This case exhibits all the elements required for the household to become a source for new product ideas.

- a consumer with sufficient disposable income and free time to enable him to work in a specialized household production;
- the consumer accumulates human capital and satisfies his own growth needs;
- a small enterprise, primarily interested in product innovation, and with the entrepreneur at the same time

gatekeeper and promoter of innovations;

- a small, but not too small market with expert consumers, who appreciate the quality of a consumer good for specialized household production.

Conclusion: Consequences for the Future-the Household as Growth Sector

The problem of consumers as sources for product ideas may be of limited interest. But the analysis of this problem leads directly to a proposition which is of general interest, namely the thesis that in comparison with the household, markets and firms will lose their importance as sources of welfare. It is thus not necessary to combat the mass-market but to use it in order to supersede it.

Economic and Social Limits to Growth

Many world crises-nutrition, energy, raw materials-indicates the end of unmitigated economic growth. Perhaps technological progress will shift these limits outward. But there are also social limits to growth (c.f. Hirsch 1976). Perhaps one day every household may have its refrigerator, washer, car, etc. But it is impossible for everybody to have the proverbial lonely vacation house or to be a highly paid executive. The very success of economic growth in the past obscured for a while the social limits to growth. But when economic growth ends or slows down, the social limits will be increasingly felt. This will inevitably sharpen social conflicts. To contain these social conflicts, Hirsch proposes more equal income distribution. This may be one possible response to this challenge. But there are others.

No Limits to Growth in Specialized Household Production

Production in the general sector of the household seems to be one of the economic sectors with the largest growth of welfare today (c.f. Burns 1975 and Gershuny 1978). This growth depends largely on material investment goods, bought in the market, and therefore indirectly on economic growth. But growth in the specialized sector or household production depends more on the availability of free time which the consumer may devote to these activities, and on accumulated human capital; material goods bought in the market are of decreasing importance. Therefore the growth of welfare in this sector is not subject to the same material limits of growth. And growth in the specialized sector of the household is also independent of social limits to growth. For, to be a photographer or a fisherman who amply satisfies his growth needs, one need not have an expensive camera outfit or a motor yacht. Expensive material investment goods only compensate for lack of time and for lack of human capital. This therefore may satisfy the social needs of a busy executive-it may gain him social status by conspicuous consumption-but it will not satisfy his growth needs (in the sense of ego growth or personality growth). It may be one of the most important tasks of socio-economic theory and of welfare policy to explore and to strengthen the unlimited growth possibilities of specialized household production that go with the growth of human capital.

PERCEIVED RISK AS A HINT FOR BETTER CONSUMER INFORMATION AND BETTER PRODUCTS:
SOME NEW APPLICATIONS OF AN OLD CONCEPT

Abstract

This paper addresses several aspects of deriving a standard for a workable information system. Basic elements of the approach presented are the analysis of consumer information demand derived from perceived risks, as well as the examination of the information supply by business and neutral sources by content analysis. Some illustrative empirical results from a study on consumer information strategies in the German automobile market are presented.

Introduction

Basically, there is no controversy about the general importance of consumer information in achieving an efficient competitive market system. All kinds of public consumer information programs, whether in Europe or in the United States, start right out from this assumption (e.g. FTC 1979). However, not all measures of consumer information policy have proved to be effective. Consumer researchers have investigated such inefficiencies mainly on the grounds that information not tailored to the information processing capabilities of consumers might not be very helpful for them after all. But information does not only have individual effects to be investigated at the level of the individual consumer, but a host of more indirect effects which result from the interaction of consumers and suppliers in the market. The nature of these effects resulting from a raise in the level of information in a market has not received much attention in the literature.

In this paper we want to present an integrated framework which makes it possible to trace both kinds of effects. From this we shall conclude that the complex interrelationship of positive and negative effects of information policy calls for the concept of a "workable information system", and for means of measuring this workability. We then develop such a measurement concept, using perceived risk as a central unit of analysis. Problems in applying this concept are discussed and illustrative results from a study of the German automobile market are presented.

The Effects of Information Policy and the Need for a "Workable" Information System

Information Policy and Welfare: A Consumer-Oriented Approach

Most people would probably agree that the basic aim of consumer information policy is to enhance consumers' welfare. It seems therefore appropriate to evaluate effects of information policy from a consumer-oriented viewpoint, which conceptualizes welfare as the aggregated utility consumers derive from the consumption of goods and services. We can broadly distinguish two ways in which information policy can enhance welfare in this sense:

- on a first level welfare is enhanced if the new information enables consumers to improve their purchase decisions, i.e. helps more consumers to choose among the available alternatives the one that suits best their individual preferences;
- on a second level more information can raise welfare by inducing changes in the supply of goods and services so that these conform better to the preferences of the consumers.

Later we will have to say more about how these levels interact and how changes at the second level are induced. Here it is important to note that the kinds of effects in question involve not only consumers but also suppliers: changes in consumer demand at the first level will most certainly lead to reactions on the supply side, and changes at the second level presuppose effects on the supplier side. Hence, although we take a consumer-oriented stand in analysing the effects of information policy, such effects always involve the supplier side as well, and all effects of information policy are therefore also relevant from the viewpoint of competition policy. Thus, the interaction between consumers and suppliers is crucial for the analysis.

How informationally induced changes in the relations between consumers and suppliers can affect welfare can be demonstrated by means of a simple model. Using a multi-attribute framework, we assume that consumer i considers some attributes as important in evaluating some particular product. Then his informedness concerning this particular market can be characterized by

$$IC_i = \sum_{k=1}^{p_i} z_{ik} \quad (1)$$

where: IC_i = Informedness of consumer i

z_{ik} = Number of brands where consumer i knows attribute k

p_i = Number of attributes that consumer i considers as important.

If there is a total of m brands in this market, we have

$$0 \leq IC_i \leq m \cdot p_i \quad (2)$$

Usually, the consumer will not attain maximal information due to information cost (C) and his own propensity to acquire information (AC_i). Thus, we have

$$IC_i = f(C, AC_i, m, p_i) \quad (3)$$

The informedness of suppliers can be characterized in a similar way. We assume that consumers can be divided according to their preferences into some segments, and that the total number of attributes used by consumers in evaluating the particular product in question is q . Then the informedness of a supplier j can be written as

$$IS_j = \sum_{k=1}^q y_{jk} \quad (4)$$

where: IS_j = Informedness of supplier j

y_{jk} = Number of consumer segments where supplier j knows the value of attribute k

q = Number of attributes used by all consumers.

If the total number of consumer segments in this particular market is n , then

$$0 \leq IS_j \leq n \cdot q \quad (5)$$

It seems that the informedness of suppliers is partly dependent on the informedness of consumers. If consumers know a lot about the brands in the market and how these relate to their needs, it is easier for them to voice complaints, it is easier for suppliers to do market research, and it is easier for institutions of consumer policy to channel information about unsatisfactory products. Hence we can view the

aggregated consumer informedness (\tilde{IC}) and the supplier's individual propensity to acquire information (AS_j) as the basic determinants of his informedness:

$$IS_j = f(\tilde{IC}, AS_j, n, q) \quad (6)$$

Whenever some consumers do not know how the m brands in the market score on the p_i attributes important to them, or whenever some suppliers do not know which combinations of attribute values are preferred by the n consumer segments, some consumers will experience a welfare loss. This is because they do not realize utility U^* that would be associated with a brand that conformed perfectly to their individual preferences, but some lower utility U . The welfare loss $\Delta U = U^* - U$ can be split up into two parts:

$$\Delta U_i = \delta_i + \nu_i \quad (7)$$

where: δ_i = welfare loss resulting from the fact that a consumer i chooses among the available brands not the one coming closest to his subjective ideal brand
 ν_i = welfare loss resulting from the fact that none of the brands available is completely like the subjective ideal brand.

It is plausible to assume that the first type of welfare loss depends on the consumer's informedness,

$$\delta_i = f(IC_i) \quad (8)$$

and the second on the suppliers' aggregate informedness (\tilde{IS}) and the number of brands in the market (m):

$$\nu_i = f(\tilde{IS}, m) \quad (9)$$

This simple framework can now be used to trace some possible effects of lowering C , the cost of information. We define "cost" in a very broad sense here, so that most measures of information policy, like providing additional information, improving the quality of information, increasing the availability of existing information etc., can be viewed as special cases of "lowering cost".

Direct Information Effects and Market Effects

We distinguish two types of effects: those resulting directly from changes in the information flow (one-party effects), and those resulting from reactions of the market to such changes. For each possible effect we will list its prerequisites, possible obstacles, and ways these can be handled by public policy.

We have two direct information effects. One stems from changes in consumer behavior, the other from changes in supplier behavior. Both can increase consumers' welfare.

Lowering C may induce some consumers to acquire more information, thus raising IC_i for these consumers. This may enable them to make a better choice among the brands available, thus lowering δ_i . This effect has two prerequisites:

- a lower C must induce at least some consumers to increase IC_i . This is obviously not always the case. We know many examples where newly presented information was not used by consumers (e.g. Carman 1972; Monroe & LaPlaca 1972; Lenahan, Thomas, Taylor & Call 1973). Usually, this can be explained by deficiencies either in information content, which does not conform to the consumer's information needs (Grunert & Saile 1978), or in format, which does not conform to the consumer's information processing capabilities (Bettman & Kakkar 1977). Careful design of measures of information policy can circumvent these obstacles;
- a higher IC_i must actually result in a lower δ_i , i.e. the consumer must be able to use the additional information in his decision in an efficient way. This, too, is

not always the case. We have some experimental evidence that with increasing amounts of information consumers resort to simpler decision rules (Payne 1976; Park 1978), thus giving away possible welfare gains from a better choice. Again, careful design of the information, which takes into account how people integrate information and how this is influenced by the information format, may circumvent this obstacle.

Lowering C may also have direct informational effects on suppliers. This occurs if C raises \tilde{IC} , which in turn raises IS_j for some suppliers. That is, due to the increased informedness of consumers some suppliers know more about these consumers' preferences, for the reasons indicated above, causing them to change their products. It is also possible that the mere existence of neutral consumer information detrimental to a supplier's product may cause him to change the product. These changes in the brands on the market may cause a lower ν_i for some consumers and hence increase welfare.

Apart from the constraint that a lowering of C must not necessarily result in a rise of \tilde{IC} , as stated above, we have two more prerequisites for the supplier effect to occur and increase welfare:

- a rise in aggregate consumer informedness must actually result in better informedness of the suppliers about consumers' preferences. Poor market research on part of the supplier may inhibit this. Information policy could help greatly here by institutionalizing communication channels between consumers and suppliers, so that the latter can take advantage of the expertise of the former;
- suppliers must be motivated to use an increase in IS_j to design products which are in better accordance with the preferences of consumers. This is not necessarily so. If a supplier has acquired monopoly power to an extent that disregarding the wishes of consumers is no longer punished by the market, the welfare effect will not occur. This, however, is a problem for competition policy, which can try to enhance competitive pressure in the market and/or facilitate market entry so that unwarranted monopoly power cannot endure.

If these direct informational effects occur, the other members of the market will probably react to the new developments. This is the cause for market effects. To discuss possible market effects, it is useful to start with a general process model of the functioning of a competitive market, which was developed to explain the dynamics of competition resulting for example from a pioneering supplier taking a lead in offering a new or improved product (Herdzina 1973):

- in the action phase some supplier offers a new, improved product;
- in the substitution phase, consumers react by substituting the new product for others, thus creating increased demand and some degree of monopoly power for this supplier;
- in the reaction phase, competing suppliers react by offering improved products as well;
- in the resubstitution phase some consumers go back to their old suppliers now also offering improved products.

As a result, the monopoly power of the innovator has been eroded, but the supply has improved. Applying this general scheme to information policy, we find that both direct informational effects mentioned above trigger this whole process and hence cause market effects: if consumers change their demand due to an increased IC_i this constitutes a substitution phase with subsequent reactions, and if suppliers change their supply due to an increased IS_j this constitutes an action phase. In the course of the process additional welfare effects will result:

- consumers who, in spite of the decrease in C , did not acquire more information and continued to buy the same brand, will find that this brand is no longer available and buy a substitute. Depending on the kind of information deficit of the consumer, his preferences, and the

way products are improved, this will result in decreases in S_i and/or μ_i for these consumers;

- suppliers who did not change their product in response to the informational measure may be forced to do so because of demand reactions of the consumers. This again may lead to a decrease in μ_i for some consumers.

The realization of these effects presupposes, of course, a proper functioning of the competitive process. We tried to outline how this process can be stimulated by information policy measures. However, it is important to consider that the described effects depend on the kind of information strategies involved. Inadequate provision of information could affect the functioning of the competitive process even detrimentally.

Pursuing an "inadequate" information policy could for instance mean either to single out special product attributes, like prices, or to inform on selected groups of suppliers exclusively, as is often done in comparative testing magazines.

The possible negative effects on competition of stressing only a special attribute of a product have been demonstrated on the market for used cars, referred to as a market for "lemons". In the absence of information on further product attributes, as for example low defect rates, price becomes the exclusive indicator for the quality of the product. Then, it is a reasonable choice for sellers to refrain from costly, price-raising pre-purchase repairs and sell lower-priced "lemons" instead (Akerlof 1970, FTC 1979). Corresponding to this result, information policy which even enlarges the consumers' incomplete evaluation of products could mean to contribute to a deteriorating quality of supply and to a paralyzing of sellers' competition on quality.

Comparative testing of products can be undertaken by "neutral" institutions, i.e. by organizations, which are neither organizationally nor financially dependent on suppliers, and the results thus derived can be used for information policy strategies. If however comparative testing selects large suppliers and national brands to the detriment of small and local suppliers, consumers would be informed on parts of the existing supply only. This could induce monopolizing tendencies and bring about results which are similar to those discussed in the context of advertising effects. There, it is stressed that information by advertising can increase either the heterogeneity of supply or the concentration towards large suppliers, both effects entailing possible welfare losses by an increase in monopoly power and/or a decrease of brands supplied (Grunert & Stupening, in press).

"Adequate" consumer information policy which aims at improving the competitive market system has to avoid partial or one-sided information measures like the ones mentioned. It rather should try to alleviate consumers' choice among different products by comparable and understandable messages. Consumer information policy should try to choose an information content and format that:

- facilitates comparison on all attributes of competing products which are deemed relevant by individuals,
- analyzes all brands available, instead of particular market segments,
- adapts the information to the information processing capabilities of consumers,
- enables the consumers to react more rapidly to changes in product prices and qualities, thus spurring efficient competition.

The "Workable" Information System

If the host of effects, constraints, and policy variables described in the preceding section allow any strong conclusion, it is the one that maximal information is not an aim to be pursued by information policy, since the welfare effects are so complex that a simple maximization postulate is inappropriate. Information policy is therefore undergoing

a development similar to the one competition policy underwent a few decades ago, when it abandoned the concept of perfect competition as a policy goal in favor of a "workable" competition (Clark 1940). It seems that the concept of "workability" can be used for information policy as well: not a system of perfect information of consumers and suppliers is sought for, but a "workable information system" that tries to take advantage of the possible benefits of informed consumers and suppliers without neglecting welfare detriments resulting from inefficient or exaggerated use of information measures.

This means that information policy, just as competition policy, has to find ways in which the "workability" of an information system can be measured and evaluated. We want to propose that the workability of an information system can be assessed in three steps:

- by analysing the motivational determinants of information supply and demand. This can be termed information demand analysis;
- by analysing the information presently available in a market. This can be termed information supply analysis;
- by analysing whether consumers and suppliers are actually able to obtain in the market the information they need to make informed choices. This can be called information performance analysis.

These concepts will be elaborated in the remainder of the paper. We will concentrate on information for consumers and only hint at information for suppliers from time to time.

Assessing the Workability on the Basis of Perceived Risk: Concept and Applications

"Perceived Risk" as a Unit of Analysis

As we tried to show in the preceding section, information is not a homogeneous good. Thus, in trying to assess the workability of an information system, the question is not how much information this system does process but rather what this information is about. In order to make this a meaningful question, we must develop a unit of analysis with which to measure information content.

The basic purpose of consumer information is to enable the consumer to compare products, to find out which brand is best for him. Since usually a product has several characteristics that give rise to utility, the information must be about several product attributes. Indeed, this is what most consumer information is about. However, in order to be "information" to a consumer, two additional prerequisites must be fulfilled: the consumer must consider the attribute to be important, and he must be ignorant about the values the various brands have on this attribute. The well known concept of perceived risk comes in handy here: attribute information is helpful for the consumer in making his product choice only if this attribute is a perceived risk for him, i.e. he does not know the value some brands have on this particular attribute, but he knows that he would dislike some of the possible values the attribute can take. We thus use the term perceived risk in a multi-attribute fashion here. There can be many perceived risks associated with a particular product (e.g. Humphreys & Ingene 1980).

Information Demand: Consumer's Motivation

If a consumer perceives risks he is motivated to acquire information. Whether he will actually do so depends on a host of factors, the most prominent one being probably the expected availability of the information and the cost of obtaining it. But while a consumer motivated to acquire some information might actually do so or not depending on situational factors, an information supplied for which the consumer is not motivated will never be acquired and hence is useless and a waste of resources. Therefore, it makes sense to start with the motivational side, and use it later as a criterion in evaluating the supply side.

We propose to assess the motivational side by means of a risk analysis. This includes the following steps:

- a first consumer survey to obtain a list of possible risks consumers associate with a particular product,
- editing this list with the help of consumer experts,
- a second consumer survey to establish the relative importance of the risks for various consumer segments.

In our study of the German automobile market, the first consumer survey used an open-ended questionnaire, including questions about experiences with cars, reasons for buying a car, and main uses. The purpose was to find as many attributes as possible which at least some consumers perceive as "risks" in the sense described above. For this reason, the number of respondents surveyed was not fixed in advance. Instead, the survey was stopped when it was found that additional respondents did not contribute any new "risks" to the list. This was achieved after interviewing 60 respondents, approximately equal halves of which came from urban and rural areas. Since the aim at this stage is only to obtain a list of risks as comprehensive as possible, the sample does not have to be representative.

Experts are needed because automobiles are complex products and the answers of consumers cannot always be taken at face value. Risks perceived by consumers may no longer exist for the brands now on the market, or two risks worded differently by two respondents may actually refer to the same thing. For this reason, the advice of experts was sought and the list of risks edited accordingly. The resulting list contained 84 items.

Another important contribution of the experts results from the fact that for many risks there is no information directly available to reduce them, but rather the consumer has to use certain indicators. For example, there is no way to measure directly whether a car will rust. But if certain parts of the car body are galvanized, we can take this as an indicator that rust will be less probable. Relating indicators to risks and separating valid from invalid indicators requires considerable technical expertise and can be done only with the help of product experts.

The second consumer survey is necessary because the list of risks is a conglomerate of answers from respondents. Probably no single consumer will consider all risks of the list as important. His motivation to acquire information will probably only extend over a few risks. Therefore it is important to know the relative importance of the risks, and to identify segments of consumers according to the risks they stress. The second consumer survey tries to achieve just this. A representative sample of 500 drivers is asked to rate the relative importance of the risks. To obtain maximally differentiated answers, the method of magnitude scaling is used (Wegener 1980). Table 1 shows the results of a pretest, where 19 respondents rated a subset of 40 risks.

The results from such a risk analysis are important in assessing the workability of an information system, because they serve to approximate the total set of information consumers may be motivated to acquire. Of course, an individual consumer will be motivated to acquire only a small subset of this. But this subset is bound to vary as the consumer learns about other risks or puts the product to new uses. Therefore, the totality of possibly experienced risks serves as a useful yardstick. Especially, it makes possible to single out the information that is less likely to be helpful for consumers.

TABLE 1
Average Rating of 40 Selected Risks

RISKS	AVERAGE RATING SCORES
1. BAD TRACK-HOLDING	116.086
2. HIGH FUEL CONSUMPTION	106.221
3. LEAKING BODY	90.805
4. EXPENSIVE PARTS	90.562
5. TRANSMISSION FAILURES	88.963
6. MISPLACED HANDLING INSTRUMENTS	86.152
7. SHIVERING STEERING	83.319
8. FREQUENT ENGINE TROUBLES	79.101
9. BAD ACCELERATION	75.500
10. BAD OVERALL SIGHT	75.095
11. BAD ROAD GRIP IN WINTER	65.948
12. EASY DENTING OF BODY-SIDES	64.833
13. EASY BREAKING OF V-BELT	60.910
14. CROSSWIND-SENSITIVITY	57.634
15. INSUFFICIENT NUMBER PLATE ILLUMINATION	57.023
16. EASY CORRODING	54.881
17. CONDENSING CAR-WINDOWS	54.549
18. SMALL TANK	53.596
19. IRREGULAR WEAR OUT OF TYRES	52.901
20. UNSMOOTH GEAR	51.987
21. UNSMOOTH STEERING	50.288
22. UNSOLID CAR-ROOF	48.650
23. UNCOMFORTABLE SEATS	48.413
24. BAD HILL-CLIMB QUALITIES	44.762
25. BAD LOADING FACILITIES	42.562
26. BAD PAINTING	40.694
27. MISPLACED SPARK PLUGS	40.135
28. SQUEAKING BREAKS	36.948
29. BAD MANOEUVRABILITY	36.395
30. BAD WINDING-UP OF SAFETY BELTS	36.054
31. EASY FREEZING OF DOOR-LOCK	35.656
32. SMALL BAGGAGE BOOT	35.237
33. MISPLACED SPARE TYRE	32.640
34. UNSOLID BUMPER	32.567
35. NOISY ENGINE	31.057
36. BAD SPRING-SUSPENSION	22.858
37. SMALL GLOVE COMPARTMENT	15.668
38. PAINTING DIFFERS FROM SAMPLE	11.943
39. MISPLACED ASH-TRAYS	10.658
40. SLOW REVERSE GEAR	10.000

Information Supply: Business and Neutral Sources

The results of the risk analysis can now be used to analyse the information supply. Inasmuch as it is suitable to reduce the risks experienced by consumers?

Neglecting personal communication, product information is supplied by business and neutral sources, the former being far more prominent. The main business sources are sales brochures, sales talks, and advertisements. While the evaluation of sales talks poses a number of methodological problems (which are currently being investigated), sales brochures and advertisements can be analysed by quantitative content analysis.

In our automobile market study a sample of sales brochures and advertisements was obtained according to the following criteria:

- the analysis referred to the information supply in 1978;
- only information from manufacturers having a market share of more than 0.9 % was included, and only about models not exceeding or falling short of certain thresholds for price and cylinder capacity. This served to delimit the market;
- within these limits, all sales brochures available from

manufacturers (totalling 39 documents) were included in the analysis. However, 5 documents were dropped later for technical reasons;

- as for advertisements, 5 magazines and 4 newspapers were selected by systematic criteria. From these, issues were selected randomly, resulting in a total of 395 advertisements. Discounting duplicates, a sample size of 261 was obtained.

A content analysis involves splitting the documents into units of analysis and sorting these into categories. In this case, the sentence was used as the unit of analysis. The category system reflects two dimensions:

- which risk, if any, is alluded to in the sentence
- how this risk is dealt with.

We distinguish four ways in which a risk can be dealt with:

- the risk itself is referred to in an objectively verifiable way. Example: "this car makes 35 miles per gallon";
- the risk itself is referred to, but in a way not objectively verifiable. Example: "this car has a very good mileage";
- an indicator for the risk in question is referred to in an objectively verifiable way. Example: "the aerodynamics of this car are described by an air resistance value of 0.4";
- an indicator for the risk in question is referred to in a way not objectively verifiable. Example: "the car has a very aerodynamic body".

For 84 risks and 4 ways of dealing with a risk, this results in a total of 336 categories.

A pretest with manual coding for some selected ads and risks showed severe reliability problems, so that we decided to attempt a computer-assisted content analysis using the program TEXTPACK. Computer-assisted content analysis requires that

- all documents be transcribed to machine-readable format;
- all categories are defined in an extensive way, i.e. by a comprehensive list of words or word-combinations which, when they appear in a sentence, constitute evidence that this sentence belongs to a certain category.

Construction of the category system thus becomes a complex interactive process in which word functions are defined, tested with the data, and redefined until the validity of the category system seems satisfactory. This possibility of recoding the data as often as seems necessary to construct good categories is a main advantage of computer-assisted content analysis, along with the fact that problems of reliability are completely eliminated.

Some sample results are shown in tables 2 and 3. They show the average numbers of sentences in sales brochures and advertisements dealing with four of the more important risks in the four different ways described above.

The results show that generally the information situation in sales brochures concerning these four risks is quite satisfactory. Most sales brochures carry information about all four risks. There are, however, differences in how this is done. Objectively verifiable information is readily available for the risks concerning fuel consumption and baggage boot. This is not the case for the risks concerning the crushable zone and corrosion, where objective measurement procedures are not as popular as for the other two risks. As for corrosion, there is at least considerable information about indicators. Concerning the crushable zone, however, quite a number of sales brochures does not carry any objectively verifiable information.

Quite obviously, an advertisement can carry much less information than a sales brochure due to space limitations. On the other hand, this space limitation could serve as an incentive to present in a concise and condensed way some of the information consumers want most urgently. The data in table 3 do not bear this out. In spite of the obvious importance of these four risks, a majority of the ads in the sample does not carry any information about them. The relative coverage of the four risks, however, appears to be similar to the sales brochures.

TABLE 2
Coverage of Selected Risks in a Sample of 34 Sales Brochures

SELECTED RISK	AVERAGE NUMBER OF SENTENCES PER BROCHURE REFERRING TO:					
	RISK			INDICATOR		
	VERIFIABLE			VERIFIABLE		
	NO	YES	BOTH	NO	YES	BOTH
HIGH FUEL CONSUMPTION	3.0	10.6	1.3	1.2	5.2	-
SMALL CRUSHABLE ZONE	1.6	0.2	0.3	2.4	0.3	0.3
SMALL BAGGAGE BOOT	5.0	4.9	0.2	0.1	1.5	-
EASY CORRODING	2.9	-	-	1.2	4.6	0.7

ONE SALES BROCHURE COVERS 509.7 SENTENCES ON AVERAGE

TABLE 3
Coverage of Selected Risks in a Sample of 261 Advertisements

SELECTED RISK	AVERAGE NUMBER OF SENTENCES PER ADVERTISEMENT REFERRING TO:					
	RISK			INDICATOR		
	VERIFIABLE			VERIFIABLE		
	NO	YES	BOTH	NO	YES	BOTH
HIGH FUEL CONSUMPTION	0.14	0.22	0.09	0.07	0.15	-
SMALL CRUSHABLE ZONE	0.01	-	-	0.02	0.01	-
SMALL BAGGAGE BOOT	0.12	0.16	-	-	0.01	-
EASY CORRODING	0.03	-	-	-	0.07	-

ONE ADVERTISEMENT COVERS 13.2 SENTENCES ON AVERAGE

- Analysing the information supply like this on the basis of perceived risks can have a number of applications:
- it can be used to compare the information supply in comparable markets, to see how different information supplies affect the workability of the market;
 - it can be used to obtain hints where the development of new, standardized measurement procedures would be especially helpful for consumers, like a procedure to measure a car's susceptibility to rust;
 - it can be used to guide the development of neutral consumer information, showing where this information is most badly needed.

Of course, existing outlets of neutral consumer information

are also part of the information supply and can be analysed and criticized by the same means. The most important form of neutral consumer information is probably the product test. The results of the risk analysis can be used to assess whether the criteria used in such tests are in accordance with what consumers would like to hear. Even a quick glance at product tests shows that this is not unequivocally the case. Many times, the test engineers seem to measure the criteria most conveniently to measure, which are not necessarily the same that consumers are interested in.

Drawing on the results from a review of automobile tests in the two major German automobile magazines, these tests seem to be wanting in the following ways:

- some of the published "tests" do not even seem to merit this name; they consist merely of some casual observations made while driving the car;
- some results presented are simply copied from the manufacturers' sales brochures;
- some results could more conveniently be obtained by the consumer himself by inspecting the product;
- many risks are either not dealt with at all or are dealt with indirectly by measuring indicators whose relation to the risks is not clear.

Thus, the limited resources available for tests seem to be partly wasted to present results which can be obtained elsewhere, at the cost of information that consumers could obtain only in such tests. Such information concerns mainly:

- long time usage effects, like susceptibility to corrosion;
- technical properties relevant to risks which cannot be assessed by the consumer himself;
- technical properties which could basically be noted by the consumer, but only in special situations (like handling capabilities in winter weather).

Especially for the long time effects, adequate measurement procedures may not even be available at present. This would be an important task for basic research into comparative testing.

Table 4 shows some data concerning the coverage of some selected risks - two for each of the three categories just named - in all "tests" published in 1979 in two major German automobile magazines. The results show that many risks are covered only rarely or not at all.

TABLE 4
Coverage of Selected Risks in a Choice of 133 Automobile Tests

SELECTED TEST CATEGORIES	SELECTED RISKS	NUMBER OF AUTOMOBILE TESTS REFERRING TO SELECTED RISKS IN TWO GERMAN AUTOMOBILE MAGAZINES			
		ONE-PRODUCT TEST (144 IN TOTAL)	COMPARATIVE TEST (7 IN TOTAL)	ENDURANCE TEST (12 IN TOTAL)	Σ (133 IN TOTAL)

Information Performance: The Gap between Supply and Demand

Information demand and supply together determine inasmuch the information flow in the market is suitable to allow the actors in the market to make informed decisions. If we compare the totality of risks experienced by consumers with the information supplied by suppliers and neutral sources, the resulting gap can be said to be an indicator of the information performance in this market.

This, however, is only one possible indicator for information performance. Other possible indicators would be information usage or decision quality, which also reflect the gap between supply and demand. The direct measurement of the gap by comparing information supply and information demand is quite cumbersome and can be recommended to obtain a basis assessment of the information situation in a market. If the effect of remedial measures of information policy on information performance is to be measured, indicators like information usage or decision quality, which are less costly to obtain, are more adequate. This, too, can be done on the basis of a risk analysis, as has been shown elsewhere (Grunert 1980).

Towards an Improved Information System

An improved information system, in our view, is one where consumers get more information suitable to reduce risks perceived by them, and where suppliers get more information about risks perceived by consumers, resulting in a long-run net welfare increase for consumers. In the preceding section we have tried to show how the workability of an information system can be measured and how the results obtained can be used to hint at ways for improvement.

The examples we gave all referred to consumer information and ways to improve it. But obviously information for the suppliers is as important. If suppliers do not have adequate knowledge about the wants of consumers, no consumer information program can bring about an efficient allocation of resources. Of course, suppliers try to obtain this kind of information by market research. But market research differs widely in quality, favors the big firms, and deals with questions formulated by suppliers, which might bypass certain wants of consumers. We think that institutions of consumer policy have a vast field for action here, obtaining and canalizing information from consumers, no matter whether complaints about current products or wants for future products, and offering it to all suppliers in the pertinent market. A workable information system involves functional information flows in both directions - a fact that consumer policy has not always realized.

NEGATIVE INFORMATION: PERSPECTIVES AND RESEARCH DIRECTIONS

Marc G. Weinberger, University of Massachusetts/Amherst
Chris T. Allen, University of Massachusetts/Amherst
William R. Dillon, University of Massachusetts/Amherst

Abstract

The topic of negative information encompasses a variety of research areas which heretofore have been considered as distinct and separate from one another. The literature from each of these unique research perspectives is reviewed here and then related to the broader scope of negative information effects. Finally, possible directions for negative information research are suggested.

Introduction

Though consumer researchers have had a long tradition of interest in the impact of information on consumer decision-making, relatively little effort has been devoted to examining the effect of negative consumer information. This absence of concentrated study prevails despite dramatic growth in the amount of negative information in the marketplace. Today's manager is confronted with a hostile and often uncontrollable external information environment. Negative information offered for public consumption can be traced to consumer and environmental groups, to regulatory agencies, and even to competitors. In other instances the unfavorable information takes the form of untraceable rumor. The strength and longevity of effects of these unfavorable cues on an individual's perceptions, attitudes, and behavior are of obvious potential interest and importance to both the marketing academic and practitioner. Moreover, the impact of negative information in the marketplace would seem salient to those who study the relationships among major societal institutions because there is potentially a cumulative effect of a profusion of negative information cues on consumers' general attitudes towards business practices and institutions.

Definitionally negative information about people, products, issues or companies represents the presentation of input which somehow denigrates the object of the message. Issues such as person perception, personnel evaluation, fear appeals, rumor, product recall, counter advertising, comparison advertising, product recall reports, corrective advertising, affirmative disclosure, and self-denigrating product information all involve some aspect of negative information that may be confronted, subsequently placed in short or long-term memory, and potentially withdrawn to be used in a current or future decision. In all instances an attempt is made to either discourage some behavior or attitude and focus on establishing a new attitude or behavior.

To date research about negative information has been scattered under diverse areas in psychology, sociology and marketing. As a result micro research traditions related to negative information issues have developed within each discipline with little recognition that they relate to a common theme. The major intent of this paper is to first review some of the major paradigms and conceptual foundations which have been applied to the study of negative information. Secondly, this paper will examine empirical findings from a variety of disciplines which relate to negative information effects. Finally, some suggested directions for future research in this area will be outlined. In general, what is labeled here as negative information is not novel but the vision of the related component issues under a common rubric is new.

Explaining the Effect of Negative Information

Different experimental paradigms and theoretical constructs have emerged in generating and testing specific hypotheses concerning negative information. The simplest and most widely used research paradigm has been impression formation. In its most primitive cause and effect form a stimulus triggers some belief, attitude or action in a subject population. The impact of mediational factors such as anxiety, susceptibility to social influence, receptivity and so on are not of primary concern. In most impression formation studies unfavorable adjective descriptions or scenarios have been the stimuli employed with the target object being a known and/or unknown individual or group. Variations in the amount and intensity of negative and positive stimuli have been gauged using simple paper and pencil measures of liking, behavioral intention and so on. The advantage of this approach to studying negative information has been the ability to retain very tight internal control over the experimental setting.

A more complex extension of impression formation is attribution theory where the individual is viewed as a being who perceives a situation, examines it for key elements of information, and subsequently makes an inference about a stimulus object (Kelley 1973). To date attribution theory has served as an explanation for negative informational effects rather than as an empirical paradigm. Using an attributional framework Kanouse and Hanson (1971) suggest that negative information has the strong impact that it does because it stands out more than positive information and in Kelley's terminology would therefore have more distinctiveness. This apparently results from the fact that there are more positive cues in the individual's social environment. As a result, negative cues attract more attention and are therefore more heavily attributable to the stimulus object. This underestimation of important contextual factors is an attributional phenomenon observed in both a laboratory setting (Jones and Nisbett 1971) and at the societal level (Lazer 1980).

A more mediational view of negative information effects might be taken with both assimilation-contrast theory or threat-compliance models. Both are conceptual approaches that help explain the situational effects of an incoming stimuli in relationship to some set of individual predispositions. Assimilation - contrast theory (Sherif, Sherif and Nebergall 1965) posits that prior experience or attitude of the receiver and its relative position to that advocated in the message will determine whether it is drawn closer into the receiver's sphere (assimilated) or expelled further outside the receiver's position (contrasted). Thus, negative information consistent with the receiver's beliefs would be assimilated and that which is incompatible would be contrasted and rejected with subsequent low compliance. Since individuals bring to a setting some set of predispositions which affect their perceptions, the ability to assess these relevant predispositions might help predict the impact of negative information.

In a similar mediational vein McGuire (1968) developed a threat - compliance model where the impact of a message on opinion change is a function of one's predisposition to receive a message (receptivity) and yielding. Without considering receptivity one might expect that greater anxiety arousal would lead to greater yielding to an

influence attempt. When receptivity is factored in as a potential mediator, a negative relationship between anxiety and persuasion is expected. Receptivity adds a non-monotonic dimension to McGuire's threat - compliance analysis and emphasizes the need to consider predispositional factors like receptivity. Since much of the negative information in the consumer context represents a threat of varying magnitude, this conceptual approach might be attractive in dealing with the situational complexities of many negative information circumstances.

Empirical Research

Negative information has been investigated most often using impression formation as its basic paradigm focusing on the subareas of person perception and personnel decisions.

Person Perception

Psychologists have examined the impact of negative and positive information in the context of forming inferences or impressions about people. For example, Goodman (1950) found that trait words such as "cold" were more powerful in influencing impressions than positive trait words such as "warm." Similarly, Osgood, Succi and Tannenbaum (1957) found that, contrary to their proposed congruity principle, equally polarized positive and negative information did not have a balancing effect on impression formation; rather, in every instance of a reported error the direction of influence favored the negative information.

In 1965 Anderson found that negative adjectives seem more powerful than positive adjective sets in affecting overall evaluations. Similarly, Feldman (1966) and Richey, McClelland and Shinkunas (1967) found that the weight given negative adjectives exceeded weight given to positive adjectives when several must be combined into one overall evaluation.

Others have attempted to identify the situational variables that affect person perception. The strong impact of negative information occurred when the target person was a female rather than a male (Richey and Dwyer 1970), and when a variety of different personality variables were tested (Briscoe, Woodyard and Shaw 1967). In an examination of situational message variables Cusumano and Richey (1970) manipulated order and intensity factors and Richey, Koenigs, Richey, and Fortin (1975) varied amounts of negative and positive information. In both studies, negative information was more salient than would be predicted using a simple averaging theory. In the latter study, one piece of negative information effectively neutralized five positive behaviors. The generalizability of negative information effects receives support in a cross-cultural study conducted in Denmark where Bernadette Gray-Little (1978) found that Danes, like Americans, evince a disproportionate negative weighting scheme. Despite the Danish norms of cooperation and tolerance it appears that Danes, like Americans, are prepared to believe the worst about others.

Personnel Decisions

In the more applied context of employment and personnel decisions the impact of unfavorable information in impression formation has also been studied. Bolster and Springbett (1961) indicated that interviewers tended to give more weight to unfavorable information and subsequently these findings were replicated by Webster (1964). With a contrary note Hollman (1972), using a unique methodology, found that rather than overweighting negative information, interviewers tended to underweight positive information. The accumulated research in person perception and personnel evaluation strongly indicates that in evaluating others, negative information is more influential

than positive information.

Rumor

Rumor study represents a special type of impression formation dealing with the diffusion of positive or negative information about some commercial or non-commercial entity. From a marketer's perspective derogatory rumors present a challenge to public relations activities. Here the absence of substantive fact or the inability to establish the original source make it the most insidious type of information. Negative rumor is particularly problematic in a business context where individuals in this age of consumerism often are predisposed to believe the worst about companies and often are ready to absorb unfavorable information.

Allport and Postman (1947) suggested that the dynamics at work in the birth of a rumor were driven toward perceptual simplicity, orderliness, and completion. Researchers believe that the amount of rumor activity is a function of situational ambiguity and thematic importance. In this vein Rosnow and Fine (1976) present results which suggest that a combination of uncertainty and anxiety set the stage for rumor.

Similarly, Shibutani (1966) purports that the level of suggestibility derived from anxiety, tension, frustration, or lack of trusted information sources will play a role in affecting the readiness of a group to accept rumor. In his view rumor must be plausible and fit with persons' beliefs and inclinations. The fact that embarrassing rumors are seriously entertained, then, is an indication that many people are already predisposed to believe them.

The response to negative rumor is typically a denial. Denial by a trusted source of an absurd rumor is effective according to Shibutani, but usually denial is ineffectual because people often confuse the denial with the charge or those who have not heard the charge may find the denial unconvincing. Lasswell (1933) insists that the only really effective defense against propaganda is promotion favoring some alternative program.

Tybout, Calder and Sternthal (1979) examined in an experimental setting strategies that might be employed to combat rumor. Their results indicate as suggested by others that direct refutation is ineffective. Alternatively, the authors suggest two other strategies based on information processing theory which attempt to link rumor with some other object (storage strategy) or highlight features or services not implicated in the rumor (retrieval strategy). These two approaches had a significant impact on subjects' purchasing attitudes and behavior.

Fear Appeals

A negative information message involves an attempt to discourage some belief, attitude, preference, or behavior and therefore encourage some alternative set of ideas or actions. Fear appeals as studied by social psychologists and marketers, though not historically viewed in the context of generalized negative information, present a classic case of an attempt to discourage and in turn encourage some alternative viewpoint or action.

Hovland, Janis and Kelley (1953) viewed fear as anxiety arousal leading to a tension reducing response such as a change in one's attitudes, opinions or behavior. Janis and Feshbadi (1953) concluded from their research that low levels of fear were most effective because a great deal of fear provokes defensive reactions and interferes with yielding. Powell (1965) found that high fear produces more opinion change than mild fear when the communication was focused on a loved one, attributed to either a highly credible source or a source independent of the content. Capon and Hulbert (1973) found that the results

of mild versus high fear messages vary with a delay in post-measurement and Sigall and Helmreich (1969) purport that the context of the fear message can have a marked moderating impact on the effect of fear provoking communication. It has also been shown that the personal variables of self-esteem, perceived vulnerability, and coping style mediate the strength of fear appeals (Highbee 1969; Leventhal 1965; Ray and Wilkie 1970).

The controversy in the fear literature regarding a monotonic versus curvilinear fear - yielding relationship and the evidence of situational influences is potentially a microcosm of the broader negative information setting. As such, the fear literature should offer insight in the design of negative information research programs.

Empirical Research--The Consumer Context

In a general sense negative consumer information focused on products has been examined on a very limited basis. Arndt (1968) studied the effects of negative word-of-mouth information about a new brand of coffee and found that high risk perceivers were influenced more than low risk perceivers no matter what type of information was received. In particular though, the high risk perceivers were most strongly affected by negative word-of-mouth information while the low risk perceivers were not. Thus, it seems that risk perceptions affect receptivity to information generally and especially to negative information.

Wright (1974) focused a study on decision time and the use of information. The results indicated that as decision time compressed subjects placed a greater reliance upon unfavorable product information perhaps as a means of simplifying their task environment.

In a study using Consumers Union as the source and a detergent as the focus Lutz (1975) found that negative information had greater impact than positive information on cognitive structure and attitude. He suggests that the result might be due to the novelty and consequent higher information value of negative information.

In two studies Weinberger and Dillon (1980) and Weinberger, Dillon and Allen (1980) found strong effects of negative information. In the first study housewives were given either positive or negative ratings for a set of unbranded goods and services. Strong main effects for negative versus positive information, and product type (goods/services) were found. Significant interactions for source and rating type were uncovered where the independent rating source was a significantly stronger source of negative information than either a trade source or other housewives.

Weinberger, Dillon and Allen (1980) demonstrated the impact of negative product news information. An actual negative news story about an automobile was imbedded in a network news broadcast and its effect was assessed. Strong effects on opinions, beliefs and intentions were demonstrated in immediate and two week delayed responses. Direct rebuttals by the impacted firm had little neutralizing effect. Notably the laboratory effects conform to a sharp drop in sales that followed the actual airing of this news story.

Most negative information studies in a consumer context have not been of as general a nature as those described in the preceding section. Rather, they have focused on issues of comparative, counter and corrective advertising, self-denigrating information and product recall. The research in each of these areas will be discussed very briefly.

Comparative Advertising

Comparative advertising as negative information is distinguished by the source (competitor), format (advertising) and the typically low key intensity of messages. Lincoln and Samli (1979) reviewed the literature and found that denigrating a competitor has highly equivocal implications. For the advertiser, some consumers felt that such an approach to advertising was offensive, in some cases less believable, and in general were skeptical of claims. High intensity comparisons were found to be less informative.

Self-Denigrating Information

In most circumstances the marketer is concerned about the impact of negative information from external or uncontrollable sources. At times, however, the source of negative information might be the firm itself. This latter situation might arise from Federal Trade Commission requirements for affirmative information disclosure of certain information, corrective advertising to rectify a previous deception, or voluntary recall action. Alternatively, a firm might intentionally give some negative information about itself to enhance its overall believability.

Corrective Advertising. Corrective advertising orders have been issued by the Federal Trade Commission for the past decade in an effort to force advertisers to rectify misimpressions that develop from deceptive product claims.

Research studying the impact of corrective advertising in remedying false claims or deceptions has been mixed. Hunt (1972) and Mazis and Adkinson (1976) found that corrective ads can dissipate false claims whereas Dyer and Kuehl (1978) showed that limited exposure to corrective ads did not resolve misimpressions brought about from false ads.

Source and message intensity have been the major situational variables studied in conjunction with corrective advertising. Mazis and Adkinson (1976) found no source effects between company or the FTC while Dyer and Kuehl (1978) in a series of investigations revealed that the FTC was more effective than a company source for print media though the same effect did not occur in broadcast media.

A number of studies examined whether alternative levels of specificity produce different effects on falsely held impressions. Hunt (1974) found no significant effects of supported and unsupported ads while Dyer and Kuehl (1974) and Hunt (1973) found that high intensity correctives were more effective than low intensity messages in dispelling false impressions.

Clearly the format (advertising context), and the generally low intensity and weak dominance of the corrective message distinguish it from more blatant forms of negative information. These inherent factors might help explain the less dramatic impact of corrective advertising as a form of negative information.

Affirmative Disclosure. One strategy which the FTC used in attempting to prevent deception by advertisers has been to call for presentation of certain information which by its absence might be misleading. "May cause nausea or vomiting", "Batteries not included" and other such shreds of information are for the most part unfavorable from the advertiser's perspective. To date there is no substantive empirical work indicating whether disclaimers of this type have any impact on consumers.

In a study related to the affirmative disclosure concept, Settle and Golden (1974) conducted an experiment in which they varied the amount of negative disclaimer information which an advertiser might voluntarily include in an ad. Though their theoretical conceptualization and interpretation of results have been challenged (Hansen and Scott 1976) their findings do suggest that some negative infor-

mation about oneself in the context of expected positive information might enhance claim and source credibility. Golden and Settle's findings provide evidence that unfavorable information need not have an inherently deleterious effect and that in some contexts to give such information about oneself in mild forms may even enhance credibility.

Counter Advertising

A form of communication which has been suggested as a remedy for deceptive advertising is the counter commercial. Here a spokesperson offers counter arguments to information set forth by an advertiser or group of advertisers. Reactions to commercials about heavily sugared cereals or automobiles with poor safety records might be permitted but to date none of the counter commercials have appeared on network TV. Because the doctrine of counter advertising has not been accepted little empirical investigation of the phenomenon has been undertaken. One notable exception is Hunt (1972) who reports a significant decrease in affective attitude after exposure to such counter advertising. These results occurred whether government, consumer or original sources were employed.

Product Recall

The product recall unlike corrective or comparative advertising involves an infusion of negative information typically separate from the usual format of commercial advertising. The issue of recall results from a company marketing a product deemed to be unacceptably hazardous either by an outside agency or the company itself. Experimental work in a non-product context (Walster 1966; Shaver 1970; and Schroeder and Linder 1976) indicates that the more severe a possible injury, the more responsibility will be attributed to the person potentially at fault.

In a series of studies Mowen (1980; 1980a; 1980b) manipulated severity of injury, voluntary or coercive nature of recall, number of recalls and order of presentation of company information about the recall. In the first study Mowen (1980) found main effects for severity, coerciveness of recall, and number of prior recalls. In a follow-up investigation (Mowen 1980b), however, the company conducting a voluntary recall was surprisingly perceived as having greater responsibility for the problem than companies forced to conduct a recall. The third study in the series (Mowen 1980c) attempted to determine if the order of information released in a recall would differentially affect perceptions of the company. Results indicate that the company was perceived most favorably when they provided the most severe possible outcome first and later released reported effects at moderate levels.

Investigation of product recall is in its early stages and the dimensions which mediate its impact are still largely speculative. Based upon actual market share data presented by Wynne and Hoffer (1976) it appears however, that this form of negative information has a direct relationship to product sales and is thus an important area for future research.

Summary of Empirical Research

The divergent literature dealing with negative information tells us a great deal about its effects and its situational determinants. In circumstances where the negative information is the major input, studies in person perception, rumor, product perception and counter advertising indicate that there are powerful negative effects which can offset disproportionate positive input. In addition, person perception results have been shown to hold up in a cross-cultural environment.

The precise effect of the negative information is moderated by message, source, target, receiver and company response. The literature reviewed in the previous pages can be briefly summarized with respect to these factors:

Message. The message effects of negative information are situational as found in the message intensity studies in the fear literature. Corrective advertising and product recall research reveal that message intensity, dominance and severity of the problem play a role in determining informational impact. In addition, the context of the message including time pressure on the individual to make a decision plays a role in enhancing the deleterious effects of the unfavorable information.

Source. The empirical evidence indicates a clear interaction between negative information and message source. In the fear appeals area a credible source independent of the situation evokes the greatest effects. In a consumer context, the neutral spokesperson has been shown as a powerful source in several settings though with corrective advertising source effects research is more equivocal. In the case of comparative advertising where a competitor is the source, the impact of the unfavorable information is less powerful reflecting a potentially ineffective competitor source inherent in the comparative form of advertising.

Target. The target of the negative message can influence the impact of the information. When a loved one is the focus, when the theme is important, and when the target is a service rather than a tangible product, the impact of negative information is enhanced. One study revealed that when the negative information was about relatively unimportant features of the target and given by the firm itself the negative information could have an opposite effect and enhance the credibility of an advertiser denigrating itself.

Receiver. As suggested by McGuire (1968) the receptivity of the receivers and their predispositions can play a role in predicting informational effects. The fear literature tells us that self-esteem, vulnerability and coping styles are important mediators in accepting unfavorable input; rumor research finds that anxiety and frustration are key factors; and a word-of-mouth marketing communication study reveals that risk perception is critical. By whatever mechanism is operative these personal factors apparently impact on the receiver's receptivity and subsequent willingness to assimilate negative information.

Response. Concern for the proper response to negative information is common to several research areas. The product recall literature reveals contrary to popular belief that a voluntary recall may lead to perceptions of greater fault. Additionally, the order of company press releases of product problems giving the mild, moderate and severe recall scenarios is important. Rumor research asserts that denials tend to be ineffective and this finding has been supported in a marketing context with automobiles and hamburgers. Alternatively, response strategies focusing on storing and retrieving diversionary information have been found effective in offsetting negative rumor information.

In general this review reveals that we have limited insight into the effects of negative information in a consumer context and even less guidance for the marketer in combating negative information. The next section provides some potential research directions which are necessary to more fully explore negative information issues.

Research Directions

While there is considerable evidence for a "negative information effect", in comparison and corrective advertising contexts, the effects are mild, and with self-denigrating messages negative information has a positive effect. The implication is there may be a number of factors which qualify the impact of negative information and research is needed which examines these factors. There has not been

enough experimental research wherein a variety of situational factors have been controlled or manipulated for conclusions about the potency of negative versus positive information to be unequivocally drawn. Studies manipulating message source and content along with information valence are needed. Techniques such as functional measurement where the value of units of information are indirectly determined using efficient within subject designs might be a reasonable approach to such a task.

One of the more compelling arguments for a "negative information effect" in the American marketplace is furnished by Lutz (1975). He argues on the basis of Brock's commodity theory that negative information is more potent than positive because of its relative scarcity. If true, one should be able to demonstrate that a given bit of negative information in a particular setting or cultural environment where there is a more equal balance between negative and positive information, should have less information value and subsequently less impact. This suggests possible cross-cultural or laboratory settings where informational norms or expectations vary and where research could be conducted. Such theory based empirical investigations are essential if a systematic study of negative information effects is to be accomplished.

The fact that in prior research consumers have been exposed to negative information in a confrontational as opposed to a search (Bettman 1978) mode raises some interesting questions concerning consumers' processing of negative information. For instance, do individuals consider the valence of information as they search for it? Are some individuals more motivated to seek out negative information about a product before purchase than others? Are there particular product categories for which negative information is more actively sought prior to purchase?

It might be argued that from the consumer's viewpoint negative information is received at random time intervals and thus the heavy emphasis on the confrontational mode in past research is appropriate. An important question concerning the processing of negative information in this mode involves how and where negative information is stored in memory. Are consumers more prone to retain negative as opposed to positive information? Are individuals more apt to process and store factual information about products when it is negative? This latter question might be examined using thought listing methodologies to establish whether or not consumers are more likely to rehearse negative as opposed to positive factual information. It may be that negative information is stored in the form of a generalized negative affect about a brand. It may also be that the carryover effects of negative information are stored in non-brand-specific dispositional constructs such as consumer alienation from the marketplace (Allison 1978). An emphasis on the confrontational mode may be appropriate in studying negative information effects; however, research dealing with this mode of information processing should certainly stress delayed measurement to establish the strength and nature of the carry-over effects of negative information. In addition, knowing the secondary effect of negative word-of-mouth spread from a person in the confrontational mode to other persons in a similar or more decision oriented mode represents an important research issue.

The effects of negative information on targeted product attributes is certainly of concern to the marketer, but other types of effects are also of potential interest. Kanouse (1971) suggested that negative information might have a kind of general negative halo effect on one's enjoyment of the product as a whole. The extent of such secondary effects would provide additional evidence concerning the potency of negative information.

On a more macro level the cumulative effects of negative information in the market on basic dispositions like

alienation or consumer discontent (Lundstrom and Lamont 1976) raises important public policy issues. In a comparative study of alienation in the U.S. versus Sweden Schewe et al. (1980) found alarmingly strong perceptions of normlessness in business practices among U.S. consumers. If a potential trend toward increased consumer alienation and discontent can be linked to growth in negativity of the consumer's information environment, research regarding methods for neutralizing the cumulative effects of negative information would seem desirable.

Anomalies in the effect of negative information such as the weak effects of comparative advertising, the extent of reverse effects of some self-denigrating information, and boomerang effects of some negative information disclosures all merit investigation. Why might a ban on saccharin as a cancer causing ingredient trigger consumer hoarding of saccharin based products? Is it due to a source effect or the fact that the deleterious effects are long-term? Is it an avoidance reaction? Or is it simply the threat of withdrawal leading to greater desire as predicted by reactance theory?

It is, of course, probable that individuals will differ in their receptivity to negative information. A useful stream of research might attempt to isolate variables that are effective for identifying persons who are more or less receptive to negative information. The theoretical constructs of the assimilation-contrast/threat-compliance paradigms offer a firm basis from which to study receptivity and predispositions to receive and yield to negative messages. It would be valuable for a firm to know what type of person is going to be most influenced by negative information. Subsequent neutralizing strategies might be targeted if groups of such individuals could be isolated and their receptivity better understood.

Finally, there is the very practitioner-oriented issue of what type of communication strategies are effective in neutralizing the effects of negative information. Past studies indicate that strategies which attempt direct refutation are ineffective (Tybout, Calder, and Sternthal 1979; Weinberger, Allen, and Dillon 1980). Empirical research is needed to test other alternatives. Tybout, Calder, and Sternthal (1979) suggest a pair of response strategies for offsetting rumor effects they developed through application of an information processing conceptualization to the problem. This theory-based approach may be employed to derive other candidates for empirical evaluation in this process of identifying strategies for neutralizing the influence of negative information.

FACTORS INFLUENCING CONSUMER RESPONSES TO PRODUCT RECALLS:
A REGRESSION ANALYSIS APPROACH

John C. Mowen, Oklahoma State University
David Jolly, Oklahoma State University*
Gary S. Nickell, Oklahoma State University*

Abstract

Two hundred consumers were surveyed to determine their perceptions of four companies which had previously recalled products. The results revealed that impressions of the companies were influenced by: the knowledge that a recall had been made, the perceived danger of the defective product, the perceived corporate responsibility of the company, the knowledge of recalls by other companies, and the perceived responsibility of the company for the defect.

Introduction

Negative or unfavorable public information regarding a company and/or its products is of major concern to business. Exposure to unfavorable information results from such sources as reports of defective products, news media presentations of corporate earnings (e.g., the oil industry), and publicity concerning questionable competitive practices. An excellent case in point is the Three Mile Island nuclear incident. The negative information resulting from the incident has seriously jeopardized the future of the nuclear power industry in the United States. In a recent study regarding the effects of negative product information, Weinberger and Dillon (1979) found that: (1) unfavorable product ratings tended to have a greater impact on purchase intention than did favorable ratings (2) unfavorable product information received from an independent testing agency or peer as a source had a relatively stronger effect on purchase intentions than did similar information communicated by the trade and professional association source, and (3) consumers probably place more reliance on outside sources of information when purchasing a service as opposed to purchasing a product. These findings emphasize the necessity of an organization to react effectively when consumers receive negative information concerning that organization.

Product recalls have become a common avenue by which consumers are exposed to negative corporate information. Approximately 25 percent of all consumer goods firms listed in Fortune's 500 were involved in recall campaigns in 1974 (Kerin 1974). The Conference Board estimates that 25 million product units will be recalled every year (McGuire 1975).

Because of the increasing number of product recalls, many articles have been written on the subject from a "corporate management" perspective. Researchers have written articles concerning the physical tracing and recall of the products (Fisk and Chandran 1975; Warner 1975), contingency plans for recalling products (Kerin 1974), the impact of recalls on market share (Gray 1978; Wynne and Hoffer (1976), assessing the effectiveness of drug recalls in pharmacies (Gumbhir and Jamison 1975), surviving product recalls (Snyder 1974), and the high costs associated with product recalls (Tamarkin 1978).

For a number of reasons it is likely that the number of product recalls will continue to increase. One is the

consumer activist movement. Since the early 1960's, consumers have become more vocal in their criticisms of business organizations in general and those that may have produced a faulty product in particular. The end result is that consumers are becoming much more inclined to report defective products. A second reason is the more activist stance taken by such government agencies as the Consumer Product Safety Commission and the Food and Drug Administration. This increase in intervention is due partly to the increase in voiced demands by the consumers. A final reason for the predicted increase in recalls is the increasing complexity of products. In order for manufacturers to comply with consumer demands and regulatory requirements for safer and better quality products, the products are becoming more complex, thereby, increasing the possibility that defects will occur.

As previously mentioned, a small literature has developed based on the managerial question of "how to" recall a product. It appears, however, that only two empirical studies have been performed to specifically investigate consumer reactions to the negative information resulting from a product recall. Mowen (1979a) manipulated the three independent variables of (1) the extent of injury resulting from the defective product, (2) the length of time taken by the company to make the recall, and (3) the number of previous product recalls made by the company. The results of this study revealed that the extent of injury resulting from a defective product, the number of previous product recalls, and the length of time to recall the defective product each influenced consumer perceptions of the corporation and of a replacement product.

In a subsequent study, Mowen (1979b) manipulated the independent variables of: (1) familiar versus unknown company making the recall, (2) action or inaction by the Consumer Product Safety Commission to force the recall, and (3) whether or not other manufacturers had had similar problems. The results revealed that consumers perceived a familiar company as significantly less responsible for a defect than an unfamiliar company. It was also found, unexpectedly, that consumers perceived the company as more responsible when it acted prior to intervention by the Consumer Product Safety Commission.

In the work by Mowen, studies were conducted in which subjects received fictitious magazine articles describing a product recall. Within the articles, information was varied in order to determine the effects of certain variables on the perceptions of companies. Such an experimental approach has the advantage of establishing high internal validity. However, the external validity of the studies are suspect. In the "real world," consumers simply may not attend to product recall information. Thus, while one may find large effects in an experimental setting, in a naturalistic setting the effects may be minimal.

To overcome the above problems in using an experimental methodology, the present study utilized a survey research approach. Two hundred randomly selected subjects completed surveys asking questions about the public's perceptions of Ford Motor Company, Firestone, Inc., Corning Glass Works, Inc., and Conair, Inc. Each of the companies had previously made product recalls. Responses to the questionnaires were then analyzed by regression analysis. The dependent variable was the perception of the company, and

*David Jolly is an MBA student, and Gary Nickell is a doctoral student in social psychology.

the major predictor variables were knowledge of the recall, impressions of the danger of the product, the company's social responsibility in making the recall, the company's responsibility for the defect, the length of time to make the recall, whether or not other companies had made recalls, and whether or not the company had made previous recalls. (Several additional predictor variables were also included.) If the results of the regression analyses supported the experimental results, one would have impressive collaboration of the previous studies.

Method

Seven research assistants were assigned to obtain respondents from seven areas in a midwestern city (population 42,000). The areas were selected to represent lower middle, middle, and upper middle residential housing areas. Surveyors identified respondents through the following procedure. They would enter the area from any direction they wished. From a random numbers table, they determined which side of the street to sample from and how many houses to count down the street in order to identify the selected house. After completing the survey they would go to the first cross street, randomly select whether to go to the left or the right and then follow the same procedure as before to select the proper house. If the house was vacant, the surveyor would return twice more before selecting a new house. After selecting the house, the surveyor would determine if the respondent answering was a college student or a high school student. Such individuals were excluded from the study.

Respondents cooperated excellently with the surveyors. Only two totally refused to participate, and six others participated reluctantly. Three percent of the respondents were less than 21 years old; 48 percent were 21-25 years, 24 percent were 26 through 39 years old, and 25 percent were over 40 years of age. Ninety-six subjects were male and 105 were female. Forty-one percent of the subjects owned their own homes.

The surveyors were junior and senior students majoring in marketing, who volunteered to work on the research study. Students were carefully selected for their maturity and competency.

On the questionnaire respondents were first asked about their general experience with recalls, their age, and whether or not they owned a home. They were then asked questions concerning Conair, Corning Ware, Firestone, and Ford. Because of the length of the questionnaire, half of the subjects answered questions about Firestone and the other half about Ford. Respondents were given a copy of the questionnaire, and the interviewer would read the questions and place the answers on a code sheet. All rating scales were composed of six points with appropriate anchors designated.

Results

Twenty point four percent of the subjects reported having owned a recalled product. Of the 41 respondents owning a recalled product, 58.5 percent reported taking an action to correct the problem. The majority of the products reported to have been recalled were autos (53.0 percent), tires (10.2 percent), coffee pots (18.4 percent), and hair dryers (14.3 percent). The low rate of return of known defective products matches reports found in the popular literature (Duns Review 1979).

In the first set of data analyses the independent variables of interest (the consumer's knowledge of a recall, the perceived danger of the product, the company's social

responsibility in making the recall, the length of time to recall, the number of previous recalls by the company, the presence of recalls by other companies, and the company's responsibility for the defect) were entered into a stepwise regression and utilized to predict the dependent variable of favorability regarding the company. The analyses were performed separately on data for each of the four companies.

Looking first at the results for Conair, one finds that danger entered first in the stepwise regression ($p < .01$), and responsibility for the defect entered second ($p < .05$). The overall R^2 was .09. Thus, the greater the perceived danger of the product and the greater the perceived responsibility of the company, the less favorable was the impression of the company.

Following the same procedure as above for Corning resulted in no findings of significant effects. This is, consumer favorability toward Corning was not significantly influenced by the independent variables selected.

The analysis for Ford revealed that one significant predictor variable entered the equation. The perceived social responsibility of Ford in making the recall was significantly related to respondent's favorability towards Ford ($R^2 = .19, p < .0001$).

The analysis for Firestone showed substantially divergent results from that found above. Here the company's social responsibility in making the recall ($p < .0001$), previous knowledge of the recall by the respondent ($B = .75, p < .0001$), recalls by other corporations ($p < .05$), and danger of the product ($p < .10$) entered the equation ($R^2 = .32$). Firestone was perceived more favorably when perceived as acting socially responsibly, when respondents were aware that Firestone had recalled the tire, when the danger of the tire was perceived as low, and when other companies were known to have recalled tires. Table 1 summarizes these analyses.

TABLE 1
Significant Effects for Each Company
Using Stepwise Regression Analysis

Dependent Variable	Company			
	Conair	Corning	Ford	Firestone
Consumer's Knowledge of Recall	--	--	--	$p < .0001$
Danger of Product	$p < .01$	--	--	$p < .10$
Company's Social Responsibility	--	--	$p < .0001$	$p < .0001$
Length of Time to Make Recall	--	--	--	
Recalls by Other Companies	--	--	--	$p < .05$
Company Responsibility for Defect	$p < .05$	--	--	
Previous Recalls by Company	--	--	--	
Percentage of Variance Accounted for	9%	--	19%	32%

Discussion

The results of the present research partially support the previous work by Mowen (1979a, 1979b). Mowen previously found, using an experimental methodology, that varying the danger of the defective product, the length of time to recall, and the number of previous recalls by the company influenced consumer favorability regarding the company. Table 1 reveals that for Firestone and Conair the perceived danger of the product was significantly related to the consumers' perceptions of the company. In no cases were

knowledge of previous recalls and the length of time to make the recall significantly related to corporate perceptions.

While the perceived length of time to recall and the recognition of previous recalls failed to directly influence the perceptions of the company, these variables may operate through moderator variables. In particular, the length of time taken to make the recall may act by first influencing the perception of the company's social responsibility. Indeed, this was argued by Mowen (1979a). The argument was based on the hypothesis that consumers will tend to expect that companies will delay recalling a product for as long a time as possible in order to maintain corporate profits. On the other hand, if the company acts rapidly and decisively to recall a product, consumers will perceive it as acting against its own short term interest and in the interest of consumers. Consequently, the belief that the action to recall the product was consumeristically oriented would be augmented (Kelley 1971). For both Ford and Firestone social responsibility did enter the regression equation (both p 's $< .001$). In addition, timeliness was significantly correlated with perceived corporate social responsibility (for Firestone, $R = -.36$, $p < .0001$; for Ford, $R = -.46$, $p < .0001$). Preliminary work using path analysis supports these suggested relationships. Thus, the length of time taken to make a recall may influence perceptions of the company by first influencing the impression of the company's social responsibility. Mowen (1979a) also argued that the number of previous recalls affected perceptions by first influencing the perception of the corporation's responsibility for the defect. For Conair responsibility for the defect did enter the equation $p < .05$. However, responsibility was not significantly correlated with the number of previous recalls by the company. Indeed, the preliminary path analytic work tends to reject responsibility for the defect as a moderating variable for the number of previous recalls made by the company.

As a summary statement, evidence from the regression works partially supports the direct impact of variations in the danger of the product and of the indirect impact of the length of time taken to make the recall on consumer perceptions of a company. No evidence was found indicating that the presence of previous recalls influenced perceptions of the companies.

The results for the Firestone analysis revealed that the mere knowledge of a recall can influence corporate perceptions. A second interesting outcome of the analysis on Firestone was the number of significant predictor variables entering the equation. It is difficult to say just what factors contributed to these differential perceptions of Firestone. In terms of awareness more people were aware of the Ford recall (90.0 percent) than Firestone (71.3 percent), Conair (29.8 percent), or Corning (23.3 percent). One possibility is that direct or indirect knowledge of problems with Firestone tires may have been substantially greater than such knowledge for the other products. Of the 22 respondents who reported owning Firestone 500 tires, 13 indicated that they had had problems with the tires. Only one of the seven individuals who reported owning a Pinto indicated that they had a defective gas tank, and only two of 24 Corning percolator owners reported problems. (The problems with the hairdryers was unrelated to performance.) Based on the high percentage of individuals who had problems with the 500 tires and the large number of individuals owning the tires, it is possible that individuals may have also heard of problems with the tires from friends. Thus, personal knowledge of either a direct or indirect form may have been greater for Firestone than the other companies.

One question arising from the results involves why no significant effects were found in the analysis of the data for Corning Ware. One explanation is that with a relatively small percentage of subjects aware of the recall, it would be difficult to statistically isolate significant effects.

A second explanation is based upon experimental work performed by Mowen (1979b). In this work it was found that the impression of a well-known, highly respected company was not influenced by knowledge of a product recall to the same extent as less favorably viewed companies. Support for the speculation comes from the mean favorability of 1.7 on the six-point scale. Thus, knowledge of the Corning recall may not have influenced the respondent's impressions.

Thus far the published series of investigations performed to determine factors influencing consumer reactions to product recalls includes two experimental studies and the survey research presented in the present article. Future work should involve three separate objectives. The next major step involves the completion of the path analysis work mentioned briefly in this article to test the models developed in the Mowen (1979a, 1979b) studies. The second step will consist of replicating the previous experimental work (Mowen 1979a, Mowen 1979b) across divergent subject populations and product classes. The final stage will involve tracking over time consumer reactions to a series of companies who have made product recalls.

THEORETICAL PERSPECTIVES ON THE IMPACT OF
NEGATIVE INFORMATION: DOES VALENCE MATTER?

Carol A. Scott, University of California, Los Angeles
Alice M. Tybout, Northwestern University

Abstract

Marketing researchers and marketing practitioners have long been interested in the factors that determine which product cues, or pieces of information, are used by consumers in forming judgments. Recent marketplace events such as product recalls, dramatic news stories on product defects, and occasional wild but damaging rumors have focused practitioners' interest more specifically on the utilization of negative product cues and on ways to lessen their impact on evaluations and choice. This special session attests to the fact that some researchers also feel that we should devote some attention to the effects of negative information.

Yet, from a theoretical perspective, a focus on valence *per se* may be wrongheaded and ironically unlikely to provide us with any clear directions for moderating the impact of negative information. Using an information processing theory approach, we contend that research may be better directed toward examining those attributes of cues and of the environment in which the cues are received that make them more salient to the individual and/or more informative,¹ and thus more likely to be differentially attended to and used by consumers. A cursory review of the literature indicates that valence *per se* may not be one of these attributes. Further, we argue that researchers should investigate the effects of various cue properties on the information processing strategies or cue combination rules used by consumers as well as on the ultimate evaluation. Examining the underlying determinants of attention and cue integration will provide direction for designing more effective influence strategies. This abstract briefly sets forth this theoretical view and illustrates its value.

Does Valence Matter?

Several studies have suggested that negative information is given relatively more weight than positive information in judgment formation (e.g., Kanouse and Hanson 1971; Lutz 1975; Wright 1974). It is important to note the emphasis on differential weighting, as certainly no one would be surprised that the addition of negative cues to an information base produced less favorable evaluations. Most attitude models would predict this latter outcome (cf. Fishbein and Ajzen 1975). A strong test of the differential weighting effect is extremely difficult to conduct, though, because one must somehow devise a situation in which two pieces of information are equal on all other plausible dimensions except valence.

In this regard, it is interesting to note that most explanations proposed for the observed differential impact of negative information entail the use of some other descriptive construct that essentially pinpoints a difference other than valence between the information pieces. Thus, negative cues are not given more weight because they are negative, but rather because negative cues happen to be statistically rare (i.e., one encounters nega-

¹Fiske (1980) argues that informative cues are by definition salient or attention attracting. However, as empirical research has shown (Taylor and Fiske 1978), salient cues are not always high in informativeness.

tive information less frequently than positive information in everyday life), because they are rare in context (i.e., one negative cue amidst several positive cues in a particular context), or because they are non-modal, or extreme (i.e., the property of being "bad" on an attribute when almost all other similar objects are "good" on the attribute). As Fiske (1980) argues, cues that are rare or non-modal are more informative than common or modal cues because they discriminate between similar objects. If, as recent work in social cognition suggests, people are "cognitive misers" (Nisbett and Ross 1980; Taylor 1980), they may follow the adaptive strategy of differentially attending to these more informative cues. And, differential attention has been shown to determine the weight given to a cue in forming judgments.

One must be very careful, then, in generalizing the conclusion that negative information is weighted more heavily than non-negative information, especially to product evaluation contexts. The rarity or distinctiveness of a cue can change over time and situations independently of its valence. Many of the studies frequently cited as supporting the negative information effect, for example, have been conducted in the context of evaluating or forming impressions of other people where indeed social customs make negative information unusual or unexpected. Clearly, one can imagine product evaluation contexts where very positive information would be as rare or as distinct (e.g., an honest and reliable car repair shop). Fiske (1980) recently has demonstrated that extremely positive, and thus statistically rare, information is given more attention (as measured by looking time) and more weight in forming judgments than other cues.

A focus on the underlying properties of cues which cause differential attention (e.g., the informativeness produced by rarity or non-modality) and thus differential impact is clearly warranted by extant research. Such a focus has a number of advantages. Obviously, it will allow us to specify the conditions under which negative (or positive) information will have an especially heavy impact on product evaluations. Further, it will open the door to investigation of other properties which may affect attention to cues. A knowledge of important situational qualifiers indicates when a manager should be especially concerned about negative product information, and a knowledge of factors that produce increased attention may suggest ways of decreasing attention to certain cues, or at least enable one to counter with informational cues of equal attention value.

Apart from the relationship between cue attributes and attention, however, the information processing approach suggests that one should also be concerned with the relationship between cue attributes and cue integration processes. Certain types of cues may be processed more easily and thus be used more readily. Other types of cues may be more difficult to interpret, and thus may affect evaluations indirectly by causing the individual to shift to a different cue integration strategy. For example, information about products can be obtained through learning about other people's experiences or opinions. Experiential information may be processed fairly easily, but information from others (external information) may require more cognitive work (see Kelley 1967). This would be especially true if the external

information is presented in abstract, statistical terms (e.g., "80% of the people who tried product x found ...") as opposed to concrete, vivid terms (e.g., "When Joe Smith tried his new lawn mower ..."), as discussed by Borgida and Nisbett (1977). Thus, the source (external vs. experiential) and the format (abstract vs. concrete) of the information may affect the process by cues are combined to form judgments.

This type of reasoning formed the basis for several experiments recently conducted by the authors. Specifically, we hypothesized that receipt of negative abstract external information about a product (i.e., 80% of the people who tried it preferred another brand to it) would produce uncertainty about the true character of the product. If this information was received after actual experience with the product, we postulated that the uncertainty would be resolved by recalling the more easily processed experience cue, and that consumers would follow a simple integration strategy that entails merely adding or averaging informational cues. If the person had no experiential information, however, the uncertainty caused by the external information should motivate the individual to recall any past behaviors related to the product and to combine these cues according to the causal analysis rules described in Bem's (1972) self-perception theory.

This proved to be the case. Individuals who had agreed to try a new soft drink in return for a coupon incentive evaluated the drink less favorably than those who did not receive an incentive for trial (i.e., the typical discounting effect predicted by self-perception theory) only when the negative evaluations of others were received prior to tasting the product. On the other hand, when the negative information was received after the taste experience, all cues were simply added such that the incentive group (with the additional positive reward cue) evaluated the drink more favorably than the no incentive group. This finding was observed across several dependent measures (semantic differential scales, overall evaluation measures, behavioral intentions). Further, the incentive-information after group reported the least desire for more information about the product before using it regularly, recommending it to friends, etc.

The only problem with concluding that negative external information produced the uncertainty and thus the differences in cue integration processes is the fact that the same results were found for positive external information. Even when subjects tasted a good product and they received positive information from other people, the order of the two types of information (experiential and external) had a dramatic effect on subsequent evaluations. Thus, one must conclude at this point that the ambiguity of the external information, and not its valence caused the differential processing of cues. If this is the case, then one might expect that introducing factors to make the external information less ambiguous would extinguish this effect. Providing external information in vivid, concrete terms might be one way to achieve this.

Summary

As the discussion of new and old literature in this paper illustrates, we believe that an examination of the underlying properties of negative information that sometimes make it more informative or attention arousing or that cause individuals to shift to different cue integration strategies is a useful approach. Ecologically, negative information may possess some of these attributes. But it is important from a practical and a theoretical perspective to separate valence from other properties.

Placing the research on negative information in the more general information processing framework provides a richer basis from which to design strategies to counter negative information.²

²An excellent example of how counter-strategies can be developed is provided by Tybout, Calder, and Sternthal (in press). Using available knowledge concerning the mechanisms of cue-storage and retrieval, these authors were able to demonstrate why the refutational strategy used by McDonald's to counter the recent rumor about worms in their hamburgers was ineffective. Further, they demonstrated that other strategies, based on information processing principles, were effective in neutralizing the rumor.

VIEWER MISCOMPREHENSION OF TELEVISED COMMUNICATION:
A BRIEF REPORT OF FINDINGS¹

Jacob Jacoby, Purdue University
Wayne D. Hoyer, Purdue University²
David A. Sheluga, Purdue University²

Abstract

Some of the major findings stemming from a large scale investigation of viewer miscomprehension of televised communication are presented. These findings reveal that virtually all viewers miscomprehend to some extent, and that no communication is immune from being miscomprehended. Further, the average amount to which the core content of each communication was miscomprehended was a surprisingly high 30%. Finally, commercials seem to be slightly better comprehended than program content. A few of the implications of these data are also discussed.

Introduction

Considerable interest has recently been focussed on issues related to consumer miscomprehension of advertising. Consumer advocates, regulatory agencies, and academic researchers have been devoting an increasing amount of attention to the issues of deceptive and/or misleading advertising and their remedies (e.g., corrective advertising, affirmative disclosure statements). They have not, however, addressed the logically prior set of questions concerning the existence, degree, correlates, and causes of miscomprehension. The evidence that is available in these regards tends to be fragmentary, anecdotal, and impressionistic.

Implicit in the arguments advanced by many consumer advocates is the assumption that commercial advertising is prone to causing miscomprehension whereas other forms of communication are generally not so prone. A problem with this view, however, is that it ignores our contemporary understanding of the communication process. In contrast, an alternative assumption is virtually all forms of communication are subject to being miscomprehended. Stated somewhat differently, there is not necessarily any correspondence between a given communication as conveyed by the source and that same communication as interpreted and remembered by the receiver. This is because the meaning a receiver extracts from a given communication consists

of both directly asserted meaning (as expressed in the message) and meaning inferred by that individual receiver. These latter meanings are a unique function of each receiver's total sum of prior experiences and the set of expectations he brings to the situation (cf. Harris and Monaco 1978).

If the latter assumption is correct, then the fundamental question to be resolved is not "Does advertising cause miscomprehension?" but, rather "Is there any greater level of miscomprehension associated with advertising than is associated with other comparable forms of mass media communication?" In other words, it is conceivable that miscomprehension of advertising may not be uniquely attributable to advertising per se, but may reflect a natural error rate common to all comparable forms of one-way mass communication.

Given the lack of hard benchmark evidence, the Educational Foundation of the American Association of Advertising Agencies decided to fund three investigations on the questions surrounding miscomprehension. This report represents a highly condensed summary of the basic findings generated by the first of these investigations. The primary objectives of the present investigation were:

1. To determine whether viewers do, in fact, miscomprehend televised communication.³
2. Assuming that some degree of miscomprehension is detected, to determine whether there is a "normative range" of miscomprehension associated with televised communications.
3. To determine whether commercial advertising tends to have a rate of miscomprehension which differs from other forms of televised communication.
4. To determine whether viewers possessing certain demographic characteristics are more prone to miscomprehending televised communications than are others.

Method

Given these objectives, three core concepts needed to be operationalized. These were: (1) communications, (2) viewers, and (3) miscomprehension.

Communications

Sixty different communications which had been broadcast over TV during the six months spanning the last quarter of 1978 and first quarter of 1979 constituted the set of test communications. These communications were broadly representative of most material being broadcast over commercial television. The set of sixty communications can be grouped into three categories: commercial advertising (n=25), noncommercial advertising (n=13), and program excerpts (n=22). The commercial ads consisted of 18 ads for brands and services and 4 "image" or "corporate"

¹This paper is a highly condensed version of a monograph describing a recently conducted investigation sponsored by the American Association of Advertising Agencies. The authors acknowledge with gratitude the many constructive contributions made by the members of the Academic and Industry Review Committees established by the AAAA to monitor this project from inception to completion. The members of the Academic Review Committee were Professors Jacob Cohen (New York University), Stephen Greyser (Harvard University), and William McGuire (Yale University). The Industry Review Committee members were Mrs. Rena Bartos (J. Walter Thompson), Dr. Seymour Banks (Leo Burnett), Dr. Theodore Dunn (Benton and Bowles) and Dr. Benjamin Lipstein (originally at SSC&B, now at New York University). The full description is provided in Jacoby, Hoyer, and Sheluga (1980).

²Wayne Hoyer is now with the Department of Marketing, University of Texas at Austin, Austin, Texas. David Sheluga is now with the Quaker Oats Company, Barrington, Illinois.

³Given that the major share of national advertising is devoted to television and regulator interest has been most evident in regard to this medium, attention was confined to televised communications.

ads. The non commercial ad group included 8 public service announcements and 5 ads for social causes. Finally, the group of program excerpts consisted of 18 excerpts from popular TV programs (including national and local news) and 4 excerpts from speeches and editorials.

Viewers

The sample consisted of 2,700 people, 13 years old and older. Sampling quotas insured that there were equal numbers of males and females tested at each of 12 testing sites and that there were 386 respondents subsumed under each of the following age brackets: 13-17; 18-24; 25-34; 35-44; 45-54; 55-64; and 65+. Compared to U.S. Census Bureau data, the sample was found to be broadly representative in terms of years of formal schooling completed, household income claimed for the preceeding year, marital status, and race. As a whole, the sample had a slight upward bias in terms of both education and income. That is, it claimed to be more highly educated and reported a higher level of prior year's income than did the population at large.

Miscomprehension

A six item miscomprehension quiz (patterned after Preston and Scharbach 1971) was administered after exposure to each communication. Each quiz consisted of six brief statements which sampled the universe of important information content regarding the object of that communication. Viewers were asked to indicate whether each statement was "True" or "False" based upon what was stated or implied in the communication. Two of the six statements on each quiz were accurate (i.e., "True"); four were inaccurate (i.e., "False"). Half related to objective facts (i.e., they were accurate statements of what had been directly asserted in the communication) and half to inferences which could be drawn from what was stated in the communication regarding the product (or product equivalent).

The procedure involved intercepting potential volunteers in the twelve shopping malls and inviting them to participate in the investigation. If the individual agreed and conformed to pre-established sampling quotas, s/he was invited into the testing room. Shortly thereafter s/he viewed the first of the two communications to which s/he had been randomly assigned and then responded to the miscomprehension quiz and a questionnaire regarding that communication. This was followed by viewing the second test communication assigned and responding to the set of corresponding questionnaires.

Several points should be made regarding the assessment procedures. First, interest focussed specifically and exclusively on miscomprehension and not on any of the prior or subsequent effects usually theorized to result from communication. Thus, the forced exposure procedure -- to insure that exposure, awareness, and attention had actually occurred -- was considered appropriate.

Second, miscomprehension was assessed immediately after exposure to each communication (rather than after exposure to both communications) because of the rapid decay of memory traces found with such communications. As one example, Bogart (1967 p. 109-110) cites research to indicate that fewer than 20% of a group of 5275 respondents could recall the identity of the TV commercial they had viewed just a few minutes earlier.

Third, the procedures involved two sets of counterbalancing. On the one hand, the order of presentation of test stimuli was counterbalanced for main effects due to order. Each communication was presented a total of 90 times -- first in 45 cases and last in the other 45 cases. On the

other hand, so as to eliminate geographic biases, each of the 60 communications was tested at each site. Since each communication was involved in 90 separate tests, no less than 7 nor more than 8 of these tests took place at any one of the 12 testing sites.

Selected Findings

A series of multiple regression analyses were first conducted to determine whether variations in communication complexity,⁴ communication familiarity, product awareness-trial-usage, order of testing, or testing site exerted any appreciable effect on the miscomprehension scores obtained. In none of these analyses did these covariates cumulatively explain more than 8.4% of the variation in the scores. This suggests that miscomprehension is unaffected by variations in any of these factors.

Objective 1: Does Miscomprehension Occur?

The question "Does miscomprehension occur?" can be re-phrased as three separate questions: (a) What proportion of viewers miscomprehend at least some portion of the communications which they viewed? (b) What proportion of the meanings in the test communications were miscomprehended? (c) What proportion of the set of 60 test communications were miscomprehended?

Proportion of Viewers who Miscomprehended: Only 16.8% of the viewers "fully comprehended" (i.e., were able to correctly answer all six quiz items for) either the first or second communication which they viewed. This means that in 83.2% of the 5400 viewings (2,700 viewers X 2 test communications each), viewers miscomprehended at least some portion of the communications which they viewed.

Correctly comprehending the content of one communication did not mean that that person was necessarily able to correctly comprehend another communication. In fact, of the 16.8% who fully comprehended one of the test communications (in the sense of answering all six quiz items correctly); most (13.3%) miscomprehended some portion of the second communication which they saw. That is, only 3.5% of the viewers fully comprehended both test communications to which they were exposed (i.e., answered all 12 items correctly).

Proportions of Meanings Miscomprehended: One may also ask: To what extent was the content of the 60 test communications miscomprehended? The findings reveal that 29.6% of the (2700 respondents x 2 communications per respondent x 6 quiz items per communication =) 32,400 meanings that were tested were answered incorrectly. Both the median and model rates of Overall Miscomprehension were 28%. These figures probably underestimate the actual amount of miscomprehension, since they do not adjust for instances where viewers who did not know the correct answer managed to guess correctly.

Proportion of Communications Miscomprehended: It is noteworthy that at least some degree of miscomprehension was associated with each and every one of the 60 test communications. Across the set of 60 test communications, the level of miscomprehension ranged from a low of 11% to a high of 50%.

⁴ Complexity was assessed via a battery of eight separate indices consisting of a copy point index, assessments of both visual and auditory complexity (see Watt and Krull 1974), and an assessment of the difficulty level of the verbal copy (using the Farr, Jenkins, and Paterson 1951, version of the Flesch count).

In sum, regardless of whether considered in terms of viewers, meanings, or communications, the answer to the first research question is a resounding "yes." Miscomprehension of televised communications does occur and seems to be far more prevalent than might have been anticipated. Perfect comprehension rarely occurs and may not be generally attainable.

Objective 2: What is the Typical Range of Miscomprehension?

The interquartile range (that is, the range encompassed by the middlemost 50% of the test communications) was used to estimate the typical range of miscomprehension.⁵ Considering the entire set of 60 test communications, the interquartile range extended from 23% to 36%. Generalizing from these data suggests that one might expect anywhere from one-quarter to one-third of the material information content contained in communications that are broadcast over commercial television to be miscomprehended.

Objective 3: Is Advertising More Miscomprehended than Non-Advertising?

Program excerpts vs. commercial advertising vs. non-commercial advertising. Based on the sample of 60 test communications, the 22 program excerpts were associated with a significantly⁶ higher rate of miscomprehension (\bar{X} =32.2%) than were either the 25 commercial (\bar{X} =28.3%) or 13 non-commercial (\bar{X} =27.6%) advertisements. However, this difference is quite small and, though statistically significant, may be considered immaterial in practical terms.

Product-service advertising vs. entertainment information program excerpts. The broad three-category classification system has the potential to obscure what is perhaps the most interesting comparison of all, namely, the contrast between product-service advertising on the one hand, and entertainment-information program excerpts on the other. These are the two most frequently broadcast kinds of communication appearing on network television. This investigation examined 22 product-service advertisements and 18 entertainment and information program excerpts. Are these two kinds of televised communication associated with different levels of miscomprehension?

The answer is "yes." Entertainment-information program excerpts were associated with a small, but significantly higher rate of miscomprehension than were product-service advertisements. The mean levels of miscomprehension were 31.0% and 28.8%, and the interquartile ranges extended from 27% to 37% and 22% to 34%, respectively.

Objective 4: Are There Demographic Differences Associated with Miscomprehension?

A number of socio-demographic characteristics were assessed. These included the respondents' sex, age, marital status, employment status, race, years of formal education, and household income for the preceeding year. Only two of these factors -- age and education -- were significantly

⁵The interquartile range was employed in preference to "plus-or-minus one standard deviation from the mean" for two main reasons. First, the distribution of miscomprehension scores was decidedly not normal. Second, the interquartile range lends itself more easily to layman comprehension.

⁶All statements of "significance" refer to being statistically significant at the $P=.01$ level or better. These data have been independently checked and confirmed by our statistical consultant, Professor Jacob Cohen.

related to miscomprehension. Both younger and older viewers were more likely to miscomprehend the communications, and miscomprehension appears to decrease (although not appreciably) as amount of formal education increases. However, while statistically significant, for all intents and purposes, these relationships are so weak as to have little practical applicability.

Discussion

Based upon the findings, six specific conclusions appear justified. First, a large proportion of the American television viewing audience tends to miscomprehend communications broadcast over commercial television. The vast majority (96.5%) of the 2700 respondents in this investigation exhibited some degree of miscomprehension. Second, it would appear that no communication is immune from being miscomprehended. Each and every one of the 60 test communications was miscomprehended at least some of the time by some of the viewers.

Third, the average amount of miscomprehension associated with each of the 60 test communications was 30% (actually 29.61%). In other words, approximately 30% of the relevant informational content contained within each communication was miscomprehended. Fourth, as a preliminary estimate, the typical range of miscomprehension is 29.5% + 6.5%. That is, typical TV communications seem to have their content miscomprehended at anywhere from 23% to 36%.

Fifth, non-advertising communications were associated with higher levels of miscomprehension than were advertising communications. Of particular interest, excerpts of TV programs were miscomprehended at higher levels than were commercial advertisements (for products-brands-services). However, though statistically significant, these differences are practically trivial. Finally, for all practical purposes, no major demographic variables appear to be meaningfully associated with miscomprehension. Miscomprehension seems to be widespread throughout the populace, occurring at all age, income, and education levels in our society and to the same degree.

Selected Implications of Our Findings

Among other things, this investigation reveals that, once again, the mere provision of information does not automatically translate into this information having any effect, much less the intended effect (cf. Jacoby 1974; Jacoby, Chestnut, and Silberman 1977). Rather, the receiver/viewer brings a storehouse of past experience and an ongoing mental set to each communication transaction and tends to interpret, and misinterpret, communications in terms of these mental phenomenon. Given that it is not possible to eradicate either the influence of past experience or the individual's current mental set, it may well be impossible to eradicate miscomprehension. This leads directly to a set of implications for public policy makers, educators, and researchers alike.

Perhaps the most fundamental implication for policy makers is that, just because there is a demonstrable degree of miscomprehension associated with a particular advertisement does not necessarily mean that that particular advertising contains something out of the ordinary to provoke said miscomprehension. Such an assumption may be totally unwarranted. Indeed, the findings of the present investigation revealed that the rates of miscomprehension associated with advertising were significantly lower than the rates associated with typical program content. In other words, a certain proportion of miscomprehension may simply reflect a natural error rate associated with all types of televised communication. The ramifications that this implication has for such regulatory actions as cease and desist orders, corrective advertising, and affirmative

disclosure orders are substantial.

Of course, a reasonable argument is that the consequences of miscomprehending most TV programs tend to be trivial when compared to the consequences of miscomprehending, and then acting upon, advertising. Hence, the rate for advertising should be lower than that for other forms of televised communication. While the authors might be persuaded that advertising miscomprehension rates are probably unacceptably high, they would find completely unreasonable any attempt to use "zero-based miscomprehension" as the criterion for evaluating advertising and as a basis for formulating public policy.

Perhaps the data from the present investigation might serve a useful function in this regard. Regulatory interest in correcting misleading and/or deceptive advertising might use the boundary separating the third and fourth quartile of communications as a triggering mechanism, so that advertising which exceeds this level, while not automatically considered deceptive or misleading, would be targeted for further scrutiny. Of course, any attempt to employ such a cutoff level would have to accommodate the fact that the data adduced here probably underestimate the extent of miscomprehension present under normal viewing conditions. Further, it needs to be recognized that there may be instances (as in the case of over-the-counter and prescription pharmaceutical products) where miscomprehension rates of 10% or even 5% might be deemed totally unacceptable (see Jacoby and Small 1975).

There are parallel implications for advertisers. Given recognition of the fact that some degree of miscomprehension is likely associated with any ad and may, if detected at sufficiently high levels, become the focus of regulatory attention, advertisers might be encouraged to pressure their advertising departments and advertising agencies for lower rates of miscomprehension. Aside from concern over possible regulatory activity, there is a very practical reason for engaging in such research. Namely, by lowering the rate of miscomprehension, the advertiser would insure that more of his advertising message is being accurately comprehended. Perhaps the syndicated advertising evaluation services could be encouraged to devise and provide a "miscomprehension index" along with the other standard communication impact indices which they currently do provide.

Another implication -- one which is consistent with much previous research -- is that broadcast advertising may not be a suitable medium for communicating substantial amounts of product information, particularly complex product information. In terms of the classical hierarchy-of-effects conceptualization (Lavidge and Steiner 1961) and more contemporary models of consumer decision making (e.g., Engel, Blackwell, and Kollat 1978), perhaps the basic function of advertising is simply to stimulate awareness and generate problem recognition. Labelling and other information media would seem to be better vehicles for providing the detailed supporting information.

Conclusion

Some will no doubt quarrel with the procedural details of this investigation or with the specific findings obtained arguing, as examples, that the 30% miscomprehension rate is too high to be correct, or that commercial advertising is more readily miscomprehended than is TV programming. It may well be that these arguments are correct. No claim is made of providing definitive answers to the research questions which stimulated this investigation. The authors merely claim that the findings represent preliminary ballpark estimates which are in need of further confirmation and refinement. However, the fact remains that, even with a procedure -- involving unclutter forced

exposure and volunteer participants who were likely more attentive to the test communications than they normally would otherwise have been -- which should have reduced the rate of miscomprehension, nearly every single one of the 2700 respondents managed to miscomprehend at least some portion of the communications which they viewed, each and every one of the 60 test communications was miscomprehended, and the average amount of miscomprehension associated with any given communication was an unexpectedly high 30%. Further, these findings were quite robust, holding true for respondents of different ages, incomes, education levels, sexes, and marital status.

The implications of these findings are substantial. Perhaps foremost among these is that to require advertising -- or any other comparable form of communication, for that matter -- to conform to a "zero base" miscomprehension rate appears totally unreasonable. Further, to contend that advertising is necessarily more prone to being miscomprehended than are other forms of televised communication is similarly unreasonable. If nothing else, the present findings strongly suggest the need for a programmatic series of research investigations designed to shed considerably greater light on the various questions surrounding viewer miscomprehension of televised communications.

IMPACT OF PUBLICITY ON CORRECTIVE
ADVERTISING EFFECTS

Kenneth L. Bernhardt, Georgia State University
Thomas C. Kinnear, University of Michigan
Michael B. Mazis, American University
Bonnie B. Reece, University of Michigan

Abstract

Previous research on corrective advertising has generally involved a forced exposure in a laboratory setting using student subjects. Treatment and criterion variables have also usually been developed by the researcher independent of the real interests of regulators. This paper presents an overview of a national field study of the STP corrective advertising campaign, as it was actually undertaken by the Federal Trade Commission. The details of this study are currently under review for publication elsewhere.

Background

There have been several important corrective advertising studies conducted in a laboratory setting, but frequently subjects have viewed ads under conditions of forced exposure thereby limiting generalizability (Armstrong, Gurol and Russ 1979, Dyer and Kuehl 1974, 1976a, 1976b, 1978, Gurol 1977, Hunt 1972, 1973, Kassarian et. al. 1975). In addition, while most of the corrective campaigns have appeared in the print medium, many of the studies have concerned broadcast advertising for Listerine (Armstrong et. al. 1979, Dyer and Kuehl 1978, Gurol 1977, Mazis and Adkinson 1978, Mizerski et. al. 1979, Sawyer and Seminick 1978). Further almost all reported studies have used students as subjects. The impact on actual consumers in the marketplace is essentially unresearched.

The current research is the first to examine corrective advertising as it was actually undertaken by the Federal Trade Commission in the field. It is designed to measure, though a "before and after" design (Campbell and Stanley 1963), the effectiveness of the 1978 STP corrective advertising campaign which appeared in a number of periodicals and received substantial publicity in the news media.

In February 1978, the STP Corporation signed a consent decree under which it agreed to discontinue certain advertising claims about its motor oil additive and to make a \$700,000 settlement, including \$200,000 to place a "public notice" advertisement in 14 periodicals.

During February 5-9, 1978, several days before initiation of the "public notice" campaign, 823 persons who were at least 18 years of age, who were regular readers (read three of every four issues) of one of the target periodicals were interviewed on the telephone. While a stratified random sampling procedure was used to contact potential interviewees (as described below), a quota procedure was used to obtain a 60:40 ratio between "general public" respondents and respondents with "business related occupations."

Subsequent to these interviews, the "public notice" advertisement was placed as follows:

February 10 - Wall Street Journal
February 10 - New York Times (Financial Section)
February 13 - Washington Post
February 13 - Barron's

February 20 - Newsweek
February 20 - U.S. News & World Report
February 20 - People
February 20 - Business Week

The advertisement also appeared in the Time Business during February. However, since it was impossible to determine which Time readers received the business edition, Time was excluded from the list of relevant publications. Additionally, during March and April the advertisement appeared in Esquire, Forbes, Guns and Ammo, Harvard Business Review, and National Geographic. Since these placements appeared after Wave II was completed, readership of these periodicals was not relevant for inclusion in the samples. A second wave of 845 interviews with a separate group of respondents was conducted from February 27 through March 2 using the identical procedure followed for the first wave. Respondents were contacted shortly after initiation of the campaign in order to reduce the impact of "history effects" as a source of invalidity and to more accurately measure consumer perceptions of the advertisement. As such, the study focuses solely on short-term effects generated by the campaign and publicity. Additionally, a special sample of 197 advertising industry managers, selected from a proprietary list, was interviewed during Wave II only.

The sample, based on the Louis Harris national sample selection procedure, was selected based upon the national population of the United States, excluding Alaska and Hawaii, and those in prisons, hospitals or religious and educational institutions. Figures are updated annually by intercensal estimates provided by the Bureau of Census, with sample locations selected biannually to reflect demographic changes.

Results

The results of the campaign were measured on a number of variables: knowledge of problems about STP advertising, intention to purchase STP, attitudes toward the STP Corporation, and credibility of oil additive claims in general. Additional recall measures about the campaign were taken on Wave II participants.

The campaign and the attendant publicity had a marked effect on awareness of a problem with STP advertising, and resulted in a decrease level of intention to purchase STP. The effects of the campaign did not spill over into oil additive claims in general, nor did it negatively impact attitudes held about the STP Corporation. The effects appear to be very specific to STP.

Examination of recall results raises questions as to how these effects occurred. Both unaided and aided recall levels were extremely low. How then could the observed effects have occurred? It is our speculation that the substantial attendant publicity for the campaign (features on network television news for example) must be a significant contributor to the observed results. Unfortunately, no evidence is available to support or refute this conclusion.

CORRECTING CORRECTIVE ADVERTISING¹

Jacob Jacoby, Purdue University
Margaret C. Nelson, Purdue University
Wayne D. Hoyer, Purdue University

Abstract

Prior discussion and research on remedial (i.e., affirmative disclosure and corrective advertising) statements has addressed the impact of such statements on beliefs, attitudes, and purchase intentions. It has been implicitly assumed that such statements are satisfactorily comprehended by the general public. The present investigation tested this assumption using three heterogeneous samples (n=451) and six remedial statements proposed by the Federal Trade Commission. The findings revealed that remedial advertising statements may be miscomprehended as much as -- or even more often than -- the advertising they are supposed to remedy.

Introduction

The subject of deceptive-misleading advertising has experienced increasing regulatory and academic interest over the past decade. The remedies that can be employed in the event an ad (or ad campaign) is judged to be deceptive-misleading have also been the focus of considerable discussion. Two of the more controversial of these remedies are "corrective advertising" and "affirmative disclosure."

Corrective advertising is advertising mandated by regulators which is designed to modify an erroneous belief purportedly caused by previous advertising for the same product, brand, or service. Affirmative disclosure refers to the requirement that an advertiser provide new or additional information so that the consumer will be better able to make a more informed choice. The intent of the regulators is the same in either case: to somehow affect the consumer's belief structure regarding the advertised product, brand or service. In the case of corrective advertising, this means changing or "correcting" a purportedly erroneous belief. In the case of affirmative disclosure, this means generating a new belief. In both cases, the implicit objectives are to make consumers better decision makers and to redress sales gains as a result of what are considered to be unfair advertising practices.

Early empirical research focused on the impact that corrective advertising had on such factors as: brand awareness; attitudes toward the brand, the company (i.e., company image), and the advertisement; and purchase intentions. Later research zeroed in on the impact that such remedial advertising had on consumer beliefs.

As is readily recognized, awareness, beliefs, attitudes, and intentions are among the dependent variables traditionally employed to assess communication impact. These variables are usually major components in most widely accepted conceptualizations of the communication process. A consideration of these models -- from the hierarchy-of-effects model (Lavidge and Steiner 1961) through more contemporary conceptualizations (e.g., McGuire 1976;

Engel, Blackwell and Kollat 1978, especially Chapters 1 and 13) -- reveals in every case that some degree of comprehension is assumed to precede belief formation and change.

Hence, regulator efforts to use affirmative disclosure and corrective advertising statements to change an existing belief or to provide a new belief, and researcher efforts to assess the impact of such advertising, necessarily rest on a critical assumption -- that the logically prior step of consumer comprehension of the message has been accomplished. This assumption is as yet completely unverified. It stands to reason that before a corrective advertising or affirmative disclosure statement can exert the intended impact upon consumer beliefs, it must first be understood by the consumers toward whom it is targeted. If the meaning contained in the remedial message has not been satisfactorily comprehended, then the logically subsequent step of belief formation or change cannot be achieved.

In other words, there exists the potential for remedial statements to be at least as confusing and misleading as the original advertising messages which they were designed to counteract. The present investigation examined this possibility using the actual language proposed by the Federal Trade Commission (FTC) for implementation in a case which, as of the present writing, is still under active judicial consideration.

This case revolves around two familiar analgesic products manufactured by the Bristol-Myers Company, namely, Bufferin and Excedrin. The FTC contends that an integral part of Bufferin advertising has been the claim that Bufferin is a faster pain reliever and gentler to the stomach than plain aspirin. Similarly, it is asserted that Excedrin advertising contains the claim that the product is a more effective pain reliever than is plain aspirin. The FTC further contends that a significant proportion of American consumers now hold these beliefs as a result of exposure to television advertising.

The problem, according to the FTC staff, is that the degree of empirical proof available to support the claims is not as conclusive as the FTC staff believes it should be. Hence, the FTC staff would like consumers to know that, while a certain amount of proof is available to show that the claims may be true, the degree of proof is insufficient according to some authorities.

With the expectation that the FTC Administrative Law Judge hearing the case would rule in its favor, the FTC Complaint Counsel sent a letter to the Judge. The letter provided two sets of remedial statements, one for each product, and proposed that one of the statements in each set be mandated for the respective products.

"For inclusion in Excedrin advertising, the disclosure that:

1. Excedrin has not been proven to be a more effective pain reliever than aspirin;
- or; 2. It is not known whether Excedrin is a more effective pain reliever than aspirin;

¹This report is a highly condensed version of a longer manuscript (Jacoby, Nelson, and Hoyer, submitted).

- or; 3. There is a real question whether Excedrin is a more effective pain reliever than aspirin.
- For inclusion in Bufferin advertising, the disclosure that:
4. Bufferin has not been proven to be a faster pain reliever or gentler to the stomach than aspirin;
- or; 5. It is not known whether Bufferin is a faster pain reliever or gentler to the stomach than aspirin;
- or; 6. There is a real question whether Bufferin is a faster pain reliever or gentler to the stomach than aspirin."²

In serving as an expert witness for the defendant, the senior author expressed several opinions regarding these proposed remedial statements. Principal among these was the belief that a substantial number of consumers would either be confused as to their intended meaning, or would extract some non-intended meaning. The investigation described below is a direct outgrowth of this testimony and represents an empirical attempt to confirm (or disconfirm) these opinions.

Method

Instrument

Comprehension was assessed via a closed-ended questionnaire. A set of 8 "derived meanings" was generated for each of the six proposed remedial statements. For each such set, one (or two) of the derivations were judged roughly equivalent in meaning to the corrective statement under consideration; the other six (or seven) derivations were judged to be incorrect. Figure 1 provides an example for one of the six proposed statements. Each of the remedial statements, followed by its set of derivations, constituted a separate page in a questionnaire. The opening instructions requested that the subjects read the statements typed at the top of each page, then check as many or as few of the interpretations as they felt accurately paraphrased the meaning which they had derived. These pages were randomized across statements and respondents. In addition to the set of eight derivations, each page contained a ninth response option for "none of the choices presented above reflect the meaning I get from this statement" and a tenth option for "I am uncertain as to what the statement actually means and therefore cannot check any of the above meanings as being either correct or incorrect."

FIGURE 1

"Excedrin Has Not Been Proven To Be A More Effective Pain Reliever Than Aspirin."

1. Excedrin is a more effective pain reliever than aspirin.
2. Excedrin is not a more effective pain reliever than aspirin.
3. Excedrin is neither more nor less an effective pain reliever than aspirin.

² Fisherow, W. Benjamin. Complaint Counsel's statement concerning corrective advertising for Excedrin and Bufferin. Letter dated January 31, 1979 and sent to Montgomery K. Hyun, Administrative Law Judge. In the matter of: Bristol-Myers Company, Ted Bates and Company, Inc., and Young and Rubicam, Inc. Docket No. 8917, Federal Trade Commission.

4. Excedrin is a less effective pain reliever than aspirin.
5. Excedrin may be more effective than aspirin, but no proof whatsoever exists for this statement.
- *6. Excedrin may be more effective than aspirin, but no conclusive proof exists for this statement.
7. Excedrin may be more effective than aspirin, but no studies have yet been done which would show this to be true.
- *8. Excedrin may be more effective than aspirin, but there is at present insufficient evidence to show that this is true.
9. None of the choices presented above (1 through 8) reflect the meaning I get from this statement.
10. I am uncertain as to what the statement actually means and therefore cannot check any of the above as being either correct or incorrect.

For any given page, an individual's response was scored "correct" if he checked the one accurate derivation in the case of Bufferin, or one of the two or both accurate derivations in the case of Excedrin, and marked no other response options. An answer was scored "incorrect" either if the individual checked any of the inaccurate derivations on the page and failed to also check an accurate response, or if the individual marked the ninth response option ("None of the choices . . ."). A response was scored "confused" either if the individual marked a correct derivation as well as one or more incorrect derivations, or if the individual chose the tenth response option ("I am uncertain . . .").

Samples

Three separate samples were employed. The first consisted of 92 Purdue University undergraduates enrolled in an introductory course on consumer behavior. The second consisted of 281 members of social and fraternal organizations (Breakfast Optimists; Rotary Club; League of Women Voters, and Parent Teachers Association) in Lafayette, Indiana. The third sample consisted of 78 middle-class adult blacks living in south suburban Chicago. All subjects were volunteers and were unaware of the purposes of the investigation.

Results

Table 1 summarizes the results obtained with each of the samples. As can be seen from these data, extracting either an incorrect or confused meaning was much more prevalent than extracting the intended meaning. In other words, despite the considerable amount of thought and well-intentioned effort which underlie the development of these messages, remedial statements have the potential to generate at least as much miscomprehension as the advertising messages they were designed to counteract. However, if one were forced to make a choice from among the three versions proposed, it is clear that the "There is a real question. . ." version is best understood and least confusing.

*Note: Options 6 and 8 were judged to be accurate paraphrases of the meaning structure intended by the remedial statement.

TABLE 1

Table 1. Proportion of respondents who extracted correct, incorrect, or confused meanings from the proposed remedial statements.

	Remedial Statements					
	Excedrin			Bufferin		
	1	2	3	4	5	6
Correct						
Sample 1	.21	.23	.46	.13	.15	.33
Sample 2	.25	.17	.40	.17	.13	.25
Sample 3	.19	.15	.48	.15	.23	.23
Weighted mean	.23	.18	.43	.16	.15	.26
Incorrect						
Sample 1	.26	.20	.06	.33	.33	.33
Sample 2	.32	.40	.13	.56	.52	.41
Sample 3	.35	.33	.20	.58	.46	.35

Weighted mean	.46	.47	.44	.32	.38	.35

Sample 1 = 92 Purdue University undergraduates
 Sample 2 = 281 post-college age adults residing in Lafayette, Indiana.
 Sample 3 = 78 black adults residing in S. Sub. Chicago
 Total N = 451

Discussion

The principal objective of the present investigation was to examine the question: Are corrective advertising or affirmative disclosure statements as subject to being miscomprehended as are the advertising messages they are designed to remedy? From the data obtained, the answer would appear to be a resounding "yes". The six remedial statements proposed by the FTC staff for inclusion in Bufferin and Excedrin advertising appear to be more often associated with confused or incorrect comprehension than with correct comprehension. In other words, the implicit assumption that remedial advertising statements will automatically be accurately comprehended by the public at large seems both unwarranted and untenable.

The difficulty involved in accurately communicating meaning is often underestimated, and regulators would seem to be no exception in this regard. As Rumelhart (1977, p. 102) notes: "Of all the complex tasks the human information system carries out, perhaps the most sophisticated is language processing . . . Only when we stop and analyze the intricate reasoning that appears to underlie even the simplest cases of language comprehension can we begin to appreciate the complexity of the language understanding process."

Given that the receivers of communication messages differ substantially in terms of their past experiences and present "semantic expectations" (see Rumelhart 1977, p. 148), it is not surprising to find substantial levels of miscomprehension. The fact that high levels of miscomprehension were found for remedial statements generated and proposed by the FTC suggests caution in being quick to blame the advertiser when some consumers miscomprehend his message.

It could be argued, of course, that the relatively high rates of confusion obtained (that is, extracting the correct meaning along with some additional, but incorrect meaning) should not be of major concern since they suggest that at least some of the correct meaning was being received. However, consider Cohen's (1974, p. 9) description of the criteria used by the FTC to arrive at a finding of deception in advertising:

On the basis of FTC cases and court interpretations, an advertisement will be considered false, misleading, or deceptive when the following [applies]:

.....

An advertisement that is capable of two meanings, one of which is false, is misleading.

One might therefore reasonably ask: Should not the same criteria apply to remedial statements as well?

Perhaps the most important implication of the present investigation is that, just as is the case for advertising proper, the likely impact of remedial statements needs to be thoroughly researched before such statements are inserted in advertising. Regulatory agencies need to recognize that the language of the remedial statements which they devise may be equally (and in some cases even more) confusing to the consumer than the advertising message it is designed to correct. It cannot be safely assumed that language decided upon in good faith and with the consumer's best interests at heart will be sufficient for accomplishing its objective. There is no substitute for empirically assessing the perceived meanings of corrective advertising or affirmative disclosure statements before such remedial statements are mandated for use in advertising.

THE EFFECTS OF RECALL ON BELIEF CHANGE:
THE CORRECTIVE ADVERTISING CASE

Neil K. Allison, University of South Carolina,¹
Richard W. Mizerski, Federal Trade Commission

Abstract

This study reports the association of product or brand recall with various beliefs consumers hold about a product subject to the corrective remedy. Respondents recalling exposure to a test product's corrective ad exhibited belief change for only the target belief of the corrective message. Those subjects who were unable to recall exposure had overall beliefs similar to a control group not exposed to corrective advertising.

Introduction

The 1970's have seen the Federal Trade Commission (FTC) expand its role in consumer protection. An area of FTC jurisdiction concerns advertising that the Commission has defined to be false or misleading. This type of advertising is considered to be an unfair method of competition for which the Commission is able to enforce several remedies, the most severe and controversial being an order for corrective advertising. Such a ruling not only requires the advertiser to stop the false or deceptive communication but, in addition, to engage in a corrective advertising campaign that seeks to "... eliminate the residual effects of inaccurate or misleading information" (Wilkes and Wilcox 1974, p. 58) presented to the consumer in the previous advertising.

The most important action involving corrective advertising, in terms of both the size of the settlement and the legal precedent, was levied against Warner-Lambert's Listerine Antiseptic Mouthwash. The case against Warner-Lambert began in 1971 with an FTC complaint that Listerine ads falsely promoted the product as an "aid in preventing and ameliorating colds," because medical evidence failed to support this claim. Unlike previous corrective advertising cases, Warner-Lambert refused to sign a consent decree. In response, the FTC ordered Warner-Lambert to judicial review. This action set the legal testing ground for the FTC's power to issue and enforce the corrective advertising remedy. The order was upheld with slight modifications by the Court of Appeals for the District of Columbia in 1977, and in 1978 the U.S. Supreme Court refused to hear the case, thus establishing the legality of corrective advertising.

The modified corrective advertising order required Warner-Lambert to include the corrective message in all Listerine advertising until it had spent \$10 million, an amount equal to the average annual advertising expenditures for the previous ten-year period. The content of the message was limited to "Listerine does not cure or prevent colds, or lessen their severity." The purpose of this and all other corrective messages was to change only consumers' falsely formed beliefs about the product and not to favorably or unfavorably affect other beliefs about the product, the manufacturer, or the competition. This additional impact would be considered punitive and beyond the legal bounds of the FTC.

¹The authors would like to acknowledge the financial assistance of the University of Cincinnati, College of Business, for support of this research.

Since corrective advertising was first proposed in 1969 as a remedy for false or deceptive advertising, the FTC, and the courts in the Listerine case, have been continually developing guidelines for its use and implementation. The following are a sample of significant decisions that have had an effect on the corrective advertising rule as it is presently enforced (Maddox and Zanot 1979).

-Corrective advertising can be justified in situations where there are residual effects of an advertising campaign that is no longer running (Firestone Tire and Rubber Company Case).

-Corrective advertising must at least reach the same target with similar impact as the original deceptive advertising (Sugar Association Case).

-Corrective advertising must appear in the same media and in the same manner as the original deceptive advertising (Lens Craft Research and Development Company Case).

-Corrective advertising need not include the phrase "contrary to past advertising" (Listerine Case).

-Background sounds or music during the corrective disclosure are not allowed (Listerine Case).

The evolution of the application of corrective advertising still leaves many issues unanswered. In general, the FTC lacks objective criteria for its decision making in the corrective advertising area. For example, expenditures for a corrective campaign have been mandated in different cases to be either 25% of all media expenditures, one in four ads for corrective advertising, or the \$10 million figure in the Listerine case. Another issue that is a concern of both industry and government involves the impact of corrective advertising on the consumer. There have been a number of empirical studies with conflicting findings that address this issue (Hunt 1973a, 1973b, Dyer and Kuehl 1978, Mazis and Adkinson 1974). A recent study (Mizerski, Allison and Calvert 1980) concluded that multiple exposure to an actual corrective radio commercial had a significant influence on lowering the subjects' target belief for which that remedy was developed. At this point, it appears that corrective advertising, as it is presently implemented, is capable of removing a false belief without harming the offending advertiser or its competition.

As with any persuasive communication, standards for establishing the effectiveness of corrective advertising must be defined. A common industry technique for advertising effectiveness is recall testing. This includes aided and unaided recall performed on a day-after-exposure basis or with a more substantial time delay. (For a discussion of recall techniques, see Darrell Blaine Lucas and Stuart Henderson Britt, Measuring Advertising Effectiveness, Chapter 4). There have been many questions raised as to the validity of recall testing as a measure of advertising effectiveness. There is evidence that, over time, advertising may induce attitude change even though the specifics of the verbal content of the message itself are not recalled (Percy 1978). If this phenomena is true, then a measure of general advertising recall may be a necessary and sufficient criteria for establishing the persuasive impact of a communication, rather than a measure of

detailed information recall. This study investigates the value of a measure of general advertising recall for establishing the effectiveness of corrective advertising.

Based on previous studies of corrective advertising and research on advertising recall, the following hypotheses are proposed:

1. Experimental subjects who recall hearing a corrective advertisement will have a weaker belief that Listerine "fights colds and sore throats" (target belief) than either experimental subjects who do not recall exposure to a corrective advertisement or control subjects.
2. Experimental subjects who recall hearing a corrective advertisement will not have different levels of beliefs concerning non-target attributes of Listerine than either experimental subjects who do not recall exposure to a corrective advertisement or control subjects.
3. Experimental subjects who recall hearing a corrective advertisement will not have a different belief concerning the honesty of Listerine's manufacturer than either experimental subjects who do not recall exposure to a corrective advertisement or control subjects.
4. Experimental subjects who recall hearing a corrective advertisement will not have a different affect/attitude toward Listerine than either experimental subjects who do not recall exposure to a corrective advertisement or control subjects.

Methodology²

Sampling Plan

In order to more realistically investigate the effects of corrective advertising on consumers' cognitive structure than in previous studies (Hunt 1973a, 1973b, Dyer and Kuehl 1978, Mazis and Adkinson 1974) the natural setting of an on-campus radio station was used as the medium of the corrective advertising message. The station reaches only dormitory residents of a large mid-Western university by direct transmission via carrier current and does not broadcast to the general public, thus allowing for a controlled field experimental environment. The programming of the station follows the format of a typical contemporary rock commercial station with music, disc jockeys, news, commercials, games and give aways.

A systematic random sampling plan from a sample frame of all dormitory residents was used to make initial contact with students. Potential respondents were telephoned and asked to participate in a study to help improve the programming and format of the on-campus radio station. This guise for the corrective advertising experiment was supported by an article in the campus newspaper discussing the need for a radio station survey that was to be conducted by university personnel.

All potential subjects were first asked whether or not they were able to receive the station on the radio in their own dormitory room. Because of the nature of the carrier current transmission and how it is affected by a building's structural design, individuals next to each other in the same dorm differed in ability to receive the station. Those students who reported they were able to receive the station were considered potential experimental group subjects and those who could not were considered potential

control group subjects.

Potential experimental subjects were informed that participation would require four one-half hour listening periods over the course of a week. In order to increase participation, they were to be paid \$5 for their efforts. As a manipulation check, during each of the four experimental sessions, the disc jockey announced a "listener survey password" that had to be presented to the researchers at the end of the study in order for the subject to receive his/her pay. To make participation in the survey even more attractive, students were given a chance to win their choice of record albums in the course of the four listening sessions. Twice during each half-hour period a student's social security number was randomly drawn and read out over the air. The respondent had five minutes to telephone the radio station and claim his/her prize, thus providing an additional manipulation check. After attrition due to extensive missing data, response bias or incomplete participation, there were 49 experimental subjects available for data analysis.

Those students who could not receive the radio station and who agreed to participate were told they would need to fill out a questionnaire concerning the on-campus radio station. The four one-half hour test sessions were not mentioned to this group of control subjects. For their participation, they received 50¢ coupons to a local fast-food restaurant. There were 51 control group subjects after removing those with obvious response bias or extensive missing data. Upon conclusion of the entire study, debriefing sessions showed that no control subjects were exposed to the experimental treatments.

Experimental Treatments and Measurements

The study employed a Solomon Four-group experimental design incorporating a pre-test measurement for half of the experimental subjects and half of the control subjects. No data collected from the pre-test will be used in the analyses presented in this paper and, therefore, it will not be discussed.

The experimental subjects were required to listen to the on-campus station in their own dorm rooms for at least the four designated one-half hour periods that ran from Monday to Thursday of one week. They were requested to listen and behave during these listening periods as they normally do while listening to the radio. This was done to prevent an inordinate amount of attention on involvement in the radio broadcast, thus keeping the deception and the subjects' behavior as realistic as possible.

The corrective ad was a professionally prepared adaptation from a current Listerine TV commercial that was neither corrective nor deceptive in nature. Although the theme of this ad was not being used on radio at that time, it was eventually extended to this medium after the experiment was completed. The actual Listerine corrective advertising campaign was not aired until data collection had been completed. The corrective message was placed near the middle of three of the four half-hour test periods. This was done to help disguise the true nature of the study. Commercials for other products and services were also aired during the test sessions.

Upon completion of the experimental treatments, the subjects were requested to go to the radio station's office to fill out a questionnaire concerning their feelings and attitudes toward their listening experiences. All respondents were required to report to the station within 11 to 13 days of their last experimental exposure. This spacing of the exposure from the data gathering was done to reduce demand and to lower sensitization to the experimental treatment as well as provide a more realistic measure of advertising recall.

²The data reported in this study are part of a more detailed investigation into the effect of corrective advertising. For a more complete discussion of the methodology see Mizerski, Allison and Calvert 1980.

The post-test questionnaire consisted of demographic data, opinions and attitudes toward the radio station's programming, and attitudes and beliefs toward commercial products. There were twenty-four belief statements, four each for a brand of beer, a local audio store, the University bookstore, a brand of toothpaste, a brand of soap, and Listerine. All belief statements were presented with a seven-point horizontal scale ranging from how "unlikely" to "likely" the belief statement represented the respondent's feelings about the product or service. The belief statements for Listerine were:

1. Listerine is effective for killing germs.
2. Listerine leaves mouth feeling refreshed.
3. Listerine fights colds and sore throats (target belief of the corrective advertisement).
4. Listerine has long lasting effects.

Perceptions of honesty for Listerine and the other product/service manufacturers were measured on a seven-point horizontal belief statement ranging from "likely" to "unlikely" while the seven-point affect/attitude measure for each product/service had scale labels of "like" to "dislike." Purchase intention as based on a 0% to 100% probability the respondent would buy the particular brand of product/service the next time the need to purchase that type of product/service arose.

Upon completion of the questionnaire, each experimental subject was interviewed by one of the investigators. They were first asked for any general comments and suggestions about the radio station. Unaided recall for all commercials and advertisements was then elicited followed by aided recall of any ads not mentioned under unaided recall. Finally, the subjects were asked what they thought to be the true nature and intent of the study. All respondents thought the sole intention was a programming study for the campus radio station without any underlying commercial or other research purpose.

Control subjects received a questionnaire similar to the experimental group questionnaire in both content and structure. All questions pertaining to product/service and demographic information remained the same. Information elicited about the radio station was phrased in terms of their "favorite local radio station."

Upon completion of the data collection, a de-briefing letter was sent to all experimental and control subjects. They were informed of the true nature of the study and that the Listerine ads were test ads, although the corrective statement would be similar once the company began its corrective advertising campaign.

Analyses and Results

Based on the experimental subjects' response to the Listerine ad during the exit interview, respondents were classified as either no recall (N=36), unaided recall (N=11), or aided recall (N=2). For purpose of analysis, unaided and aided recall subjects were grouped together into one recall category (N=13). No subjects who reported recall of the Listerine ad under the aided or unaided condition were able to remember any specific corrective or non-corrective information from the advertisement thus providing a measure of only source or general recall. Due to the self-selective nature of the recall variable, a series of chi-square analyses were computed in order to check for any inherent bias between people who could recall the Listerine ad and those who could not recall the ad. No differences between recall groups were found for product usage (three levels:

nonuser, regular Listerine user, and regular other brand user), sex, class standing, age, ethnic origin or experimental grouping (pre-test vs. no pre-test group of the Solomon Four group design). These data suggest that there was no previous bias in the two groups that would affect their processing of a corrective advertisement (Table I).

TABLE I
Chi Square Analyses

Variable	χ^2	p.
Product Usage	0.77	0.68
Sex	0.00	1.00
Class Standing	2.49	0.65
Age	2.25	0.69
Ethnic Origin	0.01	0.96
Experimental Grouping	2.25	0.14

TABLE II
Analyses of Variance for Belief Variables

Variable	Group Means			F	p.
	Recall	No Recall	Control		
Belief 1 - Kills germs	5.17	4.69	5.10	.747	.48
Belief 2 - Leaves mouth refreshed	5.67	4.83	4.66	1.75	.18
Belief 3 - Fights colds and sore throats	2.29	3.86	4.61	4.17	.02
Belief 4 - Long lasting effects	4.67	4.22	4.44	.412	.66
Honesty of Manufacturer	4.83	4.77	4.50	.49	.61
Overall effect/attitude	4.75	4.00	4.00	.90	.41

Weighted one-way analyses of variance to adjust for unequal cell sizes were computed to test all hypotheses (Winer 1971, Nie, et. al, 1975). These data are presented in Table II. The only variable for which significant differences existed between recall, no recall, and control subjects was the target belief of "fights colds and sore throats," thus supporting all four hypotheses. In order to investigate whether significant differences existed between groups, a Scheffe test was performed on the third belief variable. The Scheffe test, which is an appropriate statistic to use for unequal cell sizes, is a strict or conservative post-hoc test. In order to report statistical significance, differences have to be rather substantial (Nie, et. al. 1975, Kerlinger 1973). At the $P < .05$ alpha level, the Scheffe procedure found the recall group subjects to be different from both the no recall and the control group subjects, and the no recall group to be equal to the control group.

Summary, Conclusions and Implications

Multiple exposures to an actual corrective radio advertisement had significant influence on lowering recall subjects' target belief of "fights colds and sore throats" while those subjects who did not recall the corrective ad were not effected by the experimental manipulation. No

differences between recall, no recall, and control subjects were found for any non-target beliefs, perception of honesty, or affect/attitude toward Listerine. It appears that corrective advertising can be effective for removing or negating false beliefs formed and developed by deceptive advertising without affecting other beliefs and attitudes about the product. This appears true when the consumer is able to report or recall the ad, but can occur without awareness or recall of the specific corrective information presented in the communication.

Limited external validity of these data exists due to the product and brand studies, the student sample, and the procedure and the incentives used to induce cooperation and to elicit cognitive responses. Nonetheless, the validity of these findings and significance are enhanced by the field experimental nature of this study as opposed to the laboratory settings of all other empirical research assessing the impact and effectiveness of corrective advertising. At this point, it appears that corrective advertising, as it is implemented in the Listerine case, is capable of removing a false belief without harming the offending advertiser or its competition if the consumer has had sufficient exposure and cognitive activity to develop recall of the message. Such data should be useful to policy makers in guiding future enforcement of corrective advertising in terms of amount and endurance of the corrective advertising campaign.

AN EXPERIMENTAL STUDY OF THE EFFECTS
OF COMMERCIAL TV ADVERTISING AND PRO-CONSUMER
PRODUCT TEST RESULTS ON TV

Emmanuel J. Chéron, Université du Québec, Rimouski
Jean Perrien, Université de Sherbrooke, Québec

Abstract

The relative effect of commercial TV advertising was experimentally tested in comparison with pro-consumer TV program giving product test results. The experiment involved 125 consumers who were on a shopping trip to a local store. Subjects who volunteered were asked to view a 10 minute videotape arrangement and to complete a short questionnaire. Product brand evaluation and intention to buy were the two main dependent variables. Results indicated that pro-consumer TV program had greater influence than commercial advertising. Significant interaction effects were also observed between the two sources of communication.

Introduction

With the ever increasing influence of consumerism, the Canadian Broadcasting Corporation (C.B.C.) recently sponsored a new type of TV program designed to present test results on various products and inform consumers about their rights. This new form of communication to consumers has been an immediate success as audience figures indicated as high ratings for this program as for the most popular series. The present research is designed to test the effects of this new source of communication on consumers in contrast with traditional commercial advertising.

Background

Previous research on persuasive communication has focused on influence of source credibility (Hovland 1952), learning without involvement (Krugman 1965) and various types of effects (message, presentation, communicator, audience and risk level) as studied by Levitt (1965) in the context of industrial selling. The nature of these studies was to test identical messages from different sources with similar audiences. Although the Levitt study manipulated the quality of message presentation and type of audience, sources of communication were in fact identical in message content and all under control of the marketer. As stated by Levitt: "In commercial communications particularly, no two sources selling the same product to the same audience are ever likely to employ the same message".

A research by Hempel (1966) tested the effects of printed pro-consumer information such as Consumer Reports against a tape recorded commercial sales presentation. The product involved in the study were two brands of men's white dress shirts. Respondents were college students and results indicated that Consumer Reports effects were greater than the commercial sales presentation. Contrary to expectation, no significant interaction was observed between the two sources of communication. The nature of the respondents and product (low ego-involvement) imposed limitations to the validity of the experiment, further, sources of communication differed as to their form (printed and verbal tape recorded). More validity could have been attained with a printed commercial advertising rather than a tape recording of a salesman.

Recent studies (Settle and Golden 1974, Smith and Hunt 1978) have linked the effects of commercial communication

and attribution theory. These studies tended to focus on the processes by which individual perceive and explain causal relationships and give meaning to events. Hence these studies indicated that the effect of commercial communication was greater when product claims were not all favorable. The notion of causal schemata (Kelley 1971) introduced the idea of causal inference by which individuals explain their own behavior or that of others. Individuals tend to interpret the situation (the communication) in terms of intrinsic or extrinsic factors. This process has a direct effect on inferences made by the individual about communicators' intentions. When a behavior is perceived as being caused by an external factor such as a proper payment from an advertising agency, it is most likely that there will be less confidence in the communication. However if the behavior is perceived under the influence of internal factors controlled by the actor, there is probably more confidence in the presentation.

The objective of the present research was to assess the relationships among the effects of two impersonal communication sources on consumer product brand evaluation and intention to buy. From the consumer perspective, information on products is available through personal (sales presentations, personal contacts, friends) and impersonal sources (advertising, product test results, editorials). The study was intended to experimentally compare a pro-consumer TV broadcast and commercial TV advertising both prepared on video-tapes. The design of the experiment was adapted from Hempel (1966).

Problems

This study concerns the relative effect on consumers of commercial TV information as compared with product test results such as given by consumer protection broadcasts.

More precisely, a controlled experiment was designed to answer such questions as: How do consumers react to information sources? How information sources influence product evaluation and brand choice? Does the effect of information sources vary with demographic and socioeconomic differences?

For the business community, the impact of product test results on TV may be of much consequence. Previous research by Perrien and Chéron (1979) indicated a large audience familiarity with such a program (75.3% of the respondents on an unaided recall). Further, the audience was not restricted to a socially advantaged group of consumers. Hence, if present, the effect of such information will involve more consumers than was the case with pro-consumer printed information. Following a test comparison on TV, businesses could have a strong incentive to adjust their advertising strategies and marketing mix. Facing a favorable test result, the seller could anticipate increasing demand and should adjust inventories, physical distribution arrangements and/or other marketing-mix elements. In presence of unfavorable test result, the seller could consider various advertising and/or other marketing-mix strategies to counterbalance a probable negative effect on demand.

Hypotheses

Formally, the following hypotheses were tested:

- H1 - Pro-consumer TV broadcast information on product test results will have greater influence on product evaluation and intention to buy than a similar commercial TV advertising.

The study by Hempel (1966) supported this hypothesis, further, attribution theory suggested that when behavior is perceived under control of the actor, there is more confidence in the communication. Results of a previous survey (Perrien and Chéron 1979) indicated high confidence of respondents (mean score of 5.32 on a seven point scale) in the independent nature of information as given by pro-consumer TV programs.

- H2 - There will be significant interaction between the effects of the two sources of information. The influence of one source of information will depend upon the other source of information to which the respondents is exposed.

Although the previous study (Hempel 1966) expected interaction to be significant, analysis of variance results indicated no significant departure from additivity of effects. With the expected greater influence of product test results over commercial advertising it is likely that product evaluation and intention to buy will be mainly determined by this source of communication and thus presents significant interaction with commercial advertising.

- H3 - The effect of information sources will vary with demographic and socio-economic variables. Since previous research has dealt with homogeneous student subjects, this hypothesis is proposed to explore the issue of different responses with consumers of varying age, marital status, sex and education.

Method

The relative effect of the two sources of information were experimentally tested involving the evaluation of two brands of microwave ovens (high ego-involvement products). Subjects were one hundred and twenty five real consumers who agreed to take part in an experiment on consumption while on a shopping trip to a local food and hardware store. Arrangements were made with the store manager to reserve an enclosed area with twenty seats where videotape viewing could be organized. About one out of four consumers accepted to participate, coffee and cookies were served until about fifteen consumers were recruited for each of the nine parts of the experiment.

The experiment consisted of videotape arrangements showing typically:

- 1 - A commercial TV advertising for one or two fictive brands of microwave oven (TORIKO or CGX).
- 2 - A short cartoon unrelated with the topic.
- 3 - A TV product-test as given by pro-consumer TV broadcast comparing the two fictive brands of microwave oven and favoring brand TORIKO or CGX.

Special care was involved in the preparation of the communication messages. The commercial TV advertising was of the testimonial type showing two "slices of life" scenes involving a career woman, and a secretary. Motive to use microwave oven were time, money saving and safety. Form and contents of this commercial were based on an analysis of various advertising materials for different brands of

microwave ovens. Production of the commercial was done by the audio-visual department at a major university and TV product test results were prepared with participation of the host of the C.B.C. TV broadcast.

Comparison of the two microwave ovens were presented on criteria such as protection against radiation, efficiency, oven design, price and overall test result was given favoring one of the two brands. This set of criteria was based on real tests presented in an issue of the "Canadian Consumer". Therefore, both types of messages would be regarded as externally valid.

Communication messages were tested with fifteen adult consumers. Subjects were recruited through the local boy-scout organization in exchange for a donation. Comparison of two brands of microwave ovens was presented as the object of the experiment and participants were given a questionnaire to fill in at the end of the viewing. Questions were asked on product brand evaluation, intention to buy, demographic and socioeconomic characteristics and overall impression and comments about the objective of the experiment. Comments indicated that respondents felt they were in a real situation and two out of fifteen indicated that the objective of the experiment was to measure the effect of the C.B.C. TV broadcast. One respondent suspected the objective of the experiment was to measure the influence of advertising.

In the store, consumers were randomly assigned to one of the nine combination treatments shown on figure 1.

FIGURE 1

Experimental design

Product-test results Commercial advertising	Product-test results		
	No-message	TORIKO brandname	CGX brandname
No-message	1 T_0CGX_0	4 T_0T_{TR}	7 T_0CGX_{TR}
TORIKO brandname	2 $T_{AD}CGX_0$	5 $T_{AD}T_{TR}$	8 $T_{AD}CGX_{TR}$
CGX brandname	3 $CGX_{AD}CGX_0$	6 $CGX_{AD}T_{TR}$	9 $CGX_{AD}CGX_{TR}$

As indicated, consumers might be exposed to each of nine combinations of no-message, test results and commercial advertising supporting either one or the other of the two brands of microwave ovens. In the "no-message" situation, subjects were only shown a slide presenting a microwave oven of the appropriate brand (T_0 or CGX_0 or both). Commercial advertising was of the testimonial type as mentioned above, contents of the two commercials were identical except for the brand name of the microwave oven. Product test results, as presented by the host of the program, were also identical in contents except for the winning brand name. For example, subjects assigned to cell $CGX_{AD}T_{TR}$ would be exposed to a commercial advertising favoring brand CGX and a product test result supporting brand TORIKO.

Presentation of a short cartoon between the advertising exposure and the test result contributed to add realism to the situation. All nine treatment cells were prepared beforehand on videotape so that presentation to subjects could be made on color TV screen without loss of continuity. The fact that some respondents were accompanied by

children added a source of distraction more conform to the real TV viewing situation.

Following the exposure, each respondent completed a questionnaire designed to measure product brand evaluation and intention to buy. Other information requested were: ownership of a microwave oven, viewing and frequency of viewing test results on TV and demographic and socio-economic data. The dependent variables of the experiment were the subject's brand evaluation and intention to buy recorded on a seven-point bipolar rating scale with one of the two brands at each end of the scale.

Results

Frequency data on respondents revealed that 117 out of 125 or 93.6% did not own a microwave oven and that 119 or 95.2% had seen product test result broadcasts on TV. These figures indicated a fairly homogeneous group with respect to these variables. Average age of respondents was 30, 60% were married and 57.6% were females.

Results on product evaluation and intention to buy indicated that the experimental treatment produced significant differences among the nine exposure combinations.

The two-way analysis of variance for the effects of the two types of communications on product evaluation and intention to buy is shown in table 1.

TABLE 1

Two-way ANOVA for the effects of the two types of communication messages

	PRODUCT EVALUATION			INTENTION TO BUY	
	D.F.	Mean square	F ratio	Mean square	F ratio
Product test	2	49.210	51.98**	41.90*	37.45**
Commercial	2	3.766	3.95*	3.268	4.81**
Interaction	4	5.525	5.79**	6.354	5.78**
Error	116	.954		1.095	

** Significant at .01 level: $F_{.99}(2,116) = 4.79$; $F_{.99}(4,116) = 3.43$

* Significant at .05 level: $F_{.99}(2,116) = 3.07$

Hypothesis one suggested that pro-consumer test results will have greater influence on product evaluation and intention to buy than commercial advertising. As both message effects were statistically significant a measure called "omega-square" was computed: (Hays cited by Green 1978). This measure allows to estimate the relative importance of each type of message in contributing to variation in product evaluation and intention to buy.

TABLE 2

Hay's omega-square measures

	PRODUCT EVALUATION	INTENTION TO BUY
Product test	0.400*	0.325*
Commercial	0.025*	0.034*
Interaction	0.076*	0.085*
TOTAL	0.499	0.442

* Computed according to: $\omega^2 = \frac{SS_{\text{among}} - (DF_{\text{among}} \times MSE)}{SS_{\text{total}} + MSE}$

Results in table 2 show the relative importance of the message variables on product evaluation and intention to buy. These measures can be roughly interpreted as R^2 in multiple regression. Product test messages account for 40% of the variation in product evaluation while commercial messages and interaction account respectively for 2.3% and 7.6% of the variation in product evaluation.

Overall, 50% of the variation in product evaluation is accounted for by the two message variables. Results for intention to buy indicate a lower relative importance of product test messages than for product evaluation. However relative importance of commercial messages and interaction is higher for intention to buy than for product evaluation.

Overall, relative importance measures for product evaluation and intention to buy support the hypothesis that product test results has greater influence than commercial advertising.

Hypothesis two proposed that there will be significant interaction between the effects of the two sources of information. The analysis of variance in table 1 confirm the presence of statistically significant interaction. Graphically this can be seen on figure 2.

FIGURE 2

Interaction patterns

Diagrams in figure 2 can be interpreted as follow; exposure to a commercial advertising in favor of brand TORIKO and viewing product test results in favor of brand TORIKO yielded a mean score of 1.83 for product evaluation and 1.6 for intention to buy. These scores were derived by taking the absolute difference between cell means and the mid-point on the seven-point scale featuring one brand at each end of the scale. (Overall grand mean of observations in the experiment was equal to mid-point score). Interaction effect is apparent as response functions depart from parallelism (beyond what might be expected by chance).

These results clearly confirm hypothesis two indicating that responses to one source of information will depend upon the other source of information to which the respondent is exposed.

Hypothesis three was exploratory in nature and proposed to test the effect of variations in demographic and socioeconomic variables on product brand evaluation and intention to buy. The effects of marital status, education and age indicated that although the effect of product-test results remained significant, the effect of TV commercial adverti-

sing tended to be less significant (confirming hypothesis one) and interaction was slightly less significant (disconfirming hypothesis two).

An analysis of covariance controlling for age as a concomitant variable resulted in an F ratio of .368 with associated probability of .546 for product evaluation, and an F ratio of .039 with associated probability of .843 for intention to buy. Clearly age was not a significant variable for measuring the effect of the two sources of communication on product evaluation and intention to buy.

The effect of sex as a discriminating variable revealed differences of responses to commercial advertising. Results of the two-way analysis of variance for males and females is shown on table 3 for product brand evaluation.

TABLE 3

Two-way ANOVA for male and female product brand evaluations in response to the two sources of information

	FEMALE RESPONDENTS			MALE RESPONDENTS		
	D.F.	Mean square	F ratio	D.F.	Mean square	F ratio
Product test	2	27.959	27.9**	2	22.750	24.95**
Commercial	2	6.513	6.52**	2	0.051	0.05 ^{NS}
Interaction	4	2.585	2.59*	4	3.291	3.60*
Error	63	.999		43	.912	

** Significant at .01 level: $F_{.99}(2,63) = 4.98$; $F_{.99}(2,43) = 5.13$

* Significant at .05 level: $F_{.95}(4,63) = 2.53$; $F_{.95}(4,43) = 2.61$

NS : Not significant

As can be seen in table 3, the main effect of the commercial advertising is not significant for male respondents. Similar results were obtained with intention to buy, commercial advertising although significant for female respondents was not significant for male respondents. This result confirms the marginal effect of commercial advertising as compared with product test results. As regards interaction, this effect is still significant for both male and female respondents.

Discussion

The overwhelming influence of product test results confirmed hypothesis one with the implications that businesses would be well advised to take this source of information into account for commercial strategy decisions. Relative importance of product test results tended to decrease when consumer decision was closer to the buying act (intention to buy vs product brand evaluation) as shown by omega-square measures in table 2. Previous research (Levitt 1965) indicated similar results. In relatively higher risk situations, the audience tended to discount the highly credible source of information.

Independent variables and interaction tended overall to account for less of the variation in intention to buy (44%) than of the variation in product evaluation (50%). This is consistent with results of a previous survey (Perrien and Chéron 1979) where the effects of product test result programs on TV were measured on the three components of an attitude. Scores on the conative component were lower than on the cognitive and affective components indicating decreasing effects of product test results when consumer decision was closer to action.

The presence of interaction confirming hypothesis two indicated unanticipated patterns of changes. Effects on pro-

duct evaluation and intention to buy tended to be higher when the two sources of information were in favor of two different brands rather than both in favor of the same brand (see figure 2). This situation may be accounted for by a defensive reaction in presence of intense persuasive messages such as observed in previous research (Hempel 1966) and by consumer attributional processes and effects in presence of messages with only positive claims (Smith and Hunt 1978).

Exploration of demographic and socio-economic variables revealed that sex was a discriminating variable for responses to commercial advertising. For male respondents the main effect of commercial advertising was not significant. This difference could be accounted for by the type of product chosen. Previous research (Capon and Burke 1977) indicated that microwave ovens scored high on a perceived risk scale (compared to non-durables lower priced items). These products were thought to be rather high ego-involving and implying a substantial money outlay with likely joint husband and wife buying decision. However microwave ovens are likely to be used more often by women and it is suspected that in the experiment, men had more difficulty to identify to the commercial advertising situation showing scenes involving women. Further research will have to be conducted to clarify this issue.

With respect to interaction, hypothesis three was still confirmed for both men and women. However, unanticipated results of lower product evaluation in presence of the two messages favoring the same brand rather than different brands was the results of male rather than female respondents.

Female respondents tended to show the anticipated pattern, scoring higher on product evaluation when both messages favored the same brand rather than different brands. This result although speculative would be in contradiction with previous research (Krugman 1965). Female respondents were probably more involved, and they were expected to have higher defence reaction than male respondents. However response delays may be too short and real choice situations too distant for such a tentative comment.

Some of this unexpected variation in product evaluation may be accounted for by different connotations associated with the two fictive brand names. In fact, mean cell results indicated larger variations in product evaluation and intention to buy when brand TORIKO rather than brand CGX was involved (see figure 2). In the French Canadian environment, brand name CGX was possibly less appealing to respondents than brand TORIKO.

Conclusion

The effects of commercial TV advertising and pro-consumer product test results on Canadian TV program were experimentally compared.

Findings indicated the great influence of this pro-consumer source of information. Presence of significant interaction with commercial advertising implied that the net effect of the two sources of information will be different from a simple addition of the separate effects of each source of communication.

Not only sources of communication, but message contents, seemed to have different influence on male and female respondents. Further research should investigate whether the extent of ego-involvement with the product is the same for men and women and whether fictive brand names do have different connotations. In spite of these limitations it is felt that the experiment was closer to the real situation than research conducted with student subjects within university walls.

From the seller's point of view, pro-consumer product test results on TV programs introduces a new kind of uncontrollable source of mass communication influencing product evaluation by consumers. Marketers should consider this new variable for the necessary adjustments to their marketing-mix.

From the public policy maker point of view, pro-consumer TV programs giving product test results can be viewed as an efficient means to counter-balance the effect of commercial TV advertising among the wide segment of the population less likely to be reached with printed media.

However, our findings imply that magnitude of communication effects is not easily predictable. Another problem is the relative short-term of these types of communication aggravated by the rapid turnover of brands and products on the market. Communication policy makers with consumer welfare in mind should try to reach an adequate balance between concrete, highly involving product test results and less attractive general consumer education with longer term effect.

INQUIRY RESPONSE RATES, COST AND REVENUE
PER INQUIRY OF REPETITIVE PRINT ADVERTISING

Arch G. Woodside, University of South Carolina

Abstract

How many exposures are enough? Theoretical arguments by Krugman (1972) propose that three exposures may be optimal for remembering broadcast advertising messages. Evidence presented here suggests that two exposures may be best for producing the highest direct inquiry response rates and lowest cost per inquiry from print advertisements.

Introduction

How are costs and revenues affected by repetitive advertising aimed at producing direct response inquiries and sales? Unfortunately, published reports appear to be nonexistent on the costs, number of inquiries, and revenues related to each of repeated insertions of the same advertisement in the same magazine or newspaper.

Simon (1979) has pointed out that recall and attitude measures of advertising are simply proxies for sales, and ultimately they must be related to sales. His analysis of Pomerance and Zielske's (1958; Zielske, 1959) field laboratory study comparing two 13-week media schedules indicated that "the amount of advertising impact (as measured by recall-weeks) is much higher for the every-four-weeks schedule than for the weekly schedule" (Simon 1979, p. 418). Simon noted some "severe" qualifications and criticism of this study including the following two: 1) The data were generated by just one advertising medium, direct mail, and direct mail would not be a likely medium for a staple food product (the product advertised in the study); and 2) A sales measure might show a different sort of response pattern than the recall measure used. Also, a recall measure has a built-in saturation limit (100%) that is not relevant for actual sales purposes.

Ray and his associates (Ray and Sawyer 1971, Swinyard and Ray 1977) report increases in purchase intentions of later versus first and second insertions. In the Swinyard and Ray (1977) study, female household subjects were asked the following question after receiving four direct mailings of appeals for blood donors and Red Cross volunteer workers: "If you were going to volunteer work for one of these organizations, which one would be your first choice? Second choice?" Behavioral intentions were coded as the proportion of respondents rating the Red Cross as first choice among five name social health organizations. Intention to volunteer for the Red Cross increased from 5% to 17.4% to 22.7% from the first to the second to the fourth exposures for the subjects receiving the direct mail appeals.

Information on costs, number of inquiries, and estimated revenues from a print advertising campaign which included multiple insertions of the same advertisement in the same magazines and newspaper is reported in the present article. The immediate objective of the campaign was to maximize the number of direct inquiries with the lowest possible costs. The ultimate objective of the campaign was to produce the greatest possible sales given a fixed advertising budget.

The main purpose of the research was to measure the changes in costs per inquiry (CPI) of several insertions of the same ad in each of several magazines. The same ad was repeated 3 to 13 times in 7 magazines and 1 newspaper.

Assuming a constant cost per advertisement insertion over a campaign, decreases in CPI for the second and third inser-

tions compared to the first insertion were hypothesized. Then CPI was expected to increase for later insertions. Thus, a "U" shaped relationship between CPI and the number of insertions was hypothesized.

What rationales can be provided for the expected increases in the number of inquiries for the second and third insertions compared to the first (and thus decreases in CPI given a constant cost per insertion)? Increases in recall (Swinyard and Ray 1977), and brand awareness (Stewart 1964) for second, third, and later advertisements versus an initial advertisement found in prior research provide one rationale for the hypothesis. The theoretical work of Krugman (1962; 1968; 1972) provides another rationale. Krugman develops a cognitive theory to indicate "why three exposures may be enough" to produce behavior and thus sales.

Method

The media costs, inquiry response rates, and estimated revenues (for repeated insertions in two magazines) were studied for 7 magazines and 1 newspaper which included three or more insertions of the same advertisement. The advertisement was designed to promote a direct response inquiry to receive a "free South Carolina Trip Kit." The advertisement is shown in the exhibit:

South Carolina.
It's a lot of great vacations.

Whatever kind of vacation you're looking for, you'll find it in South Carolina.

And to help you plan your vacation, we'll send you the new South Carolina Trip Kit—free! It'll tell you about things to do and places to stay. And there are maps to show you how to get there once you get here.

Wherever you go in South Carolina, you'll find a lot of great vacations. Just clip the coupon to find out how they can all be yours.

FREE SOUTH CAROLINA TRIP KIT

Name _____
Address _____
City _____
State _____ Zip _____

Mail to South Carolina Division of Tourism,
Room 000, Box 78, Columbia, S. C. 29202

Each advertisement included a unique room number in the address on the coupon to identify the magazine and specific insertion. The number of inquiries was counted per insertion for each magazine. The cost of the advertisement for each insertion was divided by the number of inquiries received, resulting in a CPI.

CPI, similar to CPM (cost per 1,000's of circulation), is often used as a measure for comparing the performances of competing magazines. A recent ad for Sport magazine compares its CPM with the CPM's for Playboy, Popular Mechanics, Popular Science, and five other magazines (Advertising Age 1980, p. 11). Data on CPI are collected by individual advertisers and are often used to answer the following question: Did the magazine or newspaper ("book") offering a low CPM also provide a low CPI in comparison to other books? The implication is that a book promoted as a "good buy" for an ad placement because of its comparatively low CPM may be, in fact, a poor buy because it delivers a comparatively high CPI for the specific ad placed. Also, a book having a comparatively high CPM may be, in fact, a good buy because its CPI is also comparatively low (cf. Woodside and Reid 1974).

Revenue per inquiry (RPI) was estimated for each of multiple insertions for two magazines in the study. A mail questionnaire was sent to samples of inquirers for each insertion six months after nearly all the inquiries were received (in October). The samples were selected systematically from each "room" for each insertion. The questionnaire had 18 questions including questions on visiting South Carolina and expenditures in South Carolina. RPI was computed by first multiplying the total number of inquiries, e.g., 500, by the percent of those survey respondents who visited South Carolina, e.g., 20 percent: $500 \times .20 = 100$. Second, the estimated number of visitors is multiplied by the average expenditure per visitor, e.g., \$30. The result is the estimated total revenue: $100 \times \$30 = \$3,000$. RPI is estimated by dividing the estimated total revenue by the total number of inquiries: $\$3,000 / 500 = \6 .

The average rate of response of questionnaires sent was 50 percent for the eight insertions studied following a second and third mailing of the questionnaire to nonrespondents. (Percentages of visits to South Carolina were not statistically different between respondents from the three mailings for each magazine.)

Results

The hypothesis was partially supported. The CPI declined from the first to the second insertions for 7 of the 8 books as shown in Figures 1 and 2. However, the relationship between CPI and the number of insertions was more "v" shaped than "u" shaped. The CPI was greater for the third insertion compared to the second and to the first insertions for 6 of the 7 books, exhibiting a "v" shaped relationship between CPI and the number of insertions.

The inquiry response rates as percents of circulation are listed in Table 1 for the three insertions in Popular Mechanics. The difference (.02%) in response rates between the January and February insertions is small but meaningful given the large circulation of the magazine. Thus, CPI drops \$0.17 or 5% with a .02% increase in inquiry response rate.

Note that RPI changes in the same direction as CPI for three insertions in Popular Mechanics. The poor evaluation implied by the relatively high CPI of \$4.27 of the March insertion is offset by the relatively high estimated RPI of \$217 for the same insertion.

FIGURE 1
COST PER INQUIRY FOR SEVEN BOOKS

FIGURE 2
PLOT OF CPI AND RPI FOR THIRTEEN INSERTIONS
IN TV GUIDE^a

^aCPI is plotted on the left vertical axis and RPI is plotted on the right vertical axis.

TABLE 1
INQUIRY RESPONSE RATES, COSTS AND REVENUES
FOR THREE INSERTIONS IN POPULAR MECHANICS

Date	Response Rate ^a	CPI	RPI
January	.46%	\$3.26	\$166
February	.48	3.09	157
March	.37	4.27	217

^aCirculation was 1,671,000 for each month.

A total of 13 weekly insertions of the ad was placed in TV-Guide starting on January 6, 1979. The resulting CPI values are shown in Figure 2. Note that a "v" shaped relationship exists for CPI and the first three insertions. CPI increases peaking at \$5.59 for the eighth insertion, and then declines to its lowest point (\$2.29 for the last insertion). These findings suggest a substantial seasonal effect of insertions on CPI. The early January ad may have attracted many inquiries intending to visit South Carolina for the spring season (and famous coastal gardens). The March 31 insertion (the last insertion) may have attracted many inquiries planning summer vacation trips. (State traced data indicate that June, July, and August followed by April are the four months having the greatest percent on nonresident travelers in South Carolina.) Thus, insertions in late February may be expected to have the highest CPI's. Unfortunately, only the limited information shown in Figure 2 is available to support this hypothesis.

Details on the circulation, costs for each ad insertion, and the percent inquiry response rate per insertion are presented in Table 2 for seven books. The percent inquiry response rates for the second compared to the first or third insertions were higher for all the books except Popular Science. The response rate declined for Popular Science from .68% to .50% to .38%. Thus, CPI increased for the second and third insertions in Popular Science since the cost for each ad insertion was constant.

In Table 3, the response rates, CPI, and available RPI are listed for the ad insertions in TV-Guide. Note that RPI continually declines substantially from \$217 to \$133 for the five insertions included in the survey research study. This may suggest that early ad insertions in the campaign may produce greater RPI than later insertions. Unfortunately, the RPI for the last insertion was not estimated to learn if the substantial drop in CPI between insertion 12 and 13 was coupled with a substantial increase in RPI.

TABLE 3
INQUIRY RESPONSE RATES, COSTS AND REVENUES
FOR THIRTEEN INSERTIONS IN TV-GUIDE

Date	Response Rate ^a	CPI	RPI
January 6	.55%	\$2.62	--
January 13	.62	2.35	\$217
January 20	.45	3.25	--
January 27	.37	3.86	--
February 3	.35	4.15	199

February 17	.31	4.66	173
February 24	.26	5.59	--
March 3	.30	4.89	--
March 10	.33	4.43	138
March 17	.34	4.27	--
March 24	.33	4.33	133
March 31	.63	2.29	--

^aCirculation was 4,267,000 for each date.

Discussion

Krugman offers the following thesis as why three exposures may be enough, "campaign effects based on, say, 20 to 30 exposures are only multiples or combinations of what happens in the first few exposures." For television advertising, he believes that the cognitive task presented by the first exposure is dominated by a "what is it?"

TABLE 2
CIRCULATION, AD COST, AND PERCENT INQUIRY RESPONSE RATE FOR REPEATED INSERTIONS

Magazine	Circulation (000)	Cost for Each Ad Insertion	Percent Inquiry Response Rate Per Insertion			
			1	2	3	4
Golf Digest	946	\$3,915	.78	.80	.64	--
Golf Magazine	724	2,840	.76	.80	.51	--

Hamilton Spectator	143	484	1.20	1.29	.94	--

^aThe cost of the first insertion was \$5,426 while the cost for each of the second, third, and fourth insertions was \$6,384.

response - an attempt to define or understand the ad stimulus. The first exposure is likely to cause high recognition scores for the second exposure. The second exposure is likely to be dominated by the evaluative response of "what of it?" where the consumer judges the personal relevance of the now somewhat familiar ad. The third exposure becomes a reminder but also the beginning of disengagement.

Assuming that print advertising requires more consumer involvement than television commercials (cf. Krugman, 1965; Robertson, 1976) might suggest that such learning with involvement requires fewer exposures for optimal effect. Readers have the opportunity to linger and ask what is it?, what of it?, and what should I do about it? In a review of the literature Sawyer and Ward (1979) concluded that "the existing evidence suggests that the audience-controlled input of print advertising may generate more immediate learning and cognitive responses than low involvement "broadcast exposures" (p. 289). Thus, higher involvement in print versus broadcast advertisements is one rationale for the finding that CPI is lowest for the second of three print exposures.

Clearly, more unobtrusive field research is needed than available currently to learn the behavioral effects of repetitive advertising exposures. The results of the reported study support an inverted V-curve relationship between inquiry response rate and exposures, and thus, a V-curve relationship between CPI and exposures given a constant cost per exposure. Further evidence with other products and services (and in tourism advertising) is needed to support or refute this prediction before the conclusion is reached that two exposures may be enough in print media vehicles.

Do the results from the present study really suggest that two exposures are enough? This implication may be inaccurate. Managers may discover that multiple insertions of related but different ads produce the greatest sales returns per advertising dollar. Varying the size of the ad and the use of color might increase the sales impact of multiple exposures. Unfortunately, the investment in research to learn the sales impact of repetitive advertising is no higher than the low levels reported by Stewart in 1964. Stewart's field experiment on repetitive newspaper advertising effects on awareness, attitude, and sales remains the best work available.

CONSUMER RESPONSE TO ADVERTISING:
IMPLICATIONS FOR COPY TESTING AND COPY

Mary Jane Schlinger, University of Illinois, Chicago

Abstract and Introduction

In a 1976 "state of the art" review, Jacoby identified several trends in research on consumer behavior. The first and most important was the attempt to apply and, more significantly, develop theory. Another was the move toward searching for cause-effect relationships. The three papers included in the session titled "Consumer Response to Advertising" exemplify these trends; they are theoretically oriented and search for explanations. There also have practical implications for the development of copytesting research, and it is those implications that are discussed in this overview.

Guilt Arousal

Chingold's paper titled "Guilt Arousing Marketing Communications: An Unexplored Variable" claims that guilt appeals are widely used in advertising and suggests that guilt arousal as persuasive device should be studied. On a broad level, this paper raises the question of how emotions in general relate to consumer responses to advertising.

"Emotion" is one of those hypothetical constructs that fall through the definitional and theoretical cracks in the jigsaw puzzle of psychology. "All experimenters know that emotion is a topic about which there is no agreement...." stated Murray in 1938. Nearly forty years later, Zimbardo and Ruch (1977) point out that psychologists still have failed to develop a precise definition of emotions, which variously are seen as motives, traits, bodily changes, and subjective feelings experienced and reported by the individual.

Lists of emotions, like lists of motives, differ both in length and content. Among those mentioned in the literature are admiration, affection, amusement, anger, anxiety, confidence, disgust, enjoyment, fear, friendliness, frustration, gratitude, guilt, hate, irritation, jealousy, love, passion, pity, pride, shame and surprise (Davitz 1969).

Although psychologists do not agree about what emotions are, there is a substantial body of research on the topic that primarily focuses on: (1) the physiology of emotional arousal; (2) the judgment of emotion in others; and, (3) the negative effects of emotion on behavior and health.

In contrast to the psychologists, consumer behavior researchers tend to have ignored the construct, except for the research on fear appeals. Chingold's paper is interesting because it suggests the possibility and potential usefulness of measuring not only guilt arousal but also a wide range of emotional, nonrational, impressionistic responses to advertising. At the present time, such reactions either are not measured, or the range is limited, e.g., to liking, amusement, empathy and irritation.

With regard to guilt, Chingold's paper prompts three observations. First, it is important to distinguish guilt as an appeal from shame. Guilt arises when the individual goes against his conscience. Shame, on the other hand, occurs when a cultural norm is violated in the presence of a real or imaginary audience. Advertising about ring-around-the collar, bad breath, underarm odor, spots on dishes, smelly carpets, and household dirt seems more likely to threaten the viewer with shame than guilt.

Guilt may be more appropriate and more often used for relatively involving products, such as low tar cigarettes, or for nonprofit and social advertising, such as anti-alcohol abuse campaigns and fund solicitations.

Second, it is a fairly common strategy for advertising to try to allay guilt about using products such as convenience goods. The purpose is to help the consumer avoid or reduce guilt arousal. One typical approach is to suggest or imply that the time saved by using the advertised brand can be devoted to more important matters -- family activities, exercise, and so on. One wonders if the guilt reduction effect of such messages is assessed.

Finally, any discussion of arousing guilt or other negative emotions must consider the moral and ethical implications. Advertising is criticized for manipulating emotions, both positive and negative, when the appeal is seen as exploitive, debasing or insulting. Rokeach (1970) has urged advertisers to avoid promoting products via destructive emotions or beliefs, i.e., negative self-conceptions and primitive fears about rejection, self-worth, self-identity and self-competence.

Celebrity Endorsers

Nearly every advertising textbook includes a typology of commercial executional styles or structural designs such as slice of life, humor, product demonstrations, celebrity endorsers, etc. (Hefzallah and Maloney 1979). The latter design is the subject of the paper by Mowen and Brown: "Effectiveness Measures of Celebrity Endorsers."

It is estimated that from five to ten percent of television commercials feature celebrities (Shimp 1979, McCollum and Spielman 1980). This is a substantial proportion, considering the disadvantages: stars can be expensive and risky for the advertiser both in terms of money and loss of control, i.e., live stars, unlike Tony the Tiger, may get involved in scandal, lose their star status, die, etc. On the other hand, the advantages that celebrities potentially can offer include credibility for the claims, attention value and memorability for the commercials, and prestige and positive affect that may be generalized to the brand.

Recently McCollum and Spielman (1980) analyzed data from hundreds of celebrity commercial tests conducted by the company over the past twelve years. Among their findings: fewer than half of the celebrity endorser commercials scored above product category norms on either clutter awareness or attitude change measures. The implication is that there is another serious risk in using celebrities: the risk that they may not "work."

Given that the use of stars is both common and chancy, it is not surprising that advertisers are keenly interested in finding ways to evaluate their potential effectiveness. Mowen and Brown approach this problem via a study that is theoretically and operationally complicated, i.e., it is based on an integration of Heider's balance theory with Kelley's attribution theory, and the resulting experiment utilizes multiple manipulations and several dependent variables. The fact that the predicted results were not obtained in the experiment may reflect inadequacies or misinterpretation of the theories (cf.

Kiesler, et. al. 1969, Eagly and Himmelfarb 1978, Kelley and Michela 1980) or inadequacies in the research design and execution.

With regard to implications for evaluating and selecting celebrity presenters, Mowen and Brown's study and the few other studies that have been published on the subject suggest that a multifaceted and multiple criteria approach will be required. Among the factors that need to be considered are the celebrity's likeableness, credibility (expertise and trustworthiness), attention value, compatibility with the brand and message, and distinctiveness with respect to endorsing one versus multiple products and brands. There definitely is a need for additional theoretically oriented research on celebrity endorsers, but the research may need to aim at theory building rather than the testing of theories borrowed from other disciplines.

Cognitive Processes

"Linear Effects of Cognitive Response to Advertising" by Percy and Lautman examines reactions to television commercials in an information processing framework. More specifically, it illustrates the practical application to copytesting of a theory, i.e., that cognitive processes mediate affective and conative reactions to advertising, and a measurement technique, i.e., the quantification of cognitive reactions by content analysis of verbatim protocols (cf. Wright 1973, Olson and Muderrisoglu 1979, and Mitchell 1980).

It is common for advertising agencies to utilize nondirected, free elicitation procedures to obtain verbatim protocols from subjects who have viewed an advertisement of commercial. Typical open-ended questions are "what went through your mind as you watched the commercial?" (or looked at the ad) and "Tell me in your own words what the advertisement said and showed." It also is common for the coding or content analysis of such protocols to be simplistic and atheoretical. For example, an analyst might count the number of respondents who: mentioned various executional elements, actions or characteristics; played back messages, stated the brand name, and made evaluative comments about the brand or execution. In copytesting research, the codes and coding procedures usually are not carefully defined, and the reliability is not measured.

In short, the content analysis of open ended verbatims generated from copytests could be, should be and probably will be improved in the future. The paper by Percy and Lautman suggests one approach, i.e., the coding of support arguments. There are, of course, many other analytic possibilities not only for coding of different types of mediating cognitions but also for linguistic analysis and the measurement of nonverbal factors such as voice pitch and response time.

There is an unanswered question about the Percy and Lautman data that is relevant to the implications of the study for copytesting. Respondents were shown a commercial for a well known brand which they had been told to watch very carefully and then asked to relate all of their thoughts while viewing the commercial. The number of support arguments elicited for each respondent was counted, and it was found that as the number of support arguments offered by a respondent increased so did her positive attitude toward the brand and her intention to buy. It is not clear what influence a viewer's prior exposure to advertising, product experience, and pre-existing knowledge, attitude and behavioral intentions with regard to the brand had on her cognitive processing of the commercial and the number of support arguments that she produced. For example, pre-existing favorable intentions to buy may have led both to more support arguments and to a high post-viewing intention to buy rating. If copy testers are to evaluate and

compare advertisements for established brands in a cognitive processing framework, then the influence of prior experience will need to be controlled or sorted out from the influence of the advertisements.

LINEAR EFFECTS IN COGNITIVE RESPONSE TO ADVERTISING

Larry Percy, Creamer Inc.
Martin R. Lautman, Associates for Research in Behavior, Inc.¹

Abstract

This paper presents the results of an exploration of linear effects in cognitive response on cognitive structure. Specifically, elicited cognitive response to advertising stimuli were related to beliefs and purchase intent associated with the advertised product. A strong linear relationship was found between supportive arguing responses and related cognitive structure measures.

Introduction

Interest in the joint cognitive response-cognitive structure model for studying the impact of persuasive communication has grown since its early presentation by Lutz and Swasy (1977). A number of studies have been reported which attempt to link the number of cognitive responses to a communication stimulus (usually in the form of advertising) with a corresponding effect upon elements of cognitive structure. Olson, Toy, and Dover (1978), for example, studying, specifically, five levels of price information, demonstrated a strong relationship between the number of counterarguments and support arguments as related to the amount of information contained in several advertisements. Wilson and Muderrisoglu (1979, 1980) have utilized much the same procedure, applying the model to an analysis of comparative advertising. In each case, strong support for the notion of the number of cognitive responses elicited from an advertising communication stimuli mediating cognitive structure was shown.

All of this research, however, has been concerned with the total or average number of cognitive responses elicited by the communication stimuli. Accepting the basic hypothesis that there is a relationship on the macro level between the number of cognitive responses and the effect upon cognitive structure measures, it is the purpose of this paper to explore beyond the total effect and consider the functional relationship between different magnitudes of cognitive response upon cognitive structure. More specifically, what will be explored is whether respondents exhibiting greater cognitive activity, operationally defined as offering a greater number of cognitive responses, also exhibit a corresponding change in cognitive structure.

Methodology

Selection of Experimental Stimuli and Respondents

The methodology was designed to test the theory of individual intensity in cognitive response by utilizing both specific communication test stimuli as well as the general experience of respondents. The specific experimental stimuli used consisted of two television commercials for a well-known brand of frozen food, with a high positive image. Each commercial featured a variety of products: one with several people featured; one only a couple. In addition, one group of respondents was not exposed to a commercial and was asked only to think about advertising for the product with which they were familiar.

To ensure a realistic response, subjects were carefully screened to be certain only those people who belong to the product's target market, and who had experience with the product category, were included. A total of 300 respondents were interviewed (female household heads, 18+, with family incomes over \$15,000), 100 in each of three widely distributed geographical markets. One-third of the respondents in each market received each of the treatment conditions. Respondents in each city were randomly assigned to treatment cells. Those assigned to the first two cells were exposed to one of two television commercials. Each respondent was exposed independently, and asked to watch the commercial very carefully, learning everything from it that they felt the advertiser wanted them to know. Next, following the general procedure advanced by Greenwald (1968) and discussed by others (cf. Calder, Insko, and Yandell 1974; Wright 1973 and 1974), respondents were asked to relate all of their thoughts while viewing the commercial. Respondents in the third cell were not shown any specific advertising; rather, they were asked for all of the things that came to mind when thinking of looking at or reading advertisements for the product. In all treatment cells thoughts were elicited and recorded one at a time.

After all thoughts were recorded, a series of questions were asked relating to selected cognitive structure measures. Each respondent was asked how likely she would be to buy the product advertised, measured over a five-point Likert type scale; then how strongly she felt the product reflected specific beliefs associated with the advertising, using a seven point balanced attitude scale.

Analytic Plan

Initially, each of the cognitive responses elicited from a respondent were classified in the manner suggested by Wright (1973). Supportive arguments were classified as those thoughts, beyond a simple copy-point playback, which evidenced a favorable reaction to the product, its use, or the belief messages communicated. Counterarguments were those thoughts that were generally directed against the product or its use, and those that refuted message claims. In addition to these critical responses, three other categories were recorded: positive and negative ad-related thoughts which addressed only the executional elements, and neutral statements. Then, rather than averaging the total number of responses elicited for each classification, those respondents offering only one thought within a classification, two thoughts, etc. were grouped. In this way it is possible to preserve the frequency of individual cognitive responses by type of response.

Each of these distributions was compared over the three treatment cells. It was hypothesized that there should be no significant difference in the general distribution of cognitive response between cells, at least for the important supportive and counterarguments, since the two commercial stimuli used had been pre-tested and both communicated the same general message beliefs; and, importantly, these were the same message beliefs generally communicated through the advertising for this brand over the last several years (a campaign which included one of the two commercials tested here). As a result, those respondents not directly stimulated by a specific commercial should nonetheless have exhibited the same, or at least similar general cognitive structures to those exposed to the commercials.

¹¹The authors would like to thank Ms. Carol Farquhar, Northwestern University, for her assistance in designing and analyzing this study.

Incidence of responses were then compared with cognitive structure measures of belief and intention to buy in order to establish whether a linear relationship might mediate cognitive structure.

Results

Table 1 shows the mean number of cognitive responses offered by classification for each treatment cell studied. The high number of supportive arguments vs. other types of cognitive responses is, no doubt, a function of the existing highly positive image of the product.

TABLE 1
SUMMARY OF MEAN NUMBER OF COGNITIVE RESPONSES ELICITED

Classification	Commercial Cell #1	Commercial Cell #2	Non-cued Cell #3	% None
Supportive arguments	2.27	2.12	2.11	11
Counterarguments	0.09	0.09	0.30	86
Positive ad-related	0.50	0.25	0.07	82
Negative ad-related	0.27	0.20	0.01	89
Neutral	1.55	2.11	1.04	27

It is generally accepted (cf. Olson, Toy, and Dover 1978) that positive and negative ad-related responses, as well as neutral responses, do not mediate cognitive structure. For this reason, along with the fact that very few respondents provided positive or negative ad-related responses, only supportive arguments and counterarguments will be analyzed. Furthermore, because of the very low total number of counterarguments elicited, and the fact that 34 of the 41 respondents offering a counterargument gave only one, the statistical analysis will further be restricted to only the supportive arguments.

The distribution of supportive arguments between treatment cells is shown in Table 2. Little difference in either the overall distribution or average number of arguments elicited appears to be in evidence. A chi-square analysis of the distribution indicated no significant difference between the distributions ($X^2 = 4.90$, d.f. = 8, $p > .05$).

TABLE 2
DISTRIBUTION OF SUPPORTIVE ARGUMENTS

Number of Supportive Arguments	Commercial Cell #1	Commercial Cell #2	Non-cued Cell #3
One	19	24	21
Two	33	27	24
Three	23	19	17
Four	8	6	12
Five or more	8	9	9

These results would suggest that there is no significant difference in the general difference in the general distribution of cognitive responses (or at least, in this case, supportive arguments) among treatment cells. Therefore, the subsequent analysis permits us to look at total response over cells where appropriate.

Belief measures for six constructs reflected in the advertising for this product were measured via a seven point attitude differential scale. Mean beliefs averaged over the six constructs for respondents offering one through five or more supportive arguments are shown in Table 3. The one inversion, between three and four supportive arguments was primarily the result of one belief construct--the only one showing low overall belief.

TABLE 3
MEAN BELIEF BY INCIDENCE OF SUPPORTIVE ARGUMENTS

Belief	Incidence of Supportive Arguments				
	1	2	3	4	5+
Belief	2.15 ^a	2.26	2.44	2.38	2.63

^aMean values reflect seven-point differential scale where -3 = very unlikely to believe and +3=very likely to believe. A 3 x 5 ANOVA of this attitudinal data (see Table 4) indicated only Support Arguments to be statistically significant--this the result of a significantly increasing linear trend as shown in Table 3. As the number of support arguments offered by a respondent increased so did his positive attitudinal evaluation of the product.

TABLE 4
ANALYSIS OF VARIANCE FOR ATTITUDINAL DATA

SOURCE	SS	d.f.	MS	F	Sig.
Treatment Cells (T)	17.33	2	8.66	0.56	n.s.
Support Arguments (S)	199.75	4	49.94	3.22	0.04
linear	179.49	1	174.49	11.59	0.01
deviations from linear	20.26	3	6.75	0.44	n.s.
T x S	158.95	8	19.87	1.28	n.s.
Residual	3,995.58	258	15.49		

Finally, the intention to purchase also appears to be strongly mediated by the number of support arguments offered by a subject. Intention did increase linearly, as shown in Table 5.

TABLE 5
INTENTION TO PURCHASE

	Incidence of Supportive Arguments				
	1	2	3	4	5+
	3.86	4.02	4.08	4.15	4.42

^aMean values reflect 5-point Likert scale where 5.0 = Definitely buy and 1.0 = Definitely would not buy

An ANOVA of this data indicated that there was a significant difference of this particular measure between treatment cells, this was occasioned by a mean purchase intent of 3.84 in Cell 1 (those who saw one of the commercials) vs. 4.04 and 4.06 (among those seeing the second commercial and those seeing no commercial, respectively). One commercial was less effective than either the other commercial or the control in generating purchase interest. However, there was no interaction between this difference and the number of support arguments elicited; and, there was a significant linear trend in support arguments, as indicated in Table 6. As the number of support arguments offered by an individual respondent increased so did her interest in buying the product.

T x S	6.51	8	0.81	0.99	n.s.
Residual	211.24	258	0.82		

Discussion

The results here indicate that there is a strong reason to suspect a linear effect mediating the relationship between cognitive response and cognitive structure. Overall belief increased with the number of support arguments offered, as did intention to purchase. Because of the high positive image nature of the product involved, one is tempted to believe these results are even more significant. Since both belief and interest are already high, to stimulate even greater interest as a function of advertising based cognitive response is surprising. Unfortunately, owing to that same high positive image, linear effects among counterarguments could not be tested because of sample size limitations. However, the trends, at least for purchase intent, suggested the predicted linear functional relationship. That is, more counterarguments resulted in lower purchase interest.

It is reasonable to predict that a similar linear relationship might be observed for products with less positive images. Here, however, one is equally likely to suspect that the quality of support arguments, not only their existence and frequency, might be of significance.

The elicitation measure used in this study differs considerably from that commonly employed in pretesting and on-air testing of advertising. Most typically, tabulations are obtained of the percentage of respondents recalling various messages. Occasionally, responses are tabulated by type of response (ad-related, sales point related, etc.). Rarely, if ever, is a coding scheme employing cognitive response categories used. Yet, the data presented here strongly suggest that the mean number of responses within cognitive response categories (a "recall-type" measure) may be a significant correlate of a motivational construct -- purchase interest. Whether these responses must be precursors of shifts in purchase interest, however, remains a critical question.

The findings of this study suggest that segmentation of groups by number of responses might reveal if there is a critical number of support arguments correlated with purchase interest; and/or, if any specific arguments or combinations of support arguments are integral to promoting purchase interest, given that the critical number of responses have been elicited. Additional commercial tests (with larger samples) would be necessary to explore these questions.

ON EXPLAINING AND PREDICTING THE
EFFECTIVENESS OF CELEBRITY ENDORSERS

John C. Mowen, Oklahoma State University
Stephen W. Brown, Arizona State University

Abstract

Consumer behavior scholars and advertising practitioners are devoting increased attention to promotional endorsements. Building upon two theories from social psychology, balance theory and attribution theory, this paper examines a new approach to explaining and predicting endorser effectiveness. More specifically, the results are presented of an experiment investigating consumers' perceptions of endorsers who promote multiple versus single products and of products promoted by multiple versus single endorsers.

Introduction

Celebrity endorsers are regularly used to promote an endless list of products, including credit cards, automobiles, headache remedies, beer, and diet programs. A number of factors have been mentioned as important in using endorsers, such as the endorser's personal qualities--reputation, believability, likeability, etc. (Nelson 1974). With the large number of products endorsed by celebrities, a natural outcome is that some celebrities endorse a number of products, e.g., Jack Nicklaus, Joe Namath. However, as noted in a monograph published by the advertising firm, Foote, Cone, and Belding (1978), care should be exercised to select an endorser not tarnished by the association with other products. Of course, "virgin" endorsers tend to be highly expensive, leading to one practical question. Does the endorsement of multiple products indeed tarnish a celebrity's effectiveness? A second practical consideration involves whether or not to use multiple endorsers, such as in advertisements for Miller's Lite Beer and American Express Credit Cards. Are there advantages in having a number of different endorsers recommend a product to offset the cost of such an approach?

As proposed previously by Mowen, Brown, and Schulman (1979) a general communications model, based upon the integration of balance theory (Heider 1958) and attribution theory (Kelley 1967) can be used to analyze factors affecting the effectiveness of product endorsers. In the Mowen, et al. study, balance theory was used to define the relationships among the triad of cognitive elements of consumer (C), endorser (E), and product (P). According to the analysis, the consumer's perceptions of an endorser and a product represent sentiment or affective relations. The relationship between the endorser and the product represents a unit connection, or a perception by the consumer of the extent with which the endorser is associated or bonded with the product. Based upon the cognitive consistency analysis, an endorser will be maximally effective when both a strong sentiment relationship exists between the consumer and the endorser, and a strong unit relationship exists between the endorser and the product. With the development of strong positive sentiment and unit relations, the consistency forces are hypothesized to cause the consumer to cognitively reorganize the weaker consumer-product (C-P) relation so as to perceive the product more favorably (Abelson and Rosenberg 1958).

The extensive literature on communicator effects (Cohen 1964, Simons, Berkowitz, and Moyer 1979, Sternthal, Phillips, and Dholakia 1978) adequately details the factors influencing the consumer-endorser (C-E) sentiment relation.

However, surprisingly little attention has been devoted to delineating the nature of unit relations in general and the relation between an endorser and a product in particular. Following the suggestions of Mowen (In Press), Mowen, et al. (1979) investigated the application of attribution theory (Kelley, 1967) as a method of analyzing the unit connection between endorser and product.

From an attribution theory perspective, consumers may be conceptualized as seeking to determine the causal reasons for a celebrity endorsing a product. The question is, does the celebrity endorse the product because of his or her belief in its positive characteristics or because of external factors, such as monetary incentives? To the extent that consumers perceive that the endorser really believes in the product, the unit connection between endorser and product (the E-P relation) is hypothesized to be strengthened.

The use of attribution theory as an approach for understanding the nature of the unit connection is new. Despite the proposition's novelty, however, several factors suggest its application. First, the concept of association, delineated by Heider (1958) to describe the nature of the unit connection, is generally considered to be one of the fundamental elements in determining causality. Attribution theory was developed to predict individuals' perceptions of social causality. Therefore, it makes conceptual sense to use attribution theory as an approach to specify the nature of the unit connection. Second, that attribution theory and balance theory may be related should not be surprising for both were analyzed first by Heider in his seminal (1958) work.

To analyze the factors potentially influencing consumer perceptions of the E-P relation, one may utilize Kelley's (1967) attributional approach for individuals having multiple observations of an endorser's actions. Kelley argued that in circumstances in which an observer has multiple observations, three sets of attributional cues are utilized to establish causality--distinctiveness, consistency, and consensus. In an advertising context, distinctiveness refers to the extent that the endorsement occurs uniquely in the presence of the product. If a celebrity endorses several products, the relation between himself and a particular product is not distinctive, leading to an inference that the nature of the particular product was not the reason for endorsement. Thus, attribution theorists tend to agree with some professional advertisers, i.e., that endorsers can become tarnished by endorsing multiple products (Foote, Cone, Belding 1978). Consistency deals with the relationship between endorser and product over time and modality. High consistency will strengthen the perceived E-P bond. For this to occur, the endorser should advocate the product over a variety of media in a long running campaign. The third criteria, consensus, concerns the consumer's perception of whether other individuals view the product similarly to the endorser. To the extent which friends, reference others, or possibly other endorsers support the product, the consumer will perceive the message to result from the nature of the product rather than from situational factors such as a payment for services. Thus, by using multiple endorsers, advertisers may be effectively utilizing the concept of consensus.

Utilizing George C. Scott, Steve McQueen, and Paul Newman as endorsers of a fictitious television set, Mowen et al. (1979) manipulated distinctiveness and consensus information available to subjects. Distinctiveness was varied by informing subjects that the endorsers had signed contracts to endorse only one product--a new television set (high distinctiveness) or the television and four additional products (low distinctiveness). Consensus was varied by depicting the fictitious company as signing only one individual to endorse the product (low consensus) or signing six celebrities to endorse the television set (high consensus).

The results of the study supported neither the balance nor the attribution theory analyses. First, the manipulation of consensus and distinctiveness information failed to influence consumer perceptions of the causality for the endorsement (the endorser-product connection), thereby, not supporting the attributional analysis. With the lack of variations in the unit connections, according to the balance analysis, one would not expect the manipulations to influence the perception of the product. In addition, several complex interactions were found involving consensus information, distinctiveness information as well as the age of the consumer. Such interactions were also not supportive of the balance analysis.

The research presented in this paper conceptually replicates the Mowen et al. (1979) research. However, two important modifications were made. First, a new product was selected for endorsement. Consumers saw a storyboard of an advertisement for a fictitious new ball point pen--the "Easy Writer." Utilizing a television set as the product in the previous experiment could have resulted in consumers perceiving risk in allowing an advertisement to influence their perceptions of a relatively costly consumer good. Furthermore, in the earlier study, the actors (Newman, McQueen, and Scott) may not have been perceived by consumers to have much relevancy to a television set. By developing advertising copy in which the endorser discussed using the pen to sign autographs, it was hoped that greater relevancy would be established. A second modification in the present study was the addition of conditions in which the endorser was said to have signed contracts to endorse products normally used by higher social status individuals. In the earlier study, the products were relatively low status--motorcycles, cigars, cologne, and rums. In the present study, higher status products were utilized (i.e., Hilton Hotels, Chivas Regal Scotch, and Mercedes Benz Automobiles) as well as the lower social status products.

The experiment emerging from these considerations was developed as a 3x3, full factorial, between subjects design. The three levels of distinctiveness were: high distinctiveness (the celebrity endorsed only the pen), low distinctiveness-low social status product, and low distinctiveness-high social status product. The three levels of consensus information were: low (no others endorsed the pen), high consensus-celebrity (Steve McQueen also endorsed the pen), and high consensus-student (a student also endorsed the pen).

Method

Procedure

Ninety-nine individuals of both sexes served as subjects. Subjects were students interviewed in their dorm rooms at a large midwestern university. Students were selected as subjects for two reasons. First, students are a primary target market for producers of ball point pens. Second, the use of a relatively young, homogeneous population allowed a more precise test of our hypotheses. In previous research, Mowen et al. (1979) found interactions between age and the variables of consensus and distinctiveness.

In order to test for other possible explanations for the results of the Mowen et al. (1979) study, it was important to hold age relatively constant in order to avoid a larger, more cumbersome experimental design.

Subjects were approached in their dorm rooms by a same sexed experimenter. The experimenter would briefly state that a new advertising campaign was being tested, and ask if they could help out. All subjects agreed to help and were then handed an experimental booklet. On the first page subjects read:

We are interested in obtaining your opinions concerning a particular test advertisement. You will be shown an advertisement and then asked several questions concerning your reaction to the ad and to the particular product described in the ad.

One important point to remember: since this is a test advertisement, it is presently in rough draft form. We ask that you keep in mind the fact that if this ad were to appear in a magazine, it would be in color and professionally laid out. Everything else, however, would remain exactly as you see it. Do you have any questions?

On the second page of the experimental booklet, subjects read material which was labeled background information. The experimenter explained that since the subject was receiving only a draft of the proposed magazine ad, he or she should get additional information. All subjects read the same first paragraph:

This advertising campaign has a total budget of \$1,200,000. The "Easy Writer" will be distributed in all 50 states and in ten foreign countries through better stationery and department stores.

Subjects then read that Paul Newman had signed a two-year contract to endorse the pen. Next, the manipulation of distinctiveness was made. In the high distinctiveness condition subjects read that "Paul Newman has refused to endorse any products other than the "Easy Writer". In the low distinctiveness, low status conditions, subjects read: "Paul Newman has also signed contracts to endorse Puerto Rican Rums, Grendiers Cigars, Yamaha X5650 motorcycles, and Brut Aftershave Cologne." In the low distinctiveness, high status conditions, subjects read: "Paul Newman has also signed contracts to endorse Hilton Hotels, Mercedes Benz Automobiles, Chivas Regal Scotch, and Botany 500 suits."

Subjects were next shown the 11 x 14 inch storyboards. The manner in which the storyboards were shown constituted the manipulation of consumer information. In low consensus conditions, subjects saw only one storyboard having a large photograph of Paul Newman on it. To the side of the photograph, the below standard endorsement was printed:

PAUL NEWMAN does. Why?

"I've signed a lot of autographs during my career. But whether I'm signing autographs or writing a check or letter, I require a superior writing instrument. And Easy Writer is very definitely a superior writing instrument."

Your Easy Writer will never skip, never stick. It is so well engineered, that it can't leak or blot, either on your fingers or on your paper. The Easy Writer flows with such ease and comfort that it actually lessens writing fatigue.

And since it's refillable, you can expect to sign your name again and again and again.

Ask for the Easy Writer in any good art, stationery or college bookstore.

In the "high consensus-celebrity" conditions, subjects saw the Paul Newman storyboard and in addition saw storyboards with pictures of Steve McQueen and George C. Scott. The same standard endorsement was printed for each of the celebrities. In the high consensus, average person conditions, subjects saw the Paul Newman storyboard plus two storyboards, each having a different picture of two male college students. To the right of the photo of the student with pen in his hand, the copy was placed.

STEVE SMITH Does. Why?

"Being a college student requires a lot of writing everyday. But whether I'm taking notes, an exam, or writing a check, I require a superior writing instrument. And Easy Writer is very definitely a superior writing instrument."

Your Easy Writer will never skip, never stick. It is so well engineered, that it can't leak or blot, either on your fingers or on your paper. The Easy Writer flows with such ease and comfort that it actually lessens writing fatigue.

And since it's refillable, you can expect to sign your name again and again and again.

Ask for the Easy Writer in any good art, stationery or college bookstore.

Dependent Variables

Eleven dependent variables were taken assessing subjects' impressions of the product, the advertisement, and the major celebrity endorser--Paul Newman. Concerning the product, subjects were asked: "How favorable an opinion do you have of the Easy Writer?", and "If you were in the market for a pen, would you buy the Easy Writer?" Concerning the advertisement, subjects were asked, "What is your overall reaction to the advertisement?" In addition, subjects rated the advertisement on a series of five semantic differential scales: interesting-dull, appealing-unappealing, believable-unbelievable, informative-uninformative, and eye-catching-not eye-catching. Concerning their impression of Paul Newman, subjects were asked: "Is Paul Newman doing the advertisement solely for the money or because he really believes in the Easy Writer?", "To what extent does Paul Newman believe in the Easy Writer?", "How likeable is Paul Newman?" and "How much do you trust Paul Newman?" All dependent measures were assessed on seven point scales anchored with appropriate descriptors. (Lower scale values indicate a more positive impression.)

Results

Subjects' perceptions of Paul Newman were analyzed first. For the question asking subjects to indicate their liking for the actor, one significant main effect was found for the consensus variable, $F(2,90) = 3.03, p < .055$. The pattern of means revealed that subjects liked Newman most when the student endorsers were also shown ($M = 1.45$) and liked Newman less when his endorsement appeared alone or in conjunction with Scott and McQueen (M , alone = 2.45; M , celebrity endorsers = 2.64).

On the two questions asking for subjects' reactions to the "Easy Writer Pen", similar effects were found. When asked for their opinion of the pen, $F(2,90) = 4.3, p < .02$ and whether they would buy the pen, $F(2,90) = 3.7, p < .05$, a main effect for distinctiveness occurred. In each case, one finds that subjects reacted more favorably to the pen in high distinctiveness ($M = 2.09$ for opinion and $M = 2.18$

for buying likelihood) than in the two low distinctiveness conditions (Opinion-HSS $M = 2.75$, Opinion-LSS = 2.56; Buy-HSS = 2.85, Buy-LSS = 2.99).

Of the six questions asking subjects to give their impressions of the advertisement, two significant effects were found, each paralleling those found directly above. On the question asking for the subjects' overall reaction to the advertisement, a main effect was found for distinctiveness $F(2,90) = 4.12, p < .02$, revealing that impressions were most favorable in the high distinctiveness conditions. (M high distinctiveness = 2.42, M HSS = 3.12, M LSS = 3.03). Similarly, subjects found the advertisement more interesting in the high distinctiveness conditions (M high distinctiveness = 2.60, M HSS = 3.15, M LSS = 3.15).

On the question asking subjects to indicate the extent which Newman believes in the product, a significant consensus by distinctiveness interaction occurred, $F(4,90) = 2.87, p < .03$. Figure 1 reveals the nature of the interaction. (Table 1 presents the means for all of the dependent variables.) As shown by Figure 1, the interaction resulted from the pattern of the "low distinctiveness-high SS product" conditions diverging substantially from the two remaining distinctiveness conditions. Thus, one finds that in the low distinctiveness-high SS conditions, subjects viewed Paul Newman as believing in the pen in "low consensus" conditions. However, in the "high consensus-celebrity" condition, belief decreases and in the "high consensus-student" conditions, perceptions of his belief drop substantially. This pattern diverges from that of the "low distinctiveness" conditions and "low distinctiveness-low SS" conditions, in which the perceptions of belief increased in the "high consensus-student" conditions. No significant effects were found for the variables assessing subjects trust in Paul Newman. On the question asking whether Newman was doing the advertisement for the money or for the product, a marginally significant interaction occurred, $F(4,90) = 2.13, p < .10$, which generally followed the same pattern as the belief variable.

Discussion

The results of the experiment generally supported the predictions for the effects of distinctiveness information, as derived from attribution theory. When the celebrity endorsed only one product, the product was seen more favorably, individuals indicated a greater interest in buying the product, subjects viewed the advertisement more favorably, and subjects responded more positively to the promotional message. These important distinctiveness effects show the value to an advertiser of establishing an exclusive agreement with a celebrity.

While generally supporting attribution theory, the results for distinctiveness information failed to support the balance theory analysis. According to the analysis, perceptions of the product are hypothesized to change as a result of a highly positive endorser being placed in a unit connection with the product. As such, high distinctiveness information should first influence subjects' perceptions of the connection between endorser and product and their view of the product. (Perception of the unit connection were operationalized as the perception that the endorser believes in the product and that the endorser is doing the endorsement for the product, not for the money). However, these perceptions were not influenced in the same manner by variations in distinctiveness information as were variables assessing perceptions of the product. Therefore, as with the Mowen et al. (1979) study, the balance theory analysis was not supported.

Turning to the results for consensus, significant main effect was found in which subjects liked Newman most when a student endorser also recommended the product.

The student subjects could apparently relate more to Newman when people like themselves (i.e. student actors) were also favorable toward the same product he was endorsing.

A complex pattern emerged in the consensus by distinctiveness interaction for the dependent variable of Newman's belief in the pen. (See Figure 1.) For high status products, Newman's association with the student endorser resulted in lower believability than in other conditions. This result suggests that advertisers should be careful not to associate a celebrity, who typically endorses high status products, in the same advertising campaign in which the "masses" also endorse the same product. In the high distinctiveness condition, a similar pattern of results occurred for the believability measure in consensus and in high consensus, celebrity endorser conditions. Higher believability resulted when Newman endorsed only the pen, and the pen was also endorsed by students. This finding supports both the distinctiveness and consensus predictions and suggests that an "exclusive" celebrity can be effectively used with lay endorsers whose characteristics (e.g. age, occupation) are similar to the target audience.

In the low distinctiveness-low social status conditions, the association of Newman and the students with the pen produced more believability for the celebrity, even when Newman was also endorsing other products. This suggests that even multiple product celebrity endorsers associated with low status products can have relatively high believability if linked with "lay endorsers" similar to the target audience.

The results from the present research differ from the earlier Mowen, et. al. (1979) study. The 1979 study supported neither the balance nor attribution theory analyses. The study reported in this paper, however, provides evidence that distinctiveness information does provide relevant input which consumers utilize in forming or not forming unit connections between the endorser and the product. Nevertheless, the complex interactions involving the types of consensus and distinctiveness information were found. In general, these interactions were not supportive of the theoretical propositions.

Conclusions

The results of this study provide some guidance for marketers, advertisers, and public policy makers. Each group should conduct careful pretesting of promotional messages to assess, a) whether the audience perceives the product more favorable when one versus multiple endorsers are used, b) audience perceptions of both the endorser and of the other products he or she endorses, and c) whether alternative market segments perceive distinctiveness and consensus information differently.

This study's findings provide a clearer answer to the question of whether an integration of balance theory and attribution theory adequately explain the effects of celebrity endorsers than the earlier study by Mowen, Brown, and Schulman (1979). This is not startling since the more recent study benefited from the earlier experience. At this point in time, little evidence exists that balance theory contributes significantly to our understanding of celebrity endorsers. According to the balance analysis, distinctiveness and consensus information are hypothesized to affect first the unit connection between endorser and product. Secondly, the distinctiveness and consensus information affect perceptions of the product. The results in the present study and in the Mowen et al. (1979) research reveal, however, that one consistently finds that distinctiveness and consensus interact to influence the unit connection measure but influence the product ratings in a non-interactive manner. Such results cannot be predicted from the balance theory approach.

The research does indicate greater applicability of concepts derived from attribution theory and in particular the distinctiveness concept. A lack of support exists, however, for predictions based upon the consensus formulation. It may be that in advertising contexts, attempts to create the impression of consensus are doomed to failure. In order for consumers to gain an impression of consensus, it is probably necessary that endorsements appear independent to consumers. That is, the endorsers need to have the appearance that each acted independently of the other and were not "bought off" by the company. However, with consumers increasingly becoming wary of advertisements, the ability to create the impression of the independence of endorsers may be impossible, even if it in fact exists.

Despite the completion of two related studies, additional work is certainly needed on the topic of endorser effectiveness. Such studies could introduce additional product types, new endorsers, non-student subjects, and different operationalizations of distinctiveness, consensus, and consistency information. Further research, including replications with extensions, will help consumer research scholars and communication practitioners better understand and measure endorser effectiveness.

GUILT AROUSING MARKETING COMMUNICATIONS: AN UNEXPLORED VARIABLE¹

Morry Chingold, Pennsylvania State University

Abstract

The relevance of guilt arousing marketing communications is developed and a rationale for investigation proposed. A brief review of the literature and a discussion of the possible inadequacy of related paradigms follows. A "working draft" conceptual model and several individual difference variables believed to be dominant are then presented. Several research questions in the form of broad hypotheses and possible approaches to measurement are offered to guide preliminary research.

Introduction

Advertising and promotion continue to be central topics within the field of marketing for practitioners and researchers alike. One avenue of inquiry has focused upon the use of emotional appeals in persuasion. Past research dealing with emotional appeals in persuasion has been multidisciplinary, attracting the interests not only of the scientific community but of special interest and regulatory agencies in the public sector as well.

As has been the case in most other fields, the bulk of research within marketing has centered upon fear arousing communications and the relationship between the level of fear and subsequent shifts in attitude or behavior. Notwithstanding a stream of research which has spanned three decades, the evidence to date has remained equivocal. This may be due in part to disparities in conceptualization or operationalization (Higbee 1969, Ray and Wilkie 1970, Sternthal and Craig 1974).

Surprisingly, however, much less attention has been afforded other plausible emotional appeals. Roseman (1979) has identified 13 distinct emotions believed to span the affective spectrum and many of these (e.g. anger, hope, guilt) seem well suited to persuasive communications. Within a marketing context, a cursory inspection of advertising themes will probably disclose advertising appeals designed to arouse or exploit a variety of emotional responses. One such emotion may be guilt.

The concept of guilt has long been dominant in such diverse fields as theology, philosophy, and counseling and psychiatry, disciplines in which guilt and guilt arousal are viewed as effective agents of attitude and behavior change (see Schneiders 1967, 1968; Stein 1968). However, it would seem that only marginal effort has been expended in examining the role of guilt in persuasive processes, a field of inquiry central to marketers and marketing theorists.

Research scarcity alone, however, is insufficient cause to merit investigation of guilt arousing communications. Preliminary interest could focus on differences existing between guilt arousing communications and other persuasive communications which also use emotional appeals but may differ theoretically, as may be the case with fear appeals.

Another incentive for investigation of guilt arousing communications, albeit less compelling, might be the sheer number of advertisements which appear to have the intention of arousing some degree of guilt in one form or another

(for some possible examples of guilt arousing communications in print media see Time 1980a, 1980b, 1980c). Wheatley and Oshikawa (1970) suggest that advertising practitioners tend to prefer positive appeals over negative or anxiety arousing appeals such as fear or guilt. In light of this preference, an impartial observer might cautiously surmise that at least some advertisers believe negative appeals to be effective for their own purposes considering the vast resources allocated for production and dissemination of these messages.

Although perceived (by the author) to be in fairly widespread use in marketing communications, guilt appeals have thus far not been investigated within the discipline. The lack of conceptualization, theory, and research has prevented greater understanding of this enigmatic marketing variable. This paper, therefore, has three purposes: 1) to introduce a new area of interest, 2) to offer a review of the literature dealing with guilt arousing persuasive communications, and 3) to attempt to conceptualize this construct and suggest research on guilt arousing marketing communications.

Research Overview

The purpose of this section is to follow the course of research which has dealt with guilt arousing communications, a particular form of negative-emotional/anxiety arousing communications. Following sections will attempt to differentiate between guilt and other negative-emotional appeals, of which fear has been singularly predominant, and to begin development of a "first draft" conceptual model.

A major obstacle which has hampered the development of a clear linkage between guilt appeals and research in the area of negative-emotional or anxiety arousing communications has been the concentration of effort in the domain of fear research. Fear appeals research prospered for more than two decades, and clearly has been the preferred negative emotion or anxiety for investigation. This state of affairs has best been exemplified by Leventhal and Tremblay (1968). In their article "Negative Emotions and Persuasion," the authors restricted their experimentation and discussion to fear alone, rather than other plausible negative emotions which may have persuasive potential such as guilt, anger or sorrow. Whether these authors believed that a fear paradigm was sufficient to explain the relationship between all negative emotions and persuasion or that all negative emotions were either interchangeably similar with or a subset of fear remains unclear. Perhaps in light of the absence of competing paradigms for other emotions or anxieties their approach was totally appropriate. It should, however, have signaled the need for conceptualization and research in new areas.

Wheatley and Oshikawa (1970) reported on the relationship between anxiety and positive and negative advertising appeals. The authors stated that researchers in the social sciences had compiled evidence sufficient to attest to the power of negative appeals and suggest that advertisers may be overlooking or minimizing an important persuasive tool. Citing past research the authors proposed that "negative communication can be effective in inducing the behavior advocated by the communicator (pg. 85)." Applying a general anxiety reduction drive model, Wheatley and Oshikawa expected that reduction of an aroused anxiety would constitute an effective reinforcement and could lead to conformity with

¹Special thanks to Dr. R. G. Roden and Peter H. Roden, University of Texas Medical Branch, and all my colleagues at Penn State for their help in the preparation of this paper.

a communicator's recommendation. This general model would seem appropriate for a variety of negative emotions or anxieties but as has often been the case only a fear manipulation constituted the negative appeal.

In contrast to many other streams of research, investigation of guilt arousing communications has not evolved through a tradition of theory building. Rather, the emphasis on fear related approaches to research in the areas of anxiety or negative appeals is also evident in the literature on guilt arousal and persuasion. Of the few investigators who have approached the issue of guilt arousing communications, most have seen fit, rightly or wrongly, to graft their research onto existing fear appeal paradigms (Haefner 1956, Zemach 1966, Yinon et al. 1976). So engaged, these researchers could hope for no more than a general level hybrid theory of guilt arousing communications juxtaposed with fear research.

More to the point, attempts at hybrid guilt theory building involved optimally matching empirical findings to existing fear models. The earliest work, by Haefner (1956), involved a manipulation of guilt in two levels, high and low, perhaps in an effort to replicate the "inverse relationship" in fear research reported by Janis and Feshback (1953, 1954). One may interpret Haefner's approach as viewing guilt as a subset or alternate form of fear. Haefner was exploring negative emotional arousal, operationalized as fear and guilt (both of which were significant), then comparing his findings to the earlier Janis and Feshback (1953, 1954) results.

Subsequent investigation of guilt arousing communications reflected changes in the dominant fear paradigm. Zemach (1966) undertook an experimental investigation of the effects of guilt arousing communications, however, the thrust of her research "piggybacked" on fear research. "In view of the paucity of observations and systematic research on guilt arousal, this study was undertaken to investigate whether principles derived from the literature on fear arousing communications might be fruitfully employed in predicting acceptance of recommendations motivated by guilt arousal (pg. 4)." Thus, Zemach's two fundamental hypotheses (the curvilinear "inverse U" relationship between level of guilt arousal and adherence to recommendations, and the dissipation of the differential effects of difference levels of guilt arousal with the lapse of time) were derived from fear research rather than a priori conceptualization. Although both hypotheses were supported, it remains unclear which, if any, theory was supported, the existing fear model or a unique guilt model.

More recently, Yinon et al. (1976) reported an experimental investigation of the effects of guilt arousing communications on acceptance of behavioral recommendations. Citing the competing fear paradigms of Janis (1967) and Leventhal (1970) as evoking "theoretical curiosity of the social psychologists," Yinon et al. sought to test Janis' (1967) contention that the curvilinear "inverse U" model also applied to guilt arousing appeals. Although the curvilinear model was supported, Yinon et al. failed to measure any individual difference variables, as Zemach (1966) had done. As well, Yinon et al. reported operational difficulties in effectively manipulating three levels of guilt, leading to a posteriori collapsing of the design, and casting at least some shadow of doubt on the experimental findings.

Kelman (1979) discussed the relationship between various emotional states and attitude change. Although Kelman (1979) did not specifically address guilt arousing communications, he did propose that guilt, as an emotional response, was among the most likely moral dilemmas to lead to attitude change. Changes in attitude may occur toward the object or issue involved in an action or toward the action itself. Kelman proposed that when justifying an action or making it more acceptable were not available as possible changes in attitude, individuals must confront the dis-

crepancy between their actions and role expectations and "may actually change their attitudes in the direction of more favorable evaluation of the object or issue involved in the action (pg. 74)." Kelman stated that these notions were derived from dissonance theory.

In summary, the paucity of guilt appeal research reported by Zemach (1966) has continued to the present. Clearly a stream of research founded upon three studies conducted over a period of twenty years could not be expected to have nurtured much theory. Rather, that research which has been reported has really been in the domain of fear research. Although one cannot dismiss this approach out of hand, the fact that guilt arousal has not received attention as a unique construct unto itself is disappointing. In light of the differences between guilt and fear to be developed below, this paper seeks to argue in favor of viewing guilt arousing communications as a distinct persuasive mechanism employing an emotional appeal theoretically different than fear. As such, a "first draft" conceptual model specific to guilt arousing communications will be proposed.

Toward a Conceptualization of Guilt Arousing Persuasion

Guilt as a Psychological Construct

As a psychological term, English and English (1976) define guilt as "a realization that one has violated ethical or moral or religious principles, together with a regretful feeling of lessened personal worth on that account." Wolman (1973) added that with the lowering of self esteem or feeling of lessened personal worth also comes a need to make retribution for the transgression. So defined, guilt may be viewed as an a posteriori emotional response which follows a particular action or thought, what Wolman (1973) called the transgression. The need to make retribution may be considered as one possible outcome resulting from a desire to reduce the level of guilt feelings to a more tolerable level, assuming some idiosyncratic threshold had been surpassed.

Unlike most other negative emotions guilt may apply equally to positive and negative outcomes (Roseman 1979). Thus, someone who shoplifts in public but is not apprehended may experience guilt even though the outcome of the act was essentially positive. Roseman maintains that both forms of guilt are phenomenologically, physiologically, and behaviorally alike inasmuch as all "guilty" people have done something "wrong" and can expect to be sanctioned by others.

Fear, in contrast, is more an anticipatory emotional response. Fear is the anxiety brought about by anticipated consequences to particular actions or cognitions, in other words an a priori emotional response. Fear results from the perception of some danger and brings about the goal of avoiding or preventing the threatened outcome. Guilt, on the other hand, arises from the perception that an individual has him/herself committed some injustice and prompts behavior designed to undo or atone for the offense (Roseman 1979). Since guilt is brought about by the actual consequences of behavior and fear is caused by the anticipated consequences of behavior, theoretically the two forms of anxiety should be different. Thus, guilt should be considered as a persuasive construct unto itself.

There is, however, a "fuzzy" area of overlap apparent between these and other forms of anxiety. Situations may arise in which it is unclear which emotion is operative or central when an individual senses "fear of guilt" or "guilt from fear" for example. Whether the response is a priori or a posteriori depends on the interpretation of the situation. "Ring around the collar" may be viewed as a fear appeal, causing one to seek to avoid or prevent this unwanted outcome, or alternatively as a guilt appeal, prompting the launderer to undo or atone for his/her error. The interrelatedness of anxieties or negative emotions is the

cause of the overlap. Roseman (1979) has identified 5 "dimensions" that give rise to emotions and relate discrete emotions to one another in a structural model of affect. Roseman's model of affect can be used to account for perceived similarities among various emotions and predict patterns of co-occurrence and sequential occurrence in complex emotional reactions.

Guilt as Cognitive Dissonance

As noted earlier, Kelman (1979) argued that guilt was a powerful agent in attitude change. Kelman referred to guilt as one of a number of moral dilemmas. In the case of guilt, attitude change would be in the form of retrospective justification for an action in the same manner postulated by dissonance theory (Festinger 1957).

Dissonance theory (Festinger 1957) can easily be adapted to the problem of guilt. Feelings of guilt are, for most individuals, clearly dissonant cognitions creating inconsistency in some cognitive and/or perceptual elements. The two central hypotheses of dissonance theory are 1) the presence of dissonance motivates the individual to reduce it, thereby achieving consonance, and 2) when dissonance is present the individual will avoid situations and behavior which will increase it.

There are some problems, however, in applying dissonance theory to the problem of guilt arousing marketing communications. Firstly, dissonance theory is very broad in nature and has been modified by a number of researchers who have specified particular conditions under which dissonance will or will not occur (Calder 1973). "The real problem has been in tying down the theory. The very looseness which invites creative derivations renders the theory all but impossible to disprove (Calder 1973, pg. 259)." Thus the broad nature of dissonance theory may render it too general to effectively deal with guilt arousing communications at all levels of analysis. Rather, individual responses to guilt appeals represent but a particular form of cognitive dissonance, in much the same way that other anxiety arousing communications and theories of cognitive consistency are related to the general theory of cognitive dissonance.

A second difficulty rests in measurement and operationalization issues. Given the voluminous research in the area of cognitive dissonance, it would seem that there has not been a generally practiced or accepted way of effectively manipulating and measuring varying levels of "aroused" cognitive dissonance, due in part to the abstractness of the construct and in part to its general nature and vagueness since cognitive dissonance can deal with any cognitive elements. In dealing with a particular form of dissonance, such as guilt arousing communications, it may prove easier to variably manipulate the construct and obtain measures of arousal. Clearly measurements in the domain of an anxiety such as guilt cannot achieve perfection, but they may be easier to fashion because of the narrower and better defined boundaries of the construct of interest. (Several possible methods for measuring aroused guilt will be discussed briefly later in the paper.)

If guilt and cognitive dissonance are but similar constructs, and not in fact one and the same, there may be marked differences between an individual's threshold for cognitive dissonance and his/her threshold for aroused guilt, or in the intensity of the individual's drive to return to the desired mental state. Similarly, one might anticipate different resolution strategies for cognitive dissonance and aroused guilt. Although the essential notion is the same, resolving the undesired mental state (dissonance or guilt), the methods available and selected may not be interchangeable or even compatible.

In general, although guilt arousal is a mental state which behaves similarly to the stipulates of dissonance theory, it is unique at the same time. More to the point,

dissonance theory is so broad and malleable that it may be adapted to encompass many diverse phenomena since it is concerned with any and all cognitions. Understanding dissonance theory may be viewed as necessary but not sufficient for understanding guilt. The specificity and particularities involved require that guilt be studied as a separate entity even though clear linkages may be drawn to dissonance theory.

Guilt as Information Processing Conflict

Investigation of guilt appeals may also view aroused guilt as a form of conflict in information processing. Berlyne (1957) described conflict as the result of competing and incompatible response tendencies. Thus, in the case of choosing between a response tendency of self gratification versus altruism, (i.e., dining out instead of renewing one's donation to the Red Cross) the conflict which may subsequently occur may be analogous to guilt. Often, the guilt or conflict may not even be known to exist until aroused, perhaps as by a communication in a marketing context.

Bettman (1979) cites Hansen (1972) and Howard and Sheth (1969) in suggesting that conflict be viewed as an equilibrium model. Individuals would be viewed as having desired optimum levels of conflict, above or below which undesired disequilibrium would occur. As with cognitive dissonance, the notion of conflict represents a form of inconsistency which would lead to a response aimed at its resolution. Kelman and Baron (1968) proposed a framework of alternative modes for resolving inconsistencies, as those created by conflicts, as well as hypotheses concerning the conditions under which the various strategies might be used.

Although guilt is clearly a form of conflict arising from competing response tendencies, a conflict resolution model would seem not to be generalizable to all guilt arousal situations. However, there is some similarity between certain forms of guilt and the special cases of avoidance-avoidance conflicts and approach-avoidance conflicts. The overlaps between guilt and information processing conflict occur, however, only with special cases of each and not as a general principle and the two are not interchangeable since approach-approach conflict is not analogous to guilt. As well, the notion of an equilibrium model for conflict seems somewhat counterintuitive when generalized to guilt. As a rule it would probably be safe to say that few individuals seek to increase their feelings of guilt because their current mental state is too free to guilt. Rather, a threshold effect appears more logical.

As was the case with cognitive dissonance theory, there are clear linkages between conflict in information processing and a conceptualization of guilt arousal in persuasion. However, there also appear to be several clear distinctions, such as the equilibrium effect and inapplicability of positive response tendencies, and it would be inappropriate to assume that information processing conflict and guilt arousal are one and the same phenomenon. Rather, in specific situations and under particular conditions they are quite similar.

In light of the dubious piggybacking on fear research which has occurred in the past, and the apparent inappropriateness of cognitive dissonance and information processing conflict as fully viable theoretical explanations, there is a need for a unique conceptualization concerned with guilt arousal in a persuasive context. A "first draft" of such a paradigm will now be proposed.

A "First Draft" Conceptualization of Guilt Arousing Communications

Given the definition of guilt as a psychological construct noted earlier, several constructs are implied which must be incorporated into a model of guilt appeals. Firstly, a hypothetical mental state of aroused guilt must be assumed

to exist. Implicit in such a construct would be the notion of an idiosyncratic threshold, that level beyond which guilt could no longer be tolerated. Since it is likely that a single communication would elicit varying degrees of aroused guilt in different individuals, the construct mental state of aroused guilt should be mediated by the associated construct susceptibility to guilt arousal, although the abstractness of this construct would make it difficult to distinguish and measure.

Assuming a communication has aroused guilt in an individual beyond the tolerance threshold, but below an intolerance threshold, the next logical construct would refer to the drive mechanism of reducing or resolving the feelings of guilt, an effort to restore moral equilibrium between the individual and his/her environment (Roseman 1979). The drive to reduce undesirable feelings of guilt manifests itself in other more abstract constructs, such as beliefs and/or attitudes in cognitive structure, a desire for additional information (possibly for purposes of bolstering or transcendence), or behavioral intent and ultimate behavior for example. It is likely, however, that another mediating variable will impact upon these abstract constructs, that being the individual's susceptibility to persuasion (which in this instance would be related to susceptibility to guilt arousal).

Given that a marketing communication had been judged to arouse guilt in a message recipient, and the message had been duly attended to, the directionality of the proposed paradigm would be as follows. Dependent upon the individual's susceptibility to guilt arousal, a mental state of aroused guilt would be expected to occur. Should the threshold for aroused guilt be surpassed in the mental state the individual would be expected to enter a drive state intent upon reduction or resolution of the evoked feelings of guilt. This drive might then bring about movement, cognitive or behavioral, to resolve the undesired mental state. A reasonable expectation would be that both the mental state of aroused guilt and subsequent resolution tendencies would be related to the individual's susceptibility to aroused guilt since those more susceptible would likely surpass the hypothesized threshold point sooner than individuals with a similar threshold but less susceptibility to guilt arousal.

Although it may be impossible to compile an exhaustive list of resolution strategies, several dominant ones with direct marketing implications bear consideration. Of interest in a marketing context would be resultant changes in beliefs, attitude or more generally, cognitive structure in the direction advocated by the communication. Such changes would depend on the individual's susceptibility to persuasion in the particular context of the communication. For example, an individual with a large latitude of rejection would likely contrast the communication as being too extreme, possibly demonstrating a polarization of attitude rather than attitude change (Sherif and Hovland 1961, Sherif 1979). Behavioral intent and ultimate behavior are also plausible vehicles for manifestation of resolution strategies, although as above, changes would depend upon susceptibility to persuasion, which in the case of guilt appeals would in turn depend upon susceptibility to guilt arousal. A further resolution strategy of consequence for marketers could be a desire for additional information, perhaps as a prelude to reevaluation and subsequent attitudinal or behavioral change.

Similar to models of cognitive dissonance, the proposed paradigm is essentially a threshold model for the hypothetical construct representing the mental state of aroused guilt. When the level of guilt surpasses the individual specific threshold, resolution of the guilt is desired. However, should the level of guilt be too high, surpassing the threshold of intolerance, it may well be that the persuasive attempt will be without impact. This may be due to possible denial or distortion of the message content to avoid intolerably high levels of guilt, rather than attempting to resolve them. Once the transgression has been

resolved (rather than denied or distorted) as with changes in cognitive structure, behavioral intent or behavior, the individual would cease efforts to reduce the feelings of guilt, returning to a mental state in which the level of aroused guilt was below the threshold.

In sum, by arousing feelings of guilt which refer to a particular context and that surpass a given threshold (but not the threshold of absolute intolerance), an individual would be expected to attempt to alleviate such feelings, possibly through changes in cognitive structure, behavioral intent or behavior. If the feelings of guilt were aroused by a marketing communication which included recommendations, implicit or explicit, leading to a reduction of guilt, the recommendations would more likely be adhered to as mediated by susceptibility to aroused guilt and/or persuasion in terms of attitude, behavioral intent or behavior than if the recommendation were posited without the accompanying guilt arousing communication. (A graphic representation of the "first draft" model can be seen in Figure 1.)

Some Possible Individual Difference Variables

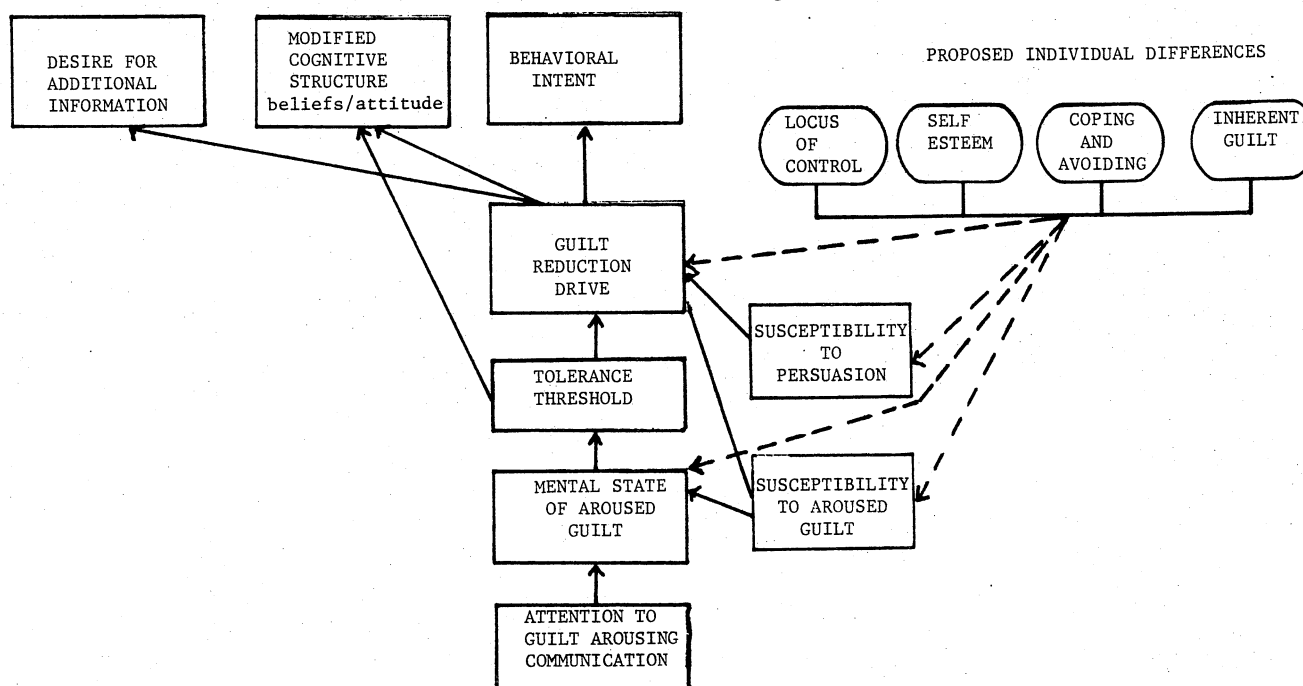

A number of individual difference variables may be hypothesized to mediate the efficacy of guilt arousing communications in a given population. Although many such variables are generalizable to other forms of persuasion, some are more closely linked to the paradigm proposed herein. Since one may conceptualize a great number of relevant individual difference variables, only those considered of significant impact will be discussed at this early stage of model building.

One trait related to many forms of persuasion is locus of control (Rotter 1966). Rotter differentiated between individuals believing in an internal locus of control or an external locus of control. In broad terms, internals perceive themselves to control their own destinies, whereas externals expect control from outside forces. Rotter argued, with the support of empirical evidence, that externals would be more prone to subtle suggestion and persuasion. With respect to guilt arousing marketing communications, one would expect that an external would more likely adhere to the recommendations advocated in the communication as a means of resolving feelings of aroused guilt. An internal might possibly seek his own solution to the moral dilemma. Thus, locus of control may mediate resolution strategies to aroused guilt.

Another general individual difference variable in persuasibility is self esteem. Leventhal and Perloe (1962) found that for certain message types subjects high in self esteem were influenced more by positive communications than by negative communications. Subjects low in self esteem showed the opposite pattern. With respect to guilt arousing communications, Zemach (1966) reported that self esteem was a powerful explanator in her investigation, although it remains unclear whether self esteem mediated overall susceptibility to persuasion alone or susceptibility to guilt arousal as well, since the two are probably correlated and it would be difficult to separate and independently measure the constructs without confounding one with the other.

Goldstein (1959) hypothesized that the acceptance or nonacceptance of recommendations contained in a persuasive appeal would be related to the subject's characteristic reaction to tension-producing stimuli based on Mainord's (1956) distinction between copers and avoiders. Coping and avoiding behavior parallels the later formulation of Kelman and Baron (1968) for handling inconsistency. Copers would be expected to exhibit greater impact of the tension-producing persuasive appeal than would avoiders. Thus, with respect to guilt arousing communications, copers should be more susceptible to high levels of aroused guilt and persuasion in general. Following Goldstein's findings, low tension-producing (i.e., guilt arousing) communications

FIGURE 1
A "First Draft" Model of Guilt Arousing Communications

would be more effective for avoiders than for copers.

A final variable which may be postulated to mediate guilt appeal effects would be a trait of self blame or inherent guilt in an individual. This psychological construct has not been applied to the area of persuasion to date, although it appears relevant when considering guilt arousing communications. Storm et al. (1958) developed the construct as well as a scale for its measurement. It would seem logical that individuals with a tendency for self blame may be more susceptible to communication induced guilt, and as such, more likely to react in accordance with the recommendations advocated in a guilt arousing communication. In contrast, it may be postulated that individuals high in inherent guilt possess higher thresholds for aroused guilt, delimiting the persuasive efficacy of guilt arousing communications. Thus, although it would seem that this construct intervenes in the persuasion process, arguments as to the directionality of the influence may support either suppression or facilitation of the guilt appeal effect.

In short, four factors have been proposed as likely individual difference variables which may mediate the effects of guilt arousing communications; locus of control, self esteem, coping and avoidance behavior, and self blame and inherent guilt. Although other variables may come into play, those noted above are likely to be prominent and are therefore worthy of consideration at this preliminary stage of the theory building process.

A Research Agenda: Some Preliminary Hypotheses

Although the graphic representation of the model (Figure 1) appears rather elaborate, a single experimental investigation could be sufficient as a preliminary test of the proposed paradigm. The research would be of an exploratory nature, centering upon a phenomenon of which little is known. Of particular interest in the study to be proposed are the following broad hypotheses:

H₁: The mental state of aroused guilt will be greater

under manipulations of moderate guilt than under minimal or maximal guilt.

- H₂: The greater the susceptibility to guilt arousal, the greater the level of aroused guilt in the mental state.
- H₃: The greater the susceptibility to aroused guilt, the greater the likelihood of a drive to resolve feelings of aroused guilt and subsequent susceptibility to the persuasive appeal.
- H₄: The greater the level of aroused guilt in the mental state, the greater the drive to resolve the feelings of guilt.
- H₅: The greater the drive to resolve feelings of guilt, the greater the changes in cognitive structure, behavioral intent, or desire for additional relevant information.

Thus, the hypotheses infer a curvilinear relationship between levels of guilt in the communication and the mental state of guilt. This reflects the double threshold effect described above. Susceptibility to aroused guilt is also hypothesized to affect the mental state of guilt, as well as the drive to resolve the feelings of guilt and subsequent susceptibility to the persuasive appeal. The drive to reduce feelings of guilt is hypothesized to be manifested in one of several ways, through changes in cognitive structure (e.g., changes in beliefs or attitudes in the advocated direction or bolstering of existing attitudes), changes in behavioral intent relevant to the message recommendations, or the desire for more information relevant to the message content, although other means may likely exist.

Measurement of Aroused Guilt

Before closing this discussion it may be useful to briefly outline some approaches to the measurement of aroused guilt since the contention of this paper has been that guilt

arousing persuasion is an unexplored and enigmatic variable in the marketing discipline. Several methods will be proposed since empirical tests should not rely on a single measure.

Given that an individual has been presented with a guilt arousing communication, a cognitive response format would appear to be the best way to begin. The first question might ask the respondent to elicit (verbally or in writing) any thoughts that the communication brought to mind. A second question might direct the respondent more towards affective responses, asking that he/she elicit any feelings or emotions that the communication made him/her feel. Conceivably these questions could "create" a great deal of data of which only a small fraction would be of interest. Coding and coder reliability would also be problems and the analyst would have to specify a priori which responses were indicative of guilt feelings and/or to what degree. Nonetheless, cognitive responses immediately after exposure might offer the best measures of aroused guilt.

Another method of measurement could be the use of a scaling technique which has respondents indicate the degree to which they feel or experience a particular emotion. Haefner (1956) used a cluster of nine adjectives as an index of guilt (ashamed, blameworthy, conscience-stricken, contrite, guilty, regretful, remorseful, repented, and sorry) judged by clinical psychologists to be relevant to that form of emotional arousal. Haefner found that his treatment groups showed substantial shifts on this cluster although he did not factor analyze them. This is essentially the method used by Zemach (1966, pg. D1, D2) to evaluate the affective responses to the communications used in her study, although she did not use all the adjectives in Haefner's cluster. Although open to demand characteristics, this method could be expected to realize useful measures of aroused guilt.

Similar to the above method, semantic differential scales could also be used to allow the respondent a means of expressing how the communication makes him/her feel. Care should be taken to avoid redundancy with any adjectives used in other scales or measures.

Lastly, attitudinal measures could be used to gauge the arousal of guilt relevant to the communication. If an advertisement was used which was intended to arouse guilt feelings over the plight of the world's underprivileged and garner charitable donations, respondents could be asked the extent to which they feel partly to blame for the plight of the poor, or the extent to which they regret not having done more to help the underprivileged. These measures are more specific to the message content but should also yield some indication of the level of guilt aroused by the communication.

In sum, several approaches to measuring aroused guilt may be used; cognitive responses, affect scales, semantic differentials, and attitudinal measures. It would be advisable to incorporate multiple measures in an experimental design to offer at least some opportunity for tests of validity.

In Conclusion

This paper has proposed that guilt arousing communications are frequently occurring phenomena in a marketing context and worthy of investigation by consumer researchers. The insufficiency of past explorations into guilt appeals and the presumed differences between guilt and related paradigms of fear, cognitive dissonance and information processing conflict provided a rationale for more focused research. Constructs were explicated and an initial "first draft" model was presented. Several individual difference variables were proposed and a research agenda was outlined in the form of broad preliminary hypotheses and approaches to measurement issues. No doubt this paper has raised more questions than it has answered but it is hoped that this first attempt at

conceptualization of the phenomenon will arouse interest and stimulate additional efforts to add increased understanding and control of this exciting marketing variable.

CONSUMER RESPONSE TO ADVERTISING: A DISCUSSION OF THREE STUDIES

Robert L. King, Virginia Polytechnic Institute and State University

Abstract

Three papers related to consumer response to advertising are discussed. Two papers report results of field investigations, one concerning linear effects in cognitive response to advertising, and the other concerning the effectiveness of celebrity endorsers. The third paper proposes a conceptualization of guilt-arousing communications. Some questions are raised concerning methodology and design of the first two studies, and some suggestions are made for extending the scope of the third paper.

Percy and Lautman's Study of Linear Effects in Cognitive Response to Advertising

The authors' report of their empirical investigation of linear effects in cognitive response to advertising is both interesting and relevant to the concerns of a substantial part of its Association for Consumer Research audience. Further, the study's design is simple, appropriate for the present investigation, and essentially well executed. Finally, the authors' make good use of recent relevant research literature, and they provide support for existing theory in this field of investigation.

If the paper contains disappointments for this reader, they center on two points. First, early in the design of their study the authors made some critical decisions which had potential for influencing their results significantly, but they did not share the rationale for these decisions with their audience. Second, the reader who seeks a relatively full discussion of the applications and implications of this research remains disappointed. While the value of parsimony may be exceeded only by its rarity in professional dialogues such as ours, in the present situation neither the authors nor the audience seems well served by the brevity of the report in these regards.

Several examples may serve to illustrate the first concern, i.e. inadequate explanation of some basic decisions related to the universe which was studied, and to the testing devices which were developed for data collection purposes in this study. A fuller explanation of issues such as the following would be helpful, particularly to prospective users who have a marketing practitioner orientation:

First, why did the authors select frozen food as the product subject for this investigation? Is it conceivable that their findings might have been substantially different had they chosen a consumer durable product such as a videotape recorder? Might the degree of product diffusion among the general population alter the nature of the responses? What are the implications of selecting a well-known brand of the product, as opposed to a lesser known brand or even a newly introduced brand of the same product type?

Second, what was the basis of the authors' decision to feature "a couple" in one experimental commercial, while using "several people" in the other? More specifically, do the people in these two advertisements represent similar or different age groups, marital statuses, social classes, and life styles, or do they reflect essentially different populations? What are the potential consequences of these similarities and differences to the responses which are forthcoming?

Third, is the definition which is suggested for the product's target market acceptable (i.e., female household heads, aged eighteen or older, with family incomes over \$15,000, who have had experience with the product category)? Are such women actually indicative of the product's target market? Or are there substantial regional, urban/rural, racial, religious, and other demographic differences in the actual target market which may not be accounted for in either the study's definition of the target market, or in the three "widely distributed" geographic areas from which respondents were selected, or both of these factors? More specifically, what does "experience with the product category" imply? Is there a measure of brand usage experience? And perhaps more important from the marketing practitioner's perspective, is attention given to differences in responses from heavy and light users of the product type?

This reader's second concern relates to the paucity of the authors' remarks about applications and implications of their findings. Specifically, how projectable are their findings across various product categories? What are the implications for promotional program development and evaluation generally, and for advertising pre-testing specifically? On the other hand, have the authors possibly generalized excessively when they refer to the broad area of "cognitive response"? Their data refer essentially to "support arguments," which are in fact a subset of "cognitive response."

In conclusion, the paper is a sound one which adds credence to existing theoretical and empirical work. However, a fuller discussion of some of the decisions underlying the study's design, and of possible applications of the findings, would have proved extremely useful.

Mowen and Brown's Study on Explaining and Predicting the Effectiveness of Celebrity Endorsers

According to legend, the first recorded instance of a modern athlete leasing his name to a commercial sponsor occurred in 1905 when Honus Wagner, shortstop for the Pittsburgh Pirates, gave the J. F. Hillerich and Son Company permission to use his name on its Louisville Slugger bats for a consideration of \$75. However, the non-smoking Wagner sued the American Tobacco Trust, which put his name on a Sweet Caporal baseball card without his permission. In 1907 Wagner appeared with Ty Cobb (who had a cigarette and a candy bar named for him) in Coca-Cola's "The Great National Drink of the Great National Game" advertising campaign ("Tinker to Evers to JWT," 1978).

Two issues which were central to the situation of 75 years ago are addressed by Mowen and Brown, who properly remind us that definitive answers have not yet been found to the questions:

(1) Does endorsement of multiple products tarnish a celebrity's effectiveness?

(2) Is it advantageous to the sponsor to use a number of different endorsers to recommend a given product?

These questions take on a new urgency in view of contemporary promotional practice, which is characterized by increasing use of celebrity endorsers, especially in tele-

vision commercials. The substantial fees paid to celebrity endorsers also give these questions a new urgency. For example, shortly before his death John Wayne filmed several commercials for Great Western Savings and Loan, a regional advertiser, under a three-year contract which paid Wayne an estimated \$1.5 million. Recent trade estimates suggest that some athletes are paid \$25,000 or more for making a single national commercial (Forkan 1979, and Morris 1979).

The authors are due appreciation, then, for raising relevant and interesting issues, and for attempting to extend previous related research. Similarly, they have provided us with a useful review of the limited literature in this area of research. In retrospect, however, one may wonder whether the cause would not have been better served had they chosen to investigate only one of these related but difficult questions, rather than both, and had they structured the design of that more limited inquiry much more tightly. More specifically, it appears that the authors have relied unduly on assumptions produced by logic as the basis of much of their study's design, when a "factual" basis could have been obtained relatively painlessly. The latter approach would have given the report's audience greater confidence in its results. Several examples are offered to illustrate this point.

First, reference is made to the possibility of respondents having perceived risk when allowing advertising to influence their perceptions of relatively costly television sets in their earlier study. In fact, was consequential risk perceived by those respondents? Why was "a new ballpoint pen" selected as the product-subject in the present study? Is its comparatively low price sufficient evidence that respondents would not perceive consequential risk if they allowed advertising to influence their perceptions of it? In short, in conducting this replication of their earlier study, did the researchers objectively measure the risk levels associated with letting advertising influence one's perceptions of various product-subjects?

Second, products are classified by status level in the report. But, are the products which are characterized as relatively "low status" (motorcycles, cigars, cologne, and rums) and "higher status" (Hilton hotels, Chivas Regal scotch, and Mercedes-Benz automobiles) in fact significantly different in their status identifications among respondents? Were these differences tested? And in any event, how does product status level relate to the research problem, as it is defined in this study?

Third, the researchers' operational measure of "relevancy" seems open to question. Does the use of a script in which the endorser of the ballpoint pen discusses its performance in signing autographs establish "greater relevancy"? Or does the authors' concern, which was expressed about respondents' perceptions of the three actors' relevancy in the television set study, call for a more objective measure of relevancy in the present study?

Fourth, similar questions can be raised concerning the operational measures of "concensus" (endorsement by multiple sources) and "distinctiveness" (endorsement by the endorser of a single product only). Also, it seems that "who" the endorser(s) is (are) must be examined. That is, did Steve McQueen represent essentially the same image to all of the respondents? Did George C. Scott? What is the impact on responses of this particular mix of endorsers? Does this mix possibly introduce additional complexities into the study?

Fifth, direct attention needs to be given to the issue of "credibility" of individual celebrity endorsers in order to understand the phenomena under investigation here. A substantial professional and trade literature exists to help us in this regard. (See Middleton 1974; Eagly and Chai-ken 1975; Dholakia and Sternthal 1977; and Morris 1979,

for example.) Unfortunately, this literature is not well represented in this study's "References" section.

Similar questions could be raised concerning other uncontrolled sources of variation, the absence of reported manipulation checks, and the rather thinly disguised experimental conditions in the research. One would hope that the authors will continue their investigation of this timely and interesting subject after reconsideration of some aspects of their operationalizations and manipulations. More rigorous testing would yield much needed guidance for business academicians and practitioners alike.

Chingold's Study of Guilt Arousing Marketing Communications

Whereas the previous papers reported results of field investigations, the present paper is essentially concerned with conceptualization of a construct for exploring an infrequently investigated phenomenon, guilt-arousing marketing communications. The author has very adequately met his three stated objectives. He introduces this largely new area of research interest for marketing communicators, acknowledging the distinction as well as the interrelationship which exists between "fear" and "guilt." His review and synthesis of the literature dealing with guilt-arousing persuasive communications, along with the accompanying bibliography, should be particularly welcomed by concerned marketing communicators. Finally, his "first draft" conceptualization of guilt-arousing communications is a fresh, thought provoking statement, although it is subject to possibly extensive revision.

Even so, some concerned academicians and practitioners in the field of marketing communications will be dissatisfied with, and less well served than was necessary by, several characteristics of the paper. First, the paper may appear to be too truncated: the first one-third of an empirical paper, omitting the methodology and analysis sections. Certainly, the paper would have been much stronger if it presented empirical findings, however tentative they might be. Failing this, it would be useful to know the author's more detailed thoughts concerning measurement approaches. Probably the major shortcoming of the paper in the eyes of its critics is its lack of a suggested research design for testing the recommended hypotheses.

Second, the reader is offered insufficient guidance in identifying specific guilt-arousing marketing communications, and in measuring the incidence of their use by marketing communicators. The author perceives guilt approaches to be in "fairly widespread use" by marketing communicators, but his perception seems to be untested in the market place. An expanded listing of contemporary examples of guilt-arousing commercials, according to the author's definition, would be quite helpful. In fact, how common are such appeals in marketing communications? We would be assisted in identifying examples if we had an improved or expanded definition of guilt-arousing communications which specifically reflected a marketing communications context. Presently we must ask whether "lowering of self esteem, or feeling of lessened personal worth" and "a need to make retribution for the transgression" (Wolman 1973) result from exposure to advertisements such as the following:

- (1) Wisk's "ring around the collar" advertisements, suggesting the housewife's distress upon finding her laundry efforts publicly wanting;
- (2) Shower-to-Shower powder advertisements, showing passengers piling into the rear seat of an automobile in order to avoid unpleasant body odor of the person in front;
- (3) Church of the Latter Day Saints advertisements, asking whether one has hugged his children today;
- (4) Crest toothpaste advertisements directed toward parents, reporting reduced incidence of tooth decay among using children of "cavity-prone" age; and
- (5) CARE and Save the Children Foundation advertisements,

showing the lean faces and hungry eyes of undernourished children.

Third, in view of the author's necessarily heavy reliance on non-marketing literature, reinforced by the paucity of references to the conceptualization's specific marketing communications implications and applications, one may wonder why he elected to develop and present his work within the context of marketing communications. With a minimum of editing, the report would seem equally applicable to a variety of essentially non-marketing communications, such as those between candidate and voter, office holder and citizen, supervisor and worker, pastor and parishioner, teacher and student, and parent and child. While it is not surprising that applications are more generalized than area-specific in the "first draft" conceptualization in a less explored field, the paper does seem unduly brief in setting forth specific marketing communications examples, implications, and applications.

The paper raises a wide range of additional issues, each of which is worthy of fuller discussion. For example, is guilt research's "piggybacking" on fear research really so "dubious"? Is the inappropriateness of cognitive dissonance and information processing for understanding guilt possibly more apparent than real? What is the relevance to the marketing communicator of such distinctions as high vs. low self-esteem, copers vs. avoiders, and high vs. low inherent guilt? Might not the suggested hypotheses take on increased relevance and be more finely tuned to the paper's title if they were expressed specifically in a marketing communications context? Might not an additional hypothesis, reflecting the possible dissipation of guilt arousal with the lapse of time, be appropriate? Could/should tolerance and intolerance thresholds of aroused guilt be incorporated into the "model"?

In conclusion, the author has developed a thought-provoking conceptualization. But one recalls his earlier statement that "a single experimental investigation could be sufficient as a preliminary test of the proposed paradigm." One would agree, while regretting that the author did not include the results of such an investigation as part of his paper, but hoping that he will continue his interesting efforts and share those results with us in the near future.

PUBLIC POLICY UPDATE: PERSPECTIVES ON THE FEDERAL TRADE COMMISSION¹

Kenneth L. Bernhardt, Georgia State University
Ronald Stiff, University of Baltimore

Abstract

This paper presents a summary of a special session devoted to a briefing on current and future developments at the FTC and the role of consumer research at the Commission. Examples of topics likely to be important for consumer research in the future are presented, together with a brief discussion of each of a number of recent research projects.

Purpose

This paper presents the highlights from a special session concerning current and future perspectives on the Federal Trade Commission. Participating in the session were Michael Pertschuk, Chairman of the FTC; Robert Reich, Director of the Agency's Office of Policy Planning; and Ronald Stiff, who was Consumer Research Advisor at the time of the session. The session was moderated by Kenneth L. Bernhardt, who had served as Consumer Research Advisor at the FTC the previous year.

The session focused on three subjects: 1) what topics are likely to become increasingly important at the FTC in the future; 2) what is the role of research at the FTC, what types of research are conducted, and what have been the successes and failures of consumer research at the Commission; 3) what are some examples of research projects that have been conducted by the FTC.

In sum, the goal of the session was to provide those attending with a briefing on not only what types of research are currently being conducted at the agency, but also to alert researchers to topics that are likely to be requiring consumer research inputs in the next few years. The rest of this summary presents the conclusions offered by the speakers at the session.

Future Areas of Interest

Six areas were identified as being hot topics for the future. It was emphasized that the FTC was not abandoning its current programs, advertising substantiation for example, but that these are not likely to be the growth areas of the future. The future growth areas which were identified are briefly described below:

1. Credit Programs. Because of the continued importance of credit in inflationary and recessionary times, this should be an increasingly important area for the FTC in coming years. Specific areas mentioned included debt collection practices, balloon payments, deficiency judgments, and the provisions included in the proposed Credit Practices Rule.
2. Comparative Disclosures. The purpose of the comparative disclosures program is to help consumers make better comparative judgments in evaluating product alternatives. Current programs in this area include energy savings comparative disclosures such as the appliance energy

- labeling program, and the insulation R-value program. The FTC is currently looking at other areas where comparative performance information would be valuable to consumers.
3. Product Quality/Defects. As consumers become more concerned with product quality and as products become more complex, this program should increase in importance. The FTC currently has been investigating product quality concerning housing, automobiles, and heat pumps.
 4. Professional Services. For the past four years, the FTC has been studying the marketing and advertising of professional services, and this program is likely to increase in importance in the next couple of years. Specifically, the agency has studied advertising and marketing by opticians, dentists, nurse practitioners, dental hygienists, lawyers, and doctors. The U.S. Appeals Court has recently affirmed the FTC decision in the American Medical Association case which removes the constraints imposed by the AMA, inhibiting doctors from advertising. The FTC is also investigating the business aspects of these professions, including such questions as whether dental clinics can be opened up in shopping centers and what qualifications should be required for ownership of clinics.
 5. New Media and Marketing. The FTC is currently investigating the "communications revolution." Such things as videodiscs, videotext, and cable communications should open up whole new areas for FTC investigation. The agency has recently completed a Media Policy Session and report on new media technology and legal change.
 6. Energy, Health Care, Transportation, Shelter, and Food. There has been a pronounced shift in the priorities the FTC assigns in evaluating potential new programs. The bulk of the programs in the future will be closely matched to their importance in terms of consumer spending. In other words, the agency will concentrate its efforts on increasing consumer savings in those areas where the potential net benefit is the greatest.

Consumer Research at the FTC

The atmosphere for research has changed considerably since the first consumer research study, costing \$1200, was funded seven years ago. The current budget contains \$1.2 million for research, almost all of which is for consumer research. This amount does not include any funds spent internally for personnel, supplies, travel, etc., but is only the amount spent on external contract research.

The evolving nature of the authorizing legislation has insured that the FTC will continue to engage in consumer research. For example, the 1980 FTC Improvements Act requires considerable economic analysis on proposed and existing regulations, and much of this analysis will be consumer research based. In addition, the political environment is contributing to an increase in consumer research--the agency must be able to defend its actions. Institutionally the agency is committed to do consumer research to help pay attention to the real world effects of its actions. Temperamentally, the agency is ready to accept and use consumer research findings.

Several of the commissioners are now asking consumer research questions of the attorneys when new regulatory programs are being proposed. For example, the questions being asked include: a) what empirical evidence do you have that

¹The views reflected in this summary statement are the views of the individuals participating in the session and do not represent the official views or policies of the Federal Trade Commission.

there is a problem requiring FTC action?; b) what empirical evidence do you have that would indicate that your recommended remedy would actually work?; and c) what empirical evidence are you gathering or have you gathered that will enable us to later evaluate whether or not the remedy is working as intended?

FTC attorneys have become very sophisticated with respect to consumer research. It's not unusual to have discussions at the agency concerning statistical significance, sample size requirements and procedures, regression and other multivariate analysis techniques. Less and less the discussions concern whether or not research is needed. Instead, the discussions center on what research would be most helpful and how to do it.

Consumer research has been helpful in halting programs that research indicated had a low probability of success. For example, a study of detergent buying behavior was done by Joel Cohen and Bill Wilkie showed that even if consumers were given product information indicating parity of performance between major brands and private labels that people would still buy the major brands. The program was eventually halted, at least in part because of the evidence that it would not work.

Consumer research has been used to help formulate programs. For example, focus groups and quantitative followup studies were conducted as part of the development of the appliance energy labeling program. The purpose of the research was to measure if consumers could understand the energy information, and to determine which formats among several alternatives were most effective in communicating the information. The research showed that expressing energy usage in dollars was far more effective than using an "energy efficiency ratio" and the final format of the label actually being used was heavily influenced by consumer research.

The identification of needed FTC action has been another result of consumer research. For example, a study of the quality of new homes purchased and experiences of the buyers indicated that defects in new housing were an important problem and that there were some builders who were not resolving problems which had a major financial impact on these consumers. The study also helped identify what the problems were, the magnitude of the consumer injury, and what types of houses had problems. This study thus helped define the nature of the problem, provided direction for possible remedies, and served as a benchmark against which the success of any government action could be later measured.

Consumer research has also been used by the FTC to help identify and prioritize advertising substantiation cases. In several instances, copy tests have been used to determine consumer perceptions of potentially deceptive and unfair advertisements to determine if a case should be initiated against the advertiser.

In spite of the successes described above, there also have been some failures in the consumer research area. The biggest failure has probably been the inability of consumer researchers to adequately explain to Presiding Officers, Administrative Law Judges, and others involved in a proceeding exactly what they have done and why it is appropriate. This inability to adequately explain what was done and why has diminished the value of the research to the decision makers involved.

Another failure of consumer research concerns lapses in the quality of individual studies done for various proceedings. Many consumer researchers have failed to recognize the higher quality standards necessary for studies done in the public arena for public policy purposes. Thus, many studies, with small sample sizes, selected inappropriately, analyzed improperly or with sloppy controls, have been thrown out or given very little weight by the decision

makers.

Examples of FTC Research Projects

Many different types of consumer research techniques have been used, including copy tests, experimental design studies, mall intercept studies, consumer mail panel surveys, and random-digit-dial telephone surveys. It has not been possible to engage in test marketing of proposed programs, but in several studies individual states, with regulations similar to those proposed at the national level, have been used as control groups to measure the impact of the programs. Listed below are examples of 16 studies that have recently been completed or are in progress at the agency. The studies represent a diversity of problems and research methodologies, but show the spectrum of the kinds of research being conducted by the FTC.

1. Unavailability of Advertised Specials. A survey of consumers' values of high levels of availability of advertised specials in grocery stores and consumer experiences with unavailability. (Report Released)
2. STP Corrective Advertising. Measures of consumer and business attitudes toward the company and the product were taken before and after the corrective message. In addition, consumer and business perceptions of the corrective ad were determined after the ad appeared. (Report Released)
3. Warranties Consumer Baseline Study. A survey of a national sample of 4,300 consumers who purchased products with warranties in 1976 was conducted to determine their knowledge of warranties and the use of this information in the purchase decision. (Report Released)
4. Automobile Warranties Content Analysis. This study analyzed the changes from 1967 through 1977 in the content of automobile warranties obtained from automobile manufacturers who had a significant share of the market. (Report Released)
5. Appliance Warranties Content Study. This study analyzed the changes in the content of warranties offered for 40 consumer products in 1978 compared to 1974. (Report Released)
6. Antacid Prospective Study. This project focused on the potential impact of warning messages in antacid television commercials on subsequent consumer behavior with regard to antacids. The study measured the impact of warnings on the target population (e.g., antacid users on a salt-free diet) to see if warnings can be effectively communicated via 30-second TV commercials. In addition, the test measured whether legitimate antacid users (not on salt-free diets) are dissuaded from using the product. Various warning messages, ranging from very specific warnings about antacids to more general warnings (e.g., read the label) were tested to measure their impact. (Report a part of OTC Drug Advertising Staff Report)
7. Appliance Energy Labeling. This is a first part of a study to assess the impact of appliance energy labels on (1) consumer purchasing patterns for appliances, (2) shifting purchases to products which use less energy, and (3) promotional practices of appliance marketers. The data will be used in conjunction with a later study to provide pre-to-post analysis of the effects of the labeling program. (Report Released)
8. Affirmative Disclosures. This project involves assessing the effectiveness of recent (since 1970) affirmative disclosure remedies. Past orders will be categorized and analyzed, and the contractor will make recommendations about future affirmative disclosure policy. (Report expected to be released in December 1980)
9. New Housing Construction. This study examines the nature, severity, and extent of defects or problems occurring in new housing. Telephone interviews were conducted with 1,812 home owners who have owned their home for 1 or 2 years. Actual home inspections were conducted for a subsample of 299 of the homes to verify consumer reported defects and costs. (Report Released)

10. Listerine Corrective Advertising. This is an analysis of consumer awareness, beliefs, and attitudes towards Listerine and the corrective advertising for the product. Initial measures were taken following the introduction of the corrective advertising campaign. The study will enable an assessment of the effectiveness of the corrective advertising over time. (Report expected to be released in December 1980)
11. Insulation R-Value. This is a baseline study measuring the extent to which consumers understand and utilize R-value information provided as a result of the rule. (Report to be released in December 1980)
12. Eyeglasses Advertising. The Bureau of Economics (BE) conducted a cross-sectional study of the effect of state eyeglass advertising restrictions on the cost and quality of eyeglasses and eye exams. (Report Released)
13. Cooling-Off Rule. This study is a post-rule evaluation of the Three Day Cooling-Off Period for Direct Sales Rule. The costs and benefits of the rule will be examined. A survey of consumers will be conducted to determine their understanding and use of the rule's provisions. A survey of direct selling companies will be conducted to determine the costs of complying with the rule. (Report expected to be released in 1981)
14. Used Car Study. This study is designed to gather baseline data on the used car market so comparisons may be made with data to be gathered in the future. Private buyers and sellers were interviewed via telephone. (Report expected to be released in 1981)
15. Advertising Information Levels. The purpose of this study is to determine how much information and what kind of information television advertising can communicate. A split-cable television system will be used to allow different amounts of information. Recall of information will be tested. (Report expected to be released in 1981)
16. Care Labeling Study. This study will gather baseline data on the extent to which consumers are being harmed by the insufficiency of information related to clothing apparel and textiles. Data will be gathered on the incidence of incorrect washing, drying, ironing and bleaching. This study will also measure the extent to which care and maintenance instructions are overly restrictive. (Report expected to be released in 1981)

THE FUTURE OF CONSUMER PROTECTION REGULATION

Michael B. Mazis, The American University

Abstract

The purpose of this paper is to provide a perspective on consumer protection regulation in the 1980's. In the course of this discussion, seven allegedly deadly sins of consumer protection are discussed. While there is some truth to each of these "deadly sins", they are not true to the degree suggested by critics of consumer regulation.

Attention About What To Regulate

There has been considerable criticism that consumer protection regulation has followed a scattergun approach in determining the areas selected for regulation. Often, the logic underlying selection of target sectors for government involvement is unknown to even well-informed observers. There appears to be over-regulation in some areas and, contrary to the belief of many business persons, there is likely under-regulation in other areas. The 1980's will see several important shifts in consumer protection regulatory activity.

First, there will be a substantial shift away from advertising regulation toward regulation in other areas. Recent FTC budgets show a substantial decrease in expenditures for advertising activities, with little emphasis on new rule-making activities. The FTC, known as the Tyrannosaurus Rex of regulatory agencies, is likely to show much more discretion in promulgating new investigations and enacting additional rules over the next decade. The agency is quite aware that many of its advertising initiatives have been ill-advised both on substantive and on political grounds.

Most of the food advertising rule has been scrapped and it can be anticipated that very little of this ambitious undertaking will be enacted into final regulation. The children's advertising rule is currently in hibernation and it is unlikely to appear in a form resembling the original proposal. The FTC's over-the-counter drug rule is likely to be discarded.

Second, there will be a substantial increase in de-regulatory activities both from the FTC and HHS. Various restrictions against professional service proliferation, such as not allowing franchises and advertising, will be under serious attack by consumer protection regulators. These efforts will be met with resistance on the part of the Supreme Court, which has supported state restrictions, which bar professional service expansion. The Court has followed a "states' rights" position in overturning a major portion of the FTC's eyeglasses rule. It is unclear at this time whether the Court will allow federal agencies to preempt state law. As a result, there is likely to be a shift to additional effort at the state and local level to overturn regulatory activities which further the profession and harm the consumer. This emphasis on state and local regulation follows the shift in media patterns resulting from cable T.V. expansion and more localized T.V. programming which coincides with more careful targeting by advertisers. As a result, much of the battleground of advertising regulation may shift from the national arena to more localized efforts.

It should be noted that this emphasis on deregulatory activity or free choice may face a counter-cyclical trend. At this point, the pendulum is swinging against free choice in certain areas. For example, motorcycle helmet law repeal has resulted in an enormous increase in accidental deaths. Therefore, in the latter part of the decade there is likely to be additional concern for the consumer's health and safety.

Third, there is likely to be an emphasis on cost or pocketbook issues. In housing, there will be increased pressures by homeowners for warranties. Pressures will build on insurance companies for cost disclosures and there will be serious attempts to provide greater opportunities for alternative providers, such as banks, to sell insurance at a lower cost.

Fourth, there will continue to be a major emphasis on health and safety regulation, especially involving uncontrollable risks. Consumers believe that where information can be supplied through labeling, they are able to control risks and, therefore, product bans are unnecessary. For example, nitrate and saccharin bans are unacceptable to many consumers since they choose to decide whether they wish to be risk-takers or risk-avoiders. On the other hand, when risk cannot be controlled by the consumer, there will continue to be significant regulatory activity. For example, new laws have been passed regulating infant formula and FDA has been given additional regulatory authority in this area. FDA recently enacted patient package insert regulations which provide for additional information to be given to consumers about prescription drugs. This regulation has met with little public controversy. Efforts to protect the water supply, which involves an uncontrollable risk, will come under increased scrutiny by consumer protection regulators in the coming decade.

Finally, there will be increased concern about product liability. For example, the Supreme Court has permitted victims of the cancer-causing drug DES to sue all major DES manufacturers for damages even if the victims cannot identify the specific company that sold them the drug. Under this ruling, a company may be made to pay for damages it never caused to someone who may never have consumed its product. To escape liability the firm must prove that it could not have made the product that caused the injury. This approach departs dramatically from conventional legal practice, which generally requires a showing of direct responsibility before damages can be awarded.

This increase in product liability awards has two important consequences. First, it may reduce the need for the Consumer Product Safety Commission (CPSC) to take action since products liability cases can serve as an important deterrent to manufacturers producing unsafe products. This does not mean that CPSC is likely to be eliminated in the near future; however, the agency will find it difficult to undertake new initiatives. Second, these large awards may cause increased pressures to restrict product liability awards. Similar pressures have been noticed in the medical malpractice area.

Choice of How to Regulate

In the past, there has been an emphasis by consumer protection regulators on product bans. However, public resistance has encouraged regulators to move away from this form of regulatory activity. One major turning point involved public resistance against seat belt interlock systems, which was followed by a public outcry against proposed Laetrille and saccharin bans. A few years ago, FDA routinely passed "death sentences" against entire product categories. The cranberry crop was doomed one year because some of it was contaminated by a dangerous insecticide. Cyclamates were banned on the basis of a handful of reports indicating that it might be a carcinogen when used in small amounts over a long time period. New processes for manufacturing high protein fish flour at greatly reduced costs were rejected because they ground up the entire fish, complete with waste matter.

There is likely to be a shift towards informational approaches as opposed to bans. However, during the decade, questions will be raised about whether consumers can absorb all the information presented, understand the information and use the information in decisionmaking. For example, can consumers understand DOT's complex tire rating system? Several studies have shown the futility of FTC's detailed food advertising disclosures in advertising. Can consumers understand complicated risk information such as is available based on animal testing? Questions will be raised about the processibility of the information disseminated through government regulation.

There will also be a shift from rule making to case-by-case adjudication to avoid the political pressure imposed by legislative vetoes over proposed regulation. The battle over legislative vetoes is likely to persist over the next several years. As Elliot Levitas one of the leaders of the legislative vetoes has suggested, "We are returning to the people the control over these regulations and at the same time we have sensitized the "bureaucracy". However Stanley Cohen from Advertising Age has suggested, "It will enable powerful interests to affect the regulatory process in secret, behind the closed doors of individual committees and in individual members' offices." As the decade begins, the proponents of legislative vetoes appear to be winning the war. However the increased burden on Congress to cope with the extensive lobbying will eliminate additional pressures for legislative veto efforts towards the end of the decade.

Finally, there will be increased emphasis on enforcing current regulations rather than on initiating new regulations. While this is a welcome change for many people, there may be negative effects. Regulators will be content to develop a scorecard of politically safe enforcement actions, which may represent little consumer gain, but may create the illusion of regulator victories.

Sensitivity to Political Pressures and to the Political Process

There is a serious question as to whether regulators' alleged insensitivity to political pressures is a sin or virtue. As the decade begins we are witnessing an end to truly independent regulatory agencies, since they are becoming increasingly politicized. We note the specter of the FTC Chairman Michael Pertschuk being "roasted" on the

Hill rather than serving in his role as an independent commissioner. During the decade, regulatory agencies will develop increased sensitivity to political pressures. On the other hand, these pressures may create management difficulties, such as have been observed at the Department of Energy, since little time will exist for long-range planning. Agencies will engage in more sophisticated "lobbying," although formal lobbying efforts on the Hill are prohibited. Congressional staffs will be given information about key issues and the regulatory agency will be "positioned" as merely acting as the servant of Congressional committees who will demand that the agency initiate an investigation. Regulatory agencies will play the role of feeding ideas to legislative staffs who will hold hearings and "pressure" agencies to respond to public needs.

In addition, regulatory agencies will become more innovative in generating public pressure for needed reforms. Investigative television shows, such as Sixty Minutes or 20/20 are always seeking to expose a consumer fraud or report on an issue of general consumer interest. Regulatory agencies will become more sophisticated in using the media to further regulatory activity by generating public pressure for regulatory action.

Position of Business in Regulatory Proceedings

Business interests have reacted to what they believe is the inherent unfairness of the regulatory process. Many business persons feel that they are convicted through publicity even if they are found innocent of any wrongdoing. They charge the system is run by people who are unfamiliar and unsympathetic to the business point of view. They frequently note that the regulatory process is not conducive to outside views since agencies appear to have made a decision before the process starts.

In the 1980's, regulators will be more open to the views of business groups, due to the increased power of the business point of view in Congress. There will be attempts at joint research among business and government, although many of these efforts will fail to produce an acceptable product. Business and government legal staffs counsel against undertaking joint research activity. However, the courts will more carefully scrutinize agency rule-making, which will result in government regulators paying increased attention to evaluating low-cost alternatives proposed by business groups.

Study of How Markets Operate

Regulatory agencies will show increased understanding of business activities and evidence less myopia in promulgating new rules. There will be an increased use of academics and MBA's in regulatory agencies. However, there will continue to be domination by a single perspective at regulatory agencies. For example, lawyers will continue to dominate FTC proceedings; physicians will control FDA activities; and engineers will dominate the activities of DOE, CPSP and DOT.

There will be increased contact between business and regulatory groups, which will facilitate a greater understanding of market activity. However, there will be great difficulty arriving at mutual understandings because both business and government groups will continue to have an incentive for conflict rather than cooperation. The Washington representatives on the business side and the legal staff on the government side both have an interest in maintaining conflict.

The real breakthrough in cooperative activity will come from pressures by U.S. industry to be competitive with foreign competition. As a result, regulators will be forced to work with business interests in order to meet the threat of foreign competition. We have already seen changes in the automobile industry, with EPA and DOE working more closely with the automobile companies. In the anti-trust area there will be increased pressures to allow large firms, especially in the communications field, to meet world-wide competition.

The greatest area of cooperation will be in consumer education. Industry quality standards, such as the homeowner warranty program, will proliferate. These efforts, which have been tried by Japan and Sweden, will be tried in the United States as consumers seek more value from products.

There will be less detailed and more flexible rule-making by regulatory agencies, which reflects a greater confidence and understanding of business. There will be much more emphasis on performance standards, which monitor actual output, rather than on design standards.

Economic Analysis

In the past, there has been little economic analysis to determine if a rule is needed and to discover if a regulation is effective. There have been many proposals for increased economic analysis of proposed regulations. At present, these regulatory analysis proposals are not taken seriously by regulatory agencies. These efforts are viewed as a chore to be undertaken after regulation is developed and a regulatory analysis is developed to justify the regulation. However, as additional economists are hired by government agencies to perform regulatory analyses, economists will develop increased power. They will be able to veto regulations because it can be claimed that a regulation cannot be justified economically. However, economists will have great difficulty in undertaking new initiatives, except in the deregulation area. The economist will serve as a brake on regulatory activity and will tend to be reactive as opposed to proactive.

Use of Consumer Behavior Theory and Research

There will be great increases in regulatory agency research budgets, primarily in the evaluation and regulatory analysis areas. However, these funds can be used to support a variety of consumer projects. Overall, there will be more sophisticated government research. However, there will be little basic research into

information processing and other important areas, since most of the research will continue to concern applied efforts.

Summary

Overall, regulators will be more prudent in their choice of what to regulate. Greatest attention will be devoted to situations where markets have failed or aren't working properly. Deregulation will be emphasized as opposed to regulation. Services will come under greater scrutiny. Information remedies will be used rather than product or advertising bans. However, the problem of too much detailed information on product labels and in advertising will be an increasing problem as the decade of the 1980's concludes.

There will be greater sensitivity to political realities; however, this will be accompanied by a loss of independence by regulatory agencies who will be under increasing Congressional scrutiny. There will be increased cooperation between government and business groups, resulting largely from enhanced power of business groups with Congress. There will be increased use of economic analysis and consumer research. However, these fields will tend to be reactive rather than proactive. Economics, as a result of its greater theoretical grounding, will exert far more impact than consumer behavior research. However, consumer researchers will continue to exercise an increasingly important role. There is a difficult road ahead for consumer protection regulation, but regulators will become more prudent and perhaps more successful in their regulatory efforts.

CONSUMER POLICY ISSUES: GLOBAL TRENDS FOR THE 1980's

Graham T.T. Molitor, Public Policy Forecasting, Inc.

Abstract

Consumer laws move in cycles, the current cycle (projected for 1978-1998) including over 4,000 issues not yet adopted in America. U.S. response lags Western Europe's precursor-Sweden - typically by some 6-8 years. Implementing dates for consumer laws can be accurately forecast years ahead of time using some of 160 indicators of socio-political change.

Onslaught of Government Change

How can we tell where we are going? What's in store for the 1980's?

What lies ahead for consumer policy? The current cycle of consumer issues which began in 1978 is growing (Exhibit 1). Presently Public Policy Forecasting, Inc., is following over 4,000 separate and specific consumer issues that have not been enacted by the Federal Government.

EXHIBIT 1

PATTERNS OF CHANGE

© 1979, PUBLIC POLICY FORECASTING, INC.

New laws steadily increase. The U.S. Congress, during a two-year term, receives an average of 20,000 bills and enacts some 1,000 new laws (Exhibit 2). Added to this are an estimated 9,000 federal regulations issued annually. Compound this domestically by the 50 states which entertain some 100,000-125,000 bills yearly, of which 15-25,000 are enacted (Exhibit 3). Add inputs from some 78,218 special districts (counties, school districts, municipal authorities). Next, multiply these results by the 155 or so nations the world over and the overwhelming global magnitude of government-imposed change begins to be perceived. Steadily, and with an increasing rate of growth, this myriad of law and regulation concerns the consumer.

The impact of regulation and accompanying changes in social attitudes also has been seen in the courts. For example, in 1960, there were 50,000 product liability

claims filed; alarmingly the number had swollen to over one million by 1970. In just 3 years between 1974 and 1977, the number of product liability lawsuits filed in federal courts rose from 1,579 to 4,077. Judge and judge-and-jury awards in such cases have mushroomed as well. The record-setting 100 million dollar decision against the Ford Motor Company in a case brought as the result of alleged safety defects of a Pinto automobile is an incredible landmark award. Despite reduction of the award on appeal, the impact of just how far things could go sent waves of apprehension throughout industry. In related judicial trends verdicts against physicians in malpractice suits also dramatically raised their liability insurance costs. Ultimately, of course, it is the consumer who winds up paying.

Paradoxically, consumer legislation and regulation, especially when viewed from the citizen's, as well as from judicial and legislative viewpoints, can be counterproductive to the consumer. Witness the costs passed along to the consumer, such as inflated insurance premiums, added cost of mandatory automobile safety and environmental protection gear, overhead expended for legally mandated paperwork, and so forth.

The tide is toward more and more regulation. More and more change is in store. Large as well as small businesses stand in the growing shadow of government regulation. Products can be banned from the marketplace by the stroke of the lawmaker's pen or by a regulator's arbitrary edict. Limited government is a thing of the past; government-imposed change cannot be ignored (Exhibit 4). Wrenching dislocations may engulf the unwary or the unprepared.

What can be done to get out in front of impending public policy change?

Change. That is the key word.

Changes in public policy seldom come as a bolt out of the blue. Changes evolve.

Change is prompted by social frictions which expose abuses or wrongs. When such "social dissonance" gets out of hand and can no longer be ignored, when the momentum of forces clamoring for reform swell in numbers, government response and reform are not far behind.

The Six Indicators of Change

Six key indicators are most useful for detecting, tracking, measuring, and predicting the trend and direction of public policy change (Exhibit 5).

The process invariably begins with aberrant and unique events. Novel or bizarre, at first, such happenings go largely unnoticed. Their accumulation over time eventually leads to aggregation which helps to reveal meaningful patterns. Event patterns emerge in many different ways. Among them: innovation from introduction of new technologies and social inventions, increases in magnitude, and practical experience.

As events unfold and become the object of attention various authorities and advocates (often the "victimized") observe, analyze and begin to comment on such emerging phenomena. Authorities include the gifted few who can be found in any discipline and the geniuses who propose a

EXHIBIT 2

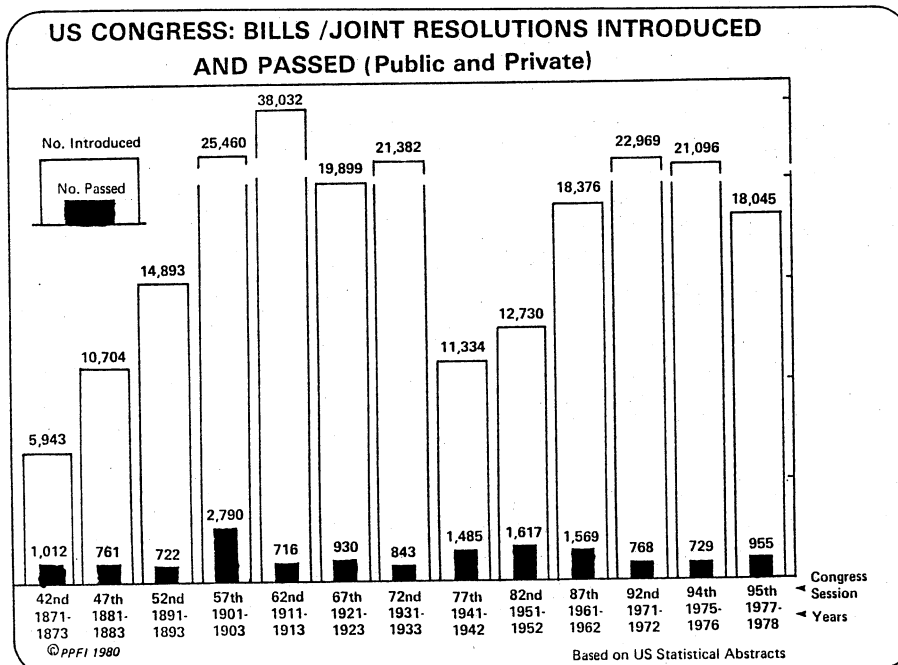

EXHIBIT 3

EXHIBIT 4

POLITICAL INVOLVEMENT IN SOLVING SOCIAL PROBLEMS

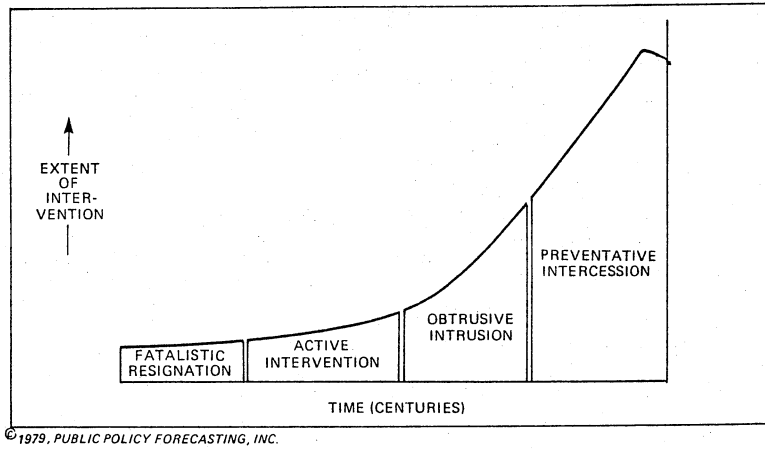

EXHIBIT 5

PATTERN OF CHANGES

theory which may take years to prove. Albert Einstein was one of these men. Less intellectually capable, but extremely vocal, are the victims of an event who can evoke such sympathy that their sufferings begin to focus widespread attention and help bring about change. Galvanizing tragedies often goad public policy change. The sinking of the Titanic on April 14, 1912, led to many reforms and some innovations in the safety of ships which carried into the age of aviation. By 1912, Congress had passed amendments to the Ship Act mandating minimum radio communications/procedures for seagoing vessels. (Later this law was amended by the Radio Act of 1927 which, in turn, was supplanted by the Federal Communications Act of 1934.) The revolutionary fringe, the deviants, cranks, and oddballs of yesterday often start a process which, though ignored at first, may have a profound impact later -- such figures as Alexander Graham Bell, the Wright Brothers, and Benjamin Franklin were not taken seriously initially. Scientific discoveries and technological breakthroughs can be, and often are, major events, even though their impact may not be felt for years.

After the events occur, they are disseminated in what may be termed leading literature, often bringing with it institutionalization in the form of organizations which incorporate the new message and provide a sustained base for advocating change. Popularizers of public policy opinion, the public-spirited crusaders -- the Ralph Naders, the Howard Jarvis types -- make their contribution. So do the prophets of gloom -- the Club of Rome pessimists. Usually such efforts are cast into public interest groups and organizations which institutionalize the cause and provide a sustained base for advancing change.

Politicians and precursor jurisdictions -- domestic and international -- sensing the winds, pick up the trends. Finally, solutions to the excesses and abuses which have been generated are enconced in legislation, regulation, judicial decision, or custom and voluntary undertakings.

The process -- leading events, leading authorities/advocates, leading literature, leading organizations, and implementation by leading political jurisdictions (domestic precursors and leading nation-states) -- tends to follow an S-shaped curve. At the outset, the intensity takes off slowly, follows a steep slope of increase, then tapers off. The curve, when accurately coordinated with time and number or frequency of phenomena indicates past and present position and gives a sense of the momentum for change continuing into the future.

Lead-Lag and Precursor Jurisdictions.

Lead-lag, as used here, describes time lapse between an event and its general adoption. As man's knowledge and capabilities have grown, lead-lag time has shortened. For example, it took hundreds of years to perfect an engine capable of flying the heavier than air ornithopter (1910) which had earlier been designed by Leonardo da Vinci (c. 1500). Only some 15 years elapsed from the time that Alexander Fleming discovered penicillin (1928) to its commercial availability (1940's). A mere 3 years is alleged to have elapsed between invention of the transistor (1948) by Schockley, et. al, and its commercial introduction.

In terms of socio-political lead-lag, it has long been recognized that certain jurisdictions are -- at least for a season in history -- precursors of change. Precursor nations are the adopters, the leaders of innovation. What occurs in these jurisdictions today often is what happens elsewhere tomorrow.

Nations may be broadly classified into three groups according to their willingness and capacity to respond and adapt to change. The first group, bold/innovators and

adopters, include (in typical chronological order) Sweden, Norway, Denmark, The Netherlands, West Germany, the United Kingdom, the United States, and Canada. Diffusion time among these nations varies as to issue. Some 6-10 years for consumer issues has been typical over the last few decades. There are few nations in this group (20-26 countries). Next come the great majority of other nations, which take from 10 to 50 years to follow the leader of the bold early innovators. They tend to range from the industrialized and advanced nations not included in the first group (Spain, Portugal, Italy, and Greece) to some of the progressive emerging nations. A minority of very poorly developed nations comprise the third group, the laggards which typically require many decades to respond to change. Frankly, they are the poorest and the least socio-economically developed nations -- Upper Volta and Zambia, for example. One must remember that the patterns, while normally consistent, are not invariant. At best, such diffusion patterns are a guide to the pace and direction of socio-political change. (Exhibit 6)

Sweden as a Precursor Nation

Over the last few decades, Sweden and the other Scandinavian nations have achieved a remarkably consistent record of "firsts" in consumer affairs. Swedish government officials are realists; indeed, in these nations, nothing succeeds like success and success depends upon tangible accomplishment. Perhaps more important they are motivated by a keen sense of and commitment to social responsibility.

Sweden has many tangible accomplishments to its credit. In the most basic terms -- terms of longevity -- the Swedish people live longer on the average than anyone else. This may be more than an accident of geography or genes. Swedish public policy places a high premium on preventive medicine and related matters. Sweden has a very low death rate from cirrhosis of the liver and a low rate of alcoholism. This is no mere coincidence. To accomplish this the nation placed many restrictions on alcohol, including high taxes based on the content of alcoholic beverages. Distilled spirits have a 90% tax as a percentage of retail price, and the tax graduates down to 50% on light foreign wines, 45% on strong beer, and 10% on very mild beer. Seven percent of Swedish inland revenue came from alcoholic beverage taxes in 1974. Furthermore, the state has a monopoly on the sale of all products with more than 3.6% alcohol, and it operates the package stores -- only 300 in the entire nation in 1976.

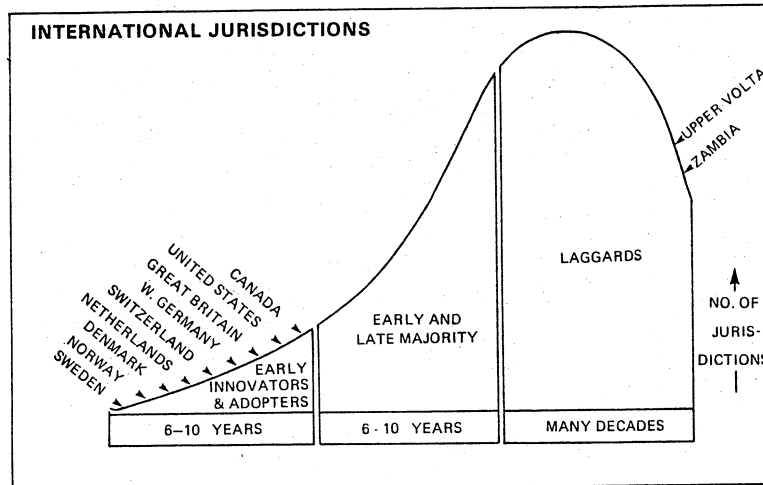

The hand of the Swedish government is felt in many other ways. Extremely stringent controls on advertising over alcohol and tobacco have been enacted. Included have been restrictions in outdoor, movie, and direct mail media to mention a few. Cigarettes must be sold with a "negative marketing approach" in which one of several regularly rotated warnings are placed on the packages. These warnings are much stronger and more persuasive than the U.S. warning. All media and information channels are used to discourage smoking.

The results? Swedes smoked 1,620 cigarettes per capita in 1970 versus 3,971 in the U.S. Part of the result of the state controls can be seen in the voluntary self-regulatory measures adopted by the Swedish Tobacco Branch Association in 1975 which included media limitations (ad bans and restrictions), advertising content restraints (e.g., limitation of pictorial displays, prohibition of pictures of humans or natural scenery unless the picture is part of the trademark), and other promotional restrictions.

Swedish action concerning alcohol, tobacco, and many other products is just a part of a large framework of preventative health measures. Swedish planners long ago

EXHIBIT 6

PATTERNS OF CHANGE

committed themselves to the proverbial ounce of prevention being worth a pound of cure. National health policy, legislated and voluntary, has fallen into line.

The United States as a Precursor Nation: Myth and Reality

Many Americans mistakenly assume that this nation's leadership is all-pervasive, that America always -- or even usually -- leads the world. However, a careful study of history reveals that America has tended to follow the legislative lead of advanced European nations. (Exhibit 7)

During the 1700's and 1800's, the lead-lag was from 30 to 60 years. In more recent times, lead-lag relationships have been contracting for many reasons (the communications and transportation revolutions, for example), and international diffusion occurs at an ever-increasing rate. During the twentieth century, the lead-lag pattern has been reduced to some 5 to 20 years.

The U.S. has often been among the very last of the great nations to legislate a number of major programs:

- The U.S. was one of the last nations to abolish slavery.
- The nation is still a hold-out on compulsory, universal health insurance.
- With the exception of a very few small nations, the U.S. is the last nation to commit itself to metric conversion.

In terms of social and consumer issues, the U.S. lead-lag has been painfully conspicuous. The U.S. adopted:

- pure food and drug laws 46 years after the United Kingdom;
- workman's compensation 37 years after Germany;
- old age assistance 46 years after Germany;
- female suffrage 27 years after New Zealand;

- unemployment insurance 30 years after France;
- national nutritional (macro-nutrient) goals 6 years after Sweden.

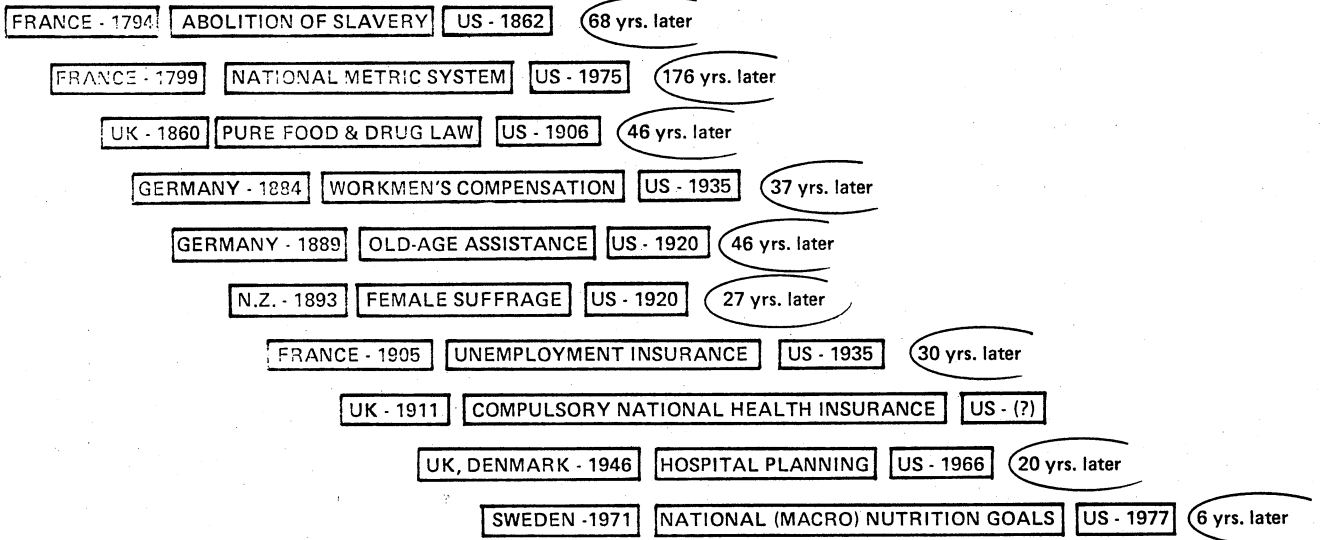

Yet, a cautionary note is in order: just because Sweden or other precursor nations have adopted innovative policy changes does not mean that, *ipso facto*, the changes will be adopted elsewhere. Innovative change and dissemination is not an inexorable process. Fatalistic attitudes are not indicated. Some changes, for example, may not get too far:

- Norway, land of the ski, banned the manufacture, importation and advertising of skateboards in 1979.
- Sweden also during 1979 banned war toys, not an unusual move for a nation that has not been at war for over 150 years.
- Sweden also has taken steps to gird children's rights by restricting and limiting the spanking or humiliation of children.
- Finnish libraries (perhaps with tongue-in-cheek) have banned a corrosive symbol of Western decadence -- a literary character who has nephews of uncertain parentage, who has protracted a romance into a 50-year long love affair without benefit of matrimony, and who runs around with his rear-end exposed. Thus, one should not be so brash as to ask a Finnish librarian for any publication featuring Donald Duck!

Domestic Precursor Jurisdictions in the United States

With minor exceptions historically, certain jurisdictions in the U.S. have been consistent innovators in public policy: New York City and State, Boston and Massachusetts, and, more recently, California, are the leaders. New Jersey often follows the policy lead of its dominant neighbor. Dade County, Florida, is a newcomer that also has moved early in adopting new legislative concepts. Illinois, once a bellweather jurisdiction, has been

INTERNATIONAL DIFFUSION OF PUBLIC POLICY Leads & Lags: Early or 1st Adopters and US

© PUBLIC POLICY FORECASTING INC., 1980

slipping from a vanguard position in recent years. Some states are notable for innovation in one or two areas rather than on a broad-spectrum basis: Oregon with respect to environmental matters, or Minnesota on consumer and environmental issues. (Exhibit 8)

EXHIBIT 8

Once four to six precursor jurisdictions have acted upon an issue, the die often is cast. Taking the cue from experience gained by the early innovators and adopters, most other states are likely to follow suit. The less affluent, less literate, less culturally advantaged places -- Mississippi, Alabama, South Dakota -- usually bring up the rear. The lead-lag time from precursor to laggard states ranges from 5 to 10 years -- sometimes longer; a similar time span has been noted between state adoption of major legislation and federal action.

Federal action is probable when a number of factors -- singly or in combination -- are present. Diverse state approaches can hinder interstate commerce, and almost invite Washington's interest to provide uniformity. State-by-state enactments can be insufficient or unable to deal effectively with problems, particularly those transcending geographic borders. Federal action can cover the interstices. In times of great urgency caused by a spectacular event (airplane crashes in the early 1920's)

PATTERNS OF CHANGE

© 1979, PUBLIC POLICY FORECASTING, INC.

or widespread condition (the Great Depression), the states may be unable to deal with the problem by themselves because of logistical, funding, or leadership problems. Again, a cautionary note -- federal action sometimes precedes state action.

Identifiable factors predispose precursor jurisdictions in the U.S. as they do in Europe:

A large amount of activity in an area (large population, as in New York, Boston, California, intrudes new problems associated with size); large expenditures (as for medicaid in these huge jurisdictions where an astounding 40% of total U.S. expenditures occurred during the mid-1970's);

Special patterns of use (sheer size giving rise to traffic strangulation control in New York and Los Angeles);

Terrain and associated meteorological conditions (bringing on confrontations with air pollution in California and Kentucky).

Philosophical predispositions are also a factor. Liberal states are generally more innovative and progressive, and thus are likely to arrogate power to government. As time goes by, reform breeds further reform. However, excess reform can turn the political climate toward conservatism. The balance between these two extremes constantly is shifting over time -- like the swing of a pendulum.

No jurisdiction has a monopoly on any ideas or issues. Thus, comprehensive analysis of legislation/regulation requires monitoring of both precursor and other jurisdictions. Public policy trend analysis can provide knowledge as to precisely where an issue stands, what issues are flashed in the pan, and what issues are most likely to run their logical course.

In addition to legislative harbingers, it is also wise to monitor court decisions. In this century, the courts, especially on the highest state and federal levels, have exercised a sense of social awareness which has often been translated into reinterpretations of the common law. U.S. courts can, in effect, make law by restating, refining, expanding or contracting its meaning. Judicial precedent often reveals shortcomings that lead to across-the-board legislative standards.

Monitoring landmark decisions, counting cases on a specific issue, following groups which test the limits of the law (e.g., Americans for Democratic Action, the American Civil Liberties Union), and measuring the time that certain cases take to reach final appeal are just some of the many methods for sensing and predicting this aspect of change. The courts have been a major change agent in a day and age when they have assumed an increasing role in legal interpretation, becoming what some observers feel is a shadow legislature.

Finally, the actions of the executive branch should be followed with care. The actions can take several forms:

1. Legislation in effect proposed by the President.
2. Legislation vetoed by the President.
3. The extent and vigor of executive enforcement of law and regulation -- or the lack thereof.
4. Occasional but weighty Presidential actions. Broadcasts to the nation are one of these. Nomination or dismissal of key appointments is another.

The Issue Universe for Consumerism

Analyzing and forecasting a particular problem area begins by charting the total issue universe. The process begins by -

- (1) identifying the broad generic issue -- consumerism in this case,
- (2) delineating the major issue sectors or groups (e.g., product safety, advertising regulation, macro-nutrient content, labeling disclosure),
- (3) sub-categorizing each sector/group into discrete units.

Some of the major issue sectors Public Policy Forecasting, Inc., has charted are diet and health; food safety and quality assurance; advertising regulation; telecommunications; sugar, alcohol and tobacco regulation; organizational and institutional response to consumerism; health care cost containment; and others.

Issues such as these are broken into subcategories in the third stage. For example, under food safety and quality assurance, Public Policy Forecasting, Inc., has identified over 275 impending issues such as food colors, other additives, additive disclosure systems, allergens (primary and secondary reactions), synergisms, Delaney Clause revision prospects, natural foods, testing protocols, procedures and standards, and so forth.

As technology advances, the list grows, often logarithmically. One food safety drive aimed at reducing sugar consumption included over 125 individual issues aggregated into 20 sub-categories. New methods of measurement allow for the detection of one part per trillion of some food ingredients -- the equivalent of one drop of vermouth in 520 railroad cars each containing 30,000 gallons of gin. Coffee has been found to contain an estimated 2,000 individual chemicals. Diesel exhaust contains over 30,000 chemical components. At these rates, almost any product can be indicted as posing a risk to health.

Increasingly, decisions will be premised on such microscopic detail. Chemical reactions, right down to the individual basic atomic elements reactions and relationships, increasingly are becoming the new frontiers of government investigation and policy making. With each potential posing risks (or benefits), the magnitude of the issue universe we are attempting to describe can hardly be underestimated.

Cyclical Change

Though consumerism does not hold the headlines as much as it did in the late '60's and early '70's -- the Ralph Nader years -- and although consumerism may seem to be receding in light of current anti-regulation and tax-cutting (Proposition 13) moods, these are but a temporary pall, a breathing space, before the next large-scale expansion of consumer issues. A growing backlog of such issues continues to build up like the pressure in a knotted house. Remove the restriction and the stream will shoot forth once more.

Consumerism tends to move in spurts or bursts, a phenomenon which is one of the major techniques of investigating public policy matters. Historic cumulative plots of major consumer laws and regulations (Exhibit 1) reveal three major cycles, each lasting about 10 to 30 years. The first, during the Progressive Era, was 20 years in duration -- 1887 to 1917, and emphasized social justice espoused by social reformers such as Lincoln Steffens and Theodore Roosevelt. A second cycle started after the war and the recovery period lasted from 1920 to the beginning

CYCLES : ADVERTISING REGULATION

© 1979, PUBLIC POLICY FORECASTING, INC.

of World War II, and climaxed vigorously during the New Deal.

Following the end of World War II, the recovery phase, and the Korean War, the third cycle, emphasizing post-war and post-industrial transition and the New Politics, lasted from the early 1950's to 1974. This period did not have much movement until 1958 with the enactment of the Automobile Disclosure Act. Following this were Senator Kefauver's drug investigations, the truth-in-packaging drive, and the Kennedy years. The fourth cycle started in 1978. Public Policy Forecasting has predicted this new cycle will last until the turn of the century. It should be noted that issues other than consumerism follow similar cycles. We have found patterns for social welfare laws, women's rights, environmentalism, and other issues.

Each of the four consumer cycles noted also included the appearance and dominance of new communication technologies (Exhibit 9): a largely literate audience reading inexpensive newspapers and magazines at the turn of the century, especially in the cities; regular radio broadcasting beginning in the mid-1920's; television starting in the early 1950's; and computers and other electronic media by the late 1970's. Each major communication mode was accompanied by advertising. In each case overzealous advertising practices introduced abuses and excesses. Such social frictions became unbearable and efforts of voluntary rectification were followed by government-mandated standards.

Each cycle occurred during a period of major socioeconomic change, accompanied by relative prosperity. Conversely, during times of military confrontation, national priorities are altered to a wartime footing, requiring tremendous economic, monetary, and manpower commitments. These displacements relegate social interest issues to a low priority. Following cessation of hostilities a two to three year period of economic readjustment also deters commitment to social policy programs of all kinds, including consumerism. Postponement does not mean abandonment, however.

Some Corporate Advantages Gained from Anticipating and Responding to Impending Consumer Issues: The Role of Forecasting

Consumer issues imposed by governments increasingly intrude on private sector activities, management prerogatives, and market decisions. Often politically, rather than rationally inspired, some of these changes can be difficult to foresee and assess. Nevertheless, short-term trends are generally clear down to the level of specific issues; longer term trends are harder to predict, but the basic directions are usually distinct. What is important in this era of rampant and pervasive change is to keep one step ahead of regulators and to stay abreast of consumer demands, which are invariably mirrored by government action later.

Some advantages business can gain from foresight are:

- Identify or corroborate new marketing opportunities and problems.
- Gain the lead time required to develop, re-design, or reformulate products and procedures. Check design soundness, establish alternate supplies, conduct test marketing surveys, reposition existing products, and so forth.
- Avoid, or at least minimize, the often costly impacts of government mandates which catch unwary managers by surprise (e.g., costly and embarrassing inventory and recall/disposal problems following bans).
- Consider undertaking coordinated industry-wide lobbying to champion, redirect, or defeat impending change, or to cooperate in writing laws that all can live with comfortably.
- In the same vein, avoid the cost and bad public relations in lobbying for lost causes.

- Exercise industry leadership by moving first and setting trends, rather than just responding in a purely reactive mode which often results in a negative public relations image. In the long run, such actions can develop positive public relations potentials by building the corporate image in ways paid advertising cannot.

- Respond positively to humanitarian causes and socially desirable goals. When there is a low ebb of consumer confidence -- as is now being experienced -- responding positively to moral and ethical issues builds corporate stature.

If one can foresee the future, one can help manage it. The past is prologue.

Short shrift must not be given to historical and global perspectives. Much can be gained from past experiences and actions taken elsewhere. Short of this we may be doomed to repeat the mistakes of history.

SWEDISH CONSUMER POLICY, ITS TRANSFERABILITY AND
RELATED RESEARCH IMPLICATIONS¹

Hans B. Thorelli, Indiana University

Abstract

An overview of recent Swedish consumer policy, public and private, constitutes the first part of this paper. The one-round Delphi study which follows is focused on future developments in Sweden. A third part briefly discusses some fascinating issues involved in technology transfer in the public policy area, with examples from consumer policy. Finally a catalog is offered of research implications suggested by the paper.

Recent Swedish Consumer Policy

A dynamic analysis of Swedish consumer policy in the 1940-1975 period was presented in Thorelli and Thorelli (1977). A more detailed, institutionally oriented survey of the pre-1970 years is found in Thorelli and Thorelli (1974). Our purpose here is to update these materials, essentially covering the years 1976-80.

The Setting

The consumerism debate in Sweden has calmed down in the last five years.² It has become less passionate, less personal and there is generally less exaggeration in argumentation. This statement is valid also for Råd och Rön, the consumer journal published by the State Consumer Board. It has almost doubled its circulation from 110,000 subscribers in 1974-75 to some 200,000 in 1979-80, despite a doubling in price to a modest \$5.50 per year. The journal now has a penetration rate about twice that of Consumer Reports. Consumer activists are given less play by the media, although there is a popularly viewed, regularly scheduled TV program.

This does not mean that either consumerism or public debate is dead. The consumerist "movement"—Sweden has no general-purpose consumerist groups—has reached a stage of maturity where it is likely to remain for a while. At the same time the climate of opinion has become more nuanced, generally a healthy development. An example is the series of eight or more articles in the Stockholm Svenska Dagbladet, March-June 1978. Another is the conference "Consumer Policy Faces the 80's" of government, academic, business and media opinion leaders arranged by the Ministry of Commerce in May 1979 and also the excellent

collection published by the Swedish Committee for Economic Development (SNS) in 1979.³

A sign of the times is some serious soul-searching going on in the State Consumer Board. This self-examination is not in any direct way related to the change from social democrat to coalition government by liberal parties. It does seem symptomatic of a readiness to accept or consider some new signals. There is also some unrest among the technical and economic professionals about what a fair number of them consider the "lawyer oligarchy" absorbed by the State Consumer Board (KOV) when it merged with the Office of the Consumer Ombudsman (KO) in 1976 and when KO also became Director General of the Board. In part the spirit of reevaluation is no doubt also related to a certain amount of soul-searching in and about the welfare state as such—also a fairly recent Swedish development.

A recurring theme in the expressions of opinion cited earlier is the need for a gradual shift in emphasis of policy from protection towards emancipation of consumers. In this context the need for a fresh look at consumer information programs is often stressed. Sweden pioneered voluntary informative labeling of consumer products, but this program was abandoned by the State Consumer Board during the years of the Left Twist. The desire for "help towards self-help" more than additional regulations was clearly manifested in a recent major academic survey of Swedish consumers (Wikstrom 1979). On the other hand, another large survey sponsored by the State Consumer Board seemed to call for more protection.⁴ Few such large-scale surveys of consumer opinions of consumer policy issues had been made before in Sweden (Thorelli, Becker, Engledow 1975, pp. 194 ff.).

New Laws and Proposals

The momentum of consumer policy proposals enacted into law or subject to scrutiny by the perennial government investigating committees characteristic of the country has been maintained in the last few years. Sweden took the ultimate step towards centralization of general consumer policy by the merger of the Office of KO and the State Consumer Board (KOV).⁵ At that time the 1971 Marketing Practices Act had been succeeded by a new Marketing Act, which strengthened the old law in two important ways.⁶

¹The author expresses his appreciation to The Swedish Bicentennial Fund for the fellowship which made this research in Sweden possible. The Fund was established in 1976 by the Government of Sweden to promote scientific and cultural relations with the United States. Dr. Sarah V. Thorelli participated in all aspects of the research. We are most grateful for the outstanding cooperation of Sven Heurgren, the Consumer Ombudsman and Director General of the State Consumer Board, and his associates at the Board, and to the Dean and staff of the Stockholm School of Economics, and literally scores of other Swedish friends.

²This is recognized by the Director General and the editors of the State Consumer Board; see Konsumenträtt och Ekonomi (1979:2), pp. 2, 30.

³Bengt Ryden, ed., Mot en ny Konsumentpolitik (Towards a New Consumer Policy, Stockholm: SNS, 1979).

⁴Konsumentundersökningen 1978-79 (Stockholm: State Consumer Board), Swedish mimeograph summary, "Konsumentpolitiken inför 80-talet," by L. Lundvall of the Board. Pending the final report some aspects of the survey have been highlighted in Råd och Rön. A few questions of this survey seemed less professionally worded than might be desired.

⁵The law chartering the reconstituted State Consumer Board is Forordning med Instruktion för Konsumentverket, SFS 1976: 429.

⁶Marknadsföringslag, 15 December 1975 (SFS 1975: 1418).

A firm (or trade association) may now be required by KO to supply product information deemed of special importance to consumers. His decisions may be appealed to the Market Court (T. and T. 1977, p. 223), in which case he has the burden of proof. The second innovation deals with the sale and rental of hazardous commodities. The marketing of such products may be prohibited.⁷ Special product control legislation was already in place for food products and goods which entail danger to the environment.

Another new law of general importance is the Consumer Credit Act of 1977.⁸ A seller or financing agency in marketing credit must give information about the effective rate of interest (including administrative charges, etc.). The same data shall again be given any individual customer before credit is granted. As a rule down payments in instalment sales should not be less than 20 percent. The new law also restricts the possibility of sellers and third parties repossessing goods in case of default.

Sweden is primed to adopt strict liability as a general rule in the sale of consumer goods through the pending law on product liability in such sales. We may note, too, that in 1981 the Central Consumer Complaints Board (ARN)--hitherto regarded as an "experimental activity" within the KOV--will be established as a fully separate activity. It would be quite premature, however, to see in this a return to decentralization of consumer policy.

The committee to study the desirability of giving KO certain powers to subpoena information from individual firms presented its first report in 1979, including a draft law providing for sweeping powers of that kind.⁹ KO in an official commentary to the report saw the need for even broader powers as far as past and present activities of firms are concerned. However, he suggested on both practical and principal grounds that his powers to require data about product planning and other future-oriented company activities be limited to cases where issues of product safety would likely be involved.

Another major report presented a draft Consumer Services Act in 1979.¹⁰ The principal investigator has discussed the proposal in detail in Journal of Consumer Policy (Bernitz 1980). Briefly, the proposed act will cover most services involving work on tangible objects, houses and land. The law governing such services is poorly developed in most countries. The act provides for freedom of contract as to the manner of performance of a service as well as to its price. However, once a contract is made, many of the proposed rules are mandatory, i.e., they cannot be set aside by contract to the detriment of the consumer. An interesting example is that the entrepreneur is liable for information furnished when marketing the service: "acts of marketing, such as advertising, should be considered as belonging to the contracting process. . . . Accordingly, a deviation from statements in

⁷The same applies to commodities which are "obviously unfit for their primary purposes." After a test case involving a notoriously poor washing machine, in which KO won only a Pyrrhic victory at the Market Court, that provision has fallen into disuse.

⁸Konsumentkreditlagen, SFS 1977: 981, amended by SFS 1978: 598.

⁹Konsumentinflytande genom Insyn?, SOU 1979: 5.

¹⁰Konsumenttjänstlag, SOU 1979: 36.

advertisements and similar communications aimed at the general public should be considered to constitute a defect in the service performed." (Bernitz 1980). Two investigating committees recently appointed should be mentioned. One is concerned with "market surveys, comparative testing and other types of product research," as well as the various uses, and the distribution of, the information resulting from such activities. The purpose of the other is an evaluation of KOV activity in the area of marketing guidelines (below).

Public Policy Enforcement

Given an ecologic view of institutions it is only natural that trends of enforcement in Swedish consumer policy have responded to environmental developments as well as to the leadership of Sven Heurgren, KO as well as Director General of KOV since the merger. It is important to remember that Mr. Heurgren--who was KO before his present appointment--is a lawyer, and that he brought much of his legal staff with him to KOV. No one may doubt that the top priority of KOV is the enforcement of the Marketing Act and related legislation. Inevitably other aspects of consumer policy--such as education, information, product testing--have suffered somewhat, at least by comparison. To a fair extent technical and economic staff at KOV have been engaged in the professional backup work necessary in effective law enforcement. Indeed, malice would have it that in effect the KOV has become an enlarged Office of the KO.

The most dramatic shift in policy enforcement has been from the brash jawboning of producers and anti-business tirades of the former Director General to the development of guidelines governing particular industries and trades. This change should be seen against the background that Swedish politics is no longer dominated by the Left Twist phalanx and that Mr. Heurgren, while aggressive and publicity-conscious, comes equipped with a sober legal temperament. He also stands for a sense of fairness, which somehow got lost in the missionary zeal of the predecessor administration.

The day-to-day handling of malpractices by particular firms has been described in Thorelli and Thorelli (1977). Of greater principal interest are the guidelines somewhat similar to the trade regulation rules of the FTC. Such guidelines are not new to the Swedish scene (T. and T. 1977, p. 219). What is new is the emphasis placed on them and the institutionalization of the system. KO himself regards the guidelines as the most important single means of influencing producers. Guidelines are typically worked out in negotiations between KOV and a trade association. Thus, the activity reintroduces in consumer policy enforcement an element of pluralism which had been on the wane during the Left Twist years. KOV has the authority to issue guidelines in the absence of an accord. However, it strives to achieve a "voluntary" agreement. If an industry member abridges the agreement, KO can take him to the Market Court, which alone can make the final decision as to the legality of a guideline.

Most of the guidelines are concerned with product safety, and many of them also prescribe certain minimum standards of product information. Advertising of alcohol and tobacco products is severely restricted. Several guides deal with energy labeling of such products as cars and major appliances. Some 30 guidelines are now published in the official KOV collection ranging from grocery store advertising and in-store information concerning "specials" on food products to safety standards for ski bindings. A similar number of proposed guidelines are in various stages of negotiation and processing, and at least another

score figure in KOV internal planning. The guideline for skateboards is significant in indicating the new trend in policy: sale of the boards is permitted with the proviso 1) that they conform to specified safety standards, 2) that they carry elaborate warnings, and 3) that the seller indicate that skateboards are unsuitable for children under 12. Norway banned skateboards outright, something Sweden could have been expected to do only six years ago.

The development of guidelines is a slow and arduous process--even in cases where the trade is eager to cooperate. It must not be forgotten that there are tens of thousands of products in the modern marketplace. The system is also not free from controversy. The Chairman of the Market Court has pointed to the risk that guidelines might thwart constructive competition, and stated that many firms are sufficiently shy of bad publicity to agree to undesirable restrictions on their freedom of action.¹¹ This same argument was also voiced by a spokesman for the Federation of Swedish Industries, which is trying to stimulate its members to request KOV to demonstrate the need for its proposals more thoroughly than heretofore. As KOV apparently feels it represents consumer interests sufficiently well, there has been little or no effort to engage individual consumers or groups thereof in its work. As KOV is well aware, it is also true that resources do not permit a systematic surveillance of compliance with the guidelines; enforcement effort is typically contingent on consumer or competitor complaint. These types of concerns provide some of the impetus behind the appointment of the investigating committee to evaluate the guidelines. The system will almost surely survive this examination, though likely in somewhat modified form.

KOV nowadays does little by way of comparative testing for consumer information (CI) purposes. Some tests are contracted for CI in Råd och Ron (occasionally even paid for out of the magazine's budget). Most of the tests handled by the technical bureau now are either on contract from individual firms or to provide backup data for guideline negotiations. KOV does participate in the Nordic Council comparative tests which are reported in some form in Råd och Ron. KOV also publishes a quarterly journal on consumer law and economics read mainly by marketing executives and lawyers, home economics teachers and other professionals. Several buying guides are also published. Occasionally a major comparative test will be undertaken, or contracted for, to provide material for a special monograph, such as the excellent ones on washing machines and dishwashers and the economics of different models of cars (acquisition, performance, maintenance, repair, taxes, insurance, etc.). A fair amount of consumer education materials for schools (involving issues of methodology as well as subject matter) is also produced.

Little is still being done about CI in the more restricted sense. The relative decline of comparative testing has been mentioned. The only novelty worth mentioning is what may be called "negotiated CI," i.e., information rules in the guidelines. Most negotiated CI is, however, product-specific, i.e., there is no common scheme or even logo, and the information required is typically confined to safety aspects. The few energy labels among the guidelines provide no information beyond the consumption of fuel or electricity under specified conditions. KO has no interest in allocating resources to a broad-spectrum voluntary

¹¹Justice Peter Westerlind in address before the consumer policy conference of the Ministry of Commerce, May 3, 1979.

informative labeling and/or quality certification program,¹² although it would be within his power to do so. He feels it is the responsibility of individual producers to decide what information they should provide beyond that which may have been mandated in the 30-odd guidelines. For several years KO also refused to support research and development of computerized CI banks, expressing the fear that they might easily become subject to abuse by advertisers or other commercial interests.

In the last five years KOV has supported a good deal of academic research more or less related to consumer policy. Some of it has been of high quality. As mentioned, it has also sponsored a major consumer survey under its own auspices. An interesting initiative is the program currently being launched establishing minimum standards for auto repair shops.

KOV has devoted some special attention to the problems of consumers living in sparsely populated areas where the local general stores and/or gas stations find it increasingly difficult to survive. Such outlets may get modest subsidies for special-purpose investments, such as freezers and mobile markets. KOV has recommended to such state bodies as the Apothecary, the Lottery, the Post Office, the Alcohol Monopoly that they remunerate these distant stores somewhat more generously than before for services performed for these agencies. These authorities were not amused. Support for home delivery services organized by local government may be obtained, and so on. Experiments have also been made with special bussing of distantly located consumers to the nearest store or community. In 1975 a law was passed creating a system of consumer advisory services (budgeting, product information, complaint advice, etc.) to be administered by local and regional government on a voluntary basis. By Fall 1979 some 178 local government units of a total of 277 had decided at least in principle to establish such services. However, only 34 of them had one or more full-time consumer advisers.¹³ Most of these plus some 30 other communities had established consumer councils within the local government structure. KO has been recommending that local consumer services be made mandatory, but there is a real question in our mind whether KOV at this time has enough educational and CI materials to back up such a system effectively.

It may be added that some special areas of public consumer policies are handled by other agencies than KOV, such as the State Food Administration and the Environmental Protection Board.

Consumer Policy at the Enterprise Level

Too often one gets the impression in academic as well as public debate that consumer policy is an activity reserved for governments. But the term reasonably applies to any organized measures to promote consumer interests (Thorelli, 1972). Thus, consumer policymakers include consumer groups, the media, educational institutions, business firms, trade and standardization associations, etc. In

¹²KO stated this in a meeting of the Stockholm group of SNS on May 12, 1980.

¹³The Stockholm office is the largest and very centrally located. However, we found that on two Fridays in May 1980 the office was closed--at a time when the city was full of shoppers. The preceding Thursdays were national holidays and all personnel had been allowed vacation days on these busy Fridays. Though stores are open the office is closed on Saturdays.

the case of individual firms the border between consumer policy and general business policy is none too clear. We shall assume merely that consumer policy refers to measures going beyond "providing a good product at a good price."

No systematic survey has been made of consumer policy at the enterprise level in Sweden. If we include--as one probably should--voluntary cooperation with KO-KOV and the Central Consumer Complaints Board here, it is clear that thousands of firms are engaged in consumer policy to varying degree. What firms do on their own, however, generally appears less impressive. Students of Professor Solveig Wikström surveyed the situation in a dozen firms, and found surprisingly little activity beyond routine complaint handling. There were remarkably few consumer affairs professionals in these firms. We got a similar impression, amplified by a well-connected spokesman of organized industry who said that "this country does not have much, and what there is, is in large part cosmetic." We interviewed the coops and a few companies and found only one truly impressive case: ICA AB, the company serving the Independent Grocers Alliance, the largest retail organization in Sweden. Its weekly magazine with a paid circulation of about 600,000 (three times that of Råd och Ron) is thoroughly consumer-oriented in terms of articles on home economics and household management. Almost every issue carries a comparative test; there is a special issue summarizing scores of tests.¹⁴ Indeed, ICA for years has sponsored a great deal more of comparative testing than has KOV. ICA plans an accelerated effort to increase interest in consumer policy at the member store level.

Government enterprises, being semi-monopolies, are not setting noble examples in this area. The State Telephone Administration, for example, has no consumer affairs department, although we understand that KOV has repeatedly recommended that one be created. At the trade association level, the Furniture Research Institute has sponsored an informative labeling program, "Furniture Facts," which has been moderately successful. This is more due to the largest dealer chains (IKEA and the cooperative department stores) wishing to carry labels on part of their assortment than to manufacturer enthusiasm. A trade group of insurance companies has established a special Insurance Consumers' Advice Bureau as a joint venture with KOV. Speaking generally, the federations of industry, wholesalers and retailers have been more willing to accept--indeed, often endorse--public consumer policy than to launch initiatives of their own.¹⁵ It would seem that thus far Swedish business at the enterprise level has been less eager to engage in independent consumer policy than have American firms as revealed in the 1975 study by Fornell. The latter in 1978 estimated the number of consumer affairs units in Swedish firms at about 20, while in the U.S. there might well be more than 1,000 (Fornell 1978). It may well be that Swedish firms have become so conditioned by welfare state thinking and KOV activity that they simply tend to feel no independent responsibility for consumer policy. We may note, however, that both the Swedish CED and the Federation of Industries have recently given the stimulation of consumer policy at the firm level a prominent place on their agendas.

¹⁴Testat av ICA-kuriren (ICA AB, 1979).

¹⁵For sample policy statements by spokesmen of these organizations, see Henell, Olof, Foretagens Reaktionen På Konsumentpolitiken (Stockholm: Raber Sjögren, 1976).

Swedish Policy: A Futurist View

To get an idea of what the future may hold in store for Swedish consumer policy we undertook what may be called a one-round Delphi. A standardized questionnaire was used to obtain from a limited number of experts their probability estimates of 22 different consumer policy "events" taking place in the 1980-85 period. All events have been mentioned as at least plausible in Swedish debate. The 18 experts consulted were government officials, academics and business executives prominently associated with public and/or private consumer policy. No less than 14 returned filled-in questionnaires. There was no difference in occupational composition of respondents and nonrespondents. Our excellent personal contacts with respondents probably had something to do with the 78 percent response rate. We list the respondents to give the reader an idea of their background and to thank them for their cooperation:

Mr. Tore Adler, The Swedish Furniture Research Institute
Mr. Jan Gillberg, Executive Director, The Federation of Swedish Marketing Associations
Mr. Sven Heurgren, KO and Director General of KOV
Dr. Ernst Johnson, Associate Professor, University of Stockholm
Dr. Claes-Robert Julander, Research Associate, Stockholm School of Economics
Dr. Lars Nieckels, Associate Professor, University of Stockholm
Dr. Tomas Ohlin, Executive Secretary, Government Commission on New Information Technology
Mr. Åke Safbeck, Central Marketing Department, Electrolux, Inc.
Dr. Sten Tengelin, Executive Director, Swedish Industry Delegation on Marketing Law and Rapporteur on Consumer Affairs, International Chamber of Commerce, Paris
Mr. Ulf Tidics, Consumer Affairs Executive, Marketing Department, Philips of Sweden, Inc.
Ms. Margareta Wernevi, Director of Consumer Affairs, Sunlight of Sweden, Inc. (a Unilever affiliate)
Dr. Solveig Wikström, Professor, University of Lund
Mr. Nils-Erik Wirsäll, Adjunct Professor, Stockholm School of Economics and Former President, ICA AB (Independent Grocers' Alliance)
Dr. Karl-Erik Wärneryd, Professor, Stockholm School of Economics

The results of the survey are indicated by Table 1. We note the large standard deviations around the means, indicating that the numbers should be taken with a grain of salt. Interestingly, only five events were given a more than even chance of occurring in the next five years. Event number 1 (better complaint handling and internal communication about complaints) anticipates a stronger commitment on the part of individual firms to consumer affairs. (So do events 7 and 14.) Events 2-5 are all concerned with consumer information and education, lending additional support to the view that a certain shift from protection-regulation towards information-education may be the direction of change in Swedish consumer policy. Event 5 should be compared with event 15. If we include as serious possibilities all events with over 40 percent mean probability assigned by the experts, the number trebles to 15 events. Note that computerized consumer information figures in both events 12 and 17, the more ambitious form being given the greater probability. The experts were also invited to volunteer other likely events. An international informative labeling and/or quality marking system with minimum performance thresholds, expanded product liability, more dialog between public and private policymakers, and more "reality-oriented" education of marketing personnel were mentioned. It should be stressed that these experts are all extremely busy people. There may well be other events which they would assign greater probability than some of those specified in the questionnaire.

TABLE 1
 PERCENT MEAN AND MODAL PROBABILITIES OF 22 CONSUMER POLICY EVENTS IN
 SWEDEN IN 1980-85, BASED ON 14 SEPARATE EXPERT ESTIMATES

Events in order of probability assigned	Mean	Standard Deviation of Mean	Mode
1. Firms strengthen complaints handling, communicate the info to product planning, quality control, etc.	68	29	85
2. Some form of standardized, multi-product consumer information system (e.g., a modernized VDN)	64	29	80
3. Obligatory consumer education in the schools	63	25	100
4. Local government consumer affairs activity becomes mandatory	54	26	100
5. Computerized checkout counters in supermarkets give receipts with price data for each individual product	54	31	50
6. Service firms flagrantly advising consumers may lose their license to do business	49	27	50
7. Internal consumer affairs departments in 100 firms	48	29	50
8. Growing number of import restrictions	44	33	50
9. Consumer representation in KOV operations	44	30	40
10. Price control made permanent	44	33	a
11. Cars banned from the core of five largest cities	43	29	50
12. Computerized consumer information one-way (via cassette, T.V., etc.)	43	23	50
13. New measures for consumers in sparsely settled areas	42	22	60
14. Additional joint business-KOV consumer advice bureaus of the insurance consumer service bureau type	42	20	60
15. Individual cans and packaged goods to be price marked even with computerized checkout system	41	25	50

Consumer Policy Precurse and Transfer

Public policy forecasting is increasingly vital to the strategic planning of both public and private policymakers. We just illustrated one of the techniques applicable. Another is to look across national borders for a country which may be a precursor of things to come in our own. Public policymakers would also be much interested in the somewhat related question as to whether, and to what extent, the precursor policy is transferable into their own environment. Given the extreme complexity of this area, and the paucity of work in it, we have only a few tentative thoughts upon it. They are essentially derived from an ecologic view of policy and institutions (T. and T. 1977).

At least three types of precurse are relevant. The first is environmental developments in the precursor country creating a latent need or problem. Latency is hard to recognize--especially in a foreign country's environment. To do this one needs an environmental scanning system with a distant early warning attachment (Ansoff 1977). The second type of precurse involves problem or need identification in public debate, often precipitated by a signal event or, more often, by a sequence of such events. The third type involves the adoption of new policies and/or institutions to deal with the problem (need) in the precursor country. Clearly, the three types of precurse often occur sequentially. However, a country may be a precursor at one of these stages but not at another. Furthermore, sometimes new policies are adopted before the need has become acute, bypassing one or both of the earlier stages.

Without getting lost in detail, it is easy to see that there are some major measurement problems here. For instance, how much public awareness of the problem (need) must there be before we have a precurse of type two? Is one a precursor at all before somebody else recognizes it? When do we have a "new" policy or institution as compared to a mere amendment of an old one?

The precursor concept is rooted squarely in the idea of transferability. If there be no transferability, why then bother to look abroad? For one to speak of transfer the policy must presumably be imported by the follower country from the precursor country, not just adopted in some kind of spontaneous diffusion process. Typically, one would expect varying degrees of adaptation in the transfer process, due to such varying environmental conditions as economic development, political values and legal system. An excellent example of adaptation in the transfer-diffusion process is the adoption of restrictive practices legislation in a dozen West European countries after World War II on the impetus of U.S. antitrust policy (Thorelli 1959). When little adaptation is called for we may speak of robustness of transferability. Robustness tends to be great at a very general level of policy, often declining with increasing specificity. For example, we have claimed that in industrially advanced countries the relative emphasis in consumer policy should be information, education, and protection (in that order), while in the LDC it should be exactly the reverse. Proceeding at a very broad level, we believe this statement is robust. Nevertheless, presumably there is a "gray area" where the switch in policy rankings takes place. An interesting example of robustness even in a rather specific situation

in spite of strong environmental variation was given by KO. In the area of product liability Sweden is likely to adopt the U.S. idea of strict liability, but the Swedes dislike the huge and often seemingly arbitrary damages meted out in U.S. cases. KO feels that there would be little risk of "sensational" settlements in Sweden, as damages traditionally have been more modest (there are no juries in Sweden) and as the local social welfare system would automatically absorb the cost of many ailments due to product failure. An illustration of considerable adaptation, on the other hand, was the strong "Swedish accent" initially given to the guideline system largely inspired by the trade regulation rules of the FTC. Transferability is a relative thing. It is easy to exaggerate both the uniqueness and sameness of countries.¹⁶ The ecologic view cautions against both extremes.

Precurse and Transfer: Sweden and the United States

In discussing precurse and transfer of environmental trends, cultural values and shifts in public opinion, it may be quite meaningful to focus on the broad national scene in both Sweden and the U.S. However, as one gets into specifics it would be unrealistic to overlook that while Sweden is a small, homogeneous and in some respects (such as public consumer policy) fairly centralized nation; the U.S. is of continental dimensions, exceedingly heterogeneous, and in many respects a highly decentralized country. In the area of consumer policy a great number of autonomous initiatives are taken at state rather than federal level.

Precurse types one and two involve changes in conditioning variables and consequent problem (or need) identification. There is relatively great transferability here due to the similarity in environmental circumstances: we are dealing with two of the handful of "post-industrial" societies in the world. As Graham T. T. Molitor (1973) and others have observed, Sweden has typically served as a precursor here. This is due to her having embraced the welfare state concept at an early stage and being a good example of the drift towards the left in economic policy, which is possibly the most significant likely global trend for the remainder of the twentieth century. The U.S. has wished to retain a greater element of individual responsibility for personal welfare, and has not veered left at anywhere near the speed of Sweden. Thus it is but natural that Sweden has been a precursor as regards such "movements" as sexual freedom, women's liberation, environmental protection (and in this area sequentially environmental pollution, resource conservation, noise reduction) and egalitarianism in the sense of making everybody equal (as distinct from equal opportunity). As regards broad consumerist trends, she was also a precursor in the early 1970s push to promote producer jawboning as a pre-sale consumer policy approach and in establishing the Central Consumer Complaints Board as a semi-independent agency in 1968 (done within the U.S. OCA in 1980). Currently, Sweden may well have a precursor role as regards both the practice of cohabitation without marriage and public concern about cohabitants' rights.

¹⁶A precisely analogous situation obtains with regard to the PIMS strategic planning data pool, as member companies agonize over to what extent policies pursued by, say the electrical machinery industry, may be applicable to, say, the farm equipment industry.

Local government activity notwithstanding, Sweden has gone further than any other nation in centralization of consumer policy. In this respect she was a precursor type three (specific policy measures) to the attempts to create a central Consumer Protection Agency in the U.S., a proposal at least temporarily abandoned in favor of a more decentralized approach not remarkably different from that initiated by the Ford administration.

In the past, there has been an unfortunate failure to distinguish precurse and transfer. At the level of general ideation it would seem that there has been some transfer from Sweden to the U.S. in the field of social welfare policy (epitomized by Marquis Childs' Sweden--The Middle Way). The notion of KO appears to have played a role in the creation of Consumer Advocates in a number of American states and major cities. However, only few specifics of U.S. consumer policy would appear to have their origin in transfer from Sweden. A big study focused on Sweden's alleged pace-setter role vis-à-vis the United States could only point to legislation establishing maximum levels of mercury in food, banning DDT and regulating the use of pesticides. Volvo also pioneered three-point safety belts as standard in 1959, before the promotion of such seat-belts became official policy in the U.S. (Forecasting International 1976). On balance, it seems clear that most of the transfer traffic actually has been in the other direction. The influential role of the FTC trade regulation rules on the Swedish guidelines system has already been mentioned. The U.S.--or individual states--were ahead on unit pricing, truth-in-lending and cyclamates. The accident reporting system adopted by the Nordic Council is directly patterned on NEISS. The Swedish coops borrowed the idea of generic foods from Jewel Tea. If there was no direct transfer, the U.S. was at least the precursor regarding labeling of automobile gasoline and appliance energy consumption as well as cigarette health warnings. Sweden is about to introduce an automotive repair service standards and control system which in its essentials is directly patterned on the California legislation.

Some Consumer Policy Research Implications

Several ideas for consumer policy research in the 1980s derive directly from the foregoing. We hear a lot about evaluation of marketing these days, although less is being done than said. Evaluation of public and private consumer policies affecting marketing is equally desirable. A comparative study of the impact of KOV guidelines and FTC TRR's (including possible dysfunctional side effects on competition, small business, etc., as well as the primary, hopefully salutary effects) would be of great interest, for example. Indeed, so would the development of more satisfactory methodology for doing such studies. The costs and benefits of product bans and recalls also needs more research.

The effectiveness of local government consumer affairs departments is a fruitful area of research. In Sweden 170+ local governments are at least nominally active and over 100 have a major commitment. Such numbers are large enough to permit statistical analysis of the determinants of effectiveness in terms of goal attainment. An important related question is what types of consumers these agencies actually reach, and whether these consumers redistribute advice and information. (If, as we suspect, many of them are Information Seekers, they will, although their actual impact remains to be evaluated.) Our Delphi study pointed to obligatory consumer education as a likely

development in Sweden. Educators know that their impact is related to both what is being taught and how it is taught. It would be fascinating to know how Illinois (a state with obligatory consumer education) high school graduates do on a functional consumer test as compared with graduates from a state with little or no consumer education. Or how students do who have used J.C. Penney Company's seemingly excellent Consumer Education Modules as compared to students taught in a more conventional way.

Consumer policy at the enterprise and trade association levels will clearly be a major thrust of the future. Much more research is needed as to what is being done in Europe and the U.S. An excellent point of departure is Fornell (1976). Such studies should be supplemented by more research aimed at how consumers actually experience company consumer policy at the marketplace level. All too frequently, there is a yawning gap between formal company policy and its actual implementation.

Consumer policy research also needs to get involved in technology assessment. From both a consumer and public policy viewpoint we need accelerated effort to evaluate private and public experimentation with the new information technology, such as interactive consumer information programs provided by Viewdata, QUBE, etc., and computerized consumer information systems. How much price information does the consumer actually need in the supermarket shopping process? And what are the measurable tradeoffs between costs and benefits here? There has been enough experimentation in both Sweden and the U.S. now with scanner-based checkout systems to do the research needed for sound policy development (e.g., Hammarkvist 1980).

As these examples and other items in the Delphi table indicate, consumer information will be a high priority area in the future. We have pointed to several desirable avenues of research in earlier publications (T. and T. 1977; Thorelli, Becker and Engledow 1975). Of increasing interest here is the Specialty Seeker, that is, the consumer who is an Information Seeker only for certain items of truly special interest to her/him--be it fur coats, cars, cameras, dishwashers or suntan lotions. To know the cumulative impact of the general and Specialty Seekers in various consumer markets would be of great interest to both private and public policymakers.

The evaluation of the total consumer policy system of a country--comprising all private as well as public policymakers and their interactive effects on the marketplace--is a topic barely scratched (Thorelli 1979). This article has also stressed the importance of research on precure, transfer, and transferability--all specialty aspects of the broader topic which is the ecology of consumer policy. Remarkably little has been accomplished here, even in the limited context of Swedish-American interaction. We need better operational definitions of the various types of precure and transfer. We need to know much more about the determinants of the relative degrees of transferability of policy between nations and cultures. And we certainly need more nitty-gritty research on actual cases of precure and transfer. Beyond transfer is the international cooperative development of consumer policy measures. Probably the best on-going example is that of the Nordic Council, which has been actively engaged in consumer policy research and development for over 20 years. The experience of the Council is valuable also as a guide to variables constraining such joint efforts.

It would be an insult to talk about consumer policy research in the 1980s without mentioning the Third World. As the decade opens the U.N. itself and various affiliates are finally beginning to take an interest in LDC consumers

and their protection, in large part stimulated to do so by the International Organization of Consumers Unions (IOCU). Unfortunately, and incredibly, there is as yet almost no solid research of direct relevance (Thorelli and Sentell 1979 and forthcoming). It would be a great pity if the U.N. and individual LDC were to become heavily engaged in policy formulation without an adequate research base, as there is every reason to believe that blind transfer of consumer policy technology from the industrialized countries is not what the LDC really need. The international consumer research community has a strong moral obligation to build that research base--and there is no time to lose.

DEFINING THE PROBLEM: THE SCOPE OF
CONSUMER CONCERN WITH FOOD LABELING

James T. Heimbach, Food & Drug Administration

Abstract

Some of the major data-gathering approaches used by the Federal Government in its examination of consumer perceptions of food labeling are described, as well as some of the overall findings. These primary findings are discussed in terms of their implications for redesigning food labels to make them more appropriate to consumer needs and more efficient as communication tools.

Food is a uniquely important commodity. It is an absolutely necessary one: no one can avoid consuming it and very few people in this country can avoid buying at least some of their food through the manufacturing/distribution network.

At the same time, food is highly complex and includes a vast variety beyond that which we can directly grow, pick or kill. Foods are composed of a plethora of substances. Some of these we need; some we should avoid; others we should limit. Different people have different needs for these substances, and different people have different tolerances for them.

Buying food is a complex activity, because the appearance, the texture, even the taste will not usually tell us much about its important characteristics. How can we help people to know the nature of the foods they buy?

The primary medium, of course, is the food label. Food labels carry a truly incredible amount of information about the contents of the container: what it is, how much is there, how much it costs, who made it, what ingredients are in it, what nutrition it provides, when it was packed or when it should be consumed, etc.

But if this panoply of information cannot be understood, if it cannot be used by people who want to use it to make the decisions they want to make, then it is worthless.

A problem, however, is that we often do not know what information consumers really want or why they want it. There has been extensive speculation, for example, that people are becoming increasingly interested in the nutritional values of their foods as one aspect of a more general involvement with physical fitness. Possibly related to this, there appears to be a sort of "back to nature" movement, involving both an outright fear of technology and a desire for more "natural" products. Assuming these trends do exist, to what extent do they translate to need for and use of label information and of what kinds of information?

Another factor is the consumer's "right to know." Virtually all consumer advocates, and possibly many consumers, feel that a person buying a product has a right to know all the characteristics of that product, whether or not he or she has any specific use for the information or will make any decisions based upon it. To what extent does this philosophy affect labeling concerns?

What about the effects of medical successes which have drastically increased life expectancy? Has this trend increased awareness and concern about low-level long-term threats to health -- the kind of thing that does no immediate harm, but may cause problems after sixty or seventy years' exposure? Are there implications for food labeling from this phenomenon?

These factors, and others, mean that we cannot rely on the old food label system to provide in any adequate form the

information consumers want and need in ways they want and need. What is needed is to look at the food label as a holistic entity, existing and functioning in a dynamic way against the backdrop of the concerns and ambitions of our consumer society.

In 1978, the Food and Drug Administration (FDA), along with the U.S. Department of Agriculture (USDA) and the Federal Trade Commission's Bureau of Consumer Protection (FTC) embarked upon a comprehensive program to evaluate the effectiveness of current food labeling and to revise food labels as necessary. The subjects of primary interest are the listing of ingredients and the nutrition label, although the entire label - as a whole - comes under scrutiny.

This paper addresses the first phase of the program: the evaluation of the nature and scope of consumer concern with food labeling and identification of problems. Later papers will discuss the remaining phases of the research and development program.

Data have been incorporated in this paper from a number of sources. The primary source is the FDA 1978 Consumer Food Labeling Survey (Heimbach and Stokes 1979), which included personal interviews with 1374 "primary food shoppers" (the person in each household who does most of the food shopping). The design was a three-stage national probability cluster sample, and the field-work was performed by Response Analysis Corporation of Princeton, N.J., in the fall of 1978.

The second major source of data is a series of public hearings held in five cities across the country in the fall of 1978, along with associated written comments from consumer groups, food and nutrition professionals, and food companies and trade associations. Over 450 individuals testified at the FDA/USDA/FTC-sponsored hearings, and the agencies' widely-publicized request for comments attracted an additional 9,400 written comments. Several hundred comments were subjected to content analysis, from which a coding system was developed and applied to the total of 9,864 oral and written comments by a team from the three agencies (U.S. Department of Health, Education and Welfare 1979).

Two additional sources of data were also used. In the fall of 1978, the then-Commissioner of FDA appeared on QUBE, the interactive cable TV system in Columbus, Ohio. In the course of his discussion of food labeling, he asked a number of multiple-choice questions about viewers' opinions. Over three thousand viewers responded, "touching in" on their home consoles, and QUBE's computer produced instantaneous tabulations (Hecht 1979). Finally, another FDA-sponsored national consumer survey completed in February, 1980, by Market Facts, Inc., also included a number of questions dealing with food labeling (Heimbach 1980).

A few words would be in order about the data-collection techniques. There is nothing new, unusual, or controversial about using survey-research data generated from national probability samples. The QUBE data and those from the hearings and written comments, on the other hand, are known to be biased: there is a large degree of respondent self-selection in these data sources. Those who chose to watch the QUBE program on food labeling and to respond to questions, and even more those who took the time to testify at public hearings or to write letters to the Government, are different: they are more interested in food labeling than the "average" consumer, they are more

concerned and dissatisfied with labeling, and they tend to be more literate and more highly educated. What then is the value of these forms of data collection?

There are two answers to this question. The first is political: these people are the "squeaky wheels" who make the system work, and to whom the Government must be responsive. It is no news to anyone that governments are more influenced by a minority who care devoutly about an issue than by a majority who do not care at all or who care very little.

The second point is that these are often the consumers with real needs. Most of us can - and do - walk into a grocery store and pull packages off the shelf with little regard for anything but the price. Many people, however, are not so fortunate: there are diabetics and prediabetics who must control their intake of sugars, hypertensives who must limit - sometimes drastically - their sodium consumption, people with cardiovascular disease who must watch cholesterol and saturated fats, pregnant and lactating women who must increase their intake of iron, elderly people who suffer calcium deficiency, people with allergies or intolerances for almost any substance imaginable, and so on. There are also numerous people who believe that it is healthier for them to eat more "natural" foods and to avoid artificial flavors and colors and preservatives; who are we to tell them they cannot do this?

Some of these needs can be extremely rare statistically and yet still be important for national policy. There are over 200,000,000 people in this country: a need which exists for only 0.01% of the public still represents over 20,000 people. Yet what is the probability that even one person with a given such low-frequency need will appear in a survey of 1,500 people? It is easy to calculate: the answer is 14% - about one chance in seven. (Even if it is assumed that each respondent can report needs of anyone in the household, the probability is still under 50%.)

Consequently, survey research using any reasonable sample sizes simply will not help us to identify many food problems or their associated labeling needs. At the same time, there is an obvious problem with relying upon needs expressed by a self-selected sample: these writers not only possess needs, they also possess literacy and the ability to process information. Many of the things they propose would not be comprehensible to other consumers who may share the problem but not the education or intelligence.

A good example is percentages. A large proportion of those who wrote in with suggestions advocated percentage ingredient labeling. But many people cannot cope with percentages. For example, in our 1979 survey we showed respondents a square divided into four quadrants, one black and three white, and asked what percentage of the square was white. Only 46% said 75% (and only 23% of those who have not completed high school). Similarly, only about two consumers in three know that if a serving provides 25% of your needs for vitamin A it would require four servings to get 100% (Heimbach 1980).

Finally, a brief statement of the obvious before we get into actual data. "Concern" with food labeling, like most other things, is not an all-or-none phenomenon, but rather a continuum. We have found that the Likert-scale approach ("extremely concerned", "somewhat concerned", etc.) does not satisfactorily express this continuum, probably because it is too tied to social desirability. Rather, we have taken the approach of moving from general free-response questions to specific direct questions, with the assumption that relatively uncued expressions of concern or of label-information needs represent stronger feelings than do those elicited only by direct questioning.

The first question to examine is that of the extent and depth of general dissatisfaction with current food labeling.

The 1978 survey began by asking respondents:

"Aside from prices, please tell me about any particular problems, difficulties or concerns which you have with food these days."

It is assumed that mentions of dissatisfaction with labeling expressed in response to this exceedingly general question - which does not even mention food labels - reveal rather strong concern with existing labeling. Overall, about 8% of respondents had something to say about labeling, most often about ingredient listing. This climbs to 10% of those who have a food-related health problem in the household, and to about 20% of the highly-educated respondents who (as revealed in later questioning) pay most attention to labels).

The most frequently voiced complaints dealt with desired information not always being available; especially calorie content, listing of ingredients, and open-dating. There were also scattered mentions of displeasure with the complexity of label information and the use of chemical and technical terminology.

A little later in the interview the following question was asked:

"Are you satisfied with the kind or amount of information that's printed on food packages and cans, or can it be improved on in some way?"

This question, being considerably more direct than the previous one, naturally elicited responses from consumers with lesser degrees of concern or dissatisfaction with food labeling. One third (33%) of all respondents indicated less than complete satisfaction with current labeling. A follow-up question revealed that again the ingredient list (or occasionally the absence of an ingredient list) accounted for the majority of all complaints, although the desire to have information about calorie content on all products was also one of the most frequently offered single responses.

The largest source of dissatisfaction with the ingredient list is its failure to include all ingredients, i.e., the fact that it sometimes uses generic terms like "spices" or "artificial flavors." This problem was mentioned by nearly 20% of those who expressed dissatisfaction with any aspect of food labeling or about 5% of all consumers.

The next most frequent request with regard to ingredient listing is to provide quantitative information to tell how much of each ingredient - especially sugar - is in the product. This was mentioned by about 16% of those who were dissatisfied with current food labeling.

Finally, the third most frequent problem with the ingredient list - named by about 13% of those who complained about food labeling - is that the ingredient list is too complicated and uses too much technical or chemical terminology.

As an aside, it might be noted that this type of problem recurs throughout the research on labeling. Some people want more information, including information of an unavoidably technical nature, while others - or often the same people - want it all simplified. The two desires are obviously somewhat incompatible. The major goal of the label development program is to somehow provide necessary technical information in sufficient detail for potential users, and at the same time avoid overloading those who will be so repelled by so much information that they will abandon attempting to look at labels at all.

The only frequently mentioned desire other than those related to the ingredient list is to have information about calorie content available on all foods, expressed by 15% of those who were dissatisfied with current labeling.

These are not strikingly large numbers, but it must be noted that they represent only consumers with rather high levels of dissatisfaction. When those questions are asked more directly the proportion advocating changes rises substantially. Demand for quantitative ingredient listing, for example, climbs to 74% under direct questioning.

The reasons for these desires for more detailed information about ingredients are not far to seek. One of the most disturbing single findings from the research program is that over half (54%) of all consumers - and 70% of those who ever look at ingredient lists - report using the ingredients information for the specific purpose of avoiding consumption of a particular ingredient. In some cases the person only desires to limit consumption, while in others the avoidance is total; in either case, fear of adverse health consequences from consuming the ingredient is the dominant concern, although weight-loss diets, taste, nutritional concerns, etc., are also mentioned occasionally.

By a large margin the ingredient of most concern - and the most avoided - is sugar, which over 25% of all consumers report trying to avoid totally or to some degree.* This is followed by salt, preservatives, artificial colors and flavors, and fats, and there is at least one person attempting to avoid or reduce consumption of almost any substance which ever occurs in food.

At this point let us put the probability sample aside and turn to the 10,000 comments from consumers who chose to write to FDA or testify at the hearings. One mild surprise, considering the wholly unrepresentative nature of this sample, was the high correspondence which actually existed between the two approaches.

Naturally, all of the people who testified or commented are concerned to some extent about food labeling -- usually to a pretty great extent -- and consequently exhibit far higher frequencies of specific complaints, but their overall pattern of responses was surprisingly similar to that obtained in the consumer survey.

TABLE 1
PERCENT OF CONSUMERS REPORTS
VARIOUS NEEDS REGARDING LABELING

	Comments and Hearings ¹	1978 Labeling Survey ²
	%	%
Provide quantitative ingredient information	35	16
Require ingredient list on <u>all</u> products	35	8
Require calorie information on <u>all</u> products	34	15
List <u>all</u> ingredients in product	32	19
Give the amount of <u>sugar</u> in product	27	9
Give the amount of <u>salt</u> in product	25	5
Require complete nutrition information on all products	10	5
Give specific sources of fats/oils	9	2
Give the drained or fill weight of canned products	8	6
Use larger print on labels	6	7
Simplify the ingredient information	1	13

1. Source: DHEW, 1979

2. Source: Heimbach and Stokes, 1979. Percentages shown are based on respondents who are dissatisfied with current labeling.

* This, by the way, again points to the differences in levels of concern expressed in response to open vs. direct questioning: when consumers were asked directly if they were attempting to modify their consumption of any of a list of two dozen substances, 80% claimed that they are making an effort to reduce their intake of sugar.

Again, the ingredient list was the major source of problems -- it was discussed by 85% of commenters -- with the nutrition label second, being addressed by 52%. Indeed, the rank-order correlation between the top specific concerns from the two approaches was .49, with only two specific complaints accounting for most of the difference.

The first of these is the demand for ingredient listing to be extended to all products, which was the 2nd most frequent desire among commenters but the 6th among all consumers. The other is the need to simplify the ingredient list, which was virtually never mentioned by commenters but was the 4th most frequent concern of those in the consumer survey. In point of fact, this was the single complaint which was mentioned more frequently by "average consumers" in absolute as well as relative terms.

In many cases, it is not clear whether differences in desires for label changes between survey respondents and commenters are due primarily to the higher level of sophistication of the latter or to the fact that people with diet-related health problems are over-represented in this group. (Unfortunately, many letters did not explain the state of health of the writer nor his/her reason for writing; however, as noted in the report on the analyses of comments (DHEW 1979), "Those who wanted more ingredient information on food labels often cited a specific health problem as the basis for their request.") For example, commenters were both absolutely and relatively more likely to demand that the sodium or salt content of a food be stated on the package, and that the specific type of fat or oil be given (as opposed to the current "contains one or more of the following"). These data are useful primarily to those suffering from hypertension or cardiovascular diseases, but the survey did show a distinct correlation between education and income and desire for all type of additional label information.

When the data from the survey are compared with that from the analysis of comments in terms of the overall patterns, however, the impact becomes quite clear. Commenters show both absolutely and relatively more desire for information about disease-linked food characteristics: sodium and potassium content, cholesterol, saturated fat, and specific sources of fats. Survey respondents, on the other hand, exhibit greater concern with the overall information load: they want such things as calorie information and a list of ingredients to appear on more products, but they also stress that the label is already too complicated and too technical and should not be made more so.

There is much more detailed information about consumer desires available from the survey, the hearings, and the written comments, but this is not the place for discussion of all of the findings, and some of them will be addressed in following papers. Rather, let us look at the overall conclusions and their implications.

First, most consumers do not appear to be strongly motivated by a philosophy of "right to know." They are essentially pragmatic, and the information they want on food labels is that for which they have use. There is some recognition that too much information can be as bad as too little.

Secondly, they are not often motivated to use current label information or to request additional information by nutritional considerations. Indeed, the desire to obtain good nutrition from food appears to take a back seat to the fear of consuming substances which are perceived to pose a threat to one's health. Probably the key finding of this phase on the research program was that, where food labels are concerned, consumers are oriented almost wholly toward avoidance of risk rather than seeking of benefits. Use of the ingredient list is primarily directed toward avoiding possibly hazardous ingredients rather than toward obtaining desired ones: sugar, salt and preservatives dominate

FOOD LABEL INFORMATION: WHAT CONSUMERS
SAY THEY WANT AND WHAT THEY NEED

Edwin C. Hackleman, Food and Drug Administration

Abstract

This paper addresses the problem of isolating the important nutrient information desired by consumers on the food label. Since consumers have been criticized for their lack of nutrition knowledge, subject areas for additional learning are studied, and personal profiles based on learning interests are developed. Finally, comparisons between nutritional expert groups and household food buyers are made on the basis of desired nutrient information.

Introduction

Considerable attention in recent years has been devoted to the nature and types of information desired by consumers on food product labels. Actually, the concern lies within the broader realm of interest in the design of what Bettman (1975) dubs "information environments" in which consumers are being exposed to larger arrays of data describing all sorts of products. Wilkie (1975) and more recently McNeil and Wilkie (1979) and Westbrook and Fornell (1979) in their discussions related to formats for durable and energy product labels have shown how such information can affect appliance purchase decisions. One can conclude that most of the investigations surrounding the issue have addressed alternative formats for supplying consumers with information about products and brands to improve their ability to choose what to buy at the marketplace.

The literature abounds with studies concerned specifically with food product label information, including units of measurement concerns (Stokes and Haddock 1972), and the presentation of nutrition information for supermarket products (e.g., Bucklin and Asam 1973; Lenahan, *et. al.* 1973; Russo 1975, 1979; Goodwin and Etgar 1980). Bettman (1975) has proposed that a concentrated list of nutrient information, conveniently displayed in a prominent place adjacent to all brands of a product, would overcome a number of limitations to information processing imposed by separate labels of nutrient information. Such a scheme utilizing a matrix display in an effort to reduce memory demands and mental search costs was studied experimentally by Goodwin and Etgar (1980) yielding inconclusive results, apparently because of a lack of understanding of nutritional information by consumers to begin with.

Still, regardless of many consumers' lack of nutrition knowledge, there is considerable evidence that more detailed nutrition data will be referred to by some segment of shoppers and can result in purchases of more nutritious products (Stokes 1972). Research contracted for by the Food and Drug Administration has shown that nutrition-labeled products are noticed and used by enough supermarket customers to judge the labeling worthwhile (Adamsy 1972). Hence, as Barksdale and French (1974) and Day (1976) predict the future will see the label increasingly used for the dissemination of nutrition information, a strategy several large processors have already used to promote a competitive differential advantage.

Closely related to the problems of what to include on the food label is the literature concerned with information load and its effect on consumer brand choice (e.g., Russo 1974; Wilkie 1974; Summers 1974; Jacoby, *et. al.* 1974; Scammon 1977). These studies have addressed the quantity of product information display and its effect on a variety of selected response variables such as aided and unaided re-

call, "correctness" of choice, confusion of information, satisfaction with formats, and so on. Although results have been mixed, the tendency has been to suggest that too little information is worse than too much, thus paralleling the public policy of greater disclosure. Most of these studies, however, have operated under controlled experimental conditions and have not examined subject differences which would necessarily influence both the amount and type of information desired on the food label.

A major purpose of this paper, therefore, will be to further investigate food label information components desired by consumers, what types of label information to which they tend to pay most attention, and what food, health, and nutrition-related issues they desire to learn more about. An attempt will also be made here to utilize segmentation techniques to uncover relationships between desired label information, learning interests, and personal characteristics of chief food buyers and their households.

Methodology

Data Base and Background

The Food and Drug Administration in cooperation with the U.S. Department of Agriculture and the Federal Trade Commission launched a major effort in 1978 to evaluate consumer usage of and satisfaction with information on food labels. Three agencies conducted a series of five hearings across the nation, designed to solicit consumer requests for revisions to the label. Several media releases were issued covering the food hearings and stressing the need for consumer feedback to encourage comments by mail. Over 9000 letters were obtained, and 450 individuals testified at the hearings, thus indicating a high degree of interest in the subject of food labeling.

During the same year the FDA's' Consumer Studies Division, Bureau of Foods, began a comprehensive program of consumer research to examine both the quantity and content of information on the food label to allow recommendations for making the label more understandable and useful to consumers. The first phase of this program generated the data base for this study. A national survey, conducted by Response Analysis Corporation, yielding a probability sample of 1374 respondents. Personal interviews averaging just over 60 minutes each took place at home utilizing a questionnaire developed by the FDA and refined through a series of 18 developmental pretests, followed by a 50-case pilot study from two geographic locations. Upon completion of the interviews with the chief food buyers another questionnaire was dropped off for completion and mail-in at the respondents' convenience. A total of 864 questionnaires were recovered.

Late in 1979 another survey instrument was prepared to collect expert information from members of the American Institute for Nutrition (AIN), the Milk Industry Foundation (MIF), the Grocery Manufacturers of America (GMA), the American Meat Institute (AMI), the Food Marketing Institute (FMI), the American Bakers' Association (ABA), the National Food Processors Association (AFPA), and a segment of consumers on the FDA mailing list who, in the past, have exhibited heavy interest in such issues as nutrition labeling. A total of 820 questionnaires were recovered, including 536 AIN members, 177 industry representatives, and 107 from the consumer segment.

the reports of what ingredient-list information is most important. Of the twelve types of information on the nutrition label rated as "very useful" by at least 50% of survey respondents, only three - protein, vitamin C, and iron - are sought while the other nine are avoided. (This is particularly significant when it is noted that thirty-eight nutrients were rated, and these nine were the only "things to be avoided" in the group -- the other 29 are all substances seen as "good for you.") Given a choice of having information about things people often get too little of vs. information about things people often get too much of, survey respondents chose the latter by a 2-to-1 margin.*

These two points together point to the conclusion that the determination of the information to include on food labels should be based primarily upon consideration of the relationship of the information to health problems and concerns. That is, top priority must be placed upon information about substances which are known to impact upon diet-related diseases and diabetes. The next priority should be those substances to which people are most commonly or most severely allergic or intolerant, and to those - such as preservatives - which do not appear to be related to health, but which many people are concerned about regardless. Other information, while its inclusion might be laudable, must be considered dispensible in comparison.

Third, information about these substances must be presented in the correct level of detail. For example, fats must be broken into saturated vs. polyunsaturated because of the known health effects, while sugars are pretty much sugars: despite much publicity about fructose and other varieties of sugars, they are all about the same to diabetics - and to teeth.

Similarly, the amount of sugar, or sodium, or saturated fat is of concern and should be available, while that of preservatives or artificial colors is not and should not. Besides the fact that avoiders of these are not working under a set tolerance level in the way, say, hypertensives are with sodium, the amounts are tiny in any one package and thus require complicated and confusing quantitative statements.

Finally, it is evident that many consumers find current labeling incomprehensible. Only 10% have any idea of what "U.S. RDA" means (accepting any statement to the effect that it refers to the amount people should consume as correct), a rather basic necessity for understanding of much of the nutrition label; only about 75% know what "net weight" means; words like "riboflavin," "hydrogenated," and "polyunsaturated" are confusing to nearly everyone (Heimbach 1980). And this refers to the total population: the plight of the socially and educationally deprived is obviously far worse. Consumers themselves are aware of this when they demand that labeling be simplified, although they rarely realize quite how wide the gap is, probably because they have simply tuned out much of the terminology. Ignoring something is the sincerest form of rejection.

It is clear that severe constraints must be placed upon the amount of information placed upon labels, that this information must be directed toward real diet-related problems, that it must not be presented at a level of detail beyond what is really needed, and that every effort must be made to find alternative ways of expressing the information in terms that will be comprehended by at least a majority of the population.

*This discussion is not to say that consumers do not seek foods with good nutritional characteristics, only that they do not often use food labels to do it. My hypothesis is that consumers decide tentatively to purchase a food on other grounds, such as advertising, package appearance, taste, nutrition, friends' recommendations, etc., and use the label as a final hurdle; i.e., they check the label to make sure there is no good reason not to buy the product.

The next five papers will discuss in more detail the Government's efforts to fulfill these goals.

The personal interviews and mail questionnaires addressed a number of concerns, including the following:

1. Consumer awareness and usage of current label information;
2. Problems encountered with usage of label information;
3. Experiences with food buying and usage;
4. Needs and desires for additional or revised information;
5. Knowledge and beliefs about food and nutrition;
6. Areas of interest for learning more about food-related issues;
7. Evaluations of media for learning more about food and nutrition;
8. Sources and types of untruthful information received about food;
9. Diet-related health problems in the U.S.

Nutrition Information

Just over 64% of the total sample claimed they paid attention to nutrient-label information. This group was subsequently asked to rate the information about 38 specific nutrients as being either "very useful," "of some use," or "of little or no use." A rating scale for each nutrient was derived by weighting these responses by 100, 50, and 0. In addition, the usefulness raw scores were subjected to principal components factor analysis in an effort to reveal underlying dimensions along which respondents may have perceived the nutrients. The average rating scores of the nutrients clustering in each relevant factor were then compared to personal characteristics of chief food buyers and their preferences for other aspects of the food label.

Learning Interests

Just under 63% of the total sample returned the mail questionnaire dropped off after the completion of the personal interview. One of the major sections of the questionnaire concerned a list of 17 food-related issues to which respondents indicated their degree of interest in learning more about.

Initially the items were ranked for a rough measure of overall interest and attention using a rating scale derived by weighting each response, similar to the procedures followed for nutrition information usefulness. Next, the items were subjected to principal-axis factor analysis to uncover any patterns in the data and to allow both sets of items to be rearranged to a smaller set of factors accounting for the inter-relationships. Factor scores derived from the analysis were regrouped into categories, and cross-tabulated with other personal characteristics of the respondents.

Results

Table 1 lists the simple frequency tabulations for each category of usefulness applied to the nutrients by the respondents. The nutrients are listed in the rank ordering derived from the rating scheme which closely parallels the fraction selecting the nutrient "very useful." Hence, a top-box analysis would produce virtually the same ordering of the nutrition information. The range of interest is quite wide for those items currently on the label. Calories were rated "very useful" by over 80% of the respondents, whereas riboflavin obtained 19%. Sugar and starch content, both not on the label, received substantial support and were above the median of those items not on the label. Respondents also desired, by over a 2-to-1 margin from a separate question, to have carbohydrates broken down into sugar, starch, and fiber.

Table 2 shows the varimax-rotated factor pattern derived from the first three factors extracted from the usefulness ratings given to the 38 nutrients. These three factors accounted for nearly 52% of the

Factor Labels	Macro-Nutrients	Important Micro-Nutrients	Unfamiliar Micro-Nutrients	

total variance in the system. All but three of the communalities exceed .4, indicating that nearly all the nutrients are closely related to at least one of the three principal components. Vitamin K and Calories possess the two lowest communalities, the latter perhaps because it is not really a nutrient. One would expect both of these variables to load higher on an additional factor.

Factor III appears to be a "who cares?" factor, since those items loading highly on it are many with which consumers are not familiar and tend to judge unuseful. The other two factors are more ambiguous, primarily because of the overlap between macronutrients often judged undesirable by consumers (e.g., saturated fat, sugar, calories, carbohydrates) and between micronutrients often judged desirable (e.g., iron, vitamin A, vitamin C, calcium). Two clear exceptions are fiber, a desired macronutrient, and sodium, an undesired micronutrient. Although protein is considered desirable, it is not clear from the double loading on factors I and II whether it is perceived as a macro- or a micronutrient.

Factor I contains "top of the label" nutrients: total fat, saturated and polyunsaturated fat, total carbohydrates, sugar, starch and fiber, calories and cholesterol. A conspicuous omission is protein which loads slightly higher on factor II. All the nutrients on factor I are frequently rated "bad for you," except for fiber and polyunsaturated fat, the latter of which receives mixed reviews. The presence of these two nutrients weighs against the argument of naming this factor, "undesirable nutrients." On the other hand, the presence of sodium and the absence of protein weighs somewhat against the label, "macronutrients."

Factor II envelopes all the lettered vitamins (A, B-6, B-12, C, D, E, and K), thiamin, protein, and minerals such as iron, calcium, phosphorus, and possibly potassium. An alternate name may also apply here, "desirable nutrient." The only argument negating this label is that sodium also loads somewhat highly here, despite a much higher loading on factor I.

Factor III is dominated by items many respondents have hardly heard of: inositol, biotin, selenium, molybdenum, folic acid, pantothenic acid, riboflavin, and so on. Also, several of these nutrients comprise elements or substances people are aware of but are not sure how useful they may be. Nutrients such as potassium, phosphorus, niacin, iodine and zinc would be examples of these.

Average usefulness scores were computed using the nutrients which loaded highest on a given factor. These scores, in turn, were broken down by the personal characteristics of households as shown in Figure 1. The slopes of the three lines permit comparisons between the demographically-defined segments. Highly educated food buyers tend to find all three types of nutrients more useful than the lower educated. High school graduates have equivalent interest in macronutrients and important micronutrients as those with some college or more. Those with college experience, however, tend to have a keener interest in unfamiliar micronutrients.

Perceived usefulness of macronutrients rises with age and does not decline until the food buyer reaches the senior citizen category. However, there is a steady decline in perceived usefulness of important micronutrients as age increases. This may, in part, be explained by an increase in interest in macronutrients and important micronutrients by food buyers with children. In addition, food buyers with household members taking vitamin or mineral supplements display greater perceived usefulness of all nutrients. Female food buyers find information on macronutrients and important micronutrients more useful than do male food buyers - indicating that obtaining nutritionally balanced diets for the family is regarded primarily as the woman's responsibility.

FIGURE 1

PERCEIVED USEFULNESS OF NUTRIENTS BY DEMOGRAPHIC SEGMENTS

Table 3 shows the 17 consumer learning interest items, rank ordered by their overall rating derived from a five-point Likert scale. There appears to be substantial interest in general for all 17 items, as the modal response for all of them was "very interested." The heaviest interest, however, enter on relationships between food intake and health or diseases such as cancer, heart disease, blood pressure, and the "Delaney Clause" -- a law which prohibits the sale of any food product containing an additive causing cancer in animals or man.

A principal-axis factor analysis of the original data matrix uncovered a two-factor solution accounting for over 66% of the variance. Table 4 shows the varimax-rotated factor matrix and the communalities associated with the loadings on the first two factors. All but one of the communalities exceed .5, indicating that nearly all the variables are closely related to one of the two principal components. "Benefits and risks of reducing diets" may possess a higher loading on a factor not extracted here. Factor I is a food additive information factor, collecting together interest in the safety, regulations, types, rationale, and benefits/risks of food additives. Factor II is a health-disease

concern factor, highlighting a strong consumer interest in those issues connecting food with heart disease, cancer, high blood pressure, weight reduction and balanced nutrition.

TABLE 3
A RANK ORDERING OF INTEREST SCORES ON
VARIOUS FOOD-RELATED ISSUES

Learning Issue	Overall Rating
The relationship between the foods you eat and cancer	63
The relationship between salt intake and blood pressure	61
The relationship between the foods you eat and heart disease	61
The "Delaney Clause"	60
How to be sure the family diet is nutritionally balanced	59
Benefits and risks of food additives	57
How and why food additives that have been regarded as safe might be banned	56
How safe levels of food additives are determined	56
How and why being overweight contributes to health problems	55
How safety of food additives is determined	55
How to read nutrition labels	55
Why some food additives are needed in some foods	54
Where a list of unpermitted food additives can be obtained	54
Where a list of permitted food additives can be obtained	53
The truth about "health" or "organic" foods	53
How food additives are regulated	51
Benefits and risks of different reducing diets	49

It is suggested by these findings that two major groups can be isolated based on their learning interest orientations in the directions described by the two factors. To further describe them, factor scores were derived from the principal components to measure the propensity of each respondent to have an interest in these directions. The sample was split into thirds along each dimension and cross-tabulated against a host of descriptive variables to obtain a profile.

A cross-tabulation analyses yielding a number of significant differences is summarized in Table 5. Concentrating first on factor I, individuals who are more likely to be interested in obtaining information on food additives would also more likely be overweight, 46 to 59 years old, reside in a larger household, and have earned a college education. These individuals either are or live with a special dieter(s) and vitamin taker(s). They are less satisfied with the freshness of their food, tend to have greater knowledge of nutrition, are extensive users of the ingredients list, report greater incidence of stale or spoiled food, and are heavy users of open dates on perishable food labels. On the other hand, individuals who are disinterested in obtaining information on food additives would also more likely be overweight, 46 to 59 years old, reside in smaller households, and have at most a high school education.¹ These individuals are not or do not live with a special dieter(s) and vitamin taker(s). Although they claim to have little knowledge of nutrition and do not pay much attention to the list of ingredients, they are more satisfied with the freshness of their food, report fewer stale or spoiled food experiences, despite little reported usage of dates on food labels.

¹The implication here is that overweight, middle-aged respondents were sharply divided into their interests, one group having much interest and the other having little or none.

Knowledge of Nutrition (Little → Extensive)	→			→		
Ingredients List Attention (Little → Extensive)	→			→		
Stale-Spoiled Food Experiences (None → Several)	→			→		
Usage of Dates on Labels (None → Frequently)	→			→		

Note: Relationships indicated by presence of arrow in table produced χ^2 significant at $P < .01$.

Interest in factor II, concerns for information related to health or disease, generates a somewhat different profile. A higher interest in these issues is shared by those who tend to be about the right weight or slightly under, white-collar workers, those living in smaller households, earning relatively high annual incomes (\$15K to over \$25K) and in possession of a college education. In addition, individuals in this group tend to be less satisfied with their food's freshness, and although they tend to use the ingredients list and dates on food labels, they claim to know little about nutrition. In contrast, consumers reporting a disinterest in health-disease information are more likely to be overweight, blue-collar workers, from larger households, earning relative low annual incomes (\$5K to \$15K) and possessing at most a high school education. These people are more satisfied with their food's freshness, although they tend not to use dates on food labels, pay little attention to the list of ingredients, and claim to have little knowledge of nutrition.

The overall ratings of the nutrient information supplied by the chief food buyers (see Table 1) were used to rank the items from 1 to 38 as shown in Table 6. Similar rating scores were obtained from the mail questionnaires which tapped industry experts, AIN members, and consumers heavily involved with the subject. Ranks from each of these groups are also shown in Table 6. Priority agreement between the judgmental groups seems high (Kendall's W = .95) overall, and pairwise agreement between the chief food buyers and each expert segment is also high. The lowest agreement (Spearman's R = .89) is obtained in a comparison with AIN members. Despite the apparent high overall agreement certain nutrients stand out from others as being judged quite differently. Vitamin C, sugar, and starch are given much higher priority by chief food buyers than by the expert groups. On the other hand, the experts tend to rate sodium (salt), calcium, iron, potassium, and riboflavin substantially more useful than household food buyers judge these nutrients.

TABLE 6

A COMPARISON OF RANKS GIVEN TO ALL NUTRIENT INFORMATION ITEMS BY CONSUMERS AND EXPERT GROUPS

Spearman's R: Chief Food Buyer vs AIN: .89; Chief Food Buyer vs Industry Groups: .91; Chief Food Buyer vs Consumer Interest: .94; Kendall's W = .95

Tables 7, 8 and 9 contain the rank orderings of the usefulness rating scores bestowed by each group upon the macronutrients, important micronutrients and unfamiliar micronutrients derived from the factor analysis. Priority agreement within these three dimensions is again relatively high, but there appears to be substantially less agreement between the groups in the case of macronutrients (Kendall's W = .83) as shown in Table 7. In particular, AIN members show the greatest disagreement with chief food buyers (Spearman's R = .50). The rank for sugar shows the greatest deviation between chief food buyers and the experts, as households tend to give this nutrient higher priority. Turning to important micronutrients shown in Table 8, there is a tendency for minerals (iron, calcium, and potassium) to be ranked higher in priority by the experts than by chief food buyers, whereas the latter tend to rank vitamins (C, E, B-12) higher than the experts. One would have expected the households to agree the least with the experts on the unfamiliar micronutrients (Table 9), but agreement between the three expert groups and households was surprisingly high. The only nutrient which seems out of place in this list is choline/lecithin, which received a higher ranking by chief food buyers.

Conclusions

It would appear that the nutrition information on the food label can be revised to include a list of nutrients the consumer would find more useful in evaluating the contents of the package. There are several nutrients not included in most nutrition information lists which consumers would like to see (e.g., sugar, starch and fiber content, separate from total carbohydrates, and vitamin D). This may be one of the reasons why nearly 26% of the sample desired to see more label information, whereas slightly over 2% desired to see less. On the other hand, some of the "standard" information appearing on nutrition labels is judged to be of little or no use by the majority of consumers (e.g., riboflavin, niacin, thiamine). In addition, many producers include a number of micronutrients on the label which the consumer cares very little about (e.g., pantothenic acid, zinc, magnesium, phosphorus, chromium, copper, biotin, selenium, inositol, etc.). These findings may help explain why nearly 27% of the chief food buyers found the label information to be confusing and why over 34% expressed dissatisfaction with the current content of the food label information. What is desired, therefore, is a finer tuned, more relevant list of nutrients and not merely a more exhaustive list contributing mass to the information load. A typical criticism has been that consumers as a whole know very little about food and nutrition and are, therefore, incapable of properly evaluating nutritional information on food labels. Since over 73% of the respondents indicated they were interested in learning more about nutrition and over 77% were interested in learning more about food additives, their lack of knowledge appears overshadowed by the desire to learn more. The learning interests focus heavily on the effect of food intake on health and disease problems--the things which generate news headlines. However, a surprisingly strong support in learning more about food additives was shown here, although consumption side affects may be noticeable only in the very long run, and many are completely safe for use. Results indicate a powerful similarity between what nutrients consumers find most useful (and useless) on the label and what the experts judge they need to see (or not see). If the chief food buyers in households are to be criticized for their lack of nutritional knowledge, one cannot in the same breath criticize their ability to decipher which nutrients they should examine most carefully when

considering a purchase.

FOOD LABEL INFORMATION: WHAT CONSUMERS
SAY THEY USE AND WHAT THEY ACTUALLY USE

Robert J. Vandenberg, Food and Drug Administration and The University of Georgia

Abstract

The purpose of this study was to assess the following question: Do consumers' self-reports of food label use correspond with what they actually use? Evidence provided here suggests they do. However, the extent of usage of specific information components of the food label (e.g., the ingredients list, the nutrition label, etc.) is dependent on individual differences.

Introduction

In 1978, a nationally representative sample of 1374 respondents was interviewed in a survey sponsored by the Division of Consumer Studies within the Food and Drug Administration. Although several other food related topics of consumer interest were addressed, the primary purpose of the survey was to assess consumer interest in, use of, and concerns with various aspects of food labels, including the ingredient list, nutrition information, package claims, open dating and other related components.

The results revealed that 76% of the respondents claim to pay some attention to the ingredient list of food products (Heimbach 1980). Additionally, over 70% (54% of all interviewed) of these consumers reported using ingredient list to avoid purchasing certain food products. In contrast to those reporting no attention paid to the ingredient list, attendors were more likely to be in good health, be very well nourished, be white, be between the ages of 31 to 59 years, be college educated and have above average incomes. The majority (94%) of the respondents also reported using open date information to tell them about the age or freshness of the product (Hackleman and Heimbach 1980). Furthermore, 80% of this group (74% of all respondents) stated they use date information in making purchase decisions. The users were again more likely to be in good health, be white, be between the ages of 31 to 45 years, be college educated, and possess above average incomes. Finally, 64% of the respondents stated they paid attention to the information on the nutrition label (Heimbach and Stokes 1979). Again, these consumers were characteristically more educated, between the ages of 31 to 59 years, white, and had higher incomes (Baumgardner, Heimbach and Stokes 1980).

Although these results are revealing, they do not address some fundamental questions concerning consumer food label use behavior. Basically, there was no means provided through which consumers' self-reports of food label use and actual usage of food labels could be independently assessed. In other words, is there a difference in what consumers say they use and what they actually use? One possible answer could be that respondents were answering the questions in a socially desirable manner (Cozby 1977). However, consumers who report attending to and using the food label are generally more educated and possess higher incomes. Indeed, of consumer demographics, education and income* account for the majority of the explained variance in reported use and satisfaction with food label information (Baumgardner, et. al. 1980). Aside from education, another factor could be the consumer's degree of concern with food label information. Some respondents may simply be more concerned with the quality of the food products they purchase and, as a result, they will be more likely to use the components of the food label.

*Education was the best single predictor with income being second best.

An extensive research project was designed, therefore, to further explore some of these issues. The basic design (to be detailed in the following section) was a two (high versus low education) by two (high versus low concern) factorial. A subsample (100) of the original nationwide sample of participants was accompanied on a shopping trip by an interviewer. The major purpose of the project was to pinpoint exactly what types of products were purchased, why the consumer made the purchase, and most importantly what information was used by them to make (or not make) a particular purchase.

Methodology

Sample

Respondents for this project were selected on the basis of three criteria. The first criterion was whether or not the respondent agreed during the original survey to participate in one or two follow-up interviews. Out of the original 1374 interviewees, 557 revealed a willingness to participate again. The second criterion was the respondent's education level (one of the independent variables). Respondents were equally divided into those relatively well educated and those less educated. Operationally, the well educated group possessed one or more years of college, and the less well educated had never attended college. The purpose of this classification was to include both respondents who are perhaps more articulate and more readily able to utilize package information and those who may have more difficulty using the information.

The final criterion (and second independent variable) was the consumer's concern regarding food label information. This was operationally defined on the basis of their responses to 11 questions from the original survey (Table 1).

TABLE 1

QUESTIONS USED TO SELECT THE HIGH
AND LOW CONCERN GROUPS

- A. Aside from prices, please tell me about any particular problems, difficulties or concerns you have with food these days?
- B. Will you please list or identify for me all of the different kinds of information you can recall that can be found on food packages and cans?
- C. Are you satisfied with the kind or amount of information that's printed on food packages and cans, or can it be improved on in some way?
- D. In what way would you like to see the information on food packages and cans improved?
- E. Which information, if any, printed on food packages and cans do you pay particular attention to or find helpful in any way? Please tell me the information you pay most attention to.
- F. Do you find any of the information on food packages and cans confusing or difficult to understand, or is it easy to understand?

- G. Have you ever noticed an ingredients list on food packages or cans?
- H. Do you ever use the ingredients information to avoid using a particular ingredient?
- I. Have you noticed any nutrition label information on food packages or cans?
- J. Do you ever pay any attention to the information shown on nutrition labels?
- K. Do you find any part of the nutrition labeling information confusing or difficult to understand, or do you feel that this information is easy to understand?

The respondent's answer to a particular question was scored, and all scores were summed to provide an overall Concern Score. Using this score, participants were then assigned to either a high concern category or low concern category. It was originally intended to acquire 100 participants with a distribution as shown in Table 2. However, due to faulty interviewing, equipment failure, etc. the final sample included 77 respondents distributed as shown on Table 2.

TABLE 2

DISTRIBUTION OF DESIRED AND FINAL
SUBSAMPLE OF PARTICIPANTS

	Well Educated	Less Well Educated	Total
High Concern	30 (30)	30 (15)	60 (45)
Low Concern	30 (13)	20 (19)	40 (32)
Total	50 (43)	50 (34)	100 (77)

Interviews

The overall interview procedure consisted of three components. The first component was an at-home interview during which the participant was asked a number of questions concerning meal planning, health problems, uses and concerns with food labels, planning for the shopping trip, and avoidance or preferences of certain food types. This portion of the study was designed to provide a profile of the consumer's shopping behavior, meal planning, etc. before leaving for the supermarket.

The second component of primary interest involved the interviewer actually accompanying the respondent on a regular shopping trip.

The interview was completely open-ended and the interviewer both tape recorded the ensuing interactions and took notes on relevant behaviors. Shoppers were asked to talk their way through the food purchases as they occurred in the store and explain in detail how they shop and use information. Shoppers were asked to describe and explain any and all sources of information used to make purchase decisions. This included information the shopper has learned from past experience, recent information from sources outside the store, (e.g., newspaper ads, information from shelf, tables or other locations within the store or information on the food label itself). The observer would prompt the shopper from time to time to clarify any confusing information.

The third component of the interview was again conducted at the respondent's home. First, the respondents were probed to determine whether they had modified their shopping be-

havior in any way, given the nature of the previous task (being accompanied on a shopping trip). Second, the respondent was asked (without seeing the product) to recall any label information on some of the products just purchased. The respondent was also asked to state any problems he/she might have had with the food label, anything that was of particular use and the interview terminated with a series of questions concerning food and meal planning. The taped interviews were transcribed into small booklets for ease of data coding so that type of product, information used for the product, whether or not it was purchased, etc. could be represented numerically.

Results

It should be noted at the outset that analysis of the data obtained in this study has barely begun, and what follows is a progress report including some preliminary summary data rather than a completed research report. Much more extensive and detailed analysis remains to be done with the data base.

Descriptive data

Table 3 depicts a simple frequency count of the top 19 products purchased by respondents. The 77 participants purchased a total of 1432 products with a mean of 18.6 products per shopper.

TABLE 3

THE TOP 19 PRODUCTS PURCHASED
ACROSS ALL RESPONDENTS

Product	Absolute Frequency	Relative Frequency (%) of Total Purchases
Fresh Vegetables	101	7.1
Canned Vegetables	86	6.0
Milk	56	3.9
Bread	51	3.6
Snacks (Pretzels, Chips, etc.)	51	3.6
Canned Goods (In General)	50	3.5
Beef/Hamburger	49	3.4
Fresh Fruit	48	3.4
Cheese/Cottage Cheese	43	3.0
Salt/Sugar	42	2.9
Margarine	41	2.9
Eggs	39	2.7

Oils/Shortenings	31	2.2
Spaghetti/Macaroni	31	2.2
Soup	31	2.2
	886	
	OR	
	62% of all purchased products (1432)	

As seen on Table 4, consumers used a total of 1132 pieces of information to purchase the products, yielding a mean of 14.7 pieces of information per shopper or about 0.8 pieces of information per product. This total does not include two types of information which were assumed to be virtually 100% used and therefore not coded: product identification (milk, cereal, etc.) and brand name.

The top category of information used (35%) was "Other", in-

cluding such classes as label claims, grades, product appearance, product description, etc. Of more importance though, was the weight placed by consumers on price in comparison to the ingredient lists and nutrition labels. Thirty-four percent of all the information was price relevant, with ingredients and nutrition information accounting for 12% and 4% respectively. Furthermore, open date information accounted for only 4% of the total information used by consumers. Finally, 11% of the information used by consumers was size and quantity of the product. This latter fact was probably related to price since consumers generally compare the size and quantity of products to get a better bargain. Again, of course, this is a preliminary analysis: not all information is available on all food products. Open dates, for example, are commonly not available on packaged foods.

TABLE 4
INFORMATION CLASSES

Type of Information	Absolute Frequency	Relative Frequency
Other Information (e.g., product appearance, description, etc.)	397	35%
Price Information	377	34%
Ingredients Information	140	12%
Size/Quantity Information	127	11%
Nutrition Information	46	4%
Open Date Information	45	4%
	1132	100%

Mean Pieces of Information per shopper = 14.7
Mean Pieces of Information per product = .79

Inferential Data

Analyses of variance were conducted on four components of the food label: (a) the ingredient list; (b) nutrition label; (c) the open date; and (d) the price. These components acted as the dependent measures in the analyses. Scores were computed such that one point was assigned per unit of information. For example, a shopper using the ingredient list 5 times for 5 different products during the trip was given a 5 for that particular dependent measure. The same process was used for the remaining three variables. The independent variables for the analyses were the two factors, education (high and low) and concern (high and low).

As seen in Table 5, only the results obtained from ingredient list use were significant to a large degree. The main effect for education was marginally significant [$F(1,73) = 3.26, p < .07$]. Consumers with a higher level of education used more ingredients information ($\bar{x} = 2.33$) than those shoppers with a lower education level ($\bar{x} = .96$). Greater significance was obtained when the concern level of the participants was analyzed [$F(1,73) = 7.33, p < .01$]. Consumers who reported a greater concern for more information used significantly more ingredients information ($\bar{x} = 2.67$) than those displaying less concern ($\bar{x} = .62$). The effects of education and concern level on ingredient list use was enhanced even more when the two factors interacted [$F(1,73) = 19.93, p < .001$]. This results because education had no real effect on ingredient list use when consumers were not concerned with it. However, participants with a high level of education and a

high concern for more information increased their use of the ingredients list substantially. Furthermore, even the less educated used the ingredient list more when they reported greater concern.

TABLE 5
RESULTS OF THE FOUR TWO-WAY
ANALYSES OF VARIANCE

Ingredients List Use					
Source	Sum of Squares	d.f.	Mean Square	F	P
Education	32.35	1	32.35	3.26	$p < .07$
Concern	72.75	1	72.75	7.33	$p < .01$
Education					
x Concern	197.90	1	197.90	19.93	$p < .001$
Error	724.86	73	9.93	---	---
\bar{x} High Education = 2.33			\bar{x} Low Education = .96		
\bar{x} High Concern = 2.67			\bar{x} Low Concern = .62		

Nutrition List Information

Source	Sum of Squares	d.f.	Mean Square	F	P
Education	.70	1	.70	.27	N.S.
Concern	8.08	1	8.08	3.11	$p < .10$
Education					
x Concern	0	1	0	0	N.S.
Error	189.67	73	2.60	---	---
\bar{x} High Education = .67			\bar{x} Low Education = .48		
\bar{x} High Concern = .92			\bar{x} Low Concern = .24		

Open Date

Source	Sum of Squares	d.f.	Mean Square	F	P
Education	3.83	1	3.83	2.92	$p < .10$
Concern	1.04	1	1.04	1.04	N.S.
Education					
x Concern	0	1	0	0	N.S.
Error	95.89	73	1.31	---	---
\bar{x} High Education = .83			\bar{x} Low Education = .37		
\bar{x} High Concern = .72			\bar{x} Low Concern = .48		

Price Information

Source	Sum of Squares	d.f.	Mean Square	F	P
Education	1.91	1	1.91	-.06	N.S.
Concern	9.34	1	9.34	.31	N.S.
Education					
x Concern	.04	1	.04	---	N.S.
Error	2232.59	73	30.58	---	---
\bar{x} High Education = 5.64			\bar{x} Low Education = 5.31		
\bar{x} High Concern = 7.00			\bar{x} Low Concern = 3.95		

Although ingredient list use was affected by consumer education and concern, nutrition list, open dating and price were not particularly influenced by these characteristics (See Table 5). Concern level had a marginal effect

on nutrition label use [$F(1,73) = 3.11, p < .10$]. Again, those who displayed a higher concern were more likely to use the nutrition list ($\bar{x} = .92$) than those with less concern ($\bar{x} = .24$). On the other hand, education had a marginal effect on open date use [$F(1,73) = 2.92, p < .10$]. More educated people were likely to use open dates ($\bar{x} = .83$) than those less educated ($\bar{x} = .37$). Education and concern levels had no effects upon participants' use of price information.

Discussion

These results tend to parallel those obtained in the past and suggest that self-reports of overall food label use correspond to a large degree with actual usage of the information. However, use and understanding of certain components (e.g., the ingredients list), were mediated by individual differences.

First, in a 1978 FDA Food Labeling Survey consumers were asked to rate on an 11-point scale how much they attended to various attributes of food products (Hackleman and Vandenberg 1980). These attributes included such aspects as price, nutrition label, product appearance, etc. Consumers ranked price first, product appearance and other similar attributes next highest, ingredient list next, and the nutrition label the least. This rank order corresponds almost perfectly with actual usage of these components on Table 4. In general, price and product appearance, etc. (i.e., the "Other" category) were used the most, the ingredient list next, and the nutrition label the least. Unfortunately, consumers were not asked on the initial survey to rate their attention to open date information. However, in pure descriptive terms, consumers' self-reports of food label use and their actual use does correspond.

The use of some components (especially the ingredient list) of the food label appear to be mediated by the education and concern level of the respondents. Education might have influenced whether or not consumers understand what the various ingredients are. However, when the consumers were not concerned with the food products, education had little effect. The consumer's concern could stem from several areas, such as the carcinogenic properties of various ingredients. These consumers might have had health problems or lived with those that do. As a result, they attend to the ingredients.

Why education and concern did not have an effect on nutrition label use and open date use is difficult to explain. Part of the reason is no doubt the fact that these label components do not appear on most products; consequently, in this study only 23 (30%) people used nutrition information and 27 (35%) open dates. And most of these people only used it once during the shopping trip. It is quite possible that further analysis will clarify the determinants of usage of these label components.

A rather simple answer is suggested for the nonsignificant results obtained when price was the dependent measure. Consumers, no matter their education, ethnic background, etc. are always seeking a good price.

In summary, consumers do appear to actually use the information on the food label they report to use. However, how consumers use various components of the overall label is mediated by certain individual differences. There is substantial evidence provided here, but future research needs to be conducted to uncover the nature of these differences and their effects on information use.

COMMERCIAL MARKET TRACKING SYSTEMS: APPLICATIONS TO
POLICY FORMATION REGARDING NUTRITION LABELING

Michael L. Stewart, Food and Drug Administration

Abstract

The first part of this paper describes the construction of a data base integrating retail market share and food package information for a sample of packaged processed foods. The data base was then employed to estimate the extent of nutrition labeling in the retail food market as well as the amount of nutrition labeling carried out voluntarily and the degree to which food manufacturers were violating the food labeling regulation by not including a nutrition label where required.

Background

Through the early and mid-1960's, emphasis in food marketing and purchasing was primarily limited to product taste, appearance, price, and convenience. Nutrition did not constitute a dominant (or even important) theme beyond the basic rubric of attempting to select at least one item from each of several basic food groups to obtain "a well-rounded meal". Beginning in the latter part of the 1960's, however, nutrition began to acquire a more dominant position for both policy-makers and consumers. In 1967, the Senate Subcommittee on Employment, Manpower and Poverty uncovered widespread malnutrition and hunger in its travels through the Delta area of Mississippi. In 1967, the Citizen's Board of Inquiry into Hunger and Malnutrition held that as of that time ten million people across the nation were suffering from hunger and malnutrition. These conclusions were further supported by the findings of the federal government's 1968 Ten-State Nutrition Survey. Therefore, in 1968 Congress established the Senate Select Committee on Nutrition and Human Needs to act as watchdog and advocate for government food programs. In 1969, President Nixon called for a White House Conference on Food, Nutrition, and Health, and one panel was detailed to deal with food packaging and labeling (Austin 1977). This panel stipulated that the principal function of a food package is to protect the product and to provide an efficient means for its distribution, while the principal function of a food label is to identify and describe the product and to provide information to promote use of the product. The panel concluded that new packaging and labeling concepts for better nutrition and nutrition information would succeed to the extent that they supported these basic functions. Three of their recommendations were:

1. initiate a comprehensive review of laws and regulations to determine whether they insure and facilitate the delivery of sound nutrition to the consumer;
2. examine attitudes, economic barriers, ethnic preferences, geographic patterns, and other factors relevant to improving nutrition and health, including full utilization of the package and the label; and
3. appoint special committees to consider specific aspects of nutrition (e.g., ways to simplify labels while at the same time making them more descriptive nutritionally).

As a direct result of the White House Conference, the Food and Drug Administration (FDA) began to explore different methods of displaying nutrition label information. In 1972, the FDA presented a proposal for a nutrition labeling regulation which was modified and issued as a final regulation in 1973 (with an effective compliance date of July, 1975). The regulation emphasized voluntary rather than mandatory labeling in an attempt to speed acceptance and to avoid litigation which would delay implementation. The main elements of the regulation stated (Austin 1977, pg. 29):

1. the presence of a nutrition label is voluntary except when a nutrient is added to a processed food and/or a nutrition claim is made;
2. the nutritional information, if present, must be presented conspicuously on or to the immediate right of the principal display panel;
3. the information presented must include serving size, servings per container, calorie/protein/carbohydrate/fat content, and the percentages of the U.S. Recommended Daily Allowances (U.S. RDA) for eight specified nutrients;
4. a claim cannot be made that a food is a significant source of a nutrient unless each serving provides at least 10% of the U.S. RDA of that nutrient, nor can a product claim nutritional superiority in a nutrient unless it contains at least 20% of the U.S. RDA for that nutrient;
5. imitation foods are required to be labeled as imitation only when they are nutritionally inferior;
6. cholesterol and fatty acid labeling is permitted but must be accompanied by the other nutrition label information;
7. samples of fabricated or fortified foods to which nutrients have been added must contain at least 100% of their labeled value, while samples of food in which there are naturally occurring nutrients must contain at least 80% of their labeled value; and
8. fortified foods containing from 50% to 150% of the U.S. RDA of any nutrient are considered to be a dietary supplement rather than an ordinary food and are thus subject to additional regulations, while food with U.S. RDA content over 150% falls into the drug classification.

Food industry response to the labeling regulation ranged from confrontation to formulation of nutrition policies and organization of new consumer departments. Throughout the 1970's the pace of nutrition-oriented product development accelerated, with the appearance of "natural" foods and soy-based textured vegetable products. Various members of the food industry utilized the new consumer awareness of nutrition as a marketing strategy to expand their market shares. Other members of the food industry felt obliged to use nutrition

labeling as a defensive marketing strategy to prevent the loss of old customers who would otherwise switch to nutrition-labeled brands (Austin 1977).

Data-based estimates of the extent of nutrition labeling are limited. The Grocery Manufacturers of America (GMA 1975) conducted a survey of 110 member and 155 non-member companies prior to the 1975 effective date for the nutrition labeling regulation. Of the 79 companies that responded, most were food manufacturers, with a few retailers included. Eighty-five percent of those manufacturers responding indicated an intent to label some if not all of their products. Of the 15% responding negatively, 58% felt that their products were inappropriate for labeling (e.g., apple butter, fresh meat, margarine, cake flour, jellies, mustard, etc.). In nearly every product category, some manufacturers planned to institute nutrition labeling, and some did not. Larger companies tended to plan to institute nutrition labeling sooner than did smaller companies.

Austin (1977), for the Market Science Institute, integrated the GMA survey and other sources to conclude that \$17.5 billion (approximately 14%) of the \$127 billion representing total U.S. food consumption (including away-from-home consumption) was nutritionally labeled. Furthermore, approximately 30% of the \$57.6 billion remaining after exclusion of away-from-home consumption, condiments, alcoholic beverages, and fresh fruits and vegetables was nutritionally labeled.

Because of the scarcity of direct data estimating the total incidence of nutrition labeling and because of the importance of overseeing and perhaps modifying the nutrition labeling regulations, the Division of Consumer Studies, Bureau of Foods, FDA implemented the formation of the "Food Label and Package Surveillance (FLAPS) Data Base". Five objectives were formulated (Schucker 1978):

1. develop a sales-based estimate of the volume-importance of packaged foods currently sold under nutrition labeling;
2. extend the nutrition labeling conclusions to individual product classes;
3. estimate the percentage of packaged foods voluntarily labeled and assess the food industry initiatives in labeling;
4. determine the quantity and volume-importance of retail food sold in violation of nutrition labeling regulations;
5. make the data base open-ended to allow examinations of trends across years.

Data collection began in 1977.

Methodology

The FLAPS data base integrates two data sources: (1) the A.C. Nielsen Directory of Supermarket Products and (2) FDA in-house compilations of package and package-label information, off-label advertising, and package construction materials. The Nielsen Directory provided the sampling frame and market information. The in-house compilation supplied all non-market information (label information, package construction, package dimensions, etc.).

Nielsen Directory - Sample Specification

The sampling universe for the initial round of the FLAPS data base (FLAPS-1) consisted of the A.C. Nielsen

Directory of Supermarket Products for April-May, 1975-76. The Nielsen Directory, part of the Nielsen Early Intelligence System (NEIS), is a syndicated sales data base concerned with merchandise movement from central warehouses to a selected sample of U.S. food stores. The information in each directory represents bimonthly statistics for two consecutive years. Weights furnished by A.C. Nielsen enable the user to project the bimonthly sample to estimate total annual retail movement in the United States. The weights are based upon: (1) the ratio of number of stores in the sample to total Nielsen-type stores in the U.S.; (2) the percent of foods in a particular product class that move through Nielsen-type stores; and (3) the fraction of the total year during which the sample was collected. The information listed in the Nielsen Directory for any single item line within a brand includes can size, average retail price, and unit and dollar movement. The market share information is aggregated to the brand and product class levels. The 411 product classes included in the Nielsen Directory were aggregated by Nielsen at the request of the FDA into 51 major supermarket food groups (e.g., product classes "Spaghetti - Dry" and "Macaroni - Dry" became members of the product group "Pasta - Dry"). Sampling consisted of a multi-stage selection process.

Product Class Selection. Product classes within each product group were rank-ordered by decreasing retail dollar sales volume. Those product classes within a product group with largest dollar volume were selected into the data base until two-thirds of the retail dollar volume for each (and every) product group was accounted for. This procedure resulted in the selection of 158 of the 411 product classes. Forty additional product classes were randomly selected from the remaining 253, resulting in a total of 198 product classes, accounting for 85% of the total retail dollar volume of the 51 product groups.

Brand Selection. Six national brands were drawn from each of the 198 product classes: (1) those three brands in each product class ranked first through third (market leaders) in terms of retail dollar sales and (2) three additional brands selected randomly from the remaining brands (non-leaders) in each product class. (If six or fewer brands were available for any one product class, all brands were selected.)

Due to restrictive agreements between the A.C. Nielsen Company and retail organizations, sales information for individual private label brands was not included in the Nielsen Directory. Therefore, a modified sampling plan for private label brands was instituted, such that those 20 product classes with the largest private label retail dollar sales volume were selected. Twenty additional product classes were randomly selected from those remaining product classes that contained private label brands. Based upon a separate listing of retail firms with one or more private label brands, those three firms with the largest total annual retail food sales and three randomly selected firms were chosen in each product class. Field personnel were permitted to pick up any private label brand in a specific product class controlled by the sampled firm.

Item Selection. A "brand" was defined to include all sizes, flavors and form variations of a product under a particular label. Selection of a specific item within a brand (e.g., Brand X whole tomatoes in can size 303 rather than Brand X peeled tomatoes in can size 300) was accomplished by selecting the item with the largest sales volume within that brand. It was decided that those items would be most likely to reflect the manufacturers' current labeling policies and most recent label formats.

Special Samples - Meat and Convenience Foods. Processed meat and poultry and products containing meat and poultry, although regulated by the U.S. Department of Agriculture (USDA), were included in the FLAPS data base to determine the current extent of nutrition labeling for those products in anticipation of the issuance of labeling regulations by the USDA similar to those of the FDA. To segregate the products from those regulated by FDA, a separate product group was created. The sampling procedure was identical to that for FDA-regulated products.

Convenience samples (store-door delivery) of bread, fresh milk, and ice cream products were collected in three major markets: New York, Chicago, and Los Angeles metropolitan areas. All brands encountered in two leading chain stores and one leading independent store in each market were purchased. This sampling procedure was instituted due to lack of available retail sales information at the brand level for this category.

In-House Data Collection

Field personnel collected 1,713 individual brand items between April, 1977 and March, 1978. These items were sent to the Washington, DC office of the FDA for processing. Products without nutrition labels were sent as empty packages. Products with nutrition labels were sent intact (unopened) and were assayed for nutrient content upon arrival. All information on package labels (including all nutrition label information) was recorded. Access was obtained to the food products advertising file of the Bureau of Consumer Protection of the Federal Trade Commission. All available magazine and newspaper advertisements, radio scripts, and television commercials (in storyboard form) were analyzed for content and classified as to presence or absence of health and/or nutrition claims that would trigger mandatory nutrition labeling. When all information to be compiled in-house had been prepared, the resulting file was merged with the Nielsen marketing data and set up as a computer file data base.

FLAPS-1 Sample Coverage

The 51 product groups (411 product classes) in the 1975-76 Nielsen Directory represented an estimated \$45.9 billion in annual retail food sales. Excluding meat and meat containing products (regulated by the USDA), milk, milk products, snacks, and carbonated soft drinks (because of the significant amount of store-door delivery), remaining food products accounted for \$38.1 billion (360 product classes).

The FLAPS-1 data base (excluding meat and meat containing products, milk, milk products, snacks and carbonated soft drinks) totaled \$22.3 billion in projected annual retail sales (158 product classes, or 1,055 brands). Employing non-leader brands as unbiased estimators for all non-leaders in sampled product classes, the \$22.3 billion was projected to \$27.3 billion. The 862 market leader and non-leader brands, all of which had brand level sales data available, represented \$23.1 billion of the \$27.3 billion in retail market sales.

Results

The data in FLAPS-1 were examined using two dependent measures: (1) percent of brands (to estimate the extent of nutrition labeling among manufacturers) and (2) share of market dollars (to estimate the impact of labeling practices upon the retail market). Unless specifically noted, all analyses and figures are based upon packaged processed foods, excluding processed meat and

meat-containing products, milk, milk products, snacks and carbonated soft drinks.

General Analysis

Approximately one third (33.5%) of the 862 national brands in the FLAPS-1 data base displayed a nutrition label (see Table 1). These nutrition labeled brands

TABLE 1

PERCENT OF PROJECTED ANNUAL RETAIL MARKET DOLLARS (AND PERCENT OF BRANDS) FOR NATIONAL BRANDS*

Nutrition Label	Nutrition Label			Σ
	S (n)	Required	Not Required	
Present		27.6% (17.4%)	19.9% (16.1%)	47.5% (33.5%)
Not Present		0.6% (0.9%)	51.9% (65.4%)	52.5% (66.5%)
Σ		28.2% (18.3%)	71.8% (81.7%)	\$23.1 billion (n = 862)

*Packaged processed foods excluding processed meat, milk, milk products, snacks and carbonated soft drinks.

accounted for 47.5% of the \$23.1 billion dollars in projected annual retail sales for national brands sampled by FLAPS-1. Approximately the same proportion of brands displayed nutrition labels (16.1%) solely on a voluntary basis as fell under the mandatory nutrition labeling requirement (17.4%) because of either an on-label nutrition claim, an off-label nutrition claim, the addition of one or more nutrients to the product, or some combination of the above. However, those brands with required nutrition labels accounted for a greater relative share of total market dollars (27.6%) than did brands with voluntary nutrition labels (19.9%) and share of market for both was greater than the corresponding percent of brands falling into those two categories. Brands in violation of nutrition labeling regulations (required label not present) represented 0.9% of all brands and 0.6% of all retail market dollars. Over half of all brands (66.5%) were not required to and chose not to display a nutrition label (but accounted for only 52.5% of the retail market).

Market Leader vs. Non-Leader Brands

Labeled vs. unlabeled. Approximately equal numbers of market leaders (N=460) and non-leaders (N=402) were sampled in FLAPS-1 (see Table 2). Market leaders accounted for a greater relative share of market dollars (\$17.2 billion) than non-leaders (\$5.9 billion), as would be expected given the definition of leaders and non-leaders: leaders represented the three largest brands in each product class in terms of retail dollar sales. A greater proportion of leader brands (40.7% of the total number of leader brands) than non-leader brands (25.4% of the total number of non-leader brands) engaged in nutrition labeling. For both leaders and non-leaders, the share of total market dollars accounted for by nutrition labeling (51.6% and 35.7%, respectively) was greater than the corresponding proportion of all leader and non-leader brands with nutrition labeling (40.7% and 25.4%, respectively).

Mandatory vs. voluntary labeling. Market leader brands with nutrition labels were divided evenly between brands with required nutrition labels (20.0%) and those engaged in voluntary nutrition labeling (20.7%). Market leaders

with required nutrition labels accounted for a larger

TABLE 2
PERCENT OF PROJECTED RETAIL MARKET DOLLARS
(AND PERCENT OF BRANDS) FOR MARKET LEADERS,
NON-LEADERS, AND PRIVATE LABELS*

Market Leaders Only

N u t r i t i o n	Nutrition Label			
	\$ (n)	Required	Not Required	Σ
Present	29.3% (20.0%)	22.3% (20.7%)	51.6% (40.7%)	
Not Present	0.7% (0.9%)	47.7% (58.4%)	48.4% (59.3%)	
Σ	30.0% (20.9%)	70.0% (79.1%)	\$17.2 billion (n = 460)	

Market Non-Leaders Only

N u t r i t i o n	Nutrition Label			
	\$ (n)	Required	Not Required	Σ
Present	22.8% (14.4%)	12.8% (10.9%)	35.7% (25.4%)	
Not Present	0.4% (1.0%)	63.9% (73.6%)	64.3% (74.6%)	
Σ	23.3% (15.4%)	76.7% (84.6%)	\$5.9 billion (n = 402)	

Private Label Brands Only

N u t r i t i o n	Nutrition Label			
	\$ (n)	Required	Not Required	Σ
Present	17.1% (19.2%)	18.8% (24.4%)	35.9% (43.5%)	
Not Present	** (0.5%)	64.1% (56.0%)	64.1% (56.5%)	
Σ	17.1% (19.7%)	82.9% (80.3%)	\$4.2 billion (n = 193)	

*Packaged processed foods excluding meat, milk, milk products, snacks, and carbonated soft drinks.

** < .05%

proportion of total market leader dollars (29.3%) than did market leaders engaged in voluntary nutrition labeling (22.3%). In both categories, however, share of market was greater than the relative proportion of brands engaged in nutrition labeling.

More non-leader brands engaged in mandatory (14.4%) than in voluntary nutrition labeling (10.9%). Furthermore, the share of market dollars accounted for by mandatory labeling among non-leaders (22.8%) was more than a proportionate increase over the share accounted for by voluntary labeling among non-leaders (12.8%).

Labeling regulation violations. Approximately the same proportion of leader (0.9%) and non-leader (1.0%) brands did not display a required nutrition label. In both instances, share of market dollars (0.7% and 0.4%, respectively) was less than the percent of brands.

Private Label Brands

Nutrition labels were present on 43.5% of all private label brands (a greater overall proportion than for either market leaders or non-leaders). In contrast to market leaders and non-leaders, however, the proportion

of private label brands with required labels (19.2%) was less than the proportion with voluntary labels (24.4%). Because of the lack of private label brand-level sales information, share of market dollars for private label brands (see Table 2) was not comparable to share of market dollars for leaders and non-leaders. Total private label dollars within a product class had been divided equally among all private label brands within that product class for purposes of analysis and thus did not reflect individual brand share differences.

Fewer private label brands violated the nutrition labeling regulations (0.5%) than either market leader (0.9%) or non-leader brands (1.0%). At the same time, more private label brands engaged in voluntary labeling (24.4%) than either market leader (20.7%) or non-leader brands (10.9%).

Association Between Labeling and Share of Market

The fact that nutrition labeled brands (in aggregate) accounted for a greater relative proportion of the retail market dollars than did non-labeled brands (and mandatory more than voluntary) was indicative of a possible association between presence (and type) of labeling and brand share of market. A point-biserial correlation for all market leader and non-leader brands produced a modest but significant positive correlation between presence/absence of a nutrition label and brand share of market ($r = .14, p < .01, n = 862$). A point-biserial correlation between mandatory/voluntary labeling and brand share of market again produced a modest but significant correlation ($r = .11, p < .01, n = 862$). However, the mandatory/voluntary labeling by brand share correlation was not significant when limited to only those brands displaying a nutrition label ($r = .05, p > .10, n = 289$).

Mandatory Nutrition Labeling Triggers (National Plus Private Label Brands)

Labels present. Of the 1,055 national and private label brands in FLAPS-1, 196 were required by regulation to display a nutrition label. The most frequent single trigger for labeling (N=86) for those brands that did display a nutrition label (N=187) was an off-label nutrition claim (see Table 3). The two remaining triggers, added nutrients (N=35) and an on-label nutrition claim (N=30) occurred with about equal frequency. Nutrition labels on the remaining 36 brands were triggered by combinations: an on-label nutrition claim plus added nutrients (N=7) and an on-label nutrition claim plus an off-label nutrition claim plus added nutrients (N=29).

Labels absent. For the nine labeling violations, the most frequent causes were on-label nutrition claims (N=4) and on-label nutrition claims plus added nutrients (N=3). The last two violations were caused by added nutrients (N=1) and an on-label nutrition claim plus an off-label nutrition claim plus added nutrients (N=1).

USDA Regulated Products

A cross-tabulation was performed for only those 210 products in FLAPS-1 regulated by USDA (see Table 4). If the products had been subsumed under FDA regulations, 2.9% of the 210 brands would have been required to display package nutrition labels. Approximately one-third of those brands (1.0% of all 210 brands) did in fact display a nutrition label. The remaining two-thirds of the brands that would have been required to display a nutrition label (1.9% of the 210 brands) would have been in violation of the labeling regulation. Out of the 9.0% of the brands that did display nutrition

	(2.9%)	(97.1%)	(100%)	

labels (either required or voluntary), 8.1% would have been considered engaged in voluntary labeling. Finally, 89.0% of the brands did not display nutrition labels but would not thereby have violated the regulation.

Conclusion

An estimated one-third of all national brand processed foods (excluding meat, milk, milk products, snacks, and carbonated soft drinks) packaged in the United States in 1976 displayed a package nutrition label. These nutrition-labeled brands accounted for slightly less than one-half of the estimated total retail dollar volume for national brand products. This figure appears consistent with Austin's (1977) estimate of 30% for national retail sales under nutrition labeling, given the differences in sample composition. (The FLAPS-1 estimate excluded all private label brands, meat and meat containing products, milk, milk products, snacks, and carbonated soft drinks in addition to the away-from-home dining, condiments, alcoholic beverages, and fresh fruits and vegetables excluded by Austin.)

Half of those brands with nutrition labels were required to display the information. Thus, one-half of nutrition labeled national brands (or one-sixth of all national

brands) either made on-label or off-label nutrition claims, added one (or more) nutrients to the product, or engaged in a combination of all three. A further one-sixth of all national brands engaged in nutrition labeling on a purely voluntary basis (i.e., although the package contained a nutrition label, no on- or off-label nutrition claims were made and no nutrients were added to the product). Brands engaged in voluntary nutrition labeling accounted for approximately one-fifth of the estimated retail dollar sales for national brands in 1976. Brands with mandatory nutrition labeling, while approximately equal in number to brands with voluntary labeling, accounted for half again (roughly three-tenths) of estimated national brand retail dollars. Thus, share of retail dollar sales was proportionately greater for nutrition-labeled than non-labeled brands and, within nutrition-labeled brands, for brands with mandatory rather than voluntary nutrition labeling. Significant albeit small positive correlations between (1) presence of nutrition labeling and share of market dollars and (2) type of nutrition labeling and share of market dollars supported the conclusion of a direct association.

A total of 0.9% of all national brands and 0.5% of all private label brands violated the nutrition labeling regulation by not displaying a required nutrition label. For national brands, the ratio of "share of retail dollars" to "percent of brands" in violation was less than 1.0. (Market share information at the brand level was not available for private label brands.) Thus, those manufacturers that violated the nutrition labeling regulation tended to be the smaller manufacturers. Label nutrition claims (with and without added nutrients) were the most frequent causes of the violations.

Whether nutrition labeling was instrumental in increasing brand share of market or whether large companies instituted nutrition labeling prior to smaller companies (or both) cannot be determined from the present data. However, the direct relationship between brand share and presence of labeling does appear consistent with the earlier GMA (1975) finding that large manufacturers intended to begin nutrition labeling before smaller companies. Later extensions of the FLAPS data base may provide insights as to the causal relationship between labeling and size of market share as trend data across time for both nutrition labeling and size of manufacturer become available.

IMPLEMENTATION OF A REVISED FOOD LABELING POLICY: EVALUATION AND TRACKING

Raymond E. Schucker, Food and Drug Administration

Abstract

The paper reviews the environment in which FDA is revising the food labeling regulations regarding nutrition information and ingredients. The problem of raising the salience of nutrition to the public is discussed from education and marketing perspectives. FDA plans are outlined for introductory consumer education on how to use the new label, including the need for evaluative research and market tracking of the rate of new label adoption by the food industry.

Background

The program of research and development in support of a revised food labeling policy will require approximately four years to bring to the point of national implementation. The first two years, 1978 and 1979, were concerned with identifying what changes should be made in food labeling information based on consumer expressions of interest from survey research, public hearings, representations of consumer need by organized consumer groups and consideration of public health as seen by food and nutrition professionals. Tentative positions on a number of food labeling issues were published in the Federal Register of December 21, 1979.

In the next two years three parallel efforts will complete the development phase of the revision of the food label. A series of experimental laboratory studies will be conducted to screen and identify the more promising label formats from among a large array of alternatives which will be created by a professional design firm. These studies are discussed in greater detail in another paper of this session. In a continuation of the tentative initiatives announced in the 1979 position paper FDA will publish, invite public comment, revise and issue specific regulations providing for certain expanded nutrition and ingredient information for which the Agency already has authority under the Food, Drug and Cosmetic Act. These include labeling the source of fat, requiring quantitative declaration of the amount of sugar, sodium and potassium, and establishing definitions for low and reduced sodium and cholesterol. A regulation defining levels for low and reduced calories became effective July 1980. For certain other desired food label changes FDA does not currently have legislative authority and will need to seek authority from Congress during this period, notably to require nutrition labeling on more foods and to extend specificity of ingredients declarations along a number of dimensions. The third effort during the remainder of the policy formulation and development stage will involve assessment of the economic impact of the proposed label changes on the food industry and the assessment of possible increased food costs against anticipated consumer benefits. Economic analysis of proposed regulatory actions is required where potential impact on the regulated industry is anticipated to exceed \$100 million.

Environment for Change

For a number of reasons, including lack of defined regulatory authority on the part of FDA, economic impact of the label revisions, or failure of the consumer laboratory research to sufficiently narrow the range of label format alternatives, it is not possible at this time to forecast in complete or final detail what the policy revisions will be or to mark a clear point in time when the process will move out of the policy formulation-

development stage into an implementation phase. However, for purposes of planning and discussion, it is convenient to establish the implementation phase as beginning in mid 1983 which is the uniform effective date set by FDA for industry compliance with final label change regulations growing out of the December, 1979 tentative positions.

Based on an FDA survey in the Fall of 1978 (Heimbach and Stokes 1979), overt consumer interest in improved food label information about nutrition or ingredients ranged between 8 - 15% among food shoppers, conservatively estimated through nondirective questioning. This is interpreted by some industry opponents of further change in food labeling as reflecting a low level of interest in label information and is raised as an objection to further regulation at this time. Whether one accepts FDA's more conservative estimate or other higher estimates of demand for information, such as have been published from time to time based on claimed use of or preference for food label information, consumer interest is not expected to increase in the near future and may even be eroding somewhat as other more pressing food concerns arise. In the general inflationary spiral of the late 1970's, accompanied by rising food prices, consumers began to become increasingly leery of Government regulatory action that might contribute to further increases in the cost of food. Most published consumer surveys continue to identify price as an overriding critical factor in food purchasing.

Of greater significance than the absolute level of consumer demand for nutrition and food ingredient information is that the nature of concern about food has generally turned away from emphasis on getting enough of the essential nutrients to avoidance of the consequences of overeating, particularly obesity. Also, uncertainty about the function, necessity and even safety of food preservatives and additives in general has led to an avoidance set among increasing numbers of consumers in their selection of food. Organized attempts are growing to press for the removal of questionable ingredients from the food supply where particularly vulnerable segments of the population are thought to be at risk. An example is the national network of parents groups that support the Feingold hypothesis linking certain color and flavor additives to hyperkinesis in young children.

The attention of the organized consumer movement in the last two years has also shifted somewhat away from the longer term issues of health and nutrition. With the exception of concern about the health effects of sugar consumerists are placing more emphasis on food safety, government control over environmental contaminants and removal of hazardous substances from foods. Nutrition labeling is not given quite the same priority as during the early and middle years of the decade, and there are no indications on the horizon that the situation will be reversed soon.

Although interest in revising the nutrition label has plateaued and counter pressures have appeared in some public sectors, interest in nutrition information has not declined among food retailers and in fact has been on the rise since publication in 1977 of suggested national dietary guidelines by the Senate Select Committee on Health and Human Needs under the chairmanship of Senator McGovern. Retailer activity accelerated in the latter 1970's as food chains began to develop and implement in-store information programs featuring nutrition. Retailer receptivity to promotional ideas and materials has

been great enough that at least one firm is now marketing an in-store nutrition information package to supermarket operators. Other chains have developed and implemented programs of their own.

Some of the retailer programs have been found to use nutrition information that is inaccurate or that makes unwarranted health claims and have been in conflict with existing FDA nutrition labeling regulations. Case law growing out of regulations issued under the Food, Drug and Cosmetic Act has led to the interpretation that food information presented in proximity to food products constitutes labeling. Thus, much if not all product-specific nutrition information that is presented in the supermarket is subject to the regulations. In the interests of minimizing consumer confusion while encouraging innovation, FDA has published a regulation permitting retailers as well as manufacturers to request temporary exemption from nutrition labeling requirements for purposes of testing alternative nutrition labeling formats at point of purchase. To date a number of retailers have sought exemptions for experimental programs, and the outlook is for food chains to continue to use in-store nutrition programs as competitive promotional and merchandising tools as long as retailers are convinced this is a service consumers want and will use.

Very little hard evidence is currently available on whether consumers actually modify their purchase behavior as a result of nutrition information disclosure at point of purchase. A recent collaborative effort (report in preparation) between Giant Food Inc. Washington, DC and the National Heart, Lung and Blood Institute tested a year long series of in-store pamphlets containing information on foods useful in an overall program of heart health maintenance. Supporting radio and newspaper advertising was also used. Sales in a matched panel of test and control stores were audited, and pre and post consumer interview surveys were conducted to track awareness and knowledge of the campaign, as well as specific elements of health information that had been presented. Some campaign effects were detected in the interview data, but no sales changes were observed that could be attributed to the nutrition information program.

Giant Food Inc. has also requested an exemption to conduct an additional two-year nutrition information program involving special shelf edge labeling for food brands that are reduced, low in, or free of sodium, cholesterol, fat and calories. Advertising will support the program in one market, while both shelf labeling and advertising will be withheld from a control market. Sales in a matched panel of stores will be tracked via electronic scanning of the universal product codes of nutrition labeled foods versus their unlabeled regular counterparts. Results of this and other experimental studies in supermarkets are not likely to be available in time to impact implementation of the label revisions in 1983.

Implementation

Although an effective date of mid 1983 has been set for industry compliance with the new or revised food labeling regulations, the individual regulations will actually issue at different points in time prior to the effective date. Some food manufacturers will begin to phase in revised labels as soon as necessary analytic information has been obtained to support newly required label declarations and when convenient with respect to label production and inventory cycles. Consumers will therefore experience a trickling in rather than an abrupt introduction of the new food label format.

Informing Versus Educating

The nutrition professional community and educators for a number of years have stressed the need for an overhaul of the basic four food groups approach to nutrition and for greater government support to develop curricula and teach nutrition at the primary and secondary levels. Viewed against the background of dissatisfaction with the level of nutrition knowledge and dietary practices of the U.S. population, FDA's program to revise the food label is seen in perspective as an effort to improve the information base which consumers need in order to make better nutritional food purchases. However, by no means does food labeling constitute education in the sense of teaching skills or modifying behavior. FDA has no legislative mandate or funding to develop curricula or otherwise to engage in basic long term education. The Agency currently envisions developing a short term, perhaps two-year program of introductory announcements and instruction on how to understand and use the revised food label. The program will be delivered through the print and broadcast media. In addition, instructional presentations such as slide shows will be distributed at the community level by FDA's field network of Consumer Affairs Officers.

Little guideline information is available on the resources and national level of effort that might be required to raise public awareness and change attitudes toward a subject so technically complex and burdened with difficult scientific vocabulary as nutrition. Even less is known about whether lasting behavioral changes can be achieved, let alone sustained, without massive support over a long period of time. The traditional education approach is generally criticized as having been less effective in raising the nutritional well being of the population than the direct interventions of food fortification or the various government supported feeding programs such as the school lunch programs.

An education framework may not be the most useful approach to determining what needs to be done to raise the nation's nutrition consciousness. The marketing approach, to take a different view, would focus on identifying then solving consumer nutrition-related needs and problems. This perspective on nutrition brings at least two issues into relief.

The first is that nutrition problems are generally perceived as not very immediate. Cardiovascular disease and hypertension may not produce a stroke or coronary for decades. Sugar in food is less popularly recognized as a promoter of calories than as a contributor to weight gain. Even overweight and obesity, although highly visible precursors of possible future health problems, may not be threatening today. In short, consumers don't have problems.

The second issue stems from the first and is the need to raise the salience of nutrition, i.e., to motivate consumers to want to behave as though tomorrow's health problems are really today's concerns. These two aspects of nutrition must be addressed in any national policy which seeks to achieve broadbased improvement in food and dietary behavior through consumer voluntary action. The magnitude of the requirement suggests that an educational approach alone will not be adequate to the task, nor does the superficial marketing analysis of the problem provide any ready suggestions as to how to solve it, or indicate the level of national effort and time frame that will be required to effect meaningful change.

Research Needs

In part because of the complexities of nutrition discussed previously, as well as time and resource

constraints, the experimental laboratory research to select an improved label format will be restricted mainly to criteria that demonstrate the consumer's ability to comprehend food label information and make appropriate product decisions regarding nutritional quality or ingredients composition. Consumer satisfaction with quality of decision making will also be used as a criterion measure in evaluating alternatives. On the other hand, the research conducted in the label development stage will not deal with consumer motivation to use information, or with intentions or other behavioral type criteria.

Unresolved Issues

Given the numerous elements of graphic design that might be used in formating nutrition and ingredients information, it is possible, even likely, the research will show that a number of alternative label information displays are equally effective in meeting the criteria of comprehensibility and utility in product decision making. Ultimately it may be appropriate to permit use of alternative formats to accomodate different package sizes and shapes. One school of thought proposes marketplace testing after the experimental laboratory type research in order to select a final label or two on the basis of demonstrated effects on food sales. However, to use a marketplace test for a run off of labels, in addition to being costly, would confound the issue of consumer ability to understand and apply information with the issue of willingness to use it. Moreover, in the typical 'noisy' market test employing a sales criterion measure, the odds do not favor the detection of consumer behavior change in response to revised nutrition label information alone in the absence of other efforts to begin to deal with the motivational side of the problem.

Use of multiple communication channels to deliver nutrition information has been proposed as a partial solution to the problem of raising the salience of nutrition, for example, by making a generic or even brand specific food information handbook available in the home for use in menu planning. Another suggestion has been to place similar information in a reference book in grocery stores, including nutrition information for fresh fruits, vegetables and meats, which are now exempt from nutrition regulations.

The current surge of retailer interest in featuring nutrition at point of purchase opens up possibilities for controlled store research using actual sales data to test variables that could enhance the impact of the revised food label as national implementation begins. An example might include use of the shelf edge to highlight selected new elements of nutrition information not previously appearing on food labels. Short term special floor displays in high traffic areas of the store might group an array of products having one or more of the same nutrition characteristics. Also, the food retailer's weekly newspaper feature ad might offer the opportunity to deliver nutrition information in conjunction with promotional pricing, which has high salience for the consumer.

Experimentation is also needed to establish the content of nutrition messages and weight of effort required in the broadcast media, use of which many believe is necessary if all sectors of the public are to be effectively reached and influenced by nutrition information. The grocery store in today's favorable retail climate is an appropriate focal point for designing and executing sensitive studies of behavior response to multi source communications, such as retailer and public service advertising, as well as locally produced radio and television shows covering nutrition related health subjects in community service time slots.

Program Evaluation

FDA's regulation permitting exemption from strict adherence to nutrition labeling for experimentation purposes includes the requirement of a formal evaluation component. On request the Division of Consumer Studies, Bureau of Foods, has been cooperating with food retailers in reviewing and offering comment on the design of such studies, which are expected to continue as in-store programs are developed to tie in with implementation of the revised labeling regulations. Evaluation studies have included the use of survey based consumer measures and store based sales criteria in pre versus post designs employing treatment groups only and also in more complex experimental designs using both treatment and control groups.

Through the mechanism of its annual food shopper survey the Agency will measure growth in consumer awareness and response to the introduction of the new label in relation to a benchmark point prior to the effective compliance date at retail. Evaluation criteria will include knowledge of newly added nutrition information, comprehension of nutrition vocabulary items targeted for revision, knowledge of new classifications for foods on key nutrients, such as calories, sodium and cholesterol, and consumer satisfaction with the quality of nutrition decisions made in food purchases.

The annual shopper survey will also be used in the evaluation of the two-year introductory education campaign now under development. Of particular concern is that the campaign, as well as the revised label, reach the poor, the undereducated and those who are not information seekers. The education campaign will include script and materials tailored to half-hour television and radio programs to be produced locally and featuring some aspect of the newly revised nutrition label as it relates to health, such as sodium and hypertension. These will be evaluated in terms of extent of acceptance by television stations for production, actual airing in local time slots, and size and composition of audience reached. Local consumer surveys will be conducted to determine relative impact of local versus national programming.

Market Tracking

For the near future, manufacturers will continue to have considerable latitude in deciding voluntarily whether to offer nutrition information at all on the food label. Until FDA obtains greater regulatory authority nutrition labeling will be required only if nutrients are added or advertising or nutrition label claims are made. Thus the rate at which the revised regulations impact the consumer will be tied in part to the extent of industry adoption and rate of changeover to the new format.

FDA will establish a benchmark level of nutrition labeling in the U.S. food supply under the current format via a food labeling and product surveillance survey which is conducted biannually based on a probability sample of packaged food products purchased from the retail shelf (Schucker 1978). Content analysis of the labels in terms of projected national sales of the sampled brands will permit tracking of the rate of changeover to the new food label by product class. The survey will also be used to assess quality of adherence to the specific labeling requirements of the regulations and to provide feedback to the regulatory compliance arm of the Bureau of Foods. Finally, label content will be tracked over time for indications of manufacturer use of nutrition and ingredient information for marketing, advertising or promotional purposes beyond simply meeting the requirements to list the information in the label section reserved for this purpose.

Summary

Consumer demand for nutrition information on the food label has plateaued recently, partly because of concern that government regulation will contribute further to inflation and rising food prices. Another factor has been the shift in concern from nutrition related food issues to health and safety questions about food additives and preservatives. Finally, concern about nutrition is turning away from nutrient deficiency to nutrient excess and health consequences of overconsumption.

In contrast, food retailers have shown growing interest in nutrition and are purchasing or developing their own in-store information programs. FDA has encouraged retailer experimentation with alternative ways to present nutrition information and by regulation requires an evaluation component to be included in such special programs. For these reasons the supermarket is an appropriate focus for experimentation during the implementation of the revised food label beginning in mid 1983. A basic need is for research to determine how to raise the salience of nutrition in the general public, to develop meaningful nutrition communications content, and to estimate the level of national effort that will be required, particularly in broadcast media.

FDA will use its annual food shopper survey to evaluate at the national level a consumer education campaign introducing the revised food label. Local consumer surveys and audience statistics will serve as a basis for evaluating television script packages designed for production by local television stations. The rate of food industry changeover to the new food label will be tracked via an ongoing biannual study based on probability sampling of packaged food products at retail.

FACTS AND FEARS: SOCIETAL PERCEPTION OF RISK¹

Abstract

Subjective judgments, whether by experts or lay people, are a major component in any risk assessment. If such judgments are faulty, efforts at public protection are likely to be misdirected. The similarities and differences between lay and expert evaluations are examined in the context of a specific set of activities and technologies.

Introduction

People respond to the hazards they perceive. If their perceptions are faulty, efforts at public and environmental protection are likely to be misdirected. For some hazards, extensive statistical data are readily available; for example, the frequency and severity of motor vehicle accidents are well documented. The hazardous effects of other familiar activities, such as the consumption of alcohol and tobacco, are less readily discernible; their assessment requires complex epidemiological and experimental studies. However, even when statistical data are plentiful, the "hard" facts can only go so far towards developing policy. At some point human judgment is needed to interpret the findings and determine their relevance.

Still other hazards, such as those associated with recombinant DNA research or nuclear power, are so new that risk assessment must be based on complex theoretical analyses such as fault trees (see Figure 1), rather than on direct experience. Despite their sophistication, these analyses too, include a large component of judgment. Someone, relying on educated intuition, must determine the structure of the problem, the consequences to be considered, and the importance of the various branches of the fault tree.

Once the analyses have been performed, they must be communicated to the various people who actually manage hazards, including industrialists, environmentalists, regulators, legislators, and voters. If these people do not see, understand, or believe these risk statistics, then distrust, conflict and ineffective hazard management are likely.

In this paper, we shall explore some of the psychological elements of the risk assessment process that are critical to the management of hazards. Our basic premises are that both the public and the experts are necessary participants in that process, that assessment is inevitably subjective, and that understanding public perceptions is crucial to effective decision making.

Determinants of Perceived Risk

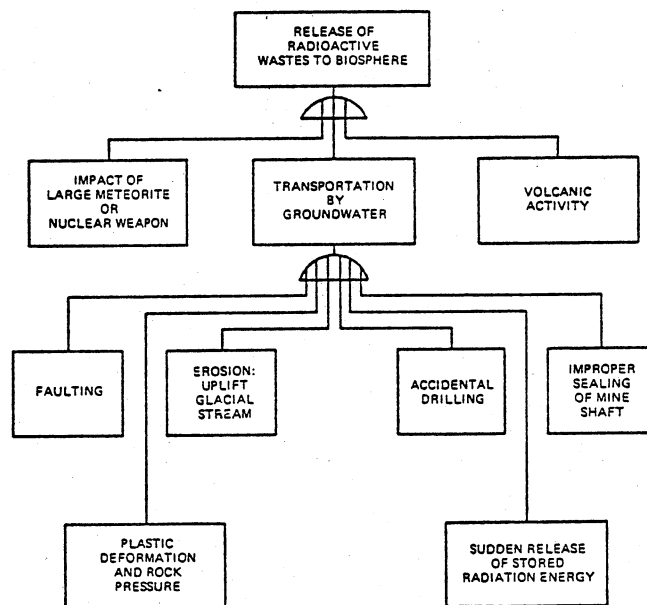

In order to aid the hazard management process, a theory of perceived risk must explain people's extreme aversion to

some hazards, their indifference to others, and the discrepancies between these reactions and experts' recommendations. Why, for example, do some communities react vigorously against locating a liquid natural gas terminal in their vicinity despite the assurances of experts that it is safe? Why, on the other hand, do many communities situated on earthquake faults or below great dams show little concern for experts' warnings? Such behavior is doubtless related to the perceived probability of possible consequences from these hazards. The studies reported below broaden the discussion. They ask, when people judge the risk inherent in a technology, are they referring only to the (possibly misjudged) number of people it could kill or also to other, more qualitative features of the risk it entails?

Quantifying Perceived Risk

In one study, we asked four different groups of people to rate 30 activities (e.g., smoking, firefighting), substances (e.g., food coloring), and technologies (e.g., railroads, aviation) according to the present risk of death from each (Fischhoff 1978, Slovic 1980(a)). Three groups were from Eugene, Oregon; they included 30 college students, 40 members of the League of Women Voters (LOVW),

³Source: P.E. McGrath, "Radioactive Waste Management," Report EURFNR 1204, Karlsruhe, Germany, 1974.

and 25 business and professional members of the "Active Club." The fourth group was composed of 15 persons selected nationwide for their professional involvement in risk assessment. This "expert" group included a geographer, an environmental policy analyst, an economist, a lawyer, a biologist, a biochemist, and a government regulator of hazardous materials.

All these people were asked, for each of the 30 items, "to consider the risk of dying (across all U.S. society as a whole) as a consequence of this activity or technology." In order to make the evaluation task easier, each activity appeared on a 3" x 5" card. Respondents were told first to study the items individually, thinking of all the possible ways someone might die from each (e.g., fatalities from non-nuclear electricity were to include deaths resulting from the mining of coal and other energy production activities as well as electrocution; motor vehicle fatalities were to include collisions with bicycles and pedestrians). Next, they were to order the items from least to most risky and, finally to assign numerical risk values by giving a rating of 10 to the least risky item and making the other ratings accordingly. They were also given additional suggestions, clarifications and encouragement to do as accurate a job as possible.

Table 1 shows how the various groups ranked these 30 activities and technologies according to riskiness. There

Home appliances	29	27	27	22
Vaccinations	30	29	29	25

^aThe ordering is based on the geometric mean risk ratings within each group. Rank 1 represents the most risky activity or technology.

were many similarities between the three groups of laypeople. For example, each group believed that motorcycles, motor vehicles and handguns were highly risky, while vaccinations, home appliances, power mowers, and football posed relatively little risk. However, there were strong differences as well. Active Club members viewed pesticides and spray cans as relatively much safer than did the other groups. Nuclear power was rated as highest in risk by the LOWV and student groups, but only eighth by the Active Club. The students viewed contraceptives as riskier and mountain climbing as safer than did the other lay groups. Experts' judgments of risk differed markedly from the judgments of laypeople. The experts viewed electric

power, surgery, swimming and X-rays as more risky than did the other groups and they judged nuclear power, police work and mountain climbing to be much less risky.

What Determines Risk Perception?

What did people mean, in this study, when they said that a particular technology was quite risky? A series of additional studies was conducted to answer this question.

Perceived risk compared to frequency of death. When people judge risk, are they simply estimating frequency of death? To answer this question, we collected the best available technical estimates of the annual number of deaths for the activities included in our study. For some, such as commercial aviation and handguns, there is good statistical evidence based on counts of known victims. For others, such as nuclear or fossil-fuel power plants, available estimates are based on uncertain inferences about incompletely understood processes, such as the effect of low doses of radiation on latent cancers. For still others, such as food coloring, we could find no estimates of annual fatalities.

For the 25 cases for which we found technical fatality estimates, we compared these estimates with perceived risk. The experts' judgments of risk were so closely related to these statistical or calculated frequencies that it seems reasonable to conclude that they both knew what the technical estimates were and viewed the risk of an activity or technology as synonymous with them. The risk judgments of laypeople, however, were only moderately related to the annual death rates, raising the possibility that, for them, risk may not be synonymous with fatalities. In particular, the perceived risk of nuclear power was remarkably high compared to its estimated number of fatalities.

Lay fatality estimates. Before concluding that perceived risk does not mean annual fatalities, we investigated the possibility that laypeople based their risk judgments on subjective fatality estimates which were inaccurate. To test this hypothesis, we asked additional groups of students and LOWV members "to estimate how many people are likely to die in the U.S. in the next year (if the next year is an average year) as a consequence of these 30 activities and technologies."

These subjective fatality estimates are shown in columns 2 and 3 of Table 2. If laypeople really equate risk with annual fatalities, their own estimates of annual fatalities, no matter how inaccurate, should be very similar to their judgments of risk. There was, however, only a low to moderate agreement between these two sets of judgments ($r = .60$ for LOWV and $.26$ for students). Of particular importance was nuclear power, which had the lowest fatality estimate and the highest perceived risk for both LOWV members and students. Overall, laypeople's risk perceptions were no more closely related to their own fatality estimates than they were to the technical estimates. Thus we can reject the idea that laypeople wanted to equate risk with annual fatalities, but were inaccurate in doing so. Apparently, laypeople incorporate other considerations besides annual fatalities into their concept of risk.

Disaster potential. One striking result is the fact that the LOWV members and students assigned nuclear power the highest risk values and the lowest annual fatality estimates. One possible explanation is that LOWV members expected nuclear power to have a low death rate in an average year, but considered it to be a high risk technology because of its potential for disaster.

In order to understand the role played by expectations of disaster in determining laypeople's risk judgments, we asked these same respondents to indicate for each activity

TABLE 2

Fatality Estimates and Disaster Multipliers for 30 Activities and Technologies

Activity or Technology	Technical Fatality Estimates	Geometric Mean Fatality Estimates Average Year		Geometric Mean Multiplier Disastrous Year	
		LOWV	Students	LOWV	Students

^a Technical estimates for nuclear power included normal operations and accidents from all phases of the fuel cycle. These estimates were found to range between 16 and 600 annual fatalities. The geometric mean of these estimates was used here.

^b Estimates were unavailable.

and technology "how many times more deaths would occur if next year were particularly disastrous rather than average." The geometric means of these multipliers are shown in columns 4 and 5 of Table 2. For most activities, people saw little potential for disaster. The striking exception is nuclear power, with a mean disaster multiplier in the neighborhood of 100.

For any individual, an estimate of the expected number of fatalities in a disastrous year could be obtained by applying the disaster multiplier to the estimated fatalities for an average year. When this was done for nuclear power, almost 40% of the respondents expected more than 10,000 fatalities if next year were a disastrous year. More than 25% expected 100,000 or more fatalities. An additional study (Slovic, in press), in which people were asked to describe their mental images of the consequences of a nuclear accident, showed an expectation that a serious accident would likely result in hundreds of thousands, even millions, of immediate deaths. These extreme estimates can be contrasted with the Reactor Safety Study's conclusion that the maximum credible nuclear accident, coincident with the most unfavorable combination of weather and population density, would cause only 3,300 prompt fatalities (U.S. Nuclear Regulatory Commission 1975). Furthermore, that study estimated the odds against an accident of this magnitude occurring next year to be about 3,000,000 : 1.

Disaster potential seems to explain much of the discrepancy between the perceived risk and the annual fatality estimates for nuclear power. Yet, because disaster plays only a small role in most of the other activities and technologies, it provides only a partial explanation of the perceived risk data.

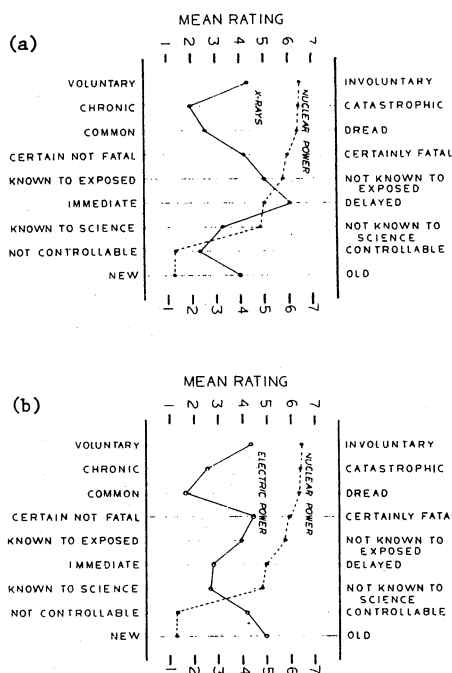

Qualitative characteristics. Are there other determinants of risk perceptions besides frequency estimates? We asked

experts, students, LOWV members and Active Club members to rate the 30 technologies and activities on nine qualitative characteristics that have been hypothesized to be important (Lowrance 1976).

The "risk profiles" made from mean ratings on these characteristics showed nuclear power to have the dubious distinction of scoring at or near the extreme on all of the characteristics associated with high risk. Its risks were seen as involuntary, delayed, unknown, uncontrollable, unfamiliar, potentially catastrophic, dreaded, and severe (certainly fatal). Figure 2 contrasts its unique risk profile with non-nuclear electric power and another radiation technology, X-rays, both of whose risks were judged to be much lower. Both electric power and X-rays were judged more voluntary, less catastrophic, less dreaded, and more familiar than nuclear power.

FIGURE 2

Rated characteristics of risk for nuclear power and related technologies.

Across all 30 items, ratings of dread and of the severity of consequences were closely related to lay judgments of risk. In fact, the risk judgments of the LOWV and student groups could be predicted almost perfectly from ratings of dread and severity, the subjective fatality estimates, and the disaster multipliers in Table 2. Experts' judgments of risk were not related to any of the nine qualitative risk characteristics.

Judged seriousness of death. In a further attempt to improve our understanding of perceived risk, we examined the hypothesis that some hazards are feared more than others because the deaths they produce are much worse than deaths from other activities. We thought, for example, that deaths from risks imposed involuntarily, from risks not under one's control, or from hazards that are particularly dreaded might be given greater weight in determining people's perceptions of risk.

However, when we asked students and LOWV members to judge the relative seriousness of a death from each of the 30 activities and technologies, the differences were slight. The most serious forms of death (from nuclear power and handguns) were judged only about 2 to 4 times worse than the least serious forms of death (from alcoholic beverages and smoking). Furthermore, across all 30 activities, judged seriousness of death was not closely related to perceived risk of death.

An Extended Study of Risk Perception

Our recent work extends these studies of risk perception to a broader set of hazards (90 instead of 30) and risk characteristics (18 instead of 9). Although data have thus far been collected only from college students, the results appear to provide further insights into the nature of risk perception. In addition, they suggest that some accepted views about the importance of the voluntary-involuntary distinction and the impact of catastrophic losses may need revision.

Design of the Study

For the extended study 90 hazards were selected to cover a very broad range of activities, substances, and technologies. To keep the rating task to a manageable size, some people judged only risks, others judged only benefits and others rated the hazards on five of the risk characteristics. Risks and benefits were rated on a 0-100 scale (from "not risky" to "extremely risky").

After rating the hazards with regard to risk, respondents were asked to rate the degree to which the present risk level would need to be adjusted to make the risk level acceptable to society. The instructions for this adjustment task read as follows:

The acceptable level of risk is not the ideal risk. Ideally, the risks should be zero. The acceptable level is a level that is "good enough," where "good enough" means you think that the advantages of increased safety are not worth the costs of reducing risk by restricting or otherwise altering the activity. For example, we can make drugs "safer" by restricting their potency; cars can be made safer, at a cost, by improving their construction or requiring regular safety inspection. We may, or may not, believe such restrictions are necessary.

If an activity's present level of risk is acceptable, no special action need be taken to increase its safety. If its riskiness is unacceptably high, serious action, such as legislation to restrict its practice, should be taken. On the other hand, there may be some activities or technologies that you believe are currently safer than the acceptable level of risk. For these activities, the risk of death could be higher than it is now before society would have to take serious action.

On the answer sheets, participants were provided with three columns labeled: (a) "Could be riskier: it would be acceptable if it were ___ times riskier;" (b) "it is presently acceptable;" and (c) "Too risky; to be acceptable: it would have to be ___ times safer."

The 18 risk characteristics included eight from the earlier study. The ninth characteristic from that study, controllability, was split into two separate characteristics representing control over the occurrence of a

mishap (preventability) and control over the consequences given that something did go wrong. The remaining characteristics were selected to represent additional concerns thought to be important by risk assessment researchers. As in the earlier study, all characteristics were rated on a bipolar 1-7 scale representing the extent to which the characteristic described the hazard. For example:

15. To what extent does pursuit of this activity, substance or technology have the potential to cause catastrophic death and destruction across the whole world?

very low catastrophic potential	1 2 3 4 5 6 7	very high catastrophic potential
---------------------------------------	---------------	--

Results

Risk characteristics. The mean ratings for the eighteen risk characteristics revealed a number of interesting findings. For example, the risks from most of these hazards were judged to be at least moderately well known to science (63 had mean ratings below 3 where 1 was labeled "known precisely"). Most risks were thought to be better known to science than to those who were exposed. The only risks for which those exposed were thought to be more knowledgeable than scientists were those from police work, marijuana, contraceptives (judged relatively unknown to both science and those exposed), boxing, skiing, hunting, and several other sporting activities.

Only 25 of the hazards were judged to be decreasing in riskiness; two of them (surgery and pregnancy/childbirth) were thought to be decreasing greatly. Risks from sixty-two hazards were judged to be increasing, thirteen of these markedly so. The risks from crime, warfare, nuclear weapons, terrorism, national defense, herbicides and nuclear power were judged to be increasing most. None of the hazards were judged to be easily reducible. The lowest of the 90 means on this characteristic was 3.2 (where 1 was labeled "easily reduced"); it was obtained for home appliances and roller coasters.

The ratings of the various risk characteristics tended to be rather highly intercorrelated, as shown in Table 3. For example, risks with catastrophic potential were also judged as quite dreaded ($r = .83$). Application of a statistical technique known as factor analysis showed that the pattern of intercorrelations could be represented by three underlying dimensions or factors. The nature of these factors can be seen in Table 3 in which the characteristics are ordered on the basis of the factor analysis. The first 12 characteristics represent the first factor; they correlate highly with one another and less highly with the remaining six characteristics. In other words, these data suggest that risks whose severity is believed not to be controllable tend also to be seen as dreaded, catastrophic, hard to prevent, fatal, inequitable, threatening to future generations, not easily reduced, increasing, involuntary, and threatening to the rater personally. The nature of these characteristics suggests that this factor be called "Dread." The second factor primarily reflects five characteristics that correlate relatively highly with one another and less highly with other characteristics. They are: observability, knowledge, immediacy of consequences, and familiarity (see Table 3). We have labeled this factor "Familiarity." The third factor is dominated by a single characteristic, the number of people exposed. This characteristic can be seen in Table 3 to be relatively independent of the other characteristics.

Just as each of the 90 hazards has a mean score on each of the 18 risk characteristics, it also has a score for each hazard on each factor. These scores give the location of

TABLE 3
Intercorrelations Among 18 Risk Characteristics
in the Extended Study

	Severity not controllable	Dread	Globally catastrophic	Little preventive control	Certain to be fatal	Risks & benefits inequitable	Catastrophic	Threatens future generations	Not easily reduced	Risks increasing	Involuntary	Affects me personally	Not observable	Unknown to those exposed	Effects immediate	New (unfamiliar)	Unknown to science	Many people exposed

11. Involuntary	.68	.58	.69	.52	.42	.77	.74	.62	.33	.44									
12. Affects me personally	.57	.64	.77	.43	.50	.71	.64	.78	.35	.67	.61								
13. Not observable	-.04	-.14	.04	-.19	-.28	.08	.00	.24	-.15	-.10	.33	.10							
14. Unknown to those exposed	.14	.05	.22	-.05	-.12	.28	.24	.35	-.20	.05	.63	.31	.79						
15. Effects immediate	.21	.15	.00	.34	.36	-.08	.11	-.29	.22	.01	-.25	-.14	-.87	-.77					
16. New (unfamiliar)	.32	.29	.32	.22	.20	.25	.18	.44	.13	.06	.36	.20	.63	.56	-.48				
17. Unknown to science	-.10	-.10	-.04	-.07	-.15	-.02	-.04	.02	-.23	.02	.13	.00	.43	.50	-.44	.32			
18. Many people exposed	-.04	.04	.23	-.14	-.11	.32	.23	.47	.03	.26	.34	.56	.37	.46	-.52	.07	-.01		

each hazard within the factor space. Figure 3 plots the hazards on Factors 1 and 2. Items at the high end of Factor 1 are all highly dreaded. Items at the negative end of Factor 1 are seen as posing risks to individuals and being injurious rather than fatal. The placement of items on the vertical dimension, Factor 2, intuitively fits the theme of familiarity and observability associated with the dimension label. Hazards lying at the extremes on Factor 2 (number exposed) are shown in Table 4.

This three-dimensional factor structure is of interest because it differs considerably from the two-dimensional structure obtained from ratings of 30 hazards on 9 characteristics (Fischhoff 1978). That structure, in which Factor 1 was labeled "severe" (i.e., certain to be fatal) and Factor 2 was labeled "high technology," had been found to be remarkably consistent across four different groups of lay and expert respondents (Slovic 1980(a)). The present results indicate that the particular set of hazards and the particular set of risk characteristics under study can have an important effect on the nature of the observed "dimensions of risk."

One point of commonality between the present analysis and the previous one is that nuclear power is an isolate in both. Although activities such as crime, nerve gas, warfare and terrorism are seen as similarly dreaded (Factor 1), none of these is judged as new or as unknown (Factor 2) as nuclear power.

TABLE 4
Hazards With Most Extreme Scores on Factor 3^a

Highest Exposure	Factor Score
Alcoholic Beverages	2.9
Caffeine	2.0

Factors 1 and 2 of the three-dimensional structure derived from interrelationships among 18 risk characteristics in the extended study. Factor 3 (not shown) reflects the number of people exposed to the hazard.

Conclusions

Although research into the nature of perceived risk is still incomplete, we offer the following tentative conclusions:

1. Perceived risk is quantifiable and predictable.
2. Groups of laypeople sometimes differ systematically in their perceptions. Experts and lay persons also differ, particularly with regard to the probability and consequences of catastrophic accidents.
3. The degree of adjustment judged necessary to make risk levels "acceptable" is strongly determined by the perceived level of current risk; the greater the perceived risk, the greater the desired reduction. Perceived benefit plays a secondary role; all else being equal, somewhat less reduction in risk is deemed necessary to make highly beneficial activities "acceptable."
4. Many of the eighteen characteristics of risk hypothesized to be important to the public do correlate highly with perceived risk and desire for risk reduction. Certain clusters of characteristics are highly inter-related across hazards indicating that they can be combined into higher-order characteristics or "factors." Three factors, labeled Dread, Familiarity, and Exposure, seem able to account for most of the interrelations among the eighteen characteristics.

CONSUMER BEHAVIOR AND ACCEPTABLE RISK:
SOME RESEARCH ISSUES*

M. Venkatesan, University of Oregon

Abstract

It is clear that the growing risk assessment literature is very relevant to the problems posed in the hazard management area for consumer products and services. However, there are some research issues that must be investigated now so that these researchers can proceed with a programmatic research emphasis. This paper has identified five such research issues.

Introduction

Product safety as an issue has reappeared vigorously with the recent disclosures and linking of "toxic shock syndrome" to the use of a certain brand of tampon. While the number of deaths reported is considerably smaller than a day's carnage on the highways, that brand of tampon is already off the market. The safety question relating to the use of saccharin is heating up. The recent legislation specifying minimum standards for the infant formula points up to another product area where lack of safety has produced tragic results, though not in vast numbers.

The recent Titan II mishap amply demonstrates that no technology is foolproof. Thus, technological risks are inherent in products developed for consumption by consumers. The right to safety has been made very explicit in the 1960s and the Delaney Amendments, the Product Safety Commission, and the like are the result of the prominence of the safety issue. Consumers are not unaware that perfect safety is impossible, and they are also cognizant of the risk-benefits relationships. Engel et al. (1978) pointed out that one of the important roles of consumer research is in establishing the level of safety that must be considered in decisions concerning the products.

As Rethans (1980) has pointed out, the assessment and management of hazards arising from technology have been of major concern to general public and to a number of governmental agencies. In order to help society cope with the technological risk, risk assessments have been undertaken in many areas. For example, the U.S. Nuclear Regulatory Commission made an assessment of the risk associated with nuclear power in their Reactor Safety Study. A number of other studies relate to hazards emanating from chemicals, other new technologies, etc. In the consumer arena, risk assessments for products are generally not made public. The only major visible effort is by the Product Safety Commission, which is concerned with technical facts of hazard assessment.

It appears from the newly emerging risk assessment literature that risk assessment has two components: one dealing with risk estimation and the other dealing with risk evaluation. As Rethans (1980) points out, the social facet of risk evaluation pertains to the importance attached to these hazards by society, and thus risk evaluation inevitably involves the judging of the "acceptability of the risk."

While some notions of perceived risk included the "physical risk" inherent in the product, no empirical work had been

undertaken to determine the "acceptable level of risk" with respect to products utilizing the "perceived risk" concept. The first study which has looked at the hazard management area for the products is by Rethans (1980). Since his paper has dealt with his study extensively, I will not detail his study here. Suffice to point out that his study makes a contribution to the important area of risk evaluation by consumers, its determinants and how to deal with product risks. The studies that are planned by Jacoby and his associates as part of their NSF-funded studies, are aimed at answering the question: "Do consumers actually consider health and safety information when making purchase, usage, and disposal decisions regarding technologically innovative products?" Thus, very little empirical evidence is currently available to make policy recommendations, nor is there enough evidence to make suggestions that will aid management decisions with respect to management of hazards relating to products. Therefore, this paper attempts to point out the relevance of this area to researchers in the consumer behavior area and to provide some guidelines regarding some of the issues that are emerging in this area.

Approaches to Acceptable Risk

It would appear that the greatest relevance is in the area of investigating the determinants of risk perception by consumers so as to aid in the evaluation of which hazards, and in what form, the consumers are willing to tolerate. Since there is no such thing as a completely risk-free product, consumers may be said to have an "acceptable level of risk." Some (Fischhoff, et al. 1980) contend that the term acceptable level of risk is a misnomer inasmuch as what we have at best is "that level of risk accepted according to a particular version of a particular kind of rationality" (p. 9). There are five approaches which appear to be currently utilized to determine the "acceptable level." They are: (1) formal analysis, (2) nonintervention, (3) procedural approaches, (4) professional standards, and (5) comparative approaches.

In the formal analysis approach, such familiar analyses as cost-benefit analysis, risk-benefit analysis, decision analysis and value-impact assessment are included. The nonintervention approach is characterized by the free market which sets prices on alternative hazard management option, and individuals choose according to price and personal definition of acceptance risk. In other words, this is an extreme position, as this approach opposes any intervention into dealings between buyers and sellers, which is conducted under the protection of a watchful and responsive legal system.

The common approach that is currently in vogue is the procedural approach. This approach relies on the political and economic forces molding the standards, by their interaction with one another and the varied feedback provided by their environment. The professional standards are provided by the technical experts most knowledgeable in a field. Finally, the comparative approaches look at the way risks have been balanced in the past or balanced at present, and they should guide the risk management decisions for the present and for future action.

As is evident, some of these approaches require some centralized decision-making body. Each approach has its pros and cons, and its limitations. None of these

* Portions of this paper are based on Fischhoff (1980) preliminary draft. Therefore, please do not quote from this paper.

approaches incorporate the subjective approach or the psychological elements of the risk assessment process that are critical in the evaluation and management of hazards relating to consumer products. Slovic et al. (1980(b)) paper examines the nature of perception of risks by individuals, which has direct relevance to researchers in consumer product safety area. They advocate a method of "expressed preferences" to get directly to the problem of perception of risk and in my judgment such a method is well suited to the study of acceptable risk for consumer products.

Slovic's (1980(b)) study attempted to ascertain what people meant when they said that a particular technology was risky. They found that the risk judgments of lay people related only moderately to the annual death rates and the risk perceptions were not closely related to their own fatality estimates. In other words, their study indicated that risk perception did not mean annual fatalities or frequency of deaths. It revealed that individual's perception of "disaster potential" played an important role in arriving at risk judgments. In addition, an array of qualitative considerations were associated with risk perception by individuals. The characteristics that are associated with risk perceptions in their study are: (1) voluntariness of risk, (2) immediacy of effect, (3) knowledge about risk, (4) to what extent are the risks known to science, (5) control over risk, (6) newness/familiar risk, (7) chronic or catastrophic nature of the risk, (8) common hazard or a dread hazard, and (9) severity of consequences.

Some Issues to Consider

Much of the individual decisions regarding choice of products relate to voluntariness of the risk. Where solutions are mandated, as in the example of air bags for automobiles, or standards of food additives, etc. such situations characterize the involuntariness of the risks on the part of consumers. While the Slovic (1980(b)) study did not find much difference in the evaluation of risk with respect to voluntariness, one would expect that in the context of consumer behavior, this consideration might play an important role. This is a major area which needs investigation by consumer researchers before proceeding to investigate other characteristics. The rationale is provided by Lorance (1976) who asserts that what is acceptable (by consumers) definitely depends on the degree to which we, as consumers, are free to opt for or decline the risk. Where individual's options are limited, such as the example where a governmental agency determines the acceptable level of risk and preempts the individual's voluntary decision-making, the involuntariness might greatly affect the perception of risk and its acceptable levels.

The second aspect which needs the attention of consumer researchers is the perception of "disaster potential." For example, in the recent incidences of toxic shock syndrome, the ailment rate is three in 100,000. However, preliminary surveys indicate that consumers may not have been concerned with average fatality per year (as in the Slovic study), but the potential catastrophic effect such products may have on the health and safety of consumers. Experts point out that not only for this product but for a variety of consumer products, testing before introduction of such products would not have been able to point out the possible hazard. That is, hazard information is unlikely to emerge before the products are marketed. This may also point up to the desirability of post-marketing surveillance in order to aid risk evaluation.

A related problem in the context of consumers is that they must rely on inferences based on what they remember hearing or observing about the hazards. Slovic (1979) points out that one heuristic that has special relevance for risk

perception is called "availability." Thus consumers can imagine or recall instances that occur frequently and numerous factors (such as recent incidences) affecting availability might distort their judgments.

Another factor that relates to consumers is the "overconfidence" factor. Many issues relating to products result in injuries rather than being fatal. In addition, their own experience as consumers without facing any hazards tend to strengthen their views that the hazards cannot be serious, particularly when an individual consumer's own hazard experience with respect to any of the risks associated with a product may be overwhelmingly benign. Thus, such overconfidence might affect their risk perception and the level of acceptable risk for a variety of products.

To aid consumers in risk perceptions, more and more warning labels are advocated for products with the hope that such information may be utilized by the consumer both for making purchase and use decisions. However, as Slovic et al. (1980(a)) point out, merely mentioning possible adverse consequences (no matter how rare) could enhance their perceived likelihood and make them appear more frightening. A recent study on a hypothetical Patient Package Insert by Keown (1980) lends some support to this notion. This is an area where considerable research is needed to help public policy makers and governmental agencies charged with investigating and recommending warning labels to products.

Another problem peculiar to consumer research may be the perception by a large number of consumers that risks associated with products are managed by competent professionals (both in the business organization and in the governmental agencies) that they need not be concerned about them. In addition, lay people seem to believe that our technological progress will solve the hazard problems. Such complacency on the part of consumers might well affect the efficiency of educational programs and the use of labels provided with the products in aiding consumer decision-making.

There are a number of other issues that should receive the attention of consumer researchers concerned with the perception of risk by consumers and how they handle such risks. Suffice to point out that the new discipline of "risk assessment" is very much relevant to researchers in the consumer behavior area, and we have a long way to go before we will be in a position to make recommendations for policy-makers.

TOWARDS DETERMINANTS OF ACCEPTABLE RISK: THE CASE OF PRODUCT RISKS¹

Arno J. Rethans, The Pennsylvania State University
Gerald S. Albaum, University of Oregon

Abstract

Discussions of product safety should distinguish between risk estimation and risk evaluation. Whereas the former is an essentially scientific and objective activity, the latter involves normative and relativistic judgments on risk acceptability. The acceptability of consumer product risks is explored by examining the relevance of a risk acceptability model emerging from the marketing, product liability and risk assessment literature. The model is found to be deserving of attention by the Consumer Product Safety Commission.

Introduction

The assessment of risks associated with consumer products involves both risk estimation and risk evaluation. Risk estimation may be thought of as the identification of (product) hazards and the measurement of their probability and consequences (Slovic, Fischhoff and Lichtenstein 1977). Risk evaluation, on the other hand, is the complex process of anticipating the societal response to risk; this could be termed the "acceptability of risk" (Otway 1975; Rowe 1977).

This distinction between the two major dimensions of risk assessment becomes important in discussions of product safety. Indeed, recognition of the dimensions of measurement and evaluation allows us to clarify the term product safety. A product is deemed safe when its attendant risks are judged to be acceptable (Lowrance 1976). This conceptualization of safety differs sharply from the simplistic dictionary definitions which consider "safe" to mean "free of risk." A product can never be absolutely free of risk. Even if technically approachable, its accompanying price tag would be prohibitive.

More importantly, the distinction between the two facets of risk assessment provides a vehicle to characterize the activities of the Consumer Product Safety Commission (CPSC). The identification of products which pose risks to the American public constitutes risk estimation. This activity is essentially empirical in nature and is in part conducted through the maintenance of the National Electronic Injury Surveillance System (NEISS). Deciding whether the public might be or should be willing to bear the estimated risks constitutes risk evaluation.

The evaluation of risk, then, is more of a normative and political activity. It involves the judging of the acceptability of the product risks. Employment of the term "acceptability" emphasizes the fact that risk management decisions are relativistic and judgmental. Indeed, the term elicits some interesting and crucial questions: "Acceptable to whom?", "Acceptable in what terms", and "What are the guides to acceptability?"

The study reported here was designed to begin to provide some empirical information on the basis of which some of the above questions may be answered. Its underlying premise is that public attitudes and values must be reflected

in the Commission's decisions on what constitutes acceptable levels of risk associated with consumer products.

Conceptual Framework For the Study

The notion of acceptability is quite pervasive, even though it is not always given explicit emphasis. A review of the appropriate literature in the areas of marketing, hazard assessment and product liability revealed several guides to judge acceptability. In this section we briefly outline these guides and their origin.

Marketing²

The CPSC is charged with the responsibility of protecting the public against unreasonable risk of injury. Unfortunately, the Product Safety Act left it to the Commission to decide what "unreasonable risk" is and how to reduce it. The National Commission on Product Safety gave the Commission some guidelines by adopting a statement by Corwin D. Edwards:

"Risks of bodily harm to users are not unreasonable when consumers understand that risks exist, can appraise their probability and severity, know how to cope with them and voluntarily accept them to get benefits that could not be obtained in less risky ways. When there is risk of this character, consumers have reasonable opportunity to protect themselves; and public authorities should hesitate to substitute their value judgments about the desirability of the risk for those of the consumers who choose to incur it." (Final Report 1970)

This statement identifies a number of product risk characteristics which are believed to influence acceptability: knowledge of risk, ability to control the risk, and voluntariness of the risk.

Product Liability Litigation

Insight into the acceptability of risks may also be gained from an examination of product liability laws. A recent report by an Interagency Task Force of Product Liability (1978) noted that to determine whether a product is designed defectively (a plaintiff's argument), risks presented by the product must be weighed against the product's utility. Hence, a product which presents a substantial risk is not necessarily defective in the eyes of the law, since it may also have "great utility."

In balancing the risks and "utility" of the product, a list of factors has been proposed by Wade (1973) and has been adopted by courts in Oregon, Arizona, and Pennsylvania (Taskforce Final Report 1978). The factors to be considered are: usefulness and desirability of product, likelihood of injury, seriousness of injury, availability of substitutes,

²In the area of marketing there has been a substantial amount of empirical research on how consumers perceive the risks associated with choice situations (Ross 1975). This research conceptualizes perceived risk as a dual component, multifaceted phenomenon including the dimension of physical risk. The literature does not however address the notion of acceptability of the risk. One possible exception may be Bettman (1973) when he distinguishes between inherent and handled risk.

¹The authors would like to acknowledge the intellectual and financial support provided by Dr. Paul Slovic and the Decision Research, Inc., Eugene, OR, in the conduct of this study.

manufacturer's ability to eliminate unsafe character, user's ability to avoid danger and user's anticipated awareness of danger.

Risk Assessment Literature

The urgent need to help society cope with risks has produced a new discipline: Risk Assessment. When performing a risk assessment, the aim is to determine the magnitude and scope of a hazard and whether society should be exposed to it (Slovic and Fischhoff 1979). Researchers in this area have hypothesized and/or identified a number of variables which influence the acceptability of risks.

Chauncey Starr (1969) employing a method of revealed preferences found a number of variables to influence risk acceptability: voluntariness of risks, benefits accruing to society and the number of people involved in the risks. He concluded that the public is willing to accept "voluntary" risks roughly 1,000 times greater than "involuntary" risks. Furthermore, it appeared that the acceptability of risk is roughly proportional to the third power of the benefits. Finally, his data indicated that the social acceptance of risk was directly influenced by public awareness of the benefits of an activity, as determined by advertising and usefulness, and the number of people participating.

Starr's initial work stimulated further work, notably by researchers at the International Institute for Applied Systems in Vienna by research associates at Decision Research, A Branch of Perceptronics, Inc. and the Clark University Center for Technology, Environment and Development. Much of the work by these researchers centers around the question of how people perceive and respond to risks. The assumption underlying this research is that individual and societal acceptance of risk, in general, is predicated upon how risks are perceived, not necessarily by actual levels or risk (Otway and Pahner 1976; Slovic, Fischhoff and Lichtenstein 1979). Indeed, it has been found that people's perceptions of risks are only moderately related to actual levels of risk and qualitative risk factors are now being examined as possible explanatory variables for perceptions of risk and risk acceptability.

A review of the work by these researchers as well as the work by Lowrance (1976) and Rowe (1977) yields a number of risk characteristics which are thought to be responsible for judgments of risk acceptability: voluntariness of risk, degree of control over risk, knowledge of risk, potential for misuse, degree of risk to special groups, the benefit/risk ratio, ease of hazard reduction, extent of societal exposure, severity of consequences, and necessity of exposure.

The Emerging Model

The literature reviewed above suggests that perceptions of risk and acceptability of risks are determined by both the quantitative and qualitative characteristics of those risks. Specifically, acceptability perceptions are hypothesized to be negatively related to such "objectively" determinable characteristics as injury frequency and injury severity. Furthermore, a set of qualitative risk characteristics are thought to be perception influences. This set of characteristics and their hypothesized relationships with acceptability perceptions include: voluntariness (+), risk knowledge (+), risk control (+), product necessity (+), foreseeability (+), exposure (+), ease of risk reduction (-), user error (-), and risk to children (-).

Objectives of the Study

The study reported in this paper represents a first attempt to explore consumer perceptions of the acceptability of the hazards associated with consumer products. The general objective of exploration translates into two research ob-

jectives: (a) determine consumers subjective perceptions of product risks and (b) examine the relevance of the emerging model of risk acceptance to the judgments of the acceptability of product risks.

Methodology of the Study

To obtain the information necessary to accomplish the stated objectives, participants in the study were asked to complete a questionnaire. Participants were asked to rate a set of consumer products on a series of seven point scales, which included societal hazard and acceptability scales as well as scales representing the risk characteristics identified in the literature review described earlier. The scales are typologically modeled after the perceived risk studies in marketing (Ross 1975) and contentwise after studies by Green and Brown (1978).

A pretest of the questionnaire suggested that the task needed to be shortened in order to secure respondent cooperation as well as to avoid respondents' fatigue and its accompanying errors. Therefore, it was decided to run a split-run technique on the risk characteristic scales. That is, two versions of the research instrument (A and B) were administered. Each version contained the societal hazard and acceptability scales and six of the twelve risk characteristics.

The products which served as stimuli in the study were included on the basis of a number of criteria. First, the set of products was to reflect the frequency range found in the CPSC data tabulation. Second, the products selected must, at the same time, reflect the severity range of the NEISS data. Third, the product definition must be unequivocal. Many of the "definitions" in the NEISS tabulations do not constitute a succinct product, but rather a product category. Finally, products to be included in the questionnaire were to be selected so as to maximize the probability of product familiarity among respondents.

Application of these criteria led to the identification of the products shown in Table 1. The categorization of the severity of injuries into low, moderate, and high follows that of the CPSC and is based on the mean severity values of the products. A mean severity of 17 or less generally indicates low severity; the range 18 to 81 usually implies moderate severity; and a mean severity over 81 implies high severity. The severity values for the products of this study are shown in parentheses in Table 1.

TABLE 1
Product Stimuli for Acceptance Study

Severity of Injury	Number of Injuries		
	Less than 10,000 per year	10,000 - 60,000 per year	More than 60,000 per year
Low	Dehumidifiers (17) Power can openers (12) Sewing machines (17)	Hammers (14) Razors/shavers (14) Scissors (12)	Knives (14) Snow skis (17)
Moderate	Xmas lights (49) Hair dryers (43)	Cosmetics (32) Garage doors (31) Playground Equip. (37) Refrigerators (22) Television sets (32) Tricycles (27)	Bathtub/shower (62) Bicycles (40) Ladders (39) Skateboards (32) Stairs/steps (31)
High	Fireworks (158) Ammonia (152) Lighters (114) Portable saws (181) Sun lamps (125) Toy balloons (126)	Swimming pools (105)	Power lawn mowers (125)

Thirty five questionnaires of form A and forty questionnaires of form B were completed by members of three civic groups in a medium sized town on the West Coast. The questionnaires were hand-delivered to the groups and returned by mail in the case of one group and returned by a group representative in the case of the other two groups. In this way, seventy-five completed and usable questionnaires were collected. A donation in the amount of five dollars was made to the organizations' treasury of each completed

questionnaire.

The overall sample consisted of 52% males and 48% females. Their ages ranged from 20 to 52 years of age with a mean age of 30.5 and a modal age of 32. Sixty-five percent of the respondents were married and 24% of them were single. With regard to education, about 50% of the respondents completed a university degree. An additional twenty-five percent noted that they had completed some university education, and 12% completed high school and/or vocational school or less. Occupationally, the groups may be characterized as predominantly white collar rather than professional. Only seven percent were blue collar workers.

Findings of the Study

Risk Acceptability Ratings

Respondents were asked to judge whether or not risks associated with each of the twenty nine products were at a socially acceptable level. The mean scores of the products on the 7-point acceptability scale are shown in the first column of Table 2. This bipolar scale has been coded such that the higher the score, the greater the acceptability of the product risks. On an absolute level, the majority of the products are considered to bear risks which are perceived to be acceptable (i.e., greater than 4.0). The most acceptable risks are those associated with hammers, sewing machines, garage doors, refrigerators, and dehumidifiers. The lesser acceptable products are fireworks, skateboards, sunlamps, power lawn mowers and cosmetics.

TABLE 2

Product Risk Acceptability and Hazard Ratings

Product	Acceptability Mean Score	Rank	Rank on Societal Hazard
Hammers	6.29	1	21
Sewing Machines	6.08	2	25
Garage doors	5.99	3	27
Refrigerators	5.87	4	24
Dehumidifiers	5.83	5	29
Stairs/steps	5.75	6	12
Scissors	5.57	7	19
Bath/shower struct.	5.56	8	16
Tricycles	5.55	9	22
Bicycles	5.52	10	11
Snow skis	5.47	11	8
Knives	5.44	12	6
Power can openers	5.44	13	26
Toy balloons	5.41	14	28
Ladders	5.37	15	10
Television sets	5.35	16	20
Swimming pools	5.31	17	5
Razor/shavers	5.28	18	17
Playground Equip.	5.07	19	14
X-mas lights	4.99	20	13
Ammonia	4.98	21	9
Lighters	4.96	22	15
Hair dryers	4.77	23	18
Power saws	4.73	24	2
Cosmetics	4.68	25	23
Power mowers	4.52	26	4
Sunlamps	4.04	27	7
Skateboards	3.88	28	3
Fireworks	3.42	29	1

The third column of Table 2 shows the participants' ranking of the hazardousness of the products included in the study. Comparing the hazardousness rankings with the acceptability rankings suggests the presence of an inverse relationship between risk and acceptability. Indeed, when computing a rank correlation between these two variables, we find a coefficient of $-.62$. Reviewing the major rank discrepancies suggests that risk acceptability is not only influenced by perceived risk, but by other considerations as well. Swimming pools, knives, and snow skis from cases in point. Each of these products were considered to be quite hazardous from a societal perspective, yet were considered to be quite acceptable. In the case of swimming pools and snow skis, this result may be explained by the high ratings of these products along the voluntariness and foreseeability characteristic. The acceptability of the risks associated with knives is probably due to its high perceived necessity and the high degree of "knowability" of the risk.

Risk Characteristics

Participants were also asked to rate each of the products on twelve, seven point scales, each of which represented a characteristic of risk. The mean ratings on these characteristics for the more hazardous and the less hazardous products are shown in Tables 3 and 4.

TABLE 3: Risk Characteristics of More Hazardous Products

Qualitative Characteristic	Fire-works	Portable power saws	Skateboards	Power mowers	Swimming pools	Average
V1. Voluntariness	5.31	5.20	5.94	4.74	5.83	5.41
V2. Risk knowledge	4.21	4.83	4.74	4.80	5.00	4.72
V3. Risk control	3.97	4.97	4.20	5.11	5.20	4.69
V4. Severity of injury	5.37	5.63	4.89	5.54	5.83	5.45
V5. Personal exposure	2.63	3.03	1.69	3.00	2.34	2.54
V6. Ease of reduction	2.47	3.35	2.74	3.68	2.94	3.04
V7. Product necessity	2.13	4.53	1.88	4.00	3.83	3.27
V8. User error	5.83	4.92	6.13	5.23	4.78	5.38
V9. Risk to children	6.23	4.40	6.35	5.08	5.92	5.60
V10. Injury frequency	2.68	2.90	3.34	2.92	3.24	3.02
V11. Foreseeability	5.73	5.38	5.58	5.13	5.10	5.38
V12. Degree of exposure	3.98	3.83	3.90	4.98	4.50	4.23

TABLE 4: Risk Characteristics of Less Hazardous Products

Qualitative Characteristic	Sewing machines	Power can openers	Garage doors	Toy balloons	Dehumidifiers	Average
V1. Voluntariness	6.00	5.43	5.11	5.63	5.00	5.43
V2. Risk knowledge	4.66	4.29	4.31	4.14	2.97	4.07
V3. Risk control	6.31	5.49	5.57	5.91	4.61	5.58
V4. Severity of injury	2.97	3.09	3.66	2.97	2.97	3.13
V5. Personal exposure	1.37	1.51	1.66	1.14	1.26	1.39
V6. Ease of reduction	3.63	4.06	3.57	3.47	3.91	3.73
V7. Product necessity	5.85	2.08	4.65	2.40	3.50	3.69
V8. User error	3.38	3.40	3.18	3.45	3.18	3.31
V9. Risk to children	3.98	3.68	4.03	5.31	3.58	4.11
V10. Injury frequency	1.22	1.35	1.35	1.40	1.16	1.29
V11. Foreseeability	3.38	2.75	3.25	2.50	1.83	2.74
V12. Degree of exposure	5.25	4.38	5.80	4.68	2.83	4.59

An examination of individual product profiles provides insight into consumers' risk and acceptability perceptions. For example, the ratings for fireworks suggest that consumers feel that risks associated with this product are perceived as rather voluntary, somewhat known to the user, and highly foreseeable. At the same time, there is a high perceived likelihood of user error accompanied by major injuries if accidents do occur. In addition, children are perceived to be rather vulnerable to the product risks. Similar profiles emerge for the other more hazardous products such as skateboards, portable power saws, and power lawn mowers.

In contrast, when examining dehumidifiers, the least hazardous product, a rather different profile is found. Although consumers admit to relatively low levels of knowledge and consider the risk somewhat unforeseeable, the perceived minor injuries associated with the product and the low perceived probability of user error seem to make this product

relatively safe and acceptable.

Similar analyses may also be made at a group level. The data in the tables allow the reader to compare "group profiles" of more hazardous versus less hazardous products. The two groups differ substantially on the characteristics of risk control, injury severity, likelihood of user error, risk to children, frequency of injury and foreseeability.

Dependence Structure

The findings discussed in the preceding section suggest that a relationship exists between perceived and acceptable risk on the one hand, and the qualitative risk characteristics on the other. This section explores this relationship by means of a correlational analysis.

In Table 5, the product moment correlations between the mean risk characteristics scores and the mean risk and acceptability ratings are shown. The scores on the risk characteristics have been coded in a positive direction to facilitate interpretation of the data. The hazard and acceptability ratings correlated significantly ($p < .01$) with the characteristics of risk knowledge, risk control, injury severity, product necessity, user error, risk to children and injury frequency.

TABLE 5: Correlation Between Risk Characteristics And Hazard/Acceptability Ratings

	Personal Hazard	Societal Hazard	Acceptability
Voluntariness	.02	.06	-.08
Risk knowledge	.29	.30	.29
Risk control	-.27	-.38	.58
Injury severity	.65	.75	-.47
Personal exposure	.52	.50	.04
Ease of risk reduction	-.49	-.50	.03
Product necessity	-.16	-.18	.68
User error	.83	.86	-.66
Risk to children	.40	.52	-.25
Injury frequency	.70	.78	-.31
Foreseeability	.79	.83	-.36
Societal exposure	-.26	-.23	.44

The majority of the observed correlations conform to the direction of the influence hypothesized in the risk assessment literature described earlier. For example, the higher the likelihood of error, the less acceptable the product is considered. Similarly, the higher the controllability of the product risk the more acceptable the product was.

Yet, not all correlations between perceived and acceptable risk and risk characteristics behaved according to expectations. The characteristic of foreseeability shows a significant negative correlation with acceptability. One would expect, however, that the more foreseeable a hazard, the more acceptable the risk. It appears that foreseeability may have more than one dimension, and that the specific dimension that is operating is a function of the risk situation. For example, Ms. King, Chairperson of the CPSC, holds that the Commission's focus should be on risks which are not readily foreseeable by the public. The emphasis in this position seems to be on serious and unexpected hazards. Given this position, one would expect a positive correlation between foreseeability and acceptability. Respondents in this study, on the other hand, seem to regard foreseeable as "knowable", i.e., a sort of 'accidents are bound to happen and therefore the product is dangerous' attitude. In this latter perspective, the negative correlation seems reasonable.

A second characteristic that does not conform to expectation is the dimension of voluntariness. The more voluntarily assumed risks are presumed to be more acceptable. Although this relationship seems to be born out in the case of some products, e.g., snow skis, the correlation across all products is near zero. One explanation for this result is that the consumer goods studied here did not differ much along this dimension.

Finally, a comment is in order about the characteristic termed ease of risk reduction. The respondents were asked how easily hazards associated with a particular product could be reduced through product redesign. A priori one would expect a relationship that suggests the more easily reduced the risk, the less acceptable the risk. That hypothesized relationship was not observed.

Predictive Validity of Risk Characteristics

Earlier in the conceptual framework section a number of attempts to predict acceptable levels of risk were reviewed. In this section the approaches to these predictions are further generalized by an attempt to develop a formula which specifies acceptability of product risks as a function of the twelve risk characteristics under consideration in this study.

Table 6 shows the result of a stepwise regression analysis in which acceptability formed the dependent variable and the risk characteristics constituted the independent variables. Specifically, the table shows the entry sequence with the accompanying increases in r-squared as well as the resulting multiple correlation coefficients. Furthermore, in the column labeled "coefficient", are recorded the unstandardized regression coefficients for the variables in the final model.

TABLE 6

Summary Table of Stepwise Regression Risk Acceptability

Step	Variable	Coefficient	Multiple r	Increase in r^2	F to enter
1.	Product necessity	0.22	0.68	0.46	22.90
2.	User error	-0.28	0.83	0.23	19.84
3.	Voluntariness	0.33	0.89	0.10	12.60
4.	Risk knowledge	0.32	0.91	0.03	3.63
5.	Foreseeability	-0.26	0.92	0.01	2.04
	Intercept	3.29			

($F = 23.65$; $df = 5,23$; $Prof > F = 0.0001$)

Although caution should always be exercised when interpreting the results of stepwise regressions, it should be pointed out that the variables entered in the model do have theoretical justifications in the risk assessment literature. That is to say, although the order in which variables enter a stepwise regression procedure is not always reflective of the relative importance of the variables, it is felt that the evidence presented seems to be converging on the variables included. The possible exception here is the voluntariness characteristic. Although no significant correlations were observed between this characteristic and hazard and acceptability ratings, it plays an important role in the regression model.

Conclusions and Recommendations

In this paper we have introduced the distinction between risk estimation and risk evaluation in the determination of product safety. This distinction alerted us to the fact that product risk management decisions include objective and scientific components as well as more normative, relativistic and judgmental components. This latter realization leads us to develop the premise that public attitudes and values should be reflected in the Commission's decisions

as to what constitutes acceptable levels of risk associated with consumer products. Consumer research can play a role in the assessment of consumers' response to the product risks.

The results of the empirical study reported in this paper suggests the relevance of the risk acceptability model which emerged from a review of the marketing, product liability and risk assessment literature. The acceptability of product risks was found to be inversely related to perceived hazardousness. An analysis for the discrepant rankings, however, suggests that consumers may incorporate into their acceptability judgments dimensions other than perceived physical risk.

Several researchers in the area of risk assessment have noted the desirability of examining selected risk characteristics as possible explanatory variables for risk acceptability perceptions. The appropriateness of the characteristics for product risks assessment was examined by a stepwise regression analysis which indicated that about 84% of the variance in the acceptability judgments can be explained by the characteristics of product necessity, user error, voluntariness, and to a lesser extent product knowledge and foreseeability. From a decisional point of view it certainly must be concluded that these qualitative characteristics deserve specific consideration by the CPSC in their product hazard management decisions. User error in particular appears to be an important variable in both risk and acceptability perceptions. This finding may suggest that respondents would be receptive to educational campaigns regarding products rating high on this characteristic. Alternatively, the Commission may review the cost effectiveness of redesigning some of the products most prone to user error.

We further suggest that product "risk profiles" illustrated in Tables 3 and 4 be developed for products with high Hazard Index ratings. Studies of each of the risk characteristics for these products can provide considerable insight into individual and societal behavior toward risk acceptance.

SOME PERSPECTIVES ON RISK ACCEPTANCE¹

Jacob Jacoby, Purdue University

Abstract

The theme of this session -- namely, that any hazard management system developed to protect consumers from the risks associated with products must take into consideration subjective (psychological) as well as technical factors -- was illustrated by considering the hazardous consequences that potentially could result from implementation of the U.S. Department of Agriculture's proposed rule on providing uncured frankfurters, bologna, and bacon to consumers. Several positive and negative aspects of the empirical research described at this session were then discussed. The paper concluded by presenting a framework for conceptualizing hazard management that is emerging from currently ongoing research into consumer awareness, comprehension and usage of health and safety information.

As many of us who teach consumer behavior tell our students, the modern era of consumer protection can be traced to President John F. Kennedy's Declaration of Consumer Rights in 1962. This Declaration described four rights: the right to be informed, the right to choose, the right to safety, and the right to be heard (or the right of redress). Partly because of its intriguing nature, to date, the lion's share of consumer research directed toward public policy issues has focused on the right to be informed (including the necessity for information to be free of deceptive or misleading connotations and the necessity for the information to be sufficiently complete so that the consumer is able to make an informed decision). It is time that a commensurate research effort be mounted in regard to product safety. As Feldman (1980, p. 73) points out: "Compared with other consumer protection issues, product safety is paramount because unlike other issues such as deceptive advertising or the failure to make good on warranties, product safety directly involves injury and loss of life."

Our objectives in this commentary are two-fold. The first is to consider selected aspects of the empirical papers presented at this session. The second is to indicate directions for future work.

Comments on the Papers Presented

The fundamental tenet which underlies these papers is that any hazard management system developed to protect consumers from the risks associated with products must take into consideration consumer psychological (that is, internal, subjective) factors as well as technical factors. As eloquently noted by Slovic, Fischhoff and Lichtenstein; "People respond to the hazards they perceive. If their perceptions are faulty, efforts at public and environmental protection [which do not consider these perceptions] are likely to be misdirected." Further: "Our basic premises are that both the public and the experts are necessary participants in [the risk assessment] process, that assessment is inevitably subjective, and that understanding public policy perceptions is crucial to effective decision making." We fully concur with this set of premises. Indeed, this point needs to be underscored; it

cannot be emphasized enough! It especially needs to be brought to the attention of policymakers and regulators who sometimes end up generating misguided and incorrect public policies through their failure to understand and take into consideration the relevant consumer psychological factors which may be operating.

On the Risk of Ignoring Consumer Psychological Factors

As a concrete illustration of how the disregard of consumer psychological factors might result in seriously increasing rather than decreasing the safety hazards associated with consumer products, consider the U. S. Department of Agriculture's efforts in regard to providing consumers with uncured (i.e., nitrite and nitrate free) meat products. Stimulated by research (which has since been discredited) that seemed to indicate that the ingestion of nitrites and nitrates was associated with unreasonably high levels of cancer, and also stimulated by consumer activists, the U.S.D.A. developed a proposed rule on the subject. The proposed rule, published in the Federal Register on August 21, 1979 and scheduled to become effective on September 20, 1979, provided that meat and meat products that were not cured with nitrates, nitrites, or other preservatives might be sold under their traditional names, so long as the word "uncured" appeared on the label as part of the product name and the label contained the following cautionary language: "No nitrate, or nitrite added; not preserved, keep refrigerated below 40° Fahrenheit at all times." (See Figure 1) The regulation also required that the uncured products be similar

FIGURE 1

UNCURED FRANKFURTER
No nitrate or nitrite added
Not preserved - Keep Refrigerated Below
40°F at all times.

in size, shape, flavor, color, consistency and general appearance to the product commonly prepared with nitrite or nitrate. In other words, the consumer would have no other cues to the fact that the frankfurter (or bacon, or balogna) she was purchasing was somehow different than frankfurters (bacon, balogna) she had purchased before -- except for the cautionary labeling prescribed by the rule.

On September 20, 1979, the National Pork Producers Council, together with three members of the U. S. House of Representatives, filed a law suit challenging the proposed rule. These plaintiffs were subsequently joined by the National Independent Meat Packers Association. Their argument was heard in Federal Court in Des Moines, Iowa, in November of 1979. In presenting their case, these plaintiffs brought forth two expert witnesses.

The first witness, an internationally acknowledged authority on the subject of food toxins, testified that eight ounces of botulism spore were sufficient to wipe out the

¹Preparation of this paper was supported, in part, by a grant from the National Science Foundation (PRA 7920585); see Jacoby and Jaccard, in progress.

population of the entire planet. He went on to state that under certain conditions (such as might happen if a high school student took an uncured bologna sandwich to school, left it in his locker on a hot day, chose not to eat it for lunch but took it to his after school game instead, and then ate it at 5:00 p.m.) deadly botulism spore could develop in as little as 8 hours.

Participating as the second expert witness, the present author testified regarding likely consumer attention to, comprehension of, and use of the cautionary labelling information. In brief, and based upon evidence obtained across more than a score of consumer information usage investigations conducted to date, the testimony pointed out that: (1) Many consumers (perhaps as many as 20%) do not read any information on the labels for frequently purchased consumer products² beyond the brand name. (2) The 80% who do read package information rarely read all the available information but tend to focus on a very small percentage of this information (e.g., price). (3) Some of those who happen to read the proposed cautionary labelling would not understand its significance. From informal research conducted by this author (e.g., asking at least 500 people in his classes and in audiences to whom he has spoken whether they understood what the word "cured" meant when it was applied to a food product) and others, it would appear that fewer than 5% of the adult population comprehends that the term "cured" refers to the inclusion of preservatives. The overwhelming majority of people seem to have no idea as to what "cured" stands for in this context and a much smaller proportion (in the order of 5% to 15%) seem to believe that cured means "smoked." Further, even though most individuals would be expected to understand the literal meaning of "Not preserved -- keep refrigerated below 40° Fahrenheit at all times," this language provides no understanding of the dire consequences that might ensue from not keeping the product refrigerated below 40° at all times. (4) Finally, even if the consumer did comprehend the full significance of this statement, once the meat had been taken from the refrigerator (and, for example, been placed in a sandwich), subsequent conditions might be out of her control and it would still be possible for the meat to be handled unsafely.

After hearing the case and considering the record, on February 12, 1980 the District Court in Iowa entered a final order enjoining the government from enforcing or applying the challenged regulations. This decision was appealed by the U.S.D.A. and reversed just a few days ago, on September 23, 1980. In noting the reasons for its reversal, the Circuit Court cited the fact that warning labels have been generally shown to be effective (how come, then, people still smoke cigarettes? etc.), and that many of the comments submitted by consumers in response to the proposed rule "demonstrated consumer awareness of the potential dangerous consequences of marketing and consuming meat products that do not contain nitrites or nitrates." The Court apparently did not recognize the danger of extrapolating from such a small and unrepresentative sample as the group of consumers who chose to send in written comments on the proposed rule. The Court further argued that "the cautionary labelling will adequately inform the consumer of how to maintain such products in a wholesome condition until consumed." Preposterous! At the present time, the National Pork Producers are considering appealing this reversal to the next highest level of the judiciary which, in this case, is the Supreme Court.

²Remember: the uncured product had to be similar in size, shape, flavor, color, and general appearance to the cured product. The only distinguishing characteristic would be the cautionary language.

To my way of thinking, the proposed rule and subsequent reversal by the Circuit Court of the District Court's decision provides a frightening example of how public policy can be misguided when only technical factors are considered and subjective, consumer psychological factors are ignored. Having served as an expert witness in more than a dozen matters, I can honestly say that I have never felt so strongly (from my perspective as a consumer researcher) that the courts and policy makers acted in complete disregard for what is known regarding human behavior -- and that this might result in tragedy of catastrophic proportion for American consumers. True, if all consumers did indeed read and understand that uncured meat had to be refrigerated at all times and acted in accord with this belief, the risk would be reduced substantially.³ However, it is highly unlikely that all consumers will read and understand the cautionary language and behave as expected. By not taking these subjective considerations into account, the government is, in my opinion, opening up a Pandora's Box and substantially increasing the health and safety hazards to which the American populace will be subjected.

As the authors of these manuscripts have noted, the consumer element in hazard management is of critical concern and cannot be neglected. If the consumer fails to recognize that a risk exists, then his behavior can not be shaped accordingly. In other words, these authors are barking up a very important tree and their efforts need to be encouraged, applauded, and hopefully supplemented by considerable research from others. It is also commendable that their efforts, particularly in the case of Slovic, Fischhoff, and Lichtenstein, are clearly long term and programmatic.

On the Empirical Work Presented

Having acknowledged the significance of this work and the genuine debt that consumer researchers owe to these individuals, we still find several shortcomings associated with the papers presented. These tend to be shortcomings which come with the territory when researchers embark on journeys over relatively unexplored terrain. Fortunately, none of these problems are insurmountable.

One entry on the negative side of the ledger is in regard to the relatively small and unrepresentative samples employed. It is conceivable that this might have been a major contributing factor in Slovic et al.'s failure to replicate the findings of dimensional structure that had been obtained in the earlier investigation by Fischhoff. A second problem would be the controversial and somewhat questionable application of such high powered analytical techniques as factor analysis (Slovic et al. 1981) and stepwise multiple regression (Rethans and Albaum 1981) to such small samples, particularly given such large numbers of variables.

However, our major concern with these studies is not the issue of sample size or the questionable application of high powered statistics to samples of such size, but the operationalizations of the core concept of risk acceptance. The measures of risk acceptance used by Slovic et al. and Rethans and Albaum are provided in Figures 2 and 3, respectively. Consideration of these measures suggests that, while the researchers may have had a very clear idea in mind of what risk acceptance was, and while their operationalizations may be technically accurate reflections of these conceptualizations, it is highly questionable whether many of their subjects adequately

³Risk would still be associated with the stages of product preparation and handling prior to its reaching the consumer.

FIGURE 2
Slovic, Fischhoff and Lichtenstein's
Operationalization of Risk Acceptance

After rating the hazards with regard to risk, respondents were asked to rate the degree to which the present risk level would need to be adjusted to make the risk level acceptable to society. The instructions for this adjustment task read as follows:

The acceptable level of risk is not the ideal risk. Ideally, the risks should be zero. The acceptable level is a level that is "good enough," where "good enough" means you think that the advantages of increased safety are not worth the costs of reducing risk by restricting or otherwise altering the activity. For example, we can make drugs "safer" by restricting their potency; cars can be made safer, at a cost, by improving their construction or requiring regular safety inspection. We may, or may not, believe such restrictions are necessary.

If an activity's present level of risk is acceptable, no special action need be taken to increase its safety. If its riskiness is unacceptably high, serious action, such as legislation to restrict its practice, should be taken. On the other hand, there may be some activities or technologies that you believe are currently safer than the acceptable level of risk. For these activities, the risk of death could be higher than it is now before society would have to take serious action.

On the answer sheets, participants were provided with three columns labeled: (a) "Could be riskier: it would be acceptable if it were ___ times riskier;" (b) "It is presently acceptable;" and (c) "Too risky; to be acceptable: it would have to be ___ times safer."

FIGURE 3
Rethan's Operationalization of Risk Acceptance
Acceptability of Risk

Now that you have evaluated the risks associated with some consumer products, we would like you to judge the acceptability of these risks. Ideally, risk should be zero. However, products with zero risk do not exist. Rather, we decide whether or not risks associated with a product are at a socially (from a societal viewpoint) acceptable level. An acceptable level is a level that is "good enough," where "good enough" means that you think that the advantages of increased safety are not worth the costs to society of reducing the risk by altering the product or restricting its use.

Please indicate your views on the acceptability of the risks by circling the number on the scale that best describes your opinion.

	From a societal viewpoint, the present level of risk of this product is:
	Very Unacceptable Very Acceptable
1. Household ammonia	1 - 2 - 3 - 4 - 5 - 6 - 7
2. Sewing machines	1 - 2 - 3 - 4 - 5 - 6 - 7
3. Snow skis	1 - 2 - 3 - 4 - 5 - 6 - 7
4. Etc.	1 - 2 - 3 - 4 - 5 - 6 - 7

understood these operationalizations. Each of these operationalizations is long, complicated, contains several difficult concepts and are the kinds of concepts with which most lay people can be expected to be unfamiliar. Interpretation of these responses necessarily rests on the assumption that the respondent comprehends both the concepts and vocabulary being used. Yet how certain can we be that the respondents satisfactorily comprehend such sentences as: "On the other hand, there may be some activities or technologies that you believe are currently safer than the acceptable level of risk."? And just how confident can we be that the typical respondent has enough understanding of the issues to be able to assess whether "the advantages of increased safety are not worth the cost to society of reducing the risks by altering the product or restricting its use."? To interpret a response to these questions as being valid assumes that the respondent understands just what the "advantages of increased safety" are, knows what "the costs to society" are, has some idea of what these costs and benefits are "worth," has an understanding of what kinds of "alterations" of the product are possible, or what kinds of "restrictions on its use" may be imposed, etc. The questions further assume that the respondents can keep all these relatively unfamiliar and complicated considerations simultaneously in mind while answering the question. They further assume at certain parts that the respondent's thinking will be unidirectional, that is, if he thinks the product shouldn't be altered, he also thinks its use shouldn't be restricted. To my way of thinking, without any attempt to confirm and validate these numerous key assumptions, none of them are tenable.

In other words, I doubt whether the majority of subjects fully and accurately comprehended the questions they were responding to. Substantial evidence in the literature on questionnaire construction exists to indicate that even simple questions are miscomprehended by large proportions of the populace. Indeed, in a set of studies described at this Conference yesterday (cf. Jacoby, Nelson and Hoyer 1981), evidence was provided to indicate that 70 to 85% of subjects trying to understand a remedial advertising statement which was only one sentence in length either incorrectly understood that statement or extracted a confused meaning from it. How much greater, then, can we expect the levels of miscomprehension to be for a passage containing ten sentences referring to complicated and unfamiliar concepts? Until such time as evidence is supplied to indicate that the respondents accurately understood the operationalizations, we must entertain the possibility that the data reflect GIGO.

Future Directions

Clearly, work needs to be directed toward developing operationalizations which are something more than a collection of words which the investigators assume are capable of adequately assessing the concept of interest. It first needs to be established that these words are properly understood by the respondents before data obtained using these measures can be interpreted as being meaningful and programmatic work using these measures is undertaken.

Beyond these empirical considerations, I believe that the research thrust outlined by these authors would benefit considerably from a closer integration with the two decades old body of literature on the issue of perceived risk. This literature began with Bauer's (1960) seminal conceptualization and has since been summarized by Cox (1967) and Ross (1975), among others. At least one hundred studies have been conducted using this concept and a large body of findings have emerged. Among these findings is the fact that at least six different types of perceived risk (including perceived safety risk) have been identi-

fied and cross validated, and that perceived safety risk correlates with overall perceived risk .67 but contributes the least amount of explained variance in overall perceived risk scores (cf. Jacoby and Kaplan 1972; Kaplan, Szymbillo and Jacoby 1974). Consideration of this body of literature further reveals that the first three conclusions offered by Slovic et al. -- namely, perceived risk is quantifiable and predictable; lay people sometimes differ systematically in their perceptions of risk; and the greater the perceived risk, the greater the desired risk production -- already have a well-established history in the consumer literature. One would hope that a merging and integration of this earlier body of research with the current approach would enable us to go beyond what is already known.

Finally, I believe that the work that is conducted needs to be placed into a broader, conceptually richer framework. One emerging approach⁴ is to consider the subject of hazard management as involving two major components: technical and social issues (see Figure 4). The technical side of the ledger consists of the identification of hazards and the measurement of these hazards in terms of their probability of occurrence and the severity of their consequences. The social side of the ledger includes risk perception (that is the probabilities and consequences as perceived by the respondents) and risk acceptance.

FIGURE 4
A Perspective on Hazard Management

<u>Hazard Management</u>	
<u>Technical Issues</u>	<u>Social Issues</u>
Identification	Risk Perception
Measurement	Perceived consequences
Probability	Subjective probability
Consequence	Risk acceptability

Our own work on consumer awareness, comprehension, and usage of health and safety information (Jacoby and Jaccard, in progress) has involved developing an elaborated perspective based upon the earlier framework. This framework has continued to evolve and the current version is offered here for critique and use by others (see Figure 5). The perspective retains the notion of technical and social (or objective and subjective) components as being fundamental.

On the technical side, the framework begins with the actual identification of hazardous conditions and hazardous consequences. Hazardous conditions are assumed to be of two main types -- those associated with the product and those which occur with the interaction between the product and the environment (where the environment is meant to include the consumer as well). Table 1 illustrates these distinctions for insecticides. Note that various hazardous conditions are believed to be associated with the product and the manner in which it is being provided for consumer use. For example, the product may (or may not) contain ingredients which are toxic and pose a safety problem for humans. The product may be packaged in a container which does not have a childproof cap and/or it may contain inadequate labelling and usage instructions. In addition, many insecticides tend to be safe in terms of their contents and packaging but will become hazardous when certain environmental conditions are present. For example, some insecticides are safe except when used in the presence of exposed flames. Other insecticides are safe except when the environment in which they are used contains either

pregnant women, asthmatics, pollen sensitive people, infants, pets, people seriously ill, or people on prescribed medications. Yet other insecticides (particularly of the spray variety) only become dangerous to humans when used in the presence of exposed food stuffs.

TABLE 1
Illustrating the distinction between hazardous conditions and hazardous consequences for the product category "Insecticides"

I. Hazardous Conditions

A. Product

1. Does not contain childproof container
2. Contains problem ingredients
 - Kepona
 - Arsenates
 - Sodium Fluoride
 - Diazinon
 - Dichlorvos
 - Captan
 - 2, 4-D
3. inadequate labeling and instructions

B. Product X environment

1. exposed flames
2. exposed food stuffs
3. pregnant women
4. asthmatics and pollen sensitive people
5. infants and children
6. pets
7. people on prescribed medications
8. people seriously ill

II. Hazardous Consequences

- poisoning
- lasting nerve damage
- miscarriages and birth defects
- affect production of liver enzymes
- cancer

The actual presence of a hazardous condition (e.g. a bald tire on a car) does not necessarily lead to a hazardous consequence (e.g., an accident). The hazardous consequences which evidence suggests are associated with insecticide usage include poisoning, lasting nerve damage, miscarriages, birth defects, a deleterious impact on the production of liver enzymes, and cancer.

While the first major aspect of technical issues involves the identification of hazardous conditions and consequences, the second aspect involves assessment of: the probability of occurrence of each hazardous condition; the probability of each hazardous condition resulting in a hazardous consequence; and the severity of the consequences should they occur.

The third element on the technical issue side involves the identification of appropriate coping measures. These may be divided into those which are preventative in nature and those which are corrective. Preventative coping measures are those which enable the individual either to reduce or completely eliminate the existence of the hazardous condition or the hazardous consequence. (An example would be the use of safety goggles when using electrical tools). Corrective coping measures are those which should be employed to correct the existence of a hazardous condition or the occurrence of a hazardous consequence, e.g., adding air to an underinflated tire (preventative) or turning the wheel of a skidding automobile in the direction of the skid while pumping the brakes rapidly (corrective).

⁴We thank Rethans for bringing this to our attention.

FIGURE 5
Toward an elaborated perspective on hazard management

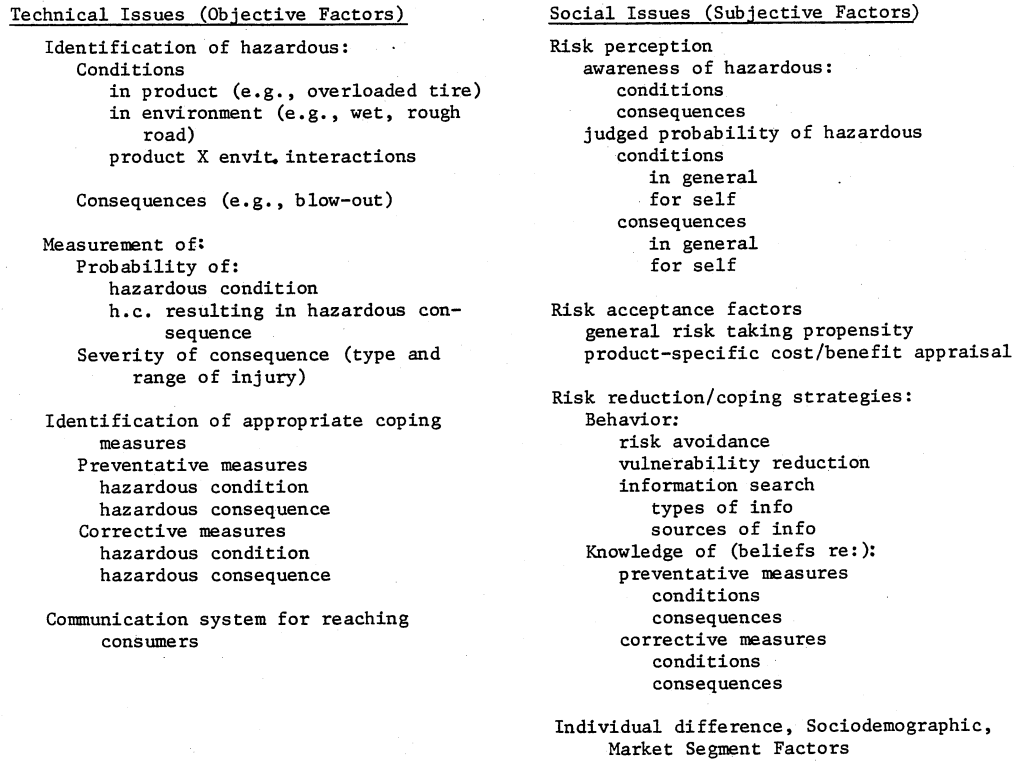

FIGURE 6
Toward integrating objective and subjective components.

		Hazardous Conditions									
		1	2	3	-	-	-	-	N		
Hazardous Consequences	1	a	b						c	d	e
	2										
	3										
	M										
	e										

- a = objective probability that the hazardous condition identified will lead to a hazardous consequence
- b = subjective (perceived) probability that the hazardous condition identified will lead to a hazardous consequence
- c = objective severity of that consequence
- d = subjective (perceived) severity of that consequence
- e = acceptance of the hazardous condition/consequence

The fourth element in the technical system would involve a consideration of the systems and procedures (media mix, execution strategies, etc.) that could/should be used for communicating the information regarding hazardous conditions, consequences, and coping measures to the consumer.

On the other side of the ledger are the subjective factors. These begin with risk perception and the consumer's awareness of the nature of the hazardous conditions and consequences associated with a particular product's use. In concert with Slovic et al. and Rethans, we firmly believe that if a consumer is unaware of either hazardous conditions or consequences, his behavior will not be affected by such conditions or consequences even though they may be serious and exist at high probability levels. In addition to awareness, one should consider the individual's probability judgments regarding these hazardous conditions and consequences as that individual believes they apply to others in general, and to himself in particular. As a preliminary attempt, Figure 6 outlines a framework for integrating some of these basic subjective factors with their objective counterparts.

Beyond the notion of risk perception, one has to take into consideration the factors affecting risk acceptance. While the consumer's perception of risk hazards and consequences may be accurate, he may still be willing (and even agree) to use a very risky product. In this regard, the authors of the papers presented at this session have identified at least a dozen factors seemingly associated with risk acceptance. To this list we would like to add the notion of "general risk-taking propensity." It appears to us that certain individuals are more inclined to be risk takers than others, and that this factor needs to somehow be taken into consideration in attempts to develop practical hazard management systems.

The subjective side of the ledger also needs to consider the risk elimination, risk reduction, and risk coping strategies that consumers can engage in. These include risk avoidance behavior (e.g., shunning the questionable product entirely), risk reduction behavior (i.e., reducing one's vulnerability to risk while maintaining at least some level of product usage), and continuing full use of the product while acquiring information regarding how to cope with hazards if and when they surface.

In this latter regard, it would be particularly useful for researchers who wish to influence public policy to identify the types of information consumers do use, and the sources to which they turn to in order to obtain this important information.

Beyond the behaviors that consumers actually engage in, one needs to assess the extent and accuracy of the beliefs consumers possess in mind regarding preventative measures and corrective measures. Again, to the extent that consumers have nonexistent or erroneous beliefs regarding corrective measures, different means for affecting their behavior will have to be employed.

Finally, any attempt to develop policies which will affect consumers at large needs to consider general individual difference and market segment factors. Certain risks tend to be much more likely, given certain combinations of market and individual difference factors. For example, it seems likely that risks are more probable with the elderly consumer, the disadvantaged consumer, the undereducated consumer, the very young consumer, etc.

Conclusion

In conclusion, we are enthused with the efforts engaged in by these researchers and would like to encourage both their efforts and others to embark on similar efforts.

However, we recommend considerable caution in accepting their results until we can be more confident that the measures of their key concept (namely, risk acceptance) are meaningful and valid.

INDIVIDUAL PREFERENCES AND PUBLIC POLICY

Robert T. Deacon, University of California, Santa Barbara

Abstract

Attempts to construct behavioral models of the public sector have resulted in the characterization of government as an exchange process, in which tax payments are the quid pro quo for public services received. The most widely discussed political-economic model follows from a characterization of citizen-voters as well informed, economically rational agents, embedded in a competitive political environment. Challenges to this theory question not only its positive implications, but also its normative content.

Introduction

The range of issues currently being raised in the field of state and local government finance is both diverse and volatile. The popular movement to limit taxes and public expenditures is probably the most visible of these, though court imposed changes in public school finance, and state and federal funding for local government programs are of continuing interest. Had a phenomenon such as tax limitation arisen a mere twenty years ago, it seems safe to speculate that the major topics of concern to the economics profession would have been with the distributional effects of tax cuts and the adequacy of alternative revenue sources to make up shortfalls. In contrast, the current literature is filled with studies of voting behavior on tax limit referenda, attempts to discover whether such phenomena are indicative of "political disequilibrium," and if so, what features a new equilibrium is likely to embody. This dramatic shift in emphasis reflects a rapid evolution in economic analysis of the public sector, one which has resulted from an attempt to conceptually bridge revenue and expenditure sides of the public budget with a behavioral paradigm (Buchanan 1975). In this emerging framework, government is characterized as an exchange process, in which taxes are the quid pro quo for services received. Individuals are endowed with essentially the same motivations, preference structures, and informational requirements faced in the private sector. But in the role of public sector consumer, the individual's opportunities and constraints are critically shaped by the nature of political institutions.

Viewing the citizen-taxpayer as consumer raises a variety of questions. What is the nature of his public sector demands, and how are they revealed? How accurately are these demands articulated, and how do public supply institutions respond to them? Can a concept of equilibrium, similar to that used to study private markets, be employed to characterize public sector outcomes? This general class of questions is addressed in the following pages. The next section briefly discusses the institution of voting, and its role as a device for revealing preferences. Following this, the concept of equilibrium in majority rule systems is explored, and competing views of the nature of the political process are examined. Concluding comments are presented in the final section. At each step, existing empirical evidence, as it relates to key conceptual questions, is briefly summarized.¹

¹More extensive discussions of several of the topics treated here appear in Deacon (1977).

Voting and Revealed Preferences

The notion that individuals act in self-interest when choosing among ballot alternatives has been implicit in public choice theory from its beginning (Bowen 1943, Downs 1957, pp. 27-45). Extension of the utility maximization hypothesis from the realm of the market to the voting booth has apparently been so natural that it is axiomatic in the theoretical literature. The view that individuals compare ballot alternatives and vote for those that offer preferred outcomes suggests the use of voting choices as information on revealed preferences for public goods.

To illustrate this approach, consider the following simplified situation (adapted from Rubinfeld 1977) involving a referendum to change the level at which a single public service is provided. Such choices are fairly common in public school districts in the U.S., where ballots offer alternative property tax levies. The preferences of individual i are represented by a conventionally shaped utility function in which the public service in question (q), and consumption of a composite private good (x_i) enter as arguments,

$$U_i = U_i(q, x_i) . \tag{1}$$

Normalizing so that the price of the private good is unity the individual's budget constraint is expressed

$$I_i = x_i + t_i E \tag{2}$$

where I_i is income, E is total public service expenditure by the jurisdiction in question, and t_i is the individual's tax share, the amount by which his tax will rise if public spending increases by one dollar. To complete the problem, spending is related to services received by a (convex) cost function for the public service

$$E = E(q) . \tag{3}$$

The consumer's preferred public sector outcome is characterized by maximizing (1) subject to (2) and (3). The solution to this problem is the consumer's desired public spending level,

$$E_i^* = D_i(t_i, I_i) . \tag{4}$$

The functional label D_i is used to indicate that the relationship is a conventional demand curve, where t_i is interpreted as a "tax price." Consequently, E_i^* is expected to be decreasing in t_i and increasing in I_i (if the public good is normal).

The demand curve is drawn in Figure 1. Suppose that the existing level of public expenditure is E_0 , and that the issue before the voter proposes a marginal increase in spending. Since voter i prefers a level of public outlays larger than E_0 , a yes vote on the proposed increase is expected. The general rule for voting on marginal increases such as this can be written:

$$\begin{aligned} \text{vote "yes" if } E_i^* > E_0 , \\ \text{vote "no" if } E_i^* < E_0 , \\ \text{abstain if } E_i^* = E_0 . \end{aligned}$$

Intuitively, if one had prior information on the shape of demand functions and on individual tax prices, then voting responses could be predicted. For example, among the class of voters who have demand curves similar to D_i

in Figure 1, those who face tax prices above t_0 would be expected to vote against the measure, while those with tax prices below t_0 would support it. Consequently, "the demand function (for public education) ought to be the most effective discriminant function for distinguishing 'yes' from 'no' votes that households cast" (Peterson 1975, p. 104).

FIGURE 1
Public Expenditure Demand

A number of public education demand functions have been estimated from school referendum data, though "probit" or "logit" techniques are usually employed in estimation rather than discriminant analysis. In some cases, individual attributes and voting choices have been available from survey data (Peterson 1975, Rubinfeld 1977). More often, however, only aggregate voting returns (e.g., by precinct) are reported, a condition that necessitates interpreting demand responses as pertaining to an average or representative voter in each group (Barkume 1978). In general, these studies have obtained significant price and income effects that are of expected sign. Moreover, since it is often reasonable to postulate that demands will depend upon other observable attributes such as age, education, family status, etc., a variety of additional hypotheses have been examined. For example, Rubinfeld (1977) found school employees much more likely to vote for tax increases than otherwise similar voters. Others have examined the effects of numbers of school age children in a family upon voting responses.²

If voting data could only be analyzed within the confines of the example developed earlier, the application of this approach would be severely limited. With noneducational referenda, diverse arrays of services may be involved in a single ballot, and payment may be exacted by changing incomes or market prices, rather than simply altering the level of a single tax. One technique that has been developed to analyze such complex alternatives employs the concept of a mixed indirect utility function (Deacon and Shapiro 1975). Within this framework, ballot choices are characterized in terms of utility comparisons, rather than

²In general, voting studies of the type described here, can only measure the relative magnitude of price and income effects. In a series of papers, Eli Noam has developed and applied a technique that permits estimation of the absolute effects of price, income, and other variables upon demands, and applied the method to the determination of optimal budgets. See Noam (1979) and references cited therein.

public expenditure demand functions, and utilities under alternative ballot outcomes are expressed as functions of income, prices, tax rates, and public goods levels. Application of this technique to referenda involving such issues as scenic resource conservation, rapid transit provision, and public hospital financing has yielded results that are generally in close accord with the underlying theory.

Prior to casting a ballot, the voter must decide whether or not to vote at all, i.e., whether the benefits of showing up at the polls exceed the costs (Downs 1957). Potential benefits depend upon the likelihood that a single vote will decide the outcome (as, for example, measured by the closeness of the election) and upon the expected difference in outcomes under the two alternatives on the ballot. Costs will vary with the imputed value of the individual's time, and the resources required to obtain and evaluate information regarding the alternatives. This economic model of the "turnout" decision has been successfully employed in a number of empirical studies (Barzel and Silberberg 1973, Chapman and Palda 1980). Moreover, it indicates that those who vote may not be a random sample of the populace. This conjecture was borne out in an analysis of the Headlee tax limitation amendment in Michigan by Gramlich *et al.* (1980), who found that nonvoters tended to be relatively uninformed or uncertain regarding the likely impacts of the measure, and generally inclined to be against it. The notion that voting costs may significantly influence electoral outcomes, by "selecting" the kinds of preferences revealed in elections, remains to be fully integrated into existing models of the collective choice process.

The analysis of voting behavior is of central importance to any model of the public economy, and must precede judgments concerning the ability of democratic systems to respond to citizens' preferences. To the extent that voting behavior is consistent with economic rationality, it becomes possible to predict outcomes and to formulate refutable hypotheses regarding the electoral process. In turn, it is the possibility of prediction that allows one to construct positive political models, and to make normative statements concerning actual political systems.

Majority Rule and the Median Voter

To address questions regarding the determinants of political outcomes and the nature of political equilibrium, an explicit model of the political process under majority rule is necessary. The first economist to suggest such a theory was Harold Hotelling (1929). The paradigm he offered was extended in a remarkable article by Howard Bowen (1943), and further refined by Downs (1957).

To motivate the development of this theory, consider the following problem. The range of possible public sector outcomes (policies) is represented as a set (a_1, a_2, \dots, a_n) , and elements of this set will be placed before the voters in a pairwise fashion. Each citizen-voter has preferences for the various alternatives, and in principle, these preferences can be represented in terms of individual utilities. Assuming that the preferences of voters are known, the problem is to predict which alternative will be chosen under simple majority rule. In general, the existence and characteristics of a solution to this problem depend upon the satisfaction of certain conditions regarding the shape of preferences and the way in which alternatives are offered.

It has been known, at least since the 18th century, that majority voting on pairs of alternatives need not exhibit transitivity. Cycles can develop in which a_1 defeats a_2 , a_2 defeats a_3 , and a_3 defeats a_1 , etc., even if the preferences of individual voters are fully transitive.

Without transitivity, equilibrium would not be possible unless some sort of stopping rule were invoked; but use of such a stopping rule makes the final outcome "path dependent," or sensitive to the order in which alternatives are offered. If, however, individual preferences satisfy a certain regularity property then the cycling problem disappears. For simplicity, suppose that indifference among pairs of alternatives is ruled out, and that the number of voters is odd. Then majority rule will be transitive if the list of alternatives (a_1, a_2, \dots, a_n) can be arranged in a sequence (a_1, a_2, \dots, a_n) such that the following condition is satisfied for each voter: If $U(a_i) > U(a_{i+j})$, then $U(a_{i+j}) > U(a_{i+j+k})$, for all $i, j, k > 0$. This statement of the so-called "single peaked" condition guarantees transitivity, though considerably weaker conditions will also suffice (Sen 1968). Intuitively, this condition is satisfied if each voter's utility, when plotted against the sequence alternatives, forms a single peaked curve, i.e., each voter has one uniquely preferred alternative, and utility declines monotonically as one moves away from this alternative in either direction.

If preferences are single peaked then the median of individually preferred outcomes is dominant in that it will be preferred by a majority of voters over any other alternative that may be paired against it. To see why this is true, let a_m be the median preferred alternative and suppose it is paired against some other alternative (a_{m+h}) that is higher in the sequence. Since a_m is the median preferred point, a simple majority of voters have preferred alternatives that are at or below a_m in the sequence; since their preferences are single peaked, each voter in this majority prefers a_m to a_{m+h} . Of course, the same argument applies to alternatives below a_m .³

For the median voter theorem to have any empirical content, the condition of single peaked preferences is clearly pivotal. In practice, there are a number of empirically important contexts in which the condition seems quite reasonable, and most theoretical and empirical applications have been restricted to such situations.⁴ The simple referendum example described in the preceding section is a case in point. The individual whose public expenditure demand is shown in Figure 1 prefers a public outlay of E_i^* . If actual spending is increased or decreased from this level, utility declines monotonically, as shown by the curve labelled U_i in Figure 2. Of course, the same argument applies to other individuals as well; correspondingly, Figure 2 also illustrates public spending preferences for two other voters, h and j . In this example, i is the median voter, and E_i^* is his preferred expenditure level. Notice that any proposal to increase (decrease) spending from E_i^* would be opposed by a majority of the electorate, h and i (i and j). (The other points labelled in Figure 2 are explained below.)

Majority Rule Equilibrium: Competitive or Noncompetitive?

If the median voter's optimum appears on the ballot it will defeat any alternative motion. But what guarantees that it will ever be placed before the voters? If motions,

³Hotelling (1929) speculated that political candidates and their platforms could be arrayed along a scale from liberal to conservative, and that this political spectrum formed a natural sequence over which individual preferences are likely to be single peaked. From this it follows that vote maximizing candidates in a two party system will be led to adopt similar platforms toward the middle (median) of the distribution of political opinion.

⁴See, however, Barzel and Deacon (1975), and Sonstelie (1979), for analysis of voting outcomes in situations where preferences are not single peaked.

FIGURE 2
Preferences and Majority Rule Outcomes

or political alternatives, are supplied competitively by political entrepreneurs who seek to maximize their chances of being elected, then the median outcome seems very likely. Nonmedian strategies simply invite defeat in this context. In noncompetitive environments, however, other outcomes are clearly possible. Since the competitive case has received primary attention in the literature, it is discussed first.

The median voter characterization of public sector outcomes has been used extensively in the analysis of state and local government spending patterns. From Figures 1 and 2, the competitive majority rule outcome (E_i^*) represents one point on the median citizen's demand curve. By relating public service expenditures in a sample of jurisdictions to the median voter's tax price, income, and other attributes expected to influence demands, the possibility of estimating an entire demand function emerges. Early attempts to apply this notion were limited to testing qualitative implications of the theory, e.g., that increases in the size of the non-residential component of the tax base reduce tax prices to all voters, and hence lead to larger expenditures (Barr and Davis 1966). Although the empirical models were somewhat loosely specified, the results obtained were sufficiently promising to encourage further research. The empirical methodology was refined considerably in a group of studies designed specifically to estimate parameters of demands for public services (Borcherding and Deacon 1972, Bergstrom and Goodman 1973). In each case, the median citizen's demand was assumed to be a log-linear (linear in logarithms) function of median income and median tax price in a jurisdiction. Specification of tax price usually presents the most difficult empirical task in such studies. An individual's tax price for a public service depends directly upon the cost of producing public output, and upon the share of total taxes paid by the citizen in question (see equations (2) and (3)). Empirically, variations in public service costs are usually related to prices of inputs (Borcherding and Deacon 1972, Deacon 1978). If services are financed by a property tax, then median tax shares can be estimated from information on median housing values and total assessed valuation in each jurisdiction (assuming that the median citizen owns and occupies a house of median value). Application of this methodology to state and local government expenditures has yielded estimates of price and income elasticities that are typically significant and of expected sign. Moreover, a degree of consensus has emerged regarding the actual magnitudes of these effects. Demands are almost invariably found to be price inelastic, with elasticities usually ranging from .2 to .6. Income elasticities are typically positive, but

less than unity, e.g., between .4 and 1.0.⁵

Identifying the relevant demand attributes for the median citizen in a jurisdiction is particularly difficult. If, for example, public service demands vary with age, the level of education, or the number of children in a household, the assumption that median demands can be uniquely related to median income and tax price alone, may well be inappropriate. Bergstrom and Goodman (1973) have developed a very useful theorem in this regard. Within the context of log-linear demands and certain regularity properties for income distributions, it provides conditions that are sufficient to specify the form of the median demand in a jurisdiction.⁶

The attempt to model demands in a public choice framework has shed light on a variety of related issues. For example, results obtained by Peterson (1975), Bergstrom and Goodman (1973) and others, are consistent with the proposition that renters perceive themselves as bearing only a fraction of the tax liability on rental property they occupy. Others have noted relationships between spending and the composition of the tax base that indicate the degree to which voters expect taxes levied on non-residential property to be borne by outsiders (Ladd 1975). These results are particularly important for public finance theory because they imply that questions regarding tax incidence and other distributive aspects of public policy cannot really be divorced from resource allocation issues, once a collective choice process is introduced. In this context, policies designed simply to redistribute tax burdens in the population, e.g., "circuit breaker" tax relief, or equalization formulas for school finance, may alter public service levels in ways that are, perhaps, predictable (Inman 1978).

In summary, a large body of theoretical and empirical research has been conditioned upon the median voter hypothesis. The fact that a measure of agreement in empirical results has emerged from diverse studies lends some support to the underlying paradigm.⁷ However, the model has by no means escaped criticism (Romer and Rosenthal 1980b). To many, the level of abstraction it employs is stratospheric; moreover, the basic premise that communities actually attain Hotelling-Bowen-Downs equilibrium has largely eluded direct tests. One source of concern is the informational requirements that the model imposes upon voters. Several authors have raised the possibility that complexity in taxing institutions may cause voters to incorrectly perceive tax liabilities. If such a misperception takes the form of "fiscal illusion," a systematic underestimation of tax bills, the effect would be to increase expenditure beyond the median voter's "fully informed" optimum. To date, however, attempts to shed empirical light upon this proposition have been rather inconclusive (Wagner 1976, Clotfelter 1978).⁸

⁵There are, however, notable exceptions. Public parks and recreation services often exhibit income elasticities greater than 1.0; estimated income elasticities for public welfare expenditures are sometimes negative.

⁶For further discussion of this theorem, and an empirical examination of the assumptions underlying it, see Inman (1978).

⁷Moreover, Peterson (1975) and Rubinfeld (1977) summarize evidence to indicate that demand estimates from median voter expenditure studies are in close agreement with results obtained from voting data.

⁸As Bergstrom and Goodman (1973) point out, a powerful law of large numbers applies to medians as well as to means. As a consequence, purely random errors in perception of tax liabilities or service levels tend to cancel out.

A methodologically more telling criticism concerns the fact that the median voter model minimizes the role of interest groups, and assigns politicians and bureaucrats the passive role of seeking out and supplying the demands of the voting middle class. This is essentially an assumption of competition in the political process, and it has been challenged by a number of writers who take a much more monopolistic view of the public economy. Niskanen (1971) was the first to develop a complete theory along these lines, and more recent attempts to formulate models of noncompetitive equilibrium in the public sector have adopted his basic approach.

According to Niskanen, government bureaus enjoy considerable monopoly power as sole suppliers of public services. Consequently, they can control the range of alternatives offered to the citizenry, or their elected representatives. Comparing market relationships in public versus private sectors, "the primary difference . . . is that the [government] bureau offers a total output in exchange for a budget, whereas a market organization offers units of output at a price" (Niskanen 1971, p. 25). In effect, bureaus have the power to confront their constituents with "all or nothing choices." In the context of a majority rule system, this amounts to a limited control over the agenda, or range of alternatives facing voters.

In Figure 2, individual i would receive utility of $U_i(0)$ if no public output were provided. If faced with an all or none offer, both i and j (a simple majority) would prefer expenditure levels up to E_N to the prospect of receiving no public service at all. By restricting the menu of available alternatives to a single pair, one of which involves no service, the monopoly bureau can effectively select any expenditure level between 0 and E_N . By way of characterizing the bureau's motives, Niskanen offers salary, perquisites of office, prestige and power as plausible maximands, but argues that in general these will be positively related to the size of the total budget. With budget maximization as an implicit goal, the Niskanen equilibrium expenditure level is E_N in Figure 2.⁹

Niskanen's budget maximization hypothesis has been recently extended by Romer and Rosenthal (1980a). In their model, the budget setting power of bureaucrats is somewhat attenuated, but significant nonetheless. The distinctive features of their approach hinge upon the existence of a "reversion level" to which public expenditures will return if the government's budget proposal is not approved. The reversion level is determined outside of their model, presumably at the constitutional stage. Returning to Figure 2, suppose the reversion level of spending is E_0 ; in effect, this is the bureau's minimum budget offer. Correspondingly, $E_R(E_0)$ is the maximum expenditure level that could gain a majority over E_0 , and thus represents equilibrium in the Romer-Rosenthal characterization. Introduction of a reversion level into the budget maximization framework yields a novel implication; in the absence of uncertainty, equilibrium expenditure is inversely related to the reversion level. "By facing the voters with a 'take-it-or-leave-it' choice, the setter [bureaucrat] exercises a threat over the voters. The worse the status quo [reversion level], the greater this threat, and consequently, the greater the gain to the setter [bureaucrat] from being able to propose the alternative" (Romer and Rosenthal 1978, pp. 35-36). Of course, this relationship only holds for reversion levels that are below the median optimum, E_i^* ; beyond that point, the equilibrium budget is

⁹It seems clear that Niskanen intended his model to apply primarily to federal governments. In any case, the degree of oversupply certainly depends upon the elasticity of demand and, hence, upon the availability of substitute services. At the local government level, the possibility of migration among jurisdictions presents substitution possibilities that are exceedingly costly at the federal level.

trivially equal to the reversion level.

Designing tests to distinguish between competitive and non-competitive political models is difficult at best. As is the case in the private sector, qualitative implications from competitive models are often fully consistent with non-competitive behavior as well. For example, in either Niskanen or Romer-Rosenthal versions of budget maximization, equilibrium public service levels are inversely related to service costs and directly related to incomes. The introduction of a reversion level in the Romer-Rosenthal framework, and its hypothesized effect upon budgets does, however, present an opportunity to separate the two models, since reversion levels should have little or no effect upon budgets in a competitive environment. Apparently the first attempt to examine this question empirically was carried out by Holcombe (1980). In Michigan, school boards have authority to levy property taxes up to a certain rate (which varies across districts) without approval of the electorate. Tax rates in excess of this statutory limit must be approved by majority vote. This system bears a very close resemblance to the Romer-Rosenthal non-competitive model with a reversion level. Holcombe (1980) presents anecdotal evidence to indicate that some districts attempted to exercise monopoly power by making non-incremental offers to the voters.¹⁰ On average, however, he found no evidence that budgets exceeded competitive levels. Intuitively, Holcombe (1980) found that excess levies were generally approved by substantial majorities (65.3 percent voting in favor, on average). Thus, school boards could evidently have obtained much larger school budgets (with smaller majorities) than were observed. More formally, Holcombe (1980) made certain simplifying assumptions regarding the general shape of individual preferences for alternative budgets, and assumed that the distribution of preferred budgets was normal within each district. Using these assumptions, together with information on election returns and the actual alternatives offered in school levy referenda, he was able to estimate the median preferred expenditure level in each school district. Comparing his estimates to actual budgets in over 200 districts, he found that observed budgets deviated from median preferred levels by a mere 2.4 percent on average. Ironically, actual levies were below his estimated median points, but the difference was not statistically significant.

The institutions of school finance referenda in Oregon are quite similar to those in Michigan. Romer and Rosenthal (1980) conducted a test of their model using data on educational expenditures and reversion levels in Oregon school districts. A negative relationship between the two variables was expected. After controlling for factors such as income, tax price, and state subventions to local districts they found that reversion levels were significantly related to school outlays, but the direction of the effect was not monotonic. Except for school districts with extremely low reversion levels, actual budgets were positively related to reversion levels, contrary to expectations.

Some additional indirect evidence on the budget maximization hypothesis has been obtained from comparisons of spending levels in jurisdictions where expenditures are set by elected representatives rather than by direct democracy. As Romer and Rosenthal point out, "the possibilities of both monopoly power acquired by elected officials and coalition of minority politics suggest that expenditures will be greater in representative democracies [than in direct democracies]" (1979b, p. 161). Both McEachern (1978) and Holcombe (1980) have examined this hypothesis

¹⁰ In one district, the reversion level was a tax rate of 6.0 mills, and the school board offered an alternative of 16.75 mills. The measure passed by a scant 1.1% (Holcombe 1980, pp. 267-268).

empirically. In the former study, debt levels in states that require a simple majority referendum to increase debt limits were compared to debt in states with no such requirements. After controlling for certain variables that might independently affect debt levels, no significant difference in per capita debt in the two groups of states was found. In a similar fashion, Holcombe (1980) compared per student educational expenditures in states that require spending referenda, to states where expenditure levels are chosen by elected officials; again, no significant differences were noted.

Finally, both Citrin (1979) and Courant, *et al.* (1980) conducted surveys of voting age citizens in states considering tax limitation referenda (California and Michigan). When asked about their preferences for increasing or decreasing government expenditures and taxes by various amounts, it was found that the median respondent desired no change; this was true not only for total spending, but for virtually all of the individual services surveyed. However, the observation that responses were consistent with competitive public sector equilibrium is rather surprising in this case, since both measures were adopted. This apparent anomaly may simply indicate the potential pitfalls in survey research, or imply that closer examination of the specific referenda in question is warranted.

Concluding Comments

The attempt to distinguish competitive from non-competitive outcomes in the public sector is clearly important. This is true for essentially the same reasons that support the study of market power in the private economy; competitive markets attain a degree of efficiency not present in monopolistic regimes. When considering the question of efficiency in the public sector, at least two concepts are important. The first, sometimes called "process efficiency," concerns the degree to which inputs are combined in a cost minimizing fashion. This topic has not been addressed in the present paper, though numerous studies have concluded that, due to the nature of the rewards system, public enterprises are not efficient in this sense. The second concept concerns whether, given the structure of costs, the correct level of public output is produced; it is this notion of efficiency that is of primary interest here. In a general sense, the level of output is "correct," if the marginal benefits of additional output just offset marginal costs. Under certain, not terribly unrealistic conditions regarding the distribution of demands and tax shares in the populace, the competitive Bowen equilibrium is efficient, or at least approximately so, in this sense (Bowen 1943).

From the empirical analysis presented to date, no strong indication of non-competitive budget maximization has emerged. However, given the limited number of attempts to test this hypothesis, final conclusions are clearly premature. In any case, the current degree of polarization in views of the public sector, with some analysts apparently believing that all outcomes are competitive and others that none are, seems inappropriate and counterproductive. It seems reasonable to speculate that the evidence on this question will eventually show some elements of monopoly power in public organizations, at least under certain conditions, as is the case in private markets. If so, the relevant questions will concern the degree of monopoly power observed and the conditions under which it is likely to occur (e.g., at which levels of government, for what kinds of services, under which types of institutional structure). With a bit of imagination, it is even possible to envision development of a public sector analog to the traditional study of industrial organization in private markets.

SUBSTITUTION BETWEEN PUBLIC AND PRIVATE GOODS: AN OVERVIEW
OF THE MARKET MEETING CONSUMER PREFERENCES¹

Charles L. Vehorn, U.S. General Accounting Office and Georgetown University

Abstract

It has often been suggested that a consumer may substitute private goods for public goods that are not provided at the consumer's desired level, but until recently research had not been undertaken on the degree of substitution. This paper presents an overview of the public-private substitution question, dealing with how researchers conceptualize the issues and how they attempt to observe consumers registering preferences.

Introduction

Many local officials make budgetary decisions based on the implicit assumption that the government has a monopoly on the provision of standard public services. However, this assumption that the government alone possesses the means to meet the preferences of citizen-consumers is often inaccurate. Instead, a number of private substitutes for public goods exist, although they may not be perfect substitutes. Thus, local decisions based on the monopoly assumption can lead to an inefficient allocation of public resources.

One fundamental difference between public and private provision is the way in which goods and services are rationed. When goods and services are provided in the private sector consumers and producers signal each other through the market process. If consumers, for example, desire more of a particular good, they bid up the price letting suppliers know it is advantageous to increase production. Consumers register changes in their preferences through this market mechanism and resources are allocated more efficiently to meet those new preferences.

In the public sector, on the other hand, middlemen drive a wedge between consumers and producers. These middlemen, whether elected or appointed public officials, have the authority to control the production process through their budgetary decisions. Thus the amount provided may vary from the amount that would have been supplied under market rationing. Because of non-market rationing and the collective nature of public goods many citizens are left dissatisfied, especially in communities where voters have heterogeneous preferences. This dissatisfaction creates incentives for a private market to spring up and fill the void. The mere existence of private substitutes for public goods indicates the market is working to meet consumer preferences.

The primary purpose of this paper is to present an overview of the public-private substitution process. First, a Lancasterian perspective is employed to provide an underlying conceptual framework for discussing the potential range of substitution (1966). Then a brief review of collective goods and their demand is given to introduce a more detailed treatment of recent attempts to observe consumers registering their preferences between public and private goods in the markets for police protection, fire protection, and education. The paper concludes by pointing out how further research in this area could provide information to aid public policy makers,

who must decide how to allocate the public's scarce resources efficiently.

The Range of Substitution between Goods

In a narrow sense of the word, substitution is simply the process of purchasing one commodity in place of another. This definition, however, fails to account for all those commodities that are not perfectly substitutable. Many commodities are closely related, yet in the eyes of the consumer not perfect substitutes, or for that matter perfect complements. It is perhaps useful to view pairs of goods as lying on a continuum according to how closely they are related. At one extreme are perfect substitutes, at the other perfect complements. In the middle are independent commodity pairs. In between either extreme and the middle is a wide range of closely related goods with some degree of substitutability or complementarity. Consumers do not make an either-or choice with these closely related goods, but select a commodity bundle with a desired mix, depending on prices, income, and tastes.

A key and sometimes neglected issue in discussing substitutability is the definition of a commodity. The traditional approach is to define a commodity as simply the physical item or service purchased -- a hamburger, a shirt, a glass of beer. If consumers desire commodities defined in this general way, it becomes difficult to explain why some consumers will drink only one particular brand of beer. If a beer is a beer, then there should be perfect substitution between brands. However, each brand of beer has its own particular taste, so consumers who are loyal to only one brand of beer are saying no other taste can substitute for the taste of my brand of beer. Thus the traditional approach to consumption overlooks the relationship between the purchase of goods and the purchase of attributes that are inherent in the goods.

A new approach to consumption, formally developed by Lancaster, specifically recognized that goods purchased in the market usually yield more than one well defined service. So it is reasonable to argue that consumers desire the satisfaction of a commodity's services or attributes when they make a market purchase. When consumers purchase housing they desire attributes like space, in the number and size of rooms, and location, with easy access to schools, transportation routes, and recreational facilities. Another example of a good with multiple attributes is the running shoe. When runners purchase shoes they are buying a series of attributes, some of which have only become available in the last few years through technological innovation. The attributes include flexibility, sole wear, rearfoot impact, forefoot impact, weight, rearfoot control, and traction.

Thus the new approach to consumer theory made attributes the object of choice by simply placing desired attributes instead of commodities into the utility function, and assuming an additive linear relationship between the two,

$$z_i = \sum_j b_{ij}q_j \quad (1)$$

where z_i = the attributes desired by consumers
($i = 1, \dots, m$)

q_j = the quantities of public and private goods ($j = 1, \dots, n$)
 b_{ij} = the amount of attribute i possessed by a unit of commodity j .

Public Goods and Consumer Demand

It can be shown that the new approach includes the traditional approach by writing equation (1) in matrix form

$$Z = BQ \quad (2)$$

where Z and Q are $(m \times 1)$ and $(n \times 1)$ column vectors respectively, and B is the $(m \times n)$ consumption technology matrix. Now if $m = n$ and the B matrix is diagonal with $b_{ii} > 0$ for all i and $b_{ij} = 0$ for $i \neq j$, then the new approach collapses to the traditional approach with a one-to-one relationship between z_i and q_j .

One important insight of the new approach to consumer theory is that changes in relative prices may result in a switch from one bundle of commodities to another because the former becomes an inefficient way to attain the desired attributes. Lancaster called this the efficiency substitution effect, which is different from, but reinforces the personal substitution effect in the traditional theory of consumption.

The efficiency substitution effect may be operative in substitution between public and private goods. Because of the nature of collective goods, which will be discussed more thoroughly in the next section, individual voters may desire more or less of the public service, i.e., under the new approach more or less of the public good's attributes. This dissatisfaction with public provision leaves the consumer with basically four options. The consumer can form a lower-level government, migrate from the locality, seek help from voluntary organizations as extra-governmental providers of collective goods, or resort to private market alternatives. The first three options imply high transaction costs, but the last option has relatively low transaction costs associated with the search for an acceptable substitute.

Even though private market alternatives exist, they are often far from perfect substitutes for public provision. In fact, as the following examples supplied by Weisbrod indicate, these goods are generally different in form from public goods (1975). If the provision of clean air is inadequate one can substitute air filters and purifiers in the home or work place. Consumers or firms can also substitute sprinkler systems for public fire protection; and locks, alarms, guns, watchdogs, or guards for public police protection.

Public police protection is an interesting example of a good with several attributes. Consumers desire crime prevention, protection activity, and a feeling of security. If the public sector does not provide the desired amount of these attributes, citizen-consumers can purchase various goods in the private market to increase protection and provide a better sense of security. These private market alternatives may be poor substitutes for policemen when it comes to apprehending a criminal, but a watchdog or burglar alarm enhances the sense of security. The private-good substitutes may be costly, but they give the consumer a degree of personal control, which is lacking in most public goods. The purchaser directly controls the watchdog or alarm for his own personal well-being. Collective goods by their non-excludable nature cannot provide this sense of individual ownership and control. In general, there are few private goods that are perfect substitutes for public goods, but the range of substitutability is wide and many private goods possess the same attributes found in public goods.

Public goods are distinct conceptually from private goods because public goods have a non-excludable and a non-exhaustible nature. A private country club, for instance, can exclude consumers from enjoying its recreational facilities, but a public park is shared by all citizens who desire to use it. The recent influx of Cuban refugees into Florida certainly caused a temporary strain on many private goods like food and clothing as suppliers' inventory became exhausted, but additional consumers cannot exhaust the supply of a "pure" public good, like national defense.

Most local public goods, however, have both private and public good characteristics. The use of a road is shared with other drivers, and due to congestion, a certain rivalness in consumption occurs. A public fire department does not exclude homeowners from protection, but it cannot simultaneously extinguish fires in separate locations because its resources are constrained. Thus studies of the demand for local public goods must incorporate this aspect of congestion into the analysis. The way Borcharding & Deacon (1972), Bergstrom & Goodman (1973), and others did this was to use a median voter demand model specifying the public good in terms of a crowding function.

Consider the total physical quantity of any local public good, q^* , which is subject to a certain degree of crowding due to the size of the population, N . Specify the crowding function as

$$q = q^*N^{-\alpha} \quad 0 \leq \alpha \leq 1. \quad (3)$$

If $\alpha = 0$, q^* is a Samuelsonian pure public good where every individual consumes the total quantity available. As α approaches 1 individuals are not able to enjoy the full amount, but must share q^* with others. When $\alpha = 1$, the individual receives the fraction $1/N$ of the total provision. Estimates of the crowding parameter for most local public goods have been closer to one than zero, indicating a low degree of "publicness."²

These estimates of crowding are consistent with another type of substitution, which is mentioned here but not pursued at length. Increasingly, the private sector is directly providing local public services. Some local governments have found it appropriate to contract out to the private sector for services like fire protection or garbage collection. The usual argument, most recently confirmed by Bennett and Johnson, is that private delivery of public services lowers costs, since the private sector operates under incentives that encourage cost effective provision (1979). Although the growth in "privatization" of public goods is an important occurrence, the substitution here is not in consumption but in the production process, which is beyond the scope of this paper.

In addition to crowding, the median voter's demand for a local public good is dependent upon income, y , the tax price or tax share, p_t , the prices of related goods (substitutes and complements), p_k , and tastes, T ,

$$q = f(p_t N^{-\alpha}, y, p_k, T). \quad (4)$$

Although many local public good demand studies recognized

²

However, there is some reason to believe that these estimates of "publicness" might be biased (King 1977).

the conceptual importance of private-good substitutes, empirical estimation of the degree of substitutability was not usually undertaken due to data unavailability. Research to shore up this empirical gap has just begun. The next section reviews recent studies that attempted to quantify the degree of substitutability.

Estimates of Public Good-Private Good Substitutability

Police Protection

Ann Bartel analyzed the demand for private protection by firms (1975). The main purpose of her study was to answer the following three questions. One, how is firm demand for protection related to business losses from crime and the probability of crime? Two, are public and private expenditures substitutes or complements? Three, does a firm choose self-protection as a substitute for market insurance, or will it spend more on protection if it has insurance?

She developed an extensive theoretical model that took into account expected losses and risk aversion, but was unable to test all of the model's implications due to data limitations. However, she was able to answer the three main questions through the use of logit analysis. A survey conducted by the SBA provided data on whether or not private firms hired guards. These data became the dependent variable in the logit analysis.

She found that firms do respond rationally to economic forces in making their protection decisions. Firms placed relatively more weight on the probability of loss than the size of anticipated losses. Also firms were willing to reduce their demand for private protection when public police protection was increased, so the two types of protection are substitutable. It appears that firms have a target level of desired protection, which is a mix between public and private protection services. Insurance, however, was not a substitute for private protection because firms could purchase insurance at a lower price if they hired private guards or protective services.

Lancaster's new approach to consumer theory is helpful in understanding Bartel's results. The attribute that firms desire is a certain level of protection at the lowest cost. So firms combine public services and private services until they obtain their desired level of protection, while at the same time judiciously choosing the mix of private protection services to minimize costs.

Clotfelter employed a conceptual approach similar to Lancaster's, except he viewed the attribute as the final output and commodities as intermediate goods (1977). This approach allowed Clotfelter to formulate the private-public choice issue in terms of a production function

$$z = f(q*N^{1-\alpha}, q') \quad (5)$$

where z = the ultimate output or attribute
 $q*N^{1-\alpha}$ = the total amount of the public good adjusted for crowding
 q' = the total amount of the private good.

Within the production framework, output can be maximized by equating the marginal rate of technical substitution between public and private inputs to the ratio of their marginal costs. This type of model indicated that the question of substitution depended on the relative costs of inputs, the state of technology, the public good characteristics of the public input, and the public institutions that decide how to raise revenue and distribute benefits.

Clotfelter's next step was to develop an empirical test that would measure the degree of substitutability between a public and private good. He chose protection against crime as the final output, z , with employment in public and private protection as the inputs. Using a CES production function, he estimated the elasticity of substitution under two assumptions. First, he assumed that the wage rates for public and private policemen were exogenous and found, through ordinary least squares on cross-sectional state data, that the elasticity of substitution was positive, .58, implying a low degree of substitutability. Then he assumed that the wage rates were endogenous and used the instrumental variable estimation technique. Under this assumption the elasticity of substitution was much larger, 2.47, suggesting considerable latitude for substitution when input prices change. An elasticity of substitution above one implies the demand for private substitutes will increase proportionately more than public wage increases, thus decreasing the relative share of public spending on a given activity. Clotfelter's estimate, 2.47, was significantly greater than zero, but the standard error was too large to confirm that the estimate was also greater than one. He concluded by suggesting that other forms of private protection besides protective employment merit consideration if we are to understand how the consumer achieves a desired level of protection.

Consumer use of various means of private security measures like locks, alarms, handguns, etc. was examined in a more recent article by Clotfelter (1978). Here he analyzed various effects from increased consumption of private protection devices. One obvious effect from increases in private protection activity is the deterrence of crime. Criminals will have to search longer and their expected returns will be smaller because of private protection activity. This gross deterrence effect, however, may be partially offset by what is termed as the isolation effect. Increases in private protection activity may erode the citizen's social responsibility for routine surveillance and reporting of suspicious activity. In addition to the gross deterrence and isolation effects, private protection activity by some could simply divert crimes to other unprotected households. This is termed the displacement effect.

Lack of appropriate data restricted Clotfelter's empirical analysis of the various effects of private protection on crime levels. Also he was unable to obtain any data regarding market interaction between private protection activity and public protection.

Fire Protection

Vehorn extended the median voter approach (Equation 4) to the demand for public goods by examining market interaction between publicly-provided and privately-provided goods for the case of fire protection (1979). The long standing difficulty, as mentioned previously, has been lack of data. In the case of fire protection, however, it was possible to obtain private good price data for homeowners insurance and fireproofing materials in different SMSAs, allowing for a cross-sectional analysis. Since public fire protection is a shared good, each consumer must make his own personal choice about whether publicly provided fire protection is his optimal amount of fire protection. Hirsch hypothesized that a substitute for public protection, to a certain degree, is the private market good insurance (1970). Vehorn conducted an empirical test of Hirsch's conjecture by estimating cross-price elasticities between public and private services in the fire protection market using a simultaneous equations framework. A simultaneous equation model was appropriate because the price of insurance

along with the firemen's wages are endogeneous factors.

In order to test for the existence of market interaction, the signs and statistical significance of the cross-price elasticity estimates had to be considered. If these elasticity estimates were positive, then it could be concluded that increases in private-good prices lead to increases in the demand for public fire protection, ceteris paribus. Vehorn found that the cross-price elasticity estimates for both insurance and fireproofing materials were positive and in most cases significant. The range for insurance was from .44 to .81 depending on how the tax share was measured and whether the observations were for SMSAs or central cities. The range for fireproofing materials was from 1.48 to 1.82.

The evidence that Vehorn presented showed price changes in private markets do indeed effect the voter's demand for public goods. His general conclusion was that in areas where the prices of private market alternatives were high the demand for public fire protection was also high.

Education

Erekson also used a median voter model to examine the interrelationship between public and private education (1978). In 1976-77, 16.8 percent of all elementary and secondary schools were non-public, so private education does provide a viable market alternative to consumers. The question remains, what is the effect of private education on the provision of public education?

One expected effect in public schools is an increase in per pupil expenditures as non-public schools attract more students. Offsetting this effect, however, is the taxpayer's decreased support for public education as more students switch to non-public education. Erekson's empirical results support the former effect, but he could not confirm the existence of the latter effect for his sample of 671 school districts in the state of New York. He also estimated a cross-price elasticity between the demand for public education and non-public tuition rates. This estimate was positive and significant in most cases indicating that private education was indeed a substitute for public education. The magnitude of the estimate, however, was small suggesting that public and private education are far from perfect substitutes. Perhaps the vast difference in the quality dimension restricts the degree of substitutability. Erekson concluded by noting that any attempt to model the demand for public education must take into account the market for private education.

Summary and Conclusions

The purpose of this paper was to present an overview of consumer substitution between public and private goods. Initially, one might think that such substitution is impossible due to the unique nature of collective goods. However, if one views the consumer as a utility maximizer who chooses between attributes rather than physical commodities, it becomes apparent that a wide range of substitution possibilities exist.

Literature in the area of public-private substitution is sparse, but growing. In general, these studies have been able to observe a moderate degree of substitution occurring. Thus citizen-consumers do have other alternatives to public provision, and some do make use of these alternatives whenever they feel that the public provision does not meet their own personal needs. However, more detailed research on specific private markets is needed to further our understanding of exactly how these markets spring up to meet consumer preferences.

Local public officials who recognize the existence of private market alternatives, instead of assuming that the public sector is a monopoly provider, can use these private markets to their advantage. Encouraging the growth of private markets to help meet the needs of citizens with diverse preferences can reduce the pressure to increase public services without expanding the budget. Budgetary pressures, in part, have been the impetus in the move towards "privatization" of public goods, and tight budgets could be the stimulus for an effort to expand the use of private market alternatives. Public sector resources could be allocated more efficiently if research provided local officials with estimates of consumer responses to such an effort.

CONSUMER INFORMATION ABOUT PUBLIC GOODS
AND THE WORKABILITY OF THE WELFARE STATE¹

Martin Pfaff, University of Augsburg and INIFES²
Ernst Kistler, INIFES

Abstract

The modern welfare state is faced by fiscal crises. Commonly scientists consider an inflation of wants the principal cause thereof. Consumer information on the public transfer system as one part of a most urgently needed consumer policy for the public sector can on the one hand cause more demand, it can help, on the other hand, to create a more rational and effective transfer system. This paper deals with the consequences of an extension of information on public goods and services. It concludes that increased understanding of and more information about public transfers is needed on normative as well as practical grounds.

The Fiscal Crisis of the Welfare State

In capitalist as well as in socialist countries discussions have arisen about the efficiency of social policy as it is practiced. Inefficiency and ineffectiveness, suboptimality in allocational, distributional, and aggregative matters have been diagnosed. During the period of world wide prosperity and growth these effects could be tolerated more readily; however, during the last few years there are definite symptoms indicating limits in the willingness of financing such inefficiencies. The reduction in economic growth thus has led to suggestions such as privatization. Not only the New Left speaks of such boundaries in financial means and of the workability of the public sector. Today social policy, in its dependence on tax revenues is faced with the sheer impossible task reconciling actual or perceived wants with available economic and social resources. Irrespective of the actual causes thereof we have to realize the dangers brought about by excessive burdens on the public transfer system. The suggested possible alternatives need further investigation. The supply of public goods, however, is not only limited in terms of economic feasibility. There are furthermore doubts, whether the goods and services provided really meet the true needs and wants of the consumer. Empirical studies show (e.g. Katz et al. 1975) that frequently people do not or cannot realize their claims on certain real or monetary grants. Other urgent problems are the growing tendencies towards bureaucratic failure and the lack of critical participative and complaining behavior by public sector consumers.

Some social scientists (Scherhorn 1975, Young 1978) suggest an introduction of consumer policy instruments into the public sector and increased education, information, and participation of consumers may solve the aforementioned problems to a large extent (INIFES 1979). This short paper cannot deal with the limitations and advances of a consumer-oriented perspective of public transfer policy. It is confined to the very specific aspect of consequences of increased consumer information for the public budget

The Problems

Two antithetic theses can be stated when we discuss the effects of consumer information:

- 1) A theory of inflation in aspiration and demand, or
 - 2) A theory of more effectiveness of public grants.
- Unquestioned, however, by proponents of both points of view and irrespective of secondary effects, we expect that more and better informed consumers imply an increase in consumer sovereignty.

An inflation in demand, leading to an overburdening of the public budgets, must be expected when we proceed from the principles of traditional economic psychology and assume strictly egoistic behavior. Consumers or representatives of interest groups in the wake of getting more information and insights into the transfer system would tend to ask for more public goods and transfer payments. On the one hand they will attempt to receive transfers hitherto de facto or formally confined to other groups; a growing awareness of feeling handicapped in comparison to other groups leads to attempt to acquire privileges for themselves as well.

On the other hand more information concerning public goods might bring about increased utilization of transfers for which they had been eligible before, for which, however, they had not exercised their rights - leading to excessive burdens on public budgets.

In contradistinction to the aforementioned arguments one can suppose that increased information - and corresponding to this more feed-back, e.g. in the form of complaining behavior - may bring about greater effectiveness in public transfers and to reductions in public spending. Not only would increased information sharpen the awareness of capacity limits of the budget; citizens may become especially aware of the character of the transfer systems as a zero-sum-game. Consumers might reduce their demands inspite of the high level of self-financing.

A consumer-oriented transfer policy must be oriented towards the preferences of consumers which, in turn, requires that consumers be well informed and able to participate in decision processes. Consumer information - in that sense - could help to improve the efficiency and effectiveness of transfer policy. The advantages of more consumer sovereignty in a "voucher-system" (Beyme 1977, p. 115) and the improvements in consumer-technology (Skarpelis-Sperk, 1978) may help overcome the selective preclusion effects brought about by lack of information. Both schools of thought mentioned before would concur on this point.

The following discussion deals with some indications regarding the validity of these hypotheses in terms of practical experience. Some conclusions for consumer policy in the public sector are drawn.

Dangers of Inflation in Demands

The recent discussion of the distributive effects of public transfers indicates that some of the assumptions of fiscal theory on the nature of public goods have to be reconsidered (Pfaff 1978). Certain groups are often excluded from the receipt of certain transfers and often rivalness in consumption does, in fact, exist; these effects are group-specific.

The common models of political decision-making, especially those of new political economy, proceed on the assumption of a truly economic man. The economic psychologists, too, believe, that people vote especially for those transfers that benefit primarily themselves. Farmers vote for farm-subsidies and turn down projects to improve urban infrastructure; the poor want more public income maintenance payments and less subsidized theatres - because they rarely visit theatres; all voters vote against higher expenditures for underdeveloped countries.

Better understanding of and information about the transfer budget, one's own and others' benefits and burdens could increase the common feeling of being treated unjustly and could further selfish motivations leading to increased demands on the system. In a parliamentary democracy the consequence would be an inflation of wants; the budgetary limitations may well lead to a neglect of urgent needs, especially of underprivileged groups which would be suppressed in the process of democratic competition. This argument seems self-evident. But in spite of this some aspects suggest that further consideration is required.

Table 1 shows the results of a 1978' opinion poll on public transfers. This table shows weighted and aggregated indices of public performance concerning monetary transfers. The specific differing interests of different groups become evident; however, we also discern, at the same time, that to a large extent people accept transfers benefiting other persons or groups. Other surveys as well indicate a high level of general endorsement on public transfer and social policy (Deimer, Kistler 1980); quite obviously, there is no complete absence of something like compassion or acceptance of the needs of the underprivileged, something like an insight into the necessity of the need of the public aid to other persons and groups - a sense of identity with others.

Possible Ways of Improving the Effectiveness of Transfer Policy

These arguments indicate that more information especially about the situation of other people and groups could lead to a reconsideration and reevaluation of one's own relative position compared to that of others with regard to the public budget constraints. There is a chance to induce more understanding of the limitations in financing public transfers and the connections between taxes and transfers. Understanding the necessity to assume burdens and to aid others could curb an excessive inflation in demand.

"Consumers better understanding of the interdependencies of needs, their causes, their changing, and their satisfaction" as a "prerequisite of critical cooperation" (Czerwonka, Schöppe, Weckbach 1976, p. 279) could lead to a more effective and rational supply of and demand for public transfers.

This assumption which is the central argument in favor of more participation of citizens/consumers in urban planning, administrative decision-making, etc. is based on diverse empirical evidence.

With regard to our specific question we shall cite two results that suggest demand-reducing or at least satisfaction-increasing effects of increased information for consumers.

A 1980 survey of young persons in the city of Augsburg showed a highly significant (.01!) relation between the satisfaction concerning transfer policy and the satisfaction with informational policy about city planning. Table 2 shows that of the persons satisfied with the informational practices only 27.4 per cent are dissatisfied with the policy measures for the young. However, 47.9 per cent of the ones dissatisfied with urban information policy are also dissatisfied with the supply of public goods.

TABLE 2

Connection between Satisfaction with Public Information Policy, Public Transfer Performance, Political Interest and Democratic Apathy - The Case of Policy Measures for the Young in the City of Augsburg (in %)

Satisfaction with Informational Activities	Satisfaction with Transfer to Own Group		Political Apathy (Belief One Can Influence Democratic Processes)		Political Interest		E
	Satisfied	Dissatisfied	Yes	No	High	Low	
Satisfied	36.9	27.4	21.2	68.2	41.7	53.6	13.9
Dissatisfied	16.2	47.9	29.3	57.1	43.7	54.1	68.2
E	19.8	41.2	26.5	58.6	45.1	51.9	-

Source: INIFES 1980.

Considering that there is only a limited connection between the satisfaction with public information and political interest, and that political apathy and lack of belief that democratic engagement can be of any influence, are higher with dissatisfied people (28.3 per cent) than with satisfied ones (21.2 per cent), we can conclude that consumer information is an important prerequisite for systems performance.

Similar considerations may apply to other groups and other transfers. In some investigations, for example, we find the assumption that better information may reduce moral-hazard behavior within the social insurance. Kruse (1979, p. 134) reports in an inquiry that 64 per cent of the persons insured in the Public Health Insurance believe that more and better information may reduce necessary and irresponsible demand for medical services.

The conclusion that informed consumers would help create a more rational transfer policy and reduce selfish aspirations surely is obvious, but difficult to prove. General practice certainly suggests that consumer information is considered important - also in the public sector. How else would we explain the flood of fancy information brochures emanating from diverse agencies.

Such information campaigns take place in all areas from energy-saving to more economy in demand for medical care. The belief in the rationality of consumer behavior goes

hand in hand with the hope that better information via more extensive participation may result in a transfer system that is better geared to consumer needs.

This aspect of higher effectiveness in public supply and individual demand is also directed towards the third of the assumptions discussed above based on the theory and practice of planning.

The idea of consumers as informational or even economic and social resources of decision-making and production of human services (see for example Gartner 1980) is based on the normative premise that consumers know best what's good for them (Pfaff 1977).

The Need for Consumer Sovereignty in the Public Sector

Transfer and social policy procedures in Western countries differ from those in socialist countries; in the latter transfers are allotted while in Western countries extensive steps on the part of the recipient in terms of applications, provision of documents and contacts with offices are necessary before receiving transfer payments. This presumes a high degree of competence and information on the part of the consumers/citizens. Especially because of these necessities some public transfers, such as public aid and assistance programs to the poor or preventive medical examination are not fully used, especially by people who really need them most.

Consumer sovereignty is dependent on a high level of knowledge - especially in the public sector.

Only informed consumers are able to realize their rights to make the best of public transfers and to articulate and perhaps to assert their needs.

Apart from the whole range of effects of more information and on the public budgets it is certain that such procedures will help consumers in their roles as potential transfer recipients.

Conclusion

This discussion could lastly not prove - especially in quantified and monetary figures - the consequences of improved information activities on the budget, last not least because secondary effects (for example employment effects in the service sector) remain outside the consideration.

However, when we view the public sector not only as a system with satisfying and pacifying tasks, but more as a "democratic social provider" ("Demokratischer Sozialstaat", Art. 20, Constitution of the Federal Republic of Germany), as a viable democratic society, there must be criteria of evaluation referring especially to the third of the hypotheses discussed above.

Under normative aspects the ongoing practice of guaranteeing rights to public transfers without providing the potential recipients according to their limitations with the necessary aid to exercise those rights is grossly deficient. Such ways of public supply, relying upon the nonrealisation of existing rights are not at all satisfactory. Furthermore, it is wrong to expect that if public agencies publish more booklets about their activities that this will necessarily lead to better information.

Discussions about the workability of the welfare state cannot convince unless they also take into consideration the perversions of social policy by the lack of information on the part of consumers. Transfer policy requires an elaborated information system. Even if an increase in demand for public payments were to be triggered especially within existing programs, we cannot accept the argument that more extensive information provides dangers to the workability

of the welfare state.

The budget might be burdened further, however, efficiency and effectiveness of transfer policy would increase - especially with regard to distributional objectives. The workability of the welfare state increases when hidden poverty is reduced and non-realised rights are exercised equally by all.

Consumer policy in the public sector might help!

VOTING PARTICIPATION IN A PUBLIC CONSUMPTION PERSPECTIVE¹

Randall G. Chapman, University of Chicago
Kristian S. Palda, Queen's University

Abstract

Data from ten Canadian provincial elections and census-derived socioeconomic variables are used to estimate a model of voting participation. The model is developed, and the empirical results are interpreted, within the context of rational voter and household investment-consumption theories.

Introduction

Voting decisions, an integral part of the household investment-consumption process, can be studied from a consumer behavior perspective. Theories of rational voting and consumer behavior are invoked in this paper to develop a voting participation model. This model is a component of a larger integrative electoral market model currently under development (Chapman and Palda 1980). The empirical results presented here relate the number of votes cast in a constituency to a range of political and socioeconomic variables using data from ten Canadian provincial elections and from the 1970 census. A goal of this paper is to test the extent to which generalizations can be made about the forces affecting voting participation. The results obtained show substantial consistency across time and provinces and are of particular interest with respect to income and education effects on voting turnout.

Theories of Voting Turnout

Participation in the political process is generally viewed as indicating the vigor of an individual's commitment to the democratic process. The most obvious manifestation of such participation is the act of voting. It is not surprising, therefore, to find that studies of electoral turnout stand at the center of attention of students of politics. Not unexpectedly, there are competing theories of voting turnout behavior.

The dominant voting paradigm among political scientists and non-economists is based on a social-psychological perspective which sees social integration as leading to a psychological attachment to the political system and thence to participation (Irvine 1976, Popkin et. al. 1975). The key concept is socialization: if an individual is socialized into the prevailing norms of society or its subgroups, he is likely to vote due to feelings of obligation. In empirical studies, education, income, age, race, and membership in certain organizations have been employed as indicators of the degree of political socialization (Kim, Petrosik, and Enokson 1975).

Economists and some political scientists prefer a theory of voting behavior which rests on the assumption, proposed by Downs, that voters are "rational": they evaluate available alternatives in light of their benefits and costs and implicitly employ a decision calculus based on maximizing expected utility (Downs 1957). In deciding whether or not to vote, the Downsian rational individuals cast their votes only when the expected utility of so doing is positive. This decision calculus can be

represented compactly by the following behavioral equation (Frolich et. al. 1978):

$$U = p_1 |D| + p_2 L - C \quad (1)$$

where:

- U = the net value (expected utility) an individual associates with voting
- p_1 = the probability of an individual's vote affecting the outcome of the election
- D = the expected differential between the winning and the second-place party
- p_2 = the probability that an individual's vote will make a difference in the survival of the democratic political system
- L = the long-run value of participation
- C = the cost of voting.

The Downsian view of the voting participation decision implies that the act has combined consumption and investment features (Stigler 1975). Not only would lower costs lead to a higher turnout (as might be expected on both consumption and investment grounds) but, in addition, we would expect a larger turnout the greater the prospective investment return to the voter.

The accent on the investment perspective is more than a pedantic quibble because the socio-psychological and economic predictive turnout models use intersecting sets of variables to operationalize their underlying constructs. The socio-psychological school holds that income, education, and age level represent suitable proxies for social integration. From the Downsian perspective, these same variables represent measures of opportunity and information processing costs of voting. The differentiating elements between the two theories are most pronounced on the side of the long-run investment costs and benefits yielded by voting, such as taxation to the haves and government transfers to the have-nots.

Why should the student of consumer behavior contemplate these two conflicting theories of voting participation with other than benign indifference? The answer lies in the enormous economic consequences of voting in our post-industrial society. The share of government expenditures in the GNP ranges from 25 percent in Japan to 33 percent in the United States to more than 50 percent in the UK, among the OECD countries, and the taxes collected to finance such expenditures represent the single largest bite out of the income of the consumer-voter-taxpayer (Palda 1980). To the extent that the consumer can influence the size of the tax bite or his social benefits by his vote, his decision to vote (and for whom) can be viewed as a discretionary "buyer-type" activity. In this sense, the sphere of voting is of legitimate concern to the marketing and consumer behavior student.

To these writers, at least, the Downsian approach appears to lead more naturally to a marketing perspective of the voting participation decision. Such a perspective would stipulate that voting represents the selection of a purchasing agent (elective representative) for a period of one or more years. This agent is endowed with powers to decide not only on the mix of public goods to be provided but also on the amount of the voter's income to be appropriated. The voting decision can thus be seen as an investment in a purchasing agent. It exhibits standard investment aspects such as a multiperiod time horizon,

¹Funding for this study was provided by a grant from the Social Science and Humanities Research Council of Canada.

revenues (public goods) and costs (taxes) to be compared on a net present value basis, scrap value of the agent's incumbency, a rate of discounting which reflects personal preferences, and risks associated with the prediction of the capital equipment's (the agent's) expected performance. (The riskiness could be proxied with survey-obtained and regression-estimated standard deviations of linear multi-attribute model coefficients. The D term in equation (1) seems most amenable to being modeled in terms of ideal point distance models and estimation procedures (Ordeshook (1976).)

To bring in consumption aspects of voting behavior, an appropriate integrating framework is that of the household production function (Wittman 1975). In the Beckerian (1965) perspective, households purchase intermediate goods in the market and combine these with their labor inputs and domestic capital equipment to produce final outputs which yield utility. The "capital equipment" within the voting context (elected purchasing agents) is not a property of the household "factory" but rather a part of the "industrial" infrastructure which, unlike in the orthodox industrial case, the household members can influence by their vote. By virtue of their personal labor skills, perhaps acquired by education, certain households will be more proficient at processing electoral information and so will be more likely to vote. Practice may lead to consumption preference and so to direct utility derived from voting. Other household characteristics, such as the presence of small children, may raise electoral consumption costs by allowing less time to acquire political information and to go to the polls.

To sum up, with some additional effort the existing theory of rational voting can be brought closer to the traditional preoccupation of consumer behavior scholars. The central economic importance of voting behavior is a sufficient justification for their attention to the voting participation phenomenon. The next section outlines a model employed to account for electoral participation in Canadian provincial elections and sketches its relationship to a Downsian-household production function approach.

A Model of Voting Participation

A comprehensive theory of voting must necessarily apply to both the decision to opt for a particular candidate (an elective purchasing agent) and the decision to vote, this paper's main concern. The Downsian rational voter theory has been substantially clarified, tested, and elaborated upon over the last 20 years. Its integration with household production theory is in its infancy. We cannot do entire justice to a complete Downs-Becker specification because we do not have access to individual level survey data which are needed to assess the party differential variable D and the p_2L term in equation (1). The model of turnout which we propose and test in this paper does, nevertheless, draw its inspiration from the rational voter theory, supplemented by recourse to the economics of information.

Our model of voting participation may be described in the following general terms:

$$\text{CAST} = f(\text{REGVOT}, \text{CLOSE}, \text{INC}, \text{ED}, \text{TOTEXP}, \text{UNEMP}, \text{FEMPAR}) \quad (2)$$

where:

- CAST = the number of votes cast (in 000s)
- REGVOT = the number of registered voters (in 000s)
- CLOSE = the difference between the vote share of the winner and the runner-up (ex post)
- INC = average per capita income (in \$000s)
- ED = percent of population over 15 years of age with at least complete high school education

- TOTEXP = the total reported campaign expenditures of all major candidates (in \$000s)
- UNEMP = the percent unemployed workers in the labor force
- FEMPAR = proportion of employed females in the total labor force.

All of the variables in equation (2) refer to a constituency in a given Canadian provincial election. The constituency socioeconomic variables -- INC, ED, UNEMP, and FEMPAR -- were obtained from special Statistics Canada runs in which the 1970 census data were geocoded along the boundaries of the provincial constituencies.

REGVOT serves as a constituency-size scaling variable. It should be noted that in Canada, unlike in the United States, voter registration is done by enumerators and does not, therefore, require voluntary effort on the part of the individual qualified citizen-voter.

CLOSE, an ex-post variable, measures the probability (p_1 in equation (1)) of an individual's vote affecting the outcome of the election (Barzel and Silberberg 1973). Theory predicts a negative sign on its coefficient: the narrower the margin, the greater the impact of each vote, the higher the incentive to turnout.

INC, the average per capita income (as of the 1970 census), has at least a three-fold interpretation. Simple economic theory suggests that there is both a substitution effect, in terms of opportunity costs facing higher income voters, as well as an income effect, related to an explanation of voting as a consumption good. These effects cut in opposite directions and offer no unambiguous qualitative conclusion as to the expected sign of this variable (Tollison, Crain, and Pautler 1975, Crain and Deaton 1977). In the absence of information on property and income subject to provincial taxation (i.e., on variables which would throw light on the investment aspect of voting), INC might reflect the taxation stake of the voter and be expected to exhibit a positive coefficient. The composite of all of these forces will determine the sign of INC. If it turns out to be negative, opportunity cost aspects predominate.

The economic theory of information would predict, ceteris paribus, a positive association between turnout and the level of education possessed by voters-consumers: the higher the education level, the lower the costs incurred in acquiring and processing political information (Goldman and Johansson 1978). As for ED, so for TOTEXP: campaign expenditures would be expected to have a positive influence on turnout as they represent the lowering of costs of information acquisition (Abrams and Settle 1978).

An economics of information perspective would also predict that the unemployed, likely to be on average less educated, could encounter higher costs in acquiring and processing electoral information. (The socio-psychological approach to electoral participation would suggest that the unemployed are disaffected with the political process, and thus would have a tendency to turn out in lesser numbers.) They would have, however, lower income opportunity costs of voting and possibly a greater stake in voting for left-leaning parties to the extent that provincial governments, rather than the federal government, can be held accountable for employment opportunities. Thus, theory is ambiguous with regard to the sign of UNEMP.

Finally, FEMPAR also has different possible interpretations as to expected sign. On one hand, high levels of female participation would be associated with higher incomes and possibly a greater "tightness" in household time allocation thus increasing opportunity costs. On the other hand, on-the-job discussions of politics and world events might lead to lower information costs.

Empirical Results

The model in equation (2) was estimated using data from each of ten Canadian provincial elections. A linear-additive functional form was chosen on the grounds of parsimony. To avoid constituency size affecting absolute campaign spending, the expenditure variable was formulated in dollars spent per registered voter (i.e., as TOTEXP/REGVOT). The results of estimating the model are reported in Table 1. It should be noted that our a priori theory led us to use one-tailed tests of significance for REGVOT, TOTEXP/REGVOT, ED, and CLOSE (where we expected three positive and one negative signs, respectively) and two-tailed tests of significance for UNEMP, INC, and FEMPAR (where theory was ambiguous with respect to signs).

Two comments are in order regarding the linear-additive functional form of the voting participation model. The model was also estimated in logarithmic form to assess the possible presence of significant interactions among the independent variables. The results obtained were consistent with those from the simpler linear-additive functional form, so the more parsimonious additive version was chosen. A second functional form issue concerns the dependent variable. The usual dependent variable in a voting participation model is TURNOUT (=CAST/REGVOT). A linear-additive model with TURNOUT as the dependent variable was estimated for comparison purposes. Its results were also consistent with our results using CAST as the dependent variable. Again, parsimony led us to prefer the simpler version.

In interpreting the empirical results, patterns of generalizability were looked for. An important feature of the research reported in this paper is the large amount of data assembled to estimate the voting participation model. Most politometric research is based on a single electoral event only. The ability to generalize from such results may be open to question. With ten elections as a data base, the results of this study lend themselves to

attempts to document generalizable and consistent patterns of voting behavior.

REGVOT, a scaling variable which standardizes for the size of the constituency, has naturally the largest (positive) impact. The high explanatory power of the model derives from simple correlations between CAST and REGVOT which are 0.90 or more in magnitude.

In three of the ten elections, per registered voter campaign expenditures have a significantly positive impact on turnout. A significantly negative effect is found in one election; no obvious explanation is available for this anomalous result. It may be noted that these four significant results occur in the largest and most urbanized Canadian provinces (Ontario and Quebec). A public policy question relates to the possible impact of campaign expenditure ceilings on voting behavior. Legislated ceilings on individual candidate expenditures were in effect in all provinces except British Columbia. The avowed purpose of spending limits is to restrict the "buying" of seats on the assumption that campaign expenditures influence voting outcomes. This assumption has been repeatedly empirically verified (Chapman and Palda 1980). Spending limitations might, therefore, have the unintended and socially undesirable side effect of constraining the flow of information from candidates to voters, thus effectively increasing the information acquisition costs to the voters and possibly leading to reduced voter participation. Our empirical results here do not support, on the whole, the hypothesis that overall constituency spending affects voting participation.

The closeness of the electoral contest has a significant impact on participation in six of the ten elections. (The negative sign of CLOSE means that as the difference between winner and runner-up narrows, turnout increases.) This result is in line with previous empirical tests of the Downsian theory and supports the view that a stronger probability of influencing the election outcome

moves the voter to cast his ballot.

Perhaps the most interesting results are derived with regard to the income and education variables, taken together. All of the ten INC coefficients are negative, of which five are significant. Nine of the ED coefficients have a positive sign; the one negative coefficient is not statistically significant. As far as we can tell, this is the first time (certainly with aggregate-level data) that the separate effects of income and education on voting participation are assessed -- and this in face of the high positive correlations between them (from 0.60 to 0.94 in our sample). The strong consistency of our results militates for the following interpretation. The substitution or opportunity cost effect predominates with regard to income: as income increases, holding education constant, voters tend to participate less since they value their time more highly. (This result comes through even though the average income measure used is not totally "pure" for it would have been preferable to use income derived from employment, unavailable to us, and to have had access to an investment-type taxation-stake variable (Denver and Hands 1974).) Higher education, on the other hand, leads to increased voter turnout as it reduces the costs of acquiring and processing political information.

Nine out of the ten coefficients of UNEMP are negative, seven of these significantly so. Six of these significant results are obtained in the industrially-oriented provinces of British Columbia, Ontario and Quebec. Since education and income determinants are held constant at their sample means, the only Downsian interpretation plausible is that the unemployed do not perceive provincial governments as capable of job creation. (Note, however, that the socialization perspective would consider the structurally unemployed as participating less in the life of the polity.)

Six of the ten FEMPAR negative coefficients are statistically significant. While there is a pattern of positive correlation between FEMPAR and INC and between FEMPAR and ED (in the 0.35 to 0.65 range), the added influence of feminine participation in the labour force is suggestive of non-trivial household time allocation costs.

In summary, the model's empirical results bear out rather convincingly the economic view of rational man faced with the decision to vote in light of his costs, benefits and the uncertainty he faces and taking account of the household context. The generally consistent pattern of the results over the ten elections has been arrived at despite the aggregate, constituency-level nature of the variables used and some strong collinearity among the socioeconomic determinants.

Concluding Remarks

The model of voting participation reported upon here constitutes the initial component of a larger recursive electoral market model which will attempt to account for party candidate success (with special emphasis on the role of campaign expenditures), candidate expenditures and the contribution generation mechanism (Chapman and Palda 1980). The elaboration and testing of this integrated model with data from the ten Canadian provincial elections is being undertaken within the framework of the rational voter theory. The pattern of consistently plausible results obtained with regard to voting participation augurs well for the forthcoming study.

MEASURING SUBJECTIVE VALUATION AND
DEMAND FOR GOVERNMENT SERVICES

Eli M. Noam, Columbia University

Abstract

The paper describes a method by which demand equations for public goods and services can be estimated. A model is described which is based on the revealed preferences in voting behavior by different groups, taking in particular account of abstentions and their frequency. The results permit the derivation of the absolute valuation for governmental services by different income groups.

Introduction

The problems of estimating demand functions in private markets, vexing as they are, still pale in comparison with those encountered in the public sector. Here we have no markets, no customers, no sales, no products, and usually no data. We have to deal with "public goods" that are fuzzy conceptually, indeterminate distributionally, and measurable indirectly. At the same time it is important for decision makers in the public sector to have some sense of the demand for the many alternative public services because of the huge governmental outlays. Some sense of the demand for competing public services would be most helpful. This is not necessarily a matter of trial and error; mistakes in determining demand functions for public goods are not self-correcting. With private goods, sooner or later a wrong demand function will come home to roost, provided that some decisions are based on them. With public goods, however, a government can go on for a long time supplying hospital beds and canals that no one wants in particular except for some small vocal groups.

Because the knowledge of public demand functions could be of considerable help in the allocation of the huge governmental budgets, a number of attempts to determine them have been made by researchers in the past. A first method of analysis is an opinion survey or controlled experiment (Bohm 1972). The difficulty with this approach, besides its cost, is that no real concept of cost exists in peoples' minds when it comes to large public expenditures. Sometimes, too, a survey is subject to manipulation by the subjects, since there is little to stop them from vastly exaggerating their politically oriented likes and dislikes. In order to avoid this problem, some authors have developed an entire theory of the type of questions that removes the incentive for manipulation (Green and Laffont 1976), or proposed methods to assign cost shares to the individual (Tideman and Tullock 1976). These methods are remarkably ingenious but probably too complex for use in practice.

A third approach is to take a look at the real world and to assume that its reality is an expression of public desires (Borcherding and Deacon 1972, Bergstrom and Goodman 1973). Thus one can compare expenditures in different jurisdictions and analyses and their relation to community characteristics such as income, education and tax rates. If affluent towns spend twice as much as poor ones on law enforcement, we have information about the relative preferences with respect to income. The question remains, however, whether the underlying assumption that political decision making accurately expresses public demand is reliable. Small bands of bureaucrats, insiders, and notables can obtain decisions according to their own preferences rather than of those of the public at large. In a society with free election contests and easy mobility

such possible divergence will probably be bridged over time. The literature on log-rolling and election-posturing (Buchanan and Tullock 1972) explain the public choice mechanism by which public preferences become policy decisions, while the so-called Tibout hypothesis (1956) of locational mobility (voting with one's feet) provides a public finance mechanism.

A fourth approach looks at decisions on the individual level, namely by voting. Concretely, this means in the case of public good issues the use of results from referenda. The advantages here are, first the realism of data: they reveal preference in concrete expenditure matters, and typically after the voter has been subject to a fair amount of information about both sides of the issue at hand. Neither is there usually a reason to suspect that voters would disguise their true preferences for some strategic purpose. Recognizing these advantages, several studies of referenda on public finance issues were undertaken. They fall into two broad categories, of which the first is an essentially empirical use of correlation studies of aggregate approval rates (Wilson and Banfield 1965, Frey and Kohn 1970, Birdsall 1965), and the second more theoretical, such as Deacon and Shapiro's study (1975) with a sophisticated model as an underpinning, but with application to only two referendum issues.

In these studies an important problem remains unresolved: voting results indicate the direction of public preference, but they do not necessarily reflect its intensity.¹ An issue may be mildly preferred or passionately desired by the same percentage of people; this will not be obvious from the voting results.

This paper describes a method to overcome such problems by deriving a model by which measures of preference for public goods can be obtained. There, preference measures can be analyzed for factors that influence them, and demand functions can then be found.

The Model

The key element of the model is its recognition of a previously completely ignored source of information from voting data, namely the rate of abstention. It is obvious that the active voting in favor or in opposition to a proposal reflects some preferences; but so does non-voting. Implicit in non-voting by a large group of people who vote on other occasions is an indication that the issue is of limited importance to them. This is particularly true with voters who are frequently called to the polls and where, therefore, the consumption aspect of voting--the exercise of the franchise--becomes secondary. In such a situation, voters are more selective in their voting; they go to the polls when the issue is subjectively important to them, and do not when they perceive the issue to be of only minor significance. It is important to contrast this analysis of differential behavior of the same group of voters over elections with those studies that compare voting behavior of different voting jurisdictions within the same election.

It may be argued that another reason for abstention exists, namely that the outcome of a vote is so predictable that an

¹Deacon and Shapiro (1975) use "Utility" to overcome this problem, but only as an intermediate theoretical construct.

individual's vote hardly matters anymore, thus reducing participation (Frohlich et al. 1978). Empirically, however, this claim turns out to be untrue, at least for the jurisdiction which was analyzed. In the course of this study an analysis of the participation rates in hundreds of referenda showed practically no correlation (.081) with the closeness of the vote. Maybe the reason is that in local voting normally no sophisticated polls are taken that predict the outcomes of the voting with a reasonable degree of accuracy; or perhaps because it requires some stake in the outcome to mount a drive in order to "get the vote out", so that such attempt will succeed only in important votes.

Thus we make two assumptions about voting behavior, denoting the perceived benefit with B and defining a voting "threshold" S such that a voter acts according to the following rules:

- (A) Vote Yes if $B > S$
- (B) Vote No if $B \leq -S$
- (C) Abstain from voting in $-S < B \leq S$

Let us postulate next that the voter is a member of a subgroup of the total population, of which we assume that

- (D) Their perceived benefits are normally distributed around some mean μ and with some variance σ^2
- (E) They follow decisions rules (A) - (C)

These assumptions are represented by Figure 1. The abscissa represents the magnitude of benefits, both positive and negative, around point 0. The units are as yet undefined. The vertical axis represents the frequency distribution of these benefits in the subgroup. Points to the right of 0 reflect positive benefits, and points to the right of S represent "yes" voting. Similarly, at points left of -S "no" voting occurs, while people whose potential benefits lie between -S and S abstain. The abstainers' proportion of total voting population is the area A, and Y and N represent yes and no voting proportions.

FIGURE 1

The objective for analyses is to determine the mean benefit for the group. Formally, this amounts to determining

²Normal distribution is a common assumption in much of the public choice of literature on spatial electoral analysis. See, e.g., Hinich and Ordeshook (1970) and Hinich, Ledyard and Ordeshook (1972).

the unknown mean μ of a normal distribution whose variance σ is also unknown, but where we know the areas Y, N, and A to exist, respectively, right of S, left of -S, and between S and -S. This can be expressed as the probabilities.

$$P\{B \leq -S\} = N \quad (1)$$

$$P\{B \leq S\} = N + A \quad (2)$$

These equations can be standardized into

$$P\{Z \leq \frac{-S-\mu}{\sigma}\} = N \quad (3)$$

$$P\{Z \leq \frac{S-\mu}{\sigma}\} = N + A \quad (4)$$

Let Z_X be the cumulative distribution function of the standardized normal distribution, and therefore

$$\frac{-S-\mu}{\sigma} = Z_N \quad (5)$$

$$\frac{S-\mu}{\sigma} = Z_{N+A} \quad (6)$$

Thus, the variance σ can be expressed, after substitutions, as

$$\sigma = \frac{-ZS}{Z_N - Z_{N+A}} \quad (7)$$

and the mean μ , using (5) and (7), is found to be

$$\begin{aligned} \mu &= -S - Z_N \sigma \\ &= -S - Z_N \left(\frac{-ZS}{Z_N - Z_{N+A}} \right) \\ &= S \left(\frac{Z_N + Z_{N+A}}{Z_N - Z_{N+A}} \right) \end{aligned} \quad (8)$$

This means that μ can be readily calculated as a multiple of S once the proportions of N and A are known and once their cumulative Z values are obtained from tables of normal distribution.

This procedure can be repeated for any number of subgroups i, resulting in a series of mean benefits μ_i which can be analyzed for their susceptibility to factors of demography, economics, etc. For most of such estimations the actual magnitude of the voting threshold S is immaterial, as long as we assume that it is constant for all subgroups. But this assumption can be relaxed, and S can instead be estimated by reversing the above procedure. Let there be observed voting behavior for certain issues, where the mean benefit μ of the normally distributed random variable B is known from some outside information as well as the proportions Y, N, and A. Then, from equations (5) and (6) we have

$$\sigma = \frac{-2\mu}{Z_N + Z_{N+A}} \quad (9)$$

which substituted into (5) results in

$$S = Z_N \frac{2\mu}{Z_N + Z_{N+A}} - \mu = \mu \left(\frac{Z_N - Z_{N+A}}{Z_N + Z_{N+A}} \right) \quad (10)$$

Thus S_i can be determined if N_i , A_i , and μ_i are known for subgroup i. Of course, for most issues μ_i will be unknown. To deal with this situation, it is assumed that

- (E) An individual's voting threshold S is constant in the short and medium term.

This assumption implies that a rational voter remains rational and that his decision calculus as to whether it is worthwhile to vote is stable, at least over a few years. The reasonableness of this assumption will receive support in the empirical part of the paper. Hence, if S can be determined in several issues, and provided that the

results are reasonably similar to each other, the average S will be used for other issues as well.

The variables that are investigated for their influence on the attitude toward government services are income and other demographic factors such as education, number of children, age, occupational category, etc. Let this be expressed by the equation³

$$\mu = \Omega \left(\frac{Y}{\bar{Y}}\right)^\delta C^\lambda X_i^{\eta_i} \quad (11)$$

where $\frac{Y}{\bar{Y}}$ = relative income as a measure for socio-economic status

C = tax cost to the individual

X_i = other demographic factors

and δ, λ, η_i = elasticities.

A special problem in the analysis of public goods is that under almost all tax systems their cost to the individual varies with his income. To the individual the tax price depends both on the total cost of the public good, V, and on his relative share of the tax burden, T/R, where T is his tax payment and R is total revenue. The tax price is therefore

$$C = \frac{T}{R} \quad (12)$$

Normally, tax contributions are an increasing function of income, either through taxation of income, property, or consumption such that

$$T = \epsilon Y^\psi \quad (13)$$

Substituting into equation (12) we then have

$$C = \frac{\epsilon Y^\psi}{R} \quad (12')$$

Substituting this in turn into the earlier equation (11)

$$\mu = \Omega \left(\frac{Y}{\bar{Y}}\right)^\delta \left(\frac{\epsilon Y^\psi}{R}\right)^\lambda X_i^{\eta_i} = \Omega \left(\frac{\epsilon Y}{R}\right)^\lambda \bar{Y}^{\psi\lambda} \left(\frac{Y}{\bar{Y}}\right)^{\delta+\psi\lambda} X_i^{\eta_i} \quad (11')$$

λ and ψ can be estimated exogenously by

$$t = \epsilon Y^\psi \quad (13)$$

and an expression for the cost-elasticity λ

$$\mu = \rho C^\lambda \quad (14)$$

which is subject to independent estimation. If ψ and λ are obtained exogenously, equation (11') simplifies into

$$\mu = \alpha \left(\frac{Y}{\bar{Y}}\right)^\beta X_i^{\eta_i}$$

where the parameters α and β are shorthand for

$$\alpha = \Omega \left(\frac{\epsilon \bar{Y}}{R}\right)^\lambda \bar{Y}^{\psi\lambda} \quad \text{and} \quad \beta = \delta + \psi\lambda \quad (15)$$

β is the "raw" or observed income elasticity. It has been corrected in the way described for changes in the tax price in order to yield the "true" income elasticity, which takes into account that as income rises the tax price also increases. $\delta = \beta - \psi\lambda$, i.e., the "real" income elasticity δ is equal to the observed "raw" income elasticity minus the product of price elasticity and the elasticity of the tax system.

³A linear function does not seem likely in light of some of the high incomes observed.

The data analysis utilized voting results from Switzerland, a country with an unusual degree of direct participation by the electorate. Among Swiss jurisdictions, Basel-Stadt is the smallest urban canton(state);⁴ it was chosen in order to reduce the effect of geographic location on voting behavior. Basel is a highly developed middle-sized city with a long civic tradition and an international location, and the preference of electorate should be illustrative.

The main method of estimation involves a cross-section analysis across relatively homogenous polling districts, where the relative income and the demographic characteristics of the district are the independent variables and the intensity of preference that is found through the model is the dependent variable.

Voting results for referenda by polling place are available in the official gazette.⁵ Demographic information is found in the Swiss national census; specifically analyzed, in addition to income, were education, number of dependent children, age, and occupation (self-employed vs. employees). The source of income data is a market research survey.⁶ Cost data for the public goods were found, quite laboriously, in the resolutions by the cantonal government to the electorate (Ratschlaege) which precede voting.⁷ The active electorate--i.e., the electorate excluding habitual non-voters against which percentages of Y, N, and A are calculated--is defined as the highest number of participants that voted in a referendum concerning cantonal matters.⁸ In order to avoid a systematic bias, one must ascertain that the average voting participation of the active electorate is not different for different income groups. An analysis of this question determined that the defined L did not display bias; average participations by the active electorate in the nearly two hundred issues that are investigated in this paper are nearly identical: for the lowest income district, 55.6%; for the median income district, 56.5%; and for the highest income district, 56.2%. This active electorate's participation rate must be distinguished from average general voting participation rate, in which low income groups display the usual lower rates.

To estimate the threshold value S_i , the procedure described earlier in equation (10) is used and issues are chosen for which the mean benefits can be estimated independently. The referendum issues that are used are votes on public utility charges and taxation,⁹ for which the financial consequences are known or are officially forecast in the above mentioned Ratschlaege or resolutions; we

⁴The use of Basel was inspired by Frey and Kohn (1970).

⁵Kantonsblatt, Basel-Stadt, on days following the referenda.

⁶PROGNOS, Konsumpotential and Filialnetz, Untersuchung über die Investitionsplanung des ACV, includes the distribution of household income of 1965 in districts. Tables made available by L. Kohn.

⁷Collected at the Cantonal Chancery and the Cantonal Archives.

⁸Respectively in each decade, maximum participation rates are for referenda held on 12/11/49; 12/5/54; 2/28/65; 10/20/74.

⁹Referenda held 12/11/49; 1/19/50; 11/24/68; 7/12/75; 6/12/77.

use these as μ_i in order to determine S_i . Table 1 shows an example for such calculation. The resultant S_i are all relatively similar to each other, with values in a band 23-34 Sfr. Very similar results were also found for the other voting precincts. Thus we find support for our assumption of a constant S . The average value (28 Sfr. or approximately \$20) is therefore assumed as the voting threshold. As mentioned before, a different magnitude of S would not change the elasticities.

TABLE 1
APPLICATION OF MODEL TO UPPER INCOME
PRECINCT (BRUDERHOLZ)

Issue	$\%Y$ (Y/L)	$\%N$ (N/L)	$\%(N+A)$	$\frac{Z_N+Z_{N+A}}{Z_N-Z_{N+A}}$	μ	S	σ
Tax Reduction	52.3	35.0	47.7	1.369	40	29.2	183.38
In-creased Progressivity in Tax Rates	17.1	61.1	82.9	-1.835	-50	27.2	88.95
Gas Utility Rates	32.2	11.6	67.8	.444	15	33.8	36.01
Water Utility Rate Change I	47.6	25.8	42.4	1.826	50	27.4	129.56
Water Utility Rate Change II	44.0	10.9	56.0	.782	25	31.9	43.18

Also calculated from statutory tables of income tax is the progressivity of the tax rate¹⁰ with respect to income as $T = \epsilon Y^{\psi} = .0000036 Y^{1.98}$. This progressivity is assumed to apply in general to the cantonal tax system, there being no sales or consumption tax and only a moderate property tax.

To find the cost elasticities λ , time series for benefits are estimated in the following way. From the multitude of referenda, those voting issues were selected that were over the years repetitive or similar to each other so as to make comparison possible over time. For example, there are several referenda about the public support to the municipal theater. Similarly, public expenditures for roads, for administrative buildings, and for schools are a frequent subject of voting. We chose therefore seven categories of public goods and services for which a number of similar referenda are available and run time series of the form (14) over the median income precinct, with different cost figures as variable. The results are listed in Table 2. The cost elasticities are found to have the negative sign which one would expect. The magnitude of the coefficients is small and fairly similar for each category. It is interesting to note that preferences are less elastic for upper class issues such as law enforcement and culture, and more elastic for lower class categories such as social programs. For the latter the cost-sensitivity is larger.

The results for the cross-section analysis of equation (12) are listed in Table 3. Nearly all of the coefficients of "true" income elasticity are statistically significant, and

		Children .6171 (1.9597)	
Foreign Aid	.7172 (4.3191)		.8241

t-statistics in parentheses.

Turning first to the income elasticities, we can observe that most are of a good size and either statistically significant or nearly so. Positive income elasticities are found for law enforcement (prosecution, prison), for education and culture, foreign aid, and highways. Negative elasticities exist for mass transit and redistributive social programs such as unemployment compensation, welfare subsidies and public hospitals. None of the other demographic factors shows consistent statistical importance; age is significant for road and mass transportation (younger people prefer highways, hospitals and old age homes), however the coefficients are fairly small. Self-employment occupation contributes to the negative attitudes towards welfare and unemployment compensation. The number of children affects the preference for mass transit, unemployment compensation, sports facilities, and education (in favor of all). Finally, education affects the preferences for support of an art museum as well as of education itself.

Because all the coefficients are fairly small, we find that relative income explains the predominant part of the preferences for public goods and services.

It is also interesting to estimate and compare preferences in absolute terms. One way to interpret the meaning of such preference values is to think of them as the maximum payment the individual would be willing to make to have the public good. Another interpretation is to think of the individual as being indifferent between having the public good, or having the stated sum of money. A larger sum would be preferable to the public good. Thus the value can also be seen as a schedule of "bribes" to have a voter change his mind if he thinks that his vote makes the difference. The income of the highest and of the lowest 20 percent of the population are substituted into the equations, and other variables are kept at median values. The results are shown in Table 4. As can be seen, the

TABLE 4

high-income individuals have a strong absolute valuation for education and law enforcement expenditures; their preferences for roads, and the art museum is positive but moderate in size. For social programs their preference is normally negative, but not strongly so. It does not equal the strong positive demand by the low income group for these expenditures. For low income people, not surprisingly, the most important issues involve services from which they benefit: public hospitals, old age homes, unemployment compensation and welfare support. Nearly all other public goods are demanded positively--which is not irrational considering their low cost to poor people--but not very intensely.

Summary

This paper describes a method to derive measures of the demand for public goods. It uses the results of referenda and incorporates variations in non-voting into a model and calculates both the elasticities of the preference intensities with respect to income and other demographic variables, and finds absolute measures of preference. The model itself is a useful extension of the analysis of voting outcomes to demand function for public goods. The empirical results are specific to a Swiss jurisdiction; similar studies should be undertaken for other countries, and this is a next step for research.

FISCAL ILLUSION AND CONSUMER SOVEREIGNTY: AN EXPLORATORY STUDY¹

Werner W. Pommerehne, University of Zurich

Abstract

Data on the Australian federal government's performance as perceived by the voters and government revenue and expenditure variables are used to estimate a model of interaction between the voters' and the government's behavior. Special emphasis is given to the role of fiscal illusion on the voters' side in evaluating government performance, and to its manipulation by the government toward securing reelection. The model is developed and the empirical results are interpreted under the perspective of consumer sovereignty.

Introduction

Consumer sovereignty refers to a process of choice in which the choice is free (most major characteristic), informed (so that the act of choice is meaningful), personal (made by and not for people), and responsible (choosers must be aware of the consequences of their choice). It is often said that these preconditions for consumer sovereignty are not fulfilled in the marketplace. Consumer advocates argue that buyers are faced with high information costs, offensive and often misleading advertising, and shoddy and unsafe goods. They have sharply attacked these obstacles to consumer choice, also criticizing the whole market economy for, among other things, the monopolistic practices applied by many producers and suppliers.

However, as was pointed out by Roland McKean (1973) in his address to the Southern Economic Association, the government sector has for the most part been ignored in these analyses and attacks, though both goods and services which are provided by market and by the government are relevant to the consumer's well-being. As he further says (1973, p. 285), "I conjecture that consumers lose more from monopoly power and non-profit incentives in the provision of most government services than from monopoly power in activities of similar magnitudes in the private economy." Under the very best of circumstances, which are rarely attainable, government sector output may approach the market in the extent to which the suppliers adapt to the consumers' desires. In reality, however, the supply side push may dominate the forces of the demand side pull in terms of the structure and pattern of public sector output, this for several reasons (see e.g. Diamond 1970, Breton 1974, Wagner 1978, Niskanen 1979): Though in a democracy there are at least two parties competing at the electoral level for the support of the voters, following an election there is only one majority for the duration of the legislative period and thus the winning party has a legal monopoly. Moreover, politicians and parties cannot be held legally liable for their promises, all the more so as the particular commodities promised are usually not very tangible entities but only vague notions. In addition, there is seldom any other recourse possible than changing one's vote at the next election. There is rarely any alternative to the government-provided goods and services; private options are often legally prohibited. Last but not least, as long as the

¹The author would like to thank Friedrich Schneider for his most helpful comments, and Sandra Stuber for editing the paper for English.

public services are financed through taxes (instead of through user charges), there is no free choice. Richard Wagner (1978, p. 95) concludes from this: "Whereas the natural state of the private sector seems to be competition, the natural state of the public sector in a democratic society appears to be monopolistic." Thus under a perspective of consumer sovereignty one would expect that consumer research, when extended to the government sphere, would have a large (and growing) area for analysis in the near future.

Though a monopolistic government has discretionary power which it can use for achieving its own ideological goals, it cannot do whatever it wishes. In the same way as a monopolist on the market is faced with the constraint of a decreasing demand curve, a monopolistic government is subject to constraints, of which the most important one in a democracy is the need to be reelected. One way for it to improve its reelection chances is to exploit fiscal illusions held by the voters. Fiscal illusion as used here is taken to mean the systematic misperception by voters of the public revenue burden they bear and the benefits they receive through government spending. It can be seen as a kind of rational ignorance in consumer choice, going back to the different natures of the various public revenue extraction items and the public services, and thus to their different information costs. It also relates to the only minor extent to which the consumers can influence the output of the public sector as compared to that of the market sector, and the weak incentives for informing oneself on the public policy under discussion and its financing that result therefrom.

In the following fiscal illusion will be analyzed in the framework of a model of interaction between the voters and the government² with Australia being taken as the concrete example, mainly because its political framework at the federal level is highly suitable for our analysis.³

Fiscal Illusion and Voters' Behavior

It is assumed that, in evaluating the government's performance, voters maximize their own utility: i.e., the extent of their support for the governing party - as measured by current popularity or by voting for the government at election time - depends on how satisfied they are with the government. Because of the high costs and low benefits involved, the consumer/voter in general has little or even no incentive for becoming fully informed about the government's performance. This is true with regard to informing oneself not only about one's present and future burden of govern-

²The general framework used here was developed by Frey and Lau (1968). Its usefulness for empirical research has been demonstrated by a series of applications, see Pommerehne, Schneider and Lafay (1980) for a recent survey.

³The federal government controls over 70% of all public revenues and expenditures, and also has the power to quickly make discretionary changes on the revenue side and, to a lesser extent, in public expenditures. For more details see Schneider and Pommerehne (1980a).

ment receipts and the benefits received through public spending programs, but also about the past, which may be discounted by the voter.

Besides this, one can expect that the information on the various revenue items which is absorbed on a day-to-day basis may be biased in a systematic way because of the different costs involved in becoming informed. These information costs are dependent on the revenue extraction system's degree of fragmentation. A three hundred year old tradition in public finance suggests that the more complex the mix of public revenue sources is, the more the individual will tend to underestimate the true burden of the cost of government. A series of small public receipts may be felt less than a single large tax, particularly if it is extended over time since small losses are more easily forgotten than large ones. Moreover, because of the varying degrees of visibility, of timing of extraction, and of hidden shifts in the revenue burden, it can be concluded that voters/taxpayers will perceive certain public revenue items (such as indirect taxes and public debt incurred) less than others (such as e.g. a pay-as-you-earn income tax). All this opens up opportunities for the government to install extraction institutions that will ceteris paribus decrease the perceived cost of government and thus favorably influence the voter's evaluation of the government's performance (Pommerehne and Schneider 1978).

Voters may also be subject to systematic misperception of the benefits of public spending. These also involve positive information costs, which - due to the nature of the public goods and services - are often much higher than in the case of market goods. Many public goods have "credence" qualities (Darby and Karni 1973) which are characteristic of goods and services that are utilized in combination with other goods composed of uncertain properties. Because the quality of many public goods is difficult to judge even after provision, their evaluation may require a greater degree of costly expertise. However, it seems to be very difficult to derive a hypothesis as to what kinds of individually perceived public services will be systematically more or less strongly felt. This problem arises because of the very great difficulty in discriminating between actual and perceived benefits. Whereas the cost of government activities to a taxpayer via taxes and other forms of fiscal extraction is, to a large extent, identifiable - so that if the perceived and actual costs can be reasonably determined, the difference can be attributed to fiscal illusion - this does not hold for the spending side. For this reason the following analysis deals mostly with taxes and other forms of government finance, and does not try to distinguish between preferences and favorably biased perception when government spending is considered.

It is also assumed that voters rarely draw a close connection between public services and their actual financing sources. This assumption may be valid as the principle of non-affectation is used at the federal level. The link between federal revenue and expenditure is further obscured by the government's ability to incur debt.

As a measure of how Australian voters/taxpayers perceive and evaluate the government's overall performance, a monthly Gallup Poll was used showing the percentage of the citizenry "willing to vote for the Australian government at a federal election" at that point. This data series for current government popularity (POP) gives us the dependent variable. Turning to the independent variables, first the revenue system's fragmentation is measured by $\frac{1}{n} \sum_{i=1}^n (REV_i)^2$, where REV_i equals the i -th revenue amount for all federal revenue items. This measure of complexity moves closer to 1 the more the government relies on only one source of income; it is $1/n$ if it uses all n revenue

sources equally (each accounting for $1/n$ of the total). In order to capture the influence of the different items on the public revenue side, the various fiscal extraction devices are grouped into two classes of direct taxes (a pay-as-you-earn income tax and assessed income tax, and a tax on dividends and interest); one class of indirect taxes (sales tax, company taxes, license fees); one of customs and various duties; and one of government debt incurred. All these variables are measured as shares of total government revenue. The various spending items are also grouped into classes: transfers (social security and welfare payments to individuals, payments to disabled people, and retraining programs); health programs, education, general and scientific research, and cultural and recreation measures; investments in transportation and communication, water and electricity supply, other public utilities, and investment grants to the states; public administration, law and order, public safety, and legislative services; and defense expenditure. These variables are all measured as shares of total expenditure. Finally, the ratio of total federal revenue to GNP is introduced to take into account perception of the increase in the overall federal revenue burden that took place during the 1970s.

Government's overall performance, as perceived by the voters, relates however not only to the provision of public goods and their financing, but also to its ability to steer the economy. This aspect, i.e. that the federal government is held responsible for the state of the economy, is captured by using a monthly Gallup survey taken since January 1970 which asks "Are you satisfied (or not) with the current economic performance of the government?" as an additional independent variable.⁴

For government popularity a negative sign and a significant coefficient are expected for the ratio of total federal revenue to GNP, and for the measure of the complexity of the whole revenue system (i.e., the lower $\sum_{i=1}^n (REV_i)^2$ is, the more the government relies on all revenue items alike and thus the higher is ceteris paribus the current popularity standing). Negative signs are also expected for those individual revenue shares which are strongly perceived. Similarly on the spending side, a positive sign is expected for those individual expenditure items which are favorably perceived by a large part of the voters. A positive sign is also expected for the perceived government economic performance (i.e. the better the perceived ability of the government to steer the economy, the more voters tend ceteris paribus to support the governing party). All data are monthly and a three-month lag is taken for all independent variables as it is assumed that the citizen needs some time to notice a change in taxing and spending (using weighted lags up to one year, no major significant changes occurred in the following estimation results). To test how good the voters' memory actually is, it is assumed for simplicity's sake that it can be measured by a lagged endogenous variable and that the same size of discount rate holds for all independent variables (i.e. a Koyck transformation is used). The results for the GLS estimation of the government popularity function for the period 1971.1 through 1977.9 is given in equation 1.⁵

⁴Perceived government economic performance is again influenced by popular indicators of the current and past states of the economy, such as the rates of unemployment and of inflation, which can be easily culled from day-to-day sources; for a detailed analysis of this relationship see Schneider and Pommerehne (1980b).

⁵More exactly, both the equation for explaining perceived economic performance (fn. 4) and that for government's popularity are simultaneously estimated by GLS technique. This also explains why the variable "Government economic performance" in equation 1 is not lagged.

POP _t	=	0.49	Intercept	(1)
(Current government popularity)				
	+	0.47** (8.99)	POP _{t-1}	
	+	0.38** (5.47)	Government economic performance _t

	-	0.33* (-2.50)	Taxes on dividends and interest _{t-3}	
	+	0.18 (1.12)	Indirect taxes _{t-3}	
	+	0.80 (1.64)	Government debt incurred _{t-3}	
	+	0.42** (4.19)	Transfer payments _{t-3}	
	+	0.12* (2.19)	Expenditure on health, education, recreation _{t-3}	
	+	0.01 (0.89)	Expenditure on transportation, water supply and electricity _{t-3}	
	-	0.42 (-1.36)	Expenditure on public administration, law and order, public safety _{t-3}	

d.f. = 62, $\bar{R}^2 = 0.97$, $h = 1.27$. The figures in parentheses below the parameter estimates indicate the *f*-values (one asterisk indicates statistical significance at the 95%, two asterisks at the 99% confidence level, using a two-tailed test); d.f. shows the degree of freedom; \bar{R}^2 is the corrected coefficient of determination; and *h* indicates the test statistics for autocorrelation.

The results show first that citizens do indeed seem to highly discount changes in the revenue and spending structures: The coefficient of the lagged endogenous variable indicates that over 95% of what happens is forgotten within the space of one year. Secondly, the government's economic performance as perceived by the voters does influence the government's overall performance (popularity) in a positive and significant way.

As expected, total revenue burden and the complexity of government's revenue system have both a negative and strongly significant influence on current government popularity. The marginal impact of these variables is also quantitatively important: An increase in, for example, total revenues as a share of GNP by 1 percentage point *ceteris paribus* reduces current popularity by 1.21 percentage points; in contrast, the marginal decrease in government economic performance of 1 percentage point is only about one-third of this (0.38 percentage point). Going to the individual revenue items, one only finds a highly significant influence on government's current popularity in the case of the two direct taxes. This result is fully in line with the

classic argument of public finance literature that direct taxes are most strongly felt, whereas indirect taxes and most other revenue items (especially government debt) are much harder to detect. Moreover, a stronger dampening impact on government support of direct (income) as compared to more indirect (sales) taxes has also been found recently for other countries, including the United States (Eismeier 1979). Looking at the spending side, one finds a significant positive marginal effect on government popularity only in the cases of transfer payments (mostly to private households) and of expenditure on health and education programs. The impact of the latter, however, is only one-third of the first. The relatively high marginal influence of transfer payments is not implausible as it may be argued that they strongly reduce uncertainty concerning future direct benefits and thus may be valued highly by voters. Even if not all voters/taxpayers end up being public transfer beneficiaries, the great majority of them may still expect to. Comparing the influences of both sides of the government budget, the total marginal influence of the revenue items is almost five times as large (in absolute terms) as that of the spending items. Again, a similar result showing a much stronger influence on voters' support for the government for the revenue side as compared to the spending side has also been found recently for the United States (Niskanen 1979).

In order to do an additional check of these empirical results, an *ex ante* forecast for the period 1977.10 through 1978.12 was done based on GLS estimates for 1971.1 through 1977.9. The prediction is clearly superior to naive forecasts (Theil's inequality coefficient is 0.05; the average root mean squared error, 0.62%; and the average mean error of deviation 0.63%), indicating that the most important variables determining evaluation of the government's overall performance have been taken into account.

To summarize: The empirical findings show that voters/taxpayers seem to be unaware of the full cost of government activities when the revenue system is fragmented and especially when those types of taxes and other means of revenue extraction are used which are harder to detect than others. There is also evidence that some spending items, such as additional transfer payments, seem to be more popular and more strongly felt than increases in other expenditures. These effects on both sides of the budget and the fact that the voters highly discount past government activities provides opportunities for the government to use its fiscal instruments in a systematic way to retain the popularity it needs to allow it to secure reelection.

Government's Behavior: The Strategic Use of Fiscal Illusion

Let us assume the existence of a government that wants to maximize its utility, here understood mainly as the pursuit of its ideological goals. Even if it is assumed that the government cannot be voted out of office in the middle of a legislative period, it is still subject to various constraints in trying to achieve its ideological goals, of which the most important is the reelection constraint. Thus the government faces a dynamic maximization problem of when to undertake what fiscal policy action in order to maximize its utility.

It is assumed that the government is not able to resolve this problem, and that it will behave in a satisficing manner. It takes the results of popularity surveys as the best current available indicator of its reelection chances. If the current popularity level of the government is high, and/or if there is plenty of time left until the next election, the government will use its various fiscal instruments

to pursue its ideological goals. In comparison with a right-wing government, a left-wing government will generally increase public sector activity including new and/or expanded spending programs. A look at the Australian governments in the 1970s shows that Labor (left-wing) governments explicitly stated preferences for more spending on education and improvements in the welfare and health care systems, and decreased outlays for national defense. The Country-Liberal (right-wing) governments stated preferences for a much smaller level of growth in current and future government activities. There were also major differences in preferences as to how to finance public expenditures. Whereas a Country-Liberal government tends to favor tax financing, a Labor government relies more on incurring additional debt.

If the reelection chances are indicated to be poor, the government will concentrate on securing reelection rather than on pursuing its ideological goals. For this purpose, the government - regardless of who is in power - will try to create favorable fiscal illusions on the part of the voters by means of a systematic revenue and spending policy, counting in the voters' short memory to aid it in this. Before an election it will decrease the more direct and strongly felt taxes in particular (such as personal income tax), and increase harder to detect revenues (especially public debt) in order to finance additional popular spending or to cover the deficit caused by the lowering of strongly felt revenues.

When formulating the use of fiscal instruments, it is assumed that in a state of low popularity the government will react all the more strongly the greater is the ratio POP*/POP (the critical level of current popularity POP* having the value of 51%). The second important factor is reflected in the discretionary variable "Time since last election" (TSLE), the obverse of time left until the next election, which takes the values 1, 2, ..., 30, 1, 1, starting with the beginning of each legislative period.⁶ The government has also to take legal obligations and the behavior of the public administration into consideration in using its revenue and spending instruments. It seems realistic to assume that the public administration does not simply follow the wishes of the government but rather tries to maximize its own utility. It tends to resist major changes because this may threaten its own position and prefers to make only small and incremental changes. It would therefore seem to be useful to take the past spending and revenue structures into consideration as these are the starting points for changes therein. In addition to the legal and administrative constraints, the government has to take changes in the balance of payments into account, as well as the size of the budget deficit (a positive sign in the case of deficit, and a negative sign for budget surplus), whose maximum equals the maximum incurable additional debt, which is set through the legal framework.

It is now possible to formulate the following equation for the i 'th fiscal instrument ($INST_{i,t}$):

$$INST_{i,t} = \begin{cases} a_1 & INST_{i,t-12} \\ a_2 & \text{Change in balance of payments}_{t-6} \\ a_3 & \text{Budget deficit deviation from the long term trend}_{t-6} \\ a_4 & \text{Current popularity standing}_{t-6} \\ a_5 & \text{Time since last election}_t \end{cases} \quad (2)$$

Administrative and economic constraints

Political constraints

⁶This formulation implies that the government's reaction six months before an election will be stronger than when the election is still far off.

$$\text{Ideological preferences} \begin{cases} + a_6 & \text{Ideological preferences of Country-Liberal governments}_t \\ + a_7 & \text{Ideological preferences of Labor governments}_t \end{cases}$$

for $i = 1, 2, \dots, 26$ ⁷.

The 26 instruments refer to 10 federal revenue and 16 spending items, and are calculated as shares of total revenue and total expenditure respectively in order to capture the changes in the structure and eliminate the typical time trend effects. The explanatory variables are lagged by six months as it is assumed that the Australian government needs at least half a year to react to political and economic changes (when a longer or more complex lag structure is used, the estimation and the forecast results do not improve significantly).

The theoretically expected signs of the administrative and economic constraints are $a_1 > 0$ (for both the revenue and spending sides), $a_2 < 0$ and $a_3 > 0$ for revenue items, and $a_4 > 0$ and $a_5 < 0$ for expenditure items. In the case of a_4 and a_5 , a decrease is expected in the share of those revenue items which are strongly felt by the voters, and an increase in popular spending items. For the two ideological parameters a_6 and a_7 the signs already discussed are expected, for example that a Labor government will have a greater preference for increases in education than Country-Liberal governments ($a_6 \text{ education} < a_7 \text{ education}$). The results of the simultaneously estimated revenue instruments are given in Table 1.

Table 1 shows that the two types of government have significant differences in their ideological preferences regarding which instruments are to be used. When there is leeway for action, as for example after an election, the right-wing government (Country-Liberal) reduces in particular the assessed income tax, the income tax on dividends and interest, and, to the greatest extent, government debt. A left-wing (Labor) government acts in the opposite manner. It increases indirect revenue items (including debt), and, among the direct taxes, especially those which will be reduced by a right-wing government. It is interesting to observe that both governments deviate from their ideological preferences regarding the revenue instruments when trying to secure reelection. Goaded by a low popularity level and/or an upcoming election, both governments significantly reduce direct taxes, the earned income tax the most. They also reduce excise taxes, which are shown separately on purchase receipts. The harder to detect revenues are deliberately not reduced; in some cases, government debt for example, they are even increased ceteris paribus.

Another interesting finding is that compared to a left-wing government, right-wing governments show a greater preference for a simple and comprehensive revenue structure that relies on relatively few and quantitatively important revenues items. However, when trying to secure reelection, both types of government follow a policy of fragmentation of the total revenue, thus creating a more favorable perception of the government on the voters' part.

An ex ante forecast was also done for 1977.10 through 1978.12 to provide an additional check of the empirical results. With one exception (government debt) the predictions for the 10 revenue items are far superior to those achieved with naive forecasting methods. The best predictions are those for direct taxes (Theil's inequality measures being

⁷The method used here to measure ideological preferences regarding the fiscal instruments is rather simple: The intercept is broken up into two dummy variables in order to capture the different use of instruments by Country-Liberal and Labor governments with a shift parameter. It is assumed that the ceteris paribus conditions are fulfilled so that ideological preferences can be measured in this way.

TABLE 1
ESTIMATION OF AUSTRALIAN GOVERNMENT POLICY FUNCTION^a

Instruments on the revenue side (as a share of total revenue)	Legal, admin. and economic constr.			Reelection constr.		Ideological constr.		Test statistics	
	Lagged endogenous instrument (t-12)	Change of balance of payments (t-6)	Budget deficit deviated from long term trend (t-6)	Current popularity standing (t-6)	Time since last election (t)	Country/Liberal (t)	Labor (t)	\bar{R}^2	h
Tax on earned income	1.08** (8.85)	-0.14** (-2.96)	0.12** (2.78)	-0.61** (-3.54)	-0.78** (-6.03)	0.89 (1.54)	-1.64* (-2.06)	0.89	1.07

Complexity of the revenue system	0.44** (3.54)	-0.21 (-1.89)	-0.34* (-2.54)	-0.24** (-2.77)	-0.30** (-3.19)	0.94** (3.88)	0.36** (2.89)	0.58	1.44

^a As it is assumed that the various instruments are not independently used by the Australian government it is very likely that the disturbances from them are correlated. If so, the technique of multivariate regression gives more efficient estimates, and is used here. For notes see eq.1.

ca. 0.20; the average root mean squared errors ca. 1.75%; and the average mean errors of deviation ca. 1.20%), i.e. those instruments which are discretionarily changed before an election (and there was a general election in March 1978).

For reasons of space the empirical results for the spending side are not presented here but only briefly discussed. Looking at the ideological differences between both types of government, Country-Liberal governments favor additional expenditure for capital formation, defense, and law and order. A Labor government prefers to decrease the last two and favors instead additional transfer programs (including foreign aid), education, and health care. Again, if a government is afraid that it will not be reelected, all transfer payments to individuals and households (but not foreign aid) are significantly further increased in addition to the most favorably perceived expenditure on education and health. This strategy of increasing especially transfer payments before an election seems to be quite common, and can be observed to operate similarly for instance for the United States (Tufté 1978, chapter 2). The ex ante forecasts which have been made to test the model's predictive ability in an election year lead to superior results for 11 of 16 spending items (evaluated by Theil's inequality coefficient which is smaller than 1). The instruments for se-

curing reelection again provide the best forecast results (with an average mean error of deviation of less than 1.5%).

If these results are compared to the findings for the revenue side, it can be seen that the use of the spending instruments is of less importance in securing reelection. This is not implausible and may simply reflect the often stated greater rigidity of the expenditure side as compared to the revenue side.⁸

To summarize: The general hypotheses in this paper are that (1) voters will be rationally underinformed and thus subject to systematic misperceptions of fiscal variables, and that (2) the government in a representative democracy will try to exploit such fiscal illusions in order to strengthen its position, especially when it is trying to secure reelection. The general framework of the analysis is that of a monopoly, though one its need for periodic popular approval. Empiri-

⁸ Additional evidence for this argument is gained when a regression is carried out with the lagged endogenous variables of the revenue and spending items (in billions of Australian dollars), thus capturing only the legal and administrative influences. The mean of the explained variance is then 82.5% for the revenue items, but 93.1% for the expenditure by categories.

cal evidence for systematic misperception of the cost of government is offered by the results for the government's popularity function: The findings show that voters/taxpayers seem to be unaware of the full cost of government activities when a complex revenue system and indirect and more hidden revenue items are used. There is also some evidence that a few spending items are favorably perceived by the majority of voters, though it remains open how much of this is due to preferences and how much due to misperception. This plus the fact that voters discount past government activities all helps to provide opportunities for the government to act as if it had a monopoly position. As the empirical results show, significant differences between the two parties' use of fiscal instruments for ideological purposes appear after an election was taken. However, when trying to secure reelection each government deviates from the pursuit of its ideological goals if necessary and uses the fiscal instruments in a predictable fashion in order to exploit fiscal illusions held by the voters.

Conclusions and Suggestions

Several conclusions and suggestions arise from this analysis, all relating to the provision and diffusion of more and better information on the government sector to politicians and consumers. However, it seems useful to distinguish between information dealing with government sector output, i.e. its product and cost, and with the institutions and processes of real world public decision-making.

To start with the first: Enough has been said in the above to conclude that the true cost of government to the consumer/taxpayer has a large grey area and may be systematically misperceived in many circumstances. Under the perspective of consumer sovereignty, which stresses the right to information leading to meaningful purchasing decisions, better knowledge of the true and of the perceived cost of government to the individual would seem desirable. Some work has begun in this direction, for example with the development of a consumer tax index for Canada (Walker 1976). Moreover, it can be expected that especially the analysis of the perceived tax burden and its determinants may profit from applied perceptual and learning psychology, and from consumer research and its techniques of direct consumer inquiry. The right to information also requires knowledge of the true and the perceived nature of government services, their quality, how long they are provided, and, for example, their spatial distribution. It would seem that this kind of information could be strongly improved using techniques of consumer and marketing research, e.g. multiattribute product analysis and hedonic price approaches (Palda 1980).

However, even if this kind of information is greatly bettered, the problem remains that there may be still only be weak incentives to exploit it. Non-neglectable costs arise to the individual voter in making collective decisions, and the additional cost of doing so on a well-informed basis may far outweigh the gains. As there are usually only a limited number of alternatives to be chosen among, a system of mandatory payments prevails, and the number of voters is large, it may even be irrational for the individual to become sufficiently informed to make an intelligent decision. Under this perspective it would be desirable to improve in particular information on the functioning of the government's institutions and on how the political process really works. This information relates to such questions as to how strong (or weak) the competition between parties in a representative democracy really is, and thus how small (or large) the leeway is that an elected government has to deviate from the voters' wishes. Moreover, it would also provide the basis for research on how the real-life political process and the functioning of government institutions can be influenced so

that the wishes of the voters are - quasi automatically - better taken into account by the government.

COMMENTS

Robert Ferber, University of Illinois

The three papers on which I have been asked to comment deal with a variety of different issues related to consumer behavior in the public sector. The first paper, by Deacon, deals with opposing views on whether the consumer, as a voter, exhibits economic rationality in making choices at the polls. The second paper, by Vehorn, raises the question of the extent to which consumers are likely to substitute private goods for public goods in their purchasing behavior. In contrast to these first two largely theoretical papers, the third paper, by Pfaff and Kistler, seeks to present empirical information on the desirability of providing consumers with better information about public programs. Since these papers are so distinct, it seems best to discuss each of them separately.

The focus of the paper by Deacon is to question whether voters are indeed as well informed and economically rational as is made out for them in voting models. Although I am not that well acquainted with this literature, the studies cited in this paper, especially those referring to the desire by voters for maintenance of the status quo, would seem to cast doubt on the hypothesis of economic rationality as usually defined. Certainly, the latter finding suggests that voters are influenced more by habit persistence than by any desire to bring marginal benefits into line with marginal costs.

One other key question discussed in this paper is whether majority rule leads to competitive or noncompetitive equilibrium. As the paper points out, the evidence on this point is mixed. My own hunch is that the evidence will continue to be mixed, since much is likely to depend on the particular situation. If a governmental body is in firm control, with an electorate that is either passive or relatively satisfied, noncompetitive equilibrium is much more likely. On the other hand, if things are in a state of ferment or the governmental body is unsure of having the support of the voter, competitive equilibrium would seem to be more probable.

From an empirical point of view, I am not convinced that the finding that voters prefer "no change" indicates competitive equilibrium. Survey experience suggests that such statements are as likely as not to reflect lethargy on the part of the respondent, or lack of information, as well as satisfaction with the status quo. It is not clear from Deacon's paper whether any attempt has been made in these prior studies to distinguish among these different possibilities.

It is also not too clear from this paper what exactly is the meaning of "majority rule equilibrium." In theory, this equilibrium is based on the median of the individually preferred outcomes. In practice, however, it is not clear how well defined this median may be, how it may be estimated and how stable it may be over time. Possibly the other studies mentioned in the paper have dealt with this problem. To me, however, this seems to impose all sorts of informational requirements on the voters that may be highly unrealistic.

The Vehorn paper deals with another aspect of market efficiency, namely, the substitutability between public and private goods. In fact, this paper might just as easily have been titled, "Complementarity and Substitutability between Public and Private Goods." In many instances, it is clear both from the paper and personal observation that

private goods do not seek to substitute for public goods, but to complement them. This is true, for example, in the case of protection services, purchase of insurance and various aspects of transportation.

It might also be noted that the finding of substitutability was based on analyses where governmental divisions were the unit of observation. A very different result could be obtained if the unit of observation were the individual family, something which would seem to be more meaningful if the focus is on understanding consumer behavior.

At the same time, there is no question that substitutability is definitely present and, as Vehorn points out, exists in the case of education. On that topic, however, I feel that one question posed in the paper is a rather odd one, namely, "What is the effect of private education on the provision of public education?" Certainly, the experience of the last few decades suggests that private education springs up in response to inadequate public education, so that perhaps the more meaningful question should be the effect of the provision, and quality, of public education on private education.

Perhaps the basic question relates to the type of services being demanded by the consumer. If these services are not being supplied by the public sector, the chances are very high that an industry will arise in the private sector to meet this need. At the same time, it should be recognized that particular services may be sought from the private sector even though they may also be available from the public sector, if the latter services are not adequate or sufficient in the mind of the consumer. It is for this reason, for example, that the life insurance industry has been flourishing despite the growing importance of the Social Security System.

Whether one refers to these services or goods as attributes or something else, one principle is still the same. (Incidentally, it is about time that people stopped referring to the attribute approach of Lancaster as "a new approach to consumption"; it is now nearly 15 years since this theory first appeared.) The fact remains that even though public services may be adequate for the majority of the people, they may still not be adequate for enough others, so that it pays for the private sector to get involved in providing similar services.

The conditions under which the provision of such private services will flourish has received some study, as noted by Vehorn, but it is also clear that much more study of this question is needed. Moreover, with the growing taxpayer revolt and the desire to minimize government involvement in the economy, such studies should hopefully also provide information on the extent to which various services should be provided by the public sector, and the extent to which supplementary services should be left to the private sector.

The paper by Pfaff and Kistler presents some survey data and comes to the conclusion that, "increased understanding of and more information about public transfers is needed on normative as well as practical grounds." These are very logical conclusions. The only problem is that it is not at all clear how they follow from the data presented in this paper.

In fact, two sets of data are presented. One set of data (Table 1) gives the results of an opinion poll taken of

some undefined population, with no indication of sample size or possible statistical significance, and with no explanation of the data. What it seems to provide is estimates of the percentages of different population groups having different attitudes toward the retention of grant-in-aid programs to old-age insurance, and to unemployment insurance, respectively, though the percentages do not total 100 percent. On the basis of these data, the conclusion is drawn that "more information especially about the situation of other people and groups could lead to a reconsideration and reevaluation of one's own relative position compared to that of others with regard to the public budget constraints . . . understanding the necessity to assume burdens and to aid others could curb an excessive inflation in demand."

Actually, what this table shows is that, for example, people receiving old-age insurance very much favor the continuation of such a program, and a substantial proportion also favor unemployment insurance. Similarly, people receiving public assistance (many of whom may also be receiving old-age insurance, but this is not clear) also heavily favor unemployment insurance.

If these data indicate anything, therefore, it is that people are very much influenced by self interest in their attitudes on public transfer programs. Moreover, they are likely to favor public transfer programs other than what they are receiving, possibly out of a feeling of sympathy and the need for mutual support to ensure maintenance of their own program. Since there is no indication in this table as to which respondents have more information or less information, the authors' earlier cited inference on the importance of information would seem to have no basis whatsoever.

The second conclusion, drawn from Table 2, seems equally doubtful. It is that "we can conclude that consumer information is an important prerequisite for systems performance." This conclusion is based on a table which shows a positive relationship between satisfaction with informational activities by young people in Augsburg and satisfaction with transfers to their own group. However, the same table shows almost equally strikingly that those who are satisfied with informational activities are much more likely than the dissatisfied to believe that one cannot influence democratic processes. Moreover, those who are satisfied with informational activities seem to have no more political interests than those who are dissatisfied.

Perhaps this table can be interpreted differently, for once more the data are not explained, and percentages do not add up to 100 percent. Also, a symbol, epsilon, is presented with no explanation of its meaning.

Under the circumstances, one can only agree with the later statement in this paper, "the conclusion that informed consumers would help create a more rational transfer policy and reduce selfish aspirations surely is obvious, but difficult to prove." Whether this point can be proven or not, at the least one would hope for a more meaningful framework for investigating this question and a reasonably careful empirical analysis.

THE IMPACT OF PROGRAM EVALUATION NEEDS ON RESEARCH METHODOLOGY

R. Bruce Hutton, University of Denver
Dennis L. McNeill, University of Denver

Abstract

This paper presents a perspective on impact evaluation research that stresses the diagnostic role of evaluation in addition to the more common end-results evaluation. This leads to several implications for research--most notably that the research should require multiple methods to accurately diagnose program effects. An example of a recent program and the attendant methodological decisions illustrate the implications of the application of this perspective to evaluation research.

Introduction

Recently an increased emphasis in program evaluation has emerged in the public sector. While several different forces have spurred this emphasis, the motivation comes principally from the growing dissatisfaction with seemingly ineffective programs (e.g. Howard and Antilla 1979) and the desire for a more systematic approach to policy decisions (e.g. Mazis and McNeill 1978).

However, the use of evaluation research by policy makers remains naive and is characterized by a justifiable hesitation as to the ability of research to evaluate complex social programs. Some of this hesitation comes from a lack of experience with research design, but there is a good portion of this reserve which is justified by the embryonic practice of program evaluation. There are inherent problems in the research field which revolve around the selection of a proper research design, development of valid dependent measures, use of appropriate analysis techniques, and drawing valid conclusions from the data. These problems are compounded by a lack of systematic feedback to the relevant disciplines regarding evaluation research that has been completed. However, as evaluation research becomes a larger part of the academic literature, it is clear that key methodological decisions have rendered many of the past evaluation efforts meaningless (see, for example, Phillips and Caider 1980).

This paper describes the design of a recent evaluation project (Hutton and McNeill 1980) which incorporated a multi-method approach to answering the questions about program impact. This approach has been suggested in the past (see Campbell and Fiske 1959, and Heeler and Ray 1972) but has received virtually no support through implementation in evaluation research. Reasons for this oversight range from cost constraints to a myopic view of the evaluation problem.

The Evaluation Problem

The literature on evaluation is replete with various terms describing evaluation typologies. Scriven (1967) describes evaluation research as formative (pretesting or developmental research) and summative (measuring program effects) evaluation. Additionally, Freeman (1976) indicates a form of evaluation called process evaluation which investigates the procedures that were used to implement a policy program. Essentially, the research questions which can be answered by evaluation are of three generic types:

• End-Result Evaluation

Did the program accomplish the goal for which it was originally designed?

• Diagnostic Evaluation

Why did the program results occur?

• Formative Evaluation

What components of the program should be included?

It should be noted that evaluation research often occurs after the program goals and components have been determined. Consequently, the role of formative evaluation is likely to be most aided by careful diagnosis of past efforts. As noted by Van Maanen (1979) much can be gained by findings with comparative groundings--those conclusions developed by contrasting programs with similar goals but different means of achieving these goals. Generically formative evaluation is different from the attempt to chronicle program effects through end-results or diagnostic research efforts.

End-result evaluation is the most common approach found in the design of evaluation studies, and, of the two tasks, is the easiest to operationalize. The end-result analysis requires a specification of the level of ultimate effect of the program (often behavior) and the design moves to that level once the program has had time to work. Clearly, goals of the program and timing of the results key the methodological decisions. Descriptive survey methods dominate the approach to this first task, although there is some use of quasi-experimental designs. However, these methods often suffer from an inherent inability to explain why results occurred (e.g., surveys) or from threats to internal validity in certain commonly used quasi-experimental designs. In this case the policy decision must then rely on post-hoc explanations of results which can never be fully defended.

Diagnostic evaluation is a different and more complex task. The goal of this research is to profile program impact in a way that understanding of the reasons for that impact can lead to adjustments in the current program and better program decisions in the future. The increased complexity of this type of research question requires the researcher to consider many more facets of program effectiveness that include the following:

- goals of the program;
- timing of program effects;
- timing of, and effects of individual program components;
- external factors which could influence program success or failure (e.g., conflicting programs already in place);
- individual difference variables in the population;

- the potential uses of the program results; and
- the time frame for future policy decisions.

The diagnostic evaluation process makes a more concentrated attempt to profile the environment in which the program must work and takes a more systematic approach to the evaluation than an end-result perspective. In addition, a diagnostic evaluation recognizes the limitation of a single methodology to answer all research questions.

The following sections will describe a case study of research design decisions which were intended to address both the diagnostic and end-result evaluation needs of a public policy program. In addition, results of the evaluation will be highlighted.

The Program to be Evaluated

The program evaluated was called the Low Cost/No Cost Energy Conservation Program (LC/NC) and was designed and implemented by the U.S. Department of Energy. The program was introduced in the six New England states in the fall of 1979 and consisted of the following components:

- A LC/NC booklet which described eleven categories of home energy conservation tips. These tips could be completed by the household for low or no cost and the eleven tips could save 25% of the home fuel costs in the winter.
- Paid advertising in radio, television, and newspapers. This activity consisted of professionally designed ads run in the New England region from November 8 to December 2, 1979.
- A showerflow control device given as an incentive with each LC/NC booklet. The device was a small plastic cone-shaped object which, when installed in a showerhead, restricts the flow of water (and use of hot water) from the shower. This was also one of the eleven LC/NC tips.
- Some public relations efforts to initially introduce the program to the region.

The focus of the program was the LC/NC booklet which was hand delivered with the showerflow device by the U.S. Postal Service to 4.5 million households in New England. All of the other program components were designed to inform the population about the program and to motivate the population--through the expected savings--to complete the LC/NC tips.

Several research questions were relevant to this program but two were prominent for the research methodology:

- Did the program stimulate LC/NC energy conservation behavior?
- Did the advertising contribute to the program success?

The first question is the end-result evaluation which essentially asks for a tally of energy conservation behaviors that resulted from the program. However, the timing of these behaviors is critical. The end of the year presents many competing demands on the consumer pocketbook and time, but due to the nature of future policy decisions results were necessary by January 1980.

The second major question which impacted on research revolved around the role of advertising in program success. Since paid advertising was a relatively new and controversial component of public programs, it was felt that the role of advertising in improving program effects should be documented. The difficulty now lay with matching methodology to evaluation needs.

Matching Evaluation Needs with Methodology

The End-Results Evaluation

Table 1 presents the basic research questions and the multi-method designs which were used to gain diagnostic answers from program results.

The end-results evaluation posed some difficult problems in design. First, the after-only design (a survey) alone would not be able to provide a systematic basis for judging what the conservation behaviors would have been without the LC/NC program (Campbell and Stanley 1963).

TABLE 1

Description of Research Designs

I.	What were the program effects?	An after-only quasi-experimental design with New England (n=1207) as the treatment condition and upstate New York (n=604) as a control were used to test the effects of the LC/NC program on conservation behaviors.
II.	What was the effect of paid television ads?	A panel study was used to gain an unobtrusive measure of advertising exposure. Of those completing the diary, 92 households were given the same questions as above to correlate television exposure to LC/NC behavior.
III.	Do the LC/NC ads have the potential to work?	The two LC/NC ads were tested in a day-after recall test to ascertain the ads' potential to inform New England and thus to contribute to program success. Males and females were approximately equally represented in the sample (n=305) testing recall of the commercials.

Thus, both high success or failure would have been easily assailed without a basis for defense. Consequently, it was decided that a comparison group design be employed.

There are many critical decisions to make in the selection of a matched control condition for this evaluation. In order to make a proper selection and to avoid the negative artifacts of this process, the goal of the evaluation must be clarified. This evaluation must show whether the LC/NC program stimulated energy conservation behavior. Thus, the matching criteria must be those that would increase the probability of response to energy conservation (e.g., severe winters, dependency on expensive fuel, etc.). In other words, the control must be at least equally ready to respond to this program due to the need for these specific conservation behaviors. It was decided that New York, particularly the upstate area which included Rochester and Buffalo and rural Genesee county, matched New England well on several a priori characteristics:

- . heating oil dependence;
- . severity of winter;
- . age and structure of homes;
- . availability of previous conservation efforts;
- and
- . demographic profile of the population.

However, because New York matched New England on the readiness to respond to conservation, the region also carried with it a considerable amount of conservation activities. These conservation activities were more prominent than New England, and, as the results were to show, caused New York to evidence more conservation behaviors prior to the program than the level found in New England. In a strict sense the groups were not matched on actual prior conservation behavior but were matched on the more critical dimensions which characterized the readiness of the region to respond to the LC/NC program. The unequal level of conservation activity cannot be ignored for it introduces some alternative hypotheses to the results that were measured after the program was in place. The alternate hypotheses affected both the analysis and the questionnaire design.

Three alternative hypotheses were most critical to this study: 1) a different group hypothesis, 2) a ceiling effect hypothesis, and 3) an alternative causal element hypothesis.

The different groups hypothesis states that people who are currently eligible for LC/NC behaviors in New York and New England are not alike. Since the current proportion of the population completing LC/NC behavior in New York is higher, the easy to persuade segments of the population may have already been reached. Comparing the responses since the program inception is probably an unfair test due to the increased difficulty of persuading later adopters in New York (Shoemaker 1979).

The ceiling effect hypothesis operates in the same direction but for a different reason. A ceiling effect would suggest there exists some asymptotic level of behavioral response to energy conservation beyond which only minor changes in behavior are possible. Thus, this potential alternative hypothesis also makes inappropriate a comparison of the responses since the LC/NC program if the initial levels of response are not comparable. The changes in New York would be smaller by definition because these responses are closer to the ceiling.

The alternative causal element states that whatever caused New York to be high is now causing the behavioral responses in New England to change.

All of the above have implications that lead the analyst to consider only the overall behavioral penetration

levels in the test between the treatment (New England) and control (New York). If overall behavioral change is greater in New England than New York for the LC/NC tips, the alternative hypothesis become unlikely explanations for the results. The different groups hypothesis is not operable since New England and the LC/NC program would be able to better penetrate the hard-to-persuade segments. The ceiling effect hypothesis would be a poor alternative since the responses would have to exceed the hypothetical ceiling for New England to produce significant behavioral change. Finally, the alternative causal element would not be a likely explanation since the LC/NC program would produce changes greater than any hypothesized other causal element.

In the case where comparison groups cannot be equated on behavior prior to the program, the analysis then must be constrained to a test of overall behavior--rather than behavior since the program. This does not overcome the matching problem but does eliminate the alternative hypothesis endemic to a pre-post comparison, and serves an additional benefit of providing a rather stringent test of program impact.

The lack of matching on prior levels of behavior has implications for the questionnaire development. The questionnaire must be developed in order to measure behavioral response to the LC/NC energy saving tips. However, because of the focus on behavior, the short duration between program introduction and measurement, and the lack of a perfect match on prior levels of LC/NC behaviors, the questionnaire content, as shown in Figure 1, must also address the following:

- . the ability of respondents to do the LC/NC tips,
- . the reading of the LC/NC booklet,
- . the timing of the completion of the tip,
- . intentions for completion of the tip, and
- . reasons for not intending to complete the LC/NC tips.

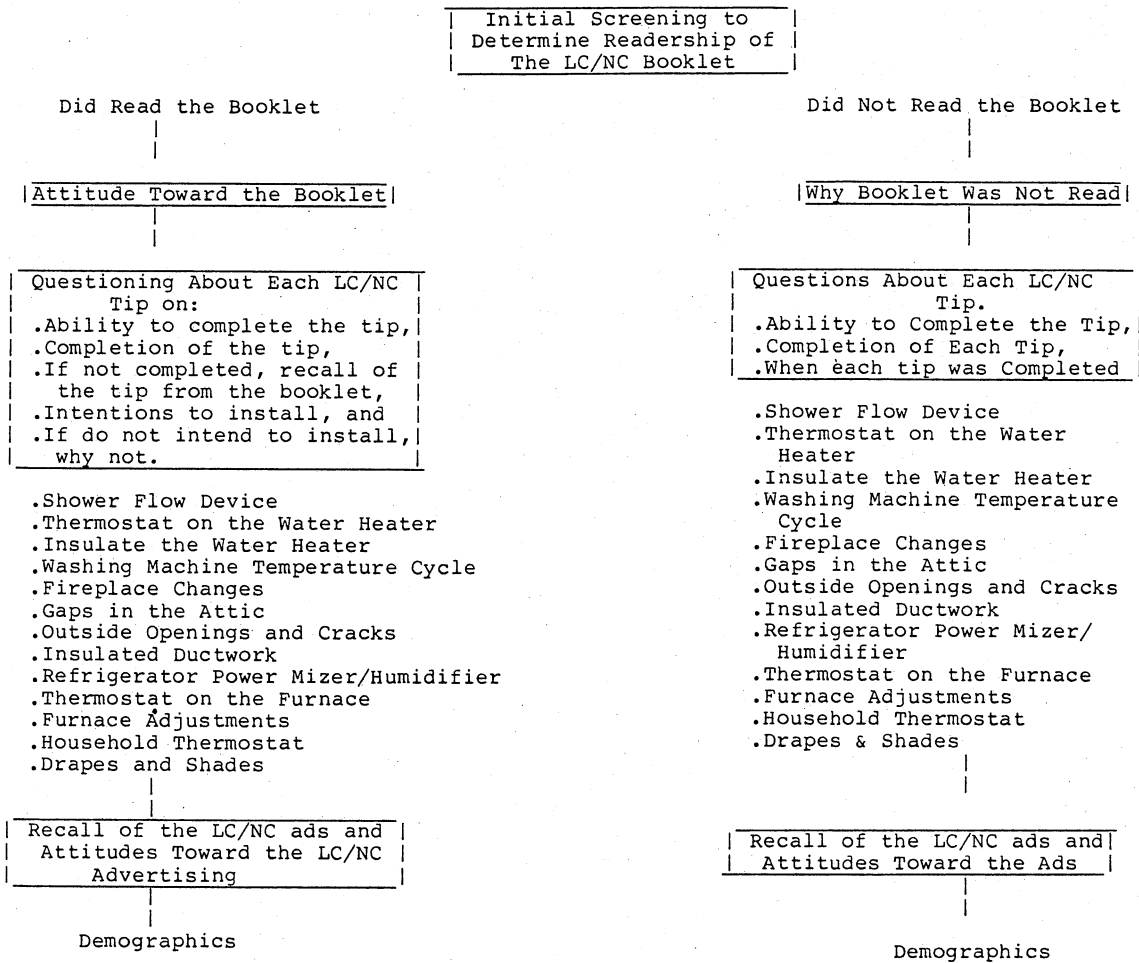

As in most studies particular attention must be given to the validity of dependent measures. In this case the concern is with the reliance upon self report behaviors, and the potential cue for "right" answers given the need to reference the LC/NC booklet. The validity of these responses was examined in two ways. The first is face validity following from the logical flow of the questions. For example, a yea-saying bias may push the respondent to say they have completed the LC/NC tip recently. If a subject said no, that the LC/NC tip had not been completed since the program, they were then asked if they saw the tip and intend to complete it later. A no answer to these two questions was followed by "why don't you intend to complete the tip?" It is here that respondents can indicate it has already been completed. In order to assess the validity of the timing of the completion of the tip, a percentage of the respondents should have followed the above sequence to indicate that the tip had been done before the program. On the face of the logic of these patterns of responses the researcher has some increased confidence in the validity of the timing of the behavior.

However, this does not address the presence of a bias to report completion of the tip when this is not the case. This was handled by a second phone call three weeks following the initial interviews to a sample of households to test the responses to key LC/NC tips. In a sample of 180 households in the treatment and control condition, 96% of the original responses were confirmed, and the remaining 4% were explained by an inability to query a knowledgeable member of the household regarding the LC/NC tips.

The final methodological consideration involves sampling in both the treatment and control condition. A probability sample of 1207 and 604 in New England and New York

FIGURE 1

The Components of the LC/NC Questionnaire

respectively was prepared from telephone exchanges in two strata—big cities, and non-metropolitan areas. The method included unlisted numbers and new listings in their correct proportion.

The Diagnostic Evaluation

The diagnostic evaluation focused on the contribution of paid television advertising and resulted in two separate studies being completed. The first answered the question of the relationship of exposure to LC/NC television ads on the impact of the LC/NC program. The second study addressed the issue of the potential of the LC/NC ads to aid program impact.

The Relationship of the LC/NC Ads to Program Impact. This study had considerable importance to this program and to others desiring to use paid advertising as a part of an integrated policy program. There were three specific goals to this aspect of the evaluation. The first was to describe the relationship between the exposure to the ads and program results. The secondary goals of this study were to examine the efficacy of the media-buying decisions and to serve as cross validation for the end-results study. The key issue for the first goal was to implement

a methodology whereby exposure to the LC/NC ads could be unobtrusively measured and related to the overall program impact. In order to accomplish this, a sample of households in the greater Boston metropolitan area were selected from an existing mail panel to keep a diary of their adult T.V. watching behavior for a period November 8 to December 2, 1979. This period corresponds to the period when paid television advertising was in operation. A sample of the diary format is found in Figure 2. An original sample of 250 households was selected and by December 15 154 (61.6%) households had mailed in the set of four completed diaries.

The task then was to code the diaries so that the television watching could be matched to the times when the LC/NC ads were shown. The relationship to the LC/NC program effects was accomplished by a telephone interview using the questionnaire from the end-results evaluation. This questionnaire was administered to 92 households from December 15 to December 24. The exposure to the LC/NC ads was then related to the impact of the LC/NC program effects.

FIGURE 2

(Sample Format)

TV Viewing Questionnaire for Saturday

	Male/Female Head of Household Watching TV?		Station No.	Program Name	Head of Household	
	No	Yes			Male	Female
7:00 AM	<input type="checkbox"/>	<input type="checkbox"/>	→ _____	_____	<input type="checkbox"/>	<input type="checkbox"/>
7:30 AM	<input type="checkbox"/>	<input type="checkbox"/>	→ _____	_____	<input type="checkbox"/>	<input type="checkbox"/>
8:00 AM	<input type="checkbox"/>	<input type="checkbox"/>	→ _____	_____	<input type="checkbox"/>	<input type="checkbox"/>
8:30 AM	<input type="checkbox"/>	<input type="checkbox"/>	→ _____	_____	<input type="checkbox"/>	<input type="checkbox"/>
9:00 AM	<input type="checkbox"/>	<input type="checkbox"/>	→ _____	_____	<input type="checkbox"/>	<input type="checkbox"/>
⋮	⋮	⋮	⋮	⋮	⋮	⋮
11:00 PM	<input type="checkbox"/>	<input type="checkbox"/>	→ _____	_____	<input type="checkbox"/>	<input type="checkbox"/>
11:30 PM	<input type="checkbox"/>	<input type="checkbox"/>	→ _____	_____	<input type="checkbox"/>	<input type="checkbox"/>

Several important considerations need to be addressed with this design. First, the amount of T.V. watching is likely to be correlated with LC/NC ad exposure. However, the key goal of this design is the assessment of increased "real world" exposure to the ads on LC/NC conservation tips. Thus, while the design cannot causally link increase repetition with program effects, it can: 1) describe the pattern of behaviors and ad exposure found in the sample population; and 2) through careful analysis constrain the ability of alternative hypotheses to explain results. In addition, the correlation between ad exposures and LC/NC behaviors is most likely to be explained by overall television watching behavior in cases where ad exposure and LC/NC behavior are linearly related.

As mentioned earlier there are two secondary goals for this study. The exposure to the ads can confirm the advertising buying decision used in this program. The advertising was purchased on the basis of cumulative gross rating points that indicated 81.5% of the population would be exposed to LC/NC ads at least 12 times. The pattern of exposure of this panel to the ads can confirm (or disconfirm) the efficacy of this media buying decision.

Further the results of the survey can serve as a comparison to the end-results evaluation methodology in terms of the penetration of the LC/NC behaviors.

The Memorability of the LC/NC Ads. In order to determine the role of paid advertising in the effects of the LC/NC program, it is necessary to rule out an alternative hypothesis that the ads cannot contribute due to poor communication effectiveness. This essentially asks "Do the LC/NC ads have the communication potential to contribute?"

This task was accomplished by testing the recall of the LC/NC ads with a random sample of commercial viewers the day after the first exposure to the ads. These tests were run on November 9 in Boston with a sample from each of the

two versions of the LC/NC ad. The sample (n=305) was screened to make sure they were in the commercial audience, and were then asked to recall the commercial and its messages. The commercial recall is then compared to industry norms for 30 second product commercials, and, in addition, the messages recalled were compared to the intent of the LC/NC program.

Thus, the diagnostic goals approach has resulted in a multi-method approach to the evaluation of the LC/NC program. This multi-method design has the advantages of removing much of the need for post-hoc guesses as to the reason for program effects and, as the next section indicates, the results provide a more complete profile of program impact.

Relating Research Output to the Research Questions

As stated earlier two research questions guided the research design. Presented below are several highlights of the results of the diagnostic evaluation of the LC/NC program.

What were the program effects?

- .. Readership of the LC/NC booklet was high (71.1% of the sample in New England).
- .. Four out of eleven LC/NC energy conservation tips evidenced significant (p<.05) improvement when comparing New England to New York.
- .. New England had completed more LC/NC energy saving tips than New York (New England 4.63 v. New York 3.96; t = 5.0, p<.001).

- .. The biggest predictor of the degree of response to the program was the amount of prior behavior. Those with the greatest response to the program had completed significantly fewer LC/NC tips prior to the program.

The results of the second research question yielded similar diagnostic findings:

- What was the relationship of paid television advertising to program effects?
 - .. The recall study indicated the LC/NC ads communicated as well as the normal 30 second commercial.
 - .. The 25% savings claim was recalled as a poor third selling point. This took on added meaning when it was found that those believing this claim did more LC/NC tips.
 - .. Advertising exposure was related to enhanced program effects when increasing exposure from very low levels (0 to 1 exposure per week) to 1 to 2 exposures per week. However, further increases in exposure were found to be a significant decrease in LC/NC behaviors. This raises the specter of an early wear out for this type of ad, and questions the use of a decision rule which is founded in a "more the better" philosophy for the use of advertising in conservation programs.
 - .. Only 9% of the males and 22% of the females reached the level of exposure that the cumulative gross rating point media-buy decision rule had indicated.

The above are highlights of the results of the LC/NC impact evaluation which attempted to empirically diagnose as well as evaluate the effects of the program. Several implications emanate from this example of perspective on evaluation.

Implications

Evaluation research is not a discipline but rather a conglomeration of applied scientists attempting to provide empirical data to policy makers regarding the effects of a public program. This lack of organization results in a very complex and important area receiving little attention and almost no systematic feedback to the impacted disciplines.

In addition, for several reasons the researcher cannot go to the policy maker for guidance. The policy maker does not have adequate training to judge research methodology and policy makers are, at the very least, hesitantly supportive of evaluation. The implication of the two previous points places a great burden on the internal standards of the researcher.

A number of factors make the decisions in research methodology difficult ones. Several of these factors are attendant to the policy programs themselves. The timing of the planning for research is often short due to the fact that evaluation is generally one of the later program decisions. This often precludes taking premeasures and places a constraint on the time for planning of the research design. In addition, decisions for future policy often have to be made before the research is completed so the research often fails to play its proper role in program planning. Also, the nature of policy programs often preclude the development of a proper control condition or make difficult the

identification of properly matched groups. Finally, the orientation of evaluators is heavily toward survey-type designs and to single-method evaluation studies. Both of the latter are severely limiting decisions.

There are clear advantages to attempting causal designs in establishing program effectiveness, ruling out alternative hypotheses, and removing the need for post-hoc theorizing in explaining results. Of equal significance is the need for multiple-methodologies to fully profile program effects. The most common perspective to evaluation is to provide end-results data. However, this ignores the fact that programs are part of an on-going activity which needs to understand program effects as well as document them. This highlights the inherent deficiency of any single study to measure impacts as well as diagnose the results for understanding. But, this often means that the individual studies undertaken may, when taken alone, evidence deficiencies. These deficiencies, however, must be taken in light of the complete profile of the evaluation effort.

This paper has presented the methodological decisions of a recent evaluation effort for the LC/NC program. In this evaluation multiple-methods were used to both strengthen the conclusions of program effects through convergence of the results of the various studies, and to provide diagnosis so that future programs could benefit from the analysis of the LC/NC tactical decisions.

RISK-BENEFIT ANALYSIS AND THE DETERMINATION OF ACCEPTABLE RISK¹

Rachel Dardis, University of Maryland
Julie Stremel, Arthur Young and Company

Abstract

Consumer safety has been regarded as a major consumer issue for many years. In recent years, this has resulted in considerable debate concerning "how much risk" is acceptable. The objectives of this paper were to develop a methodology for assessing risk and to apply the methodology to a selected consumption activity. The results indicate the role of risk-benefit analysis in the identification of "high-risk" consumption activities. This type of screening is important in view of resource limitations which preclude the development of risk reduction strategies for all consumption activities.

Introduction

Consumer safety has been regarded as a major consumer issue for many years. While there is general agreement that consumer safety can and should be increased, there is less agreement concerning the level of safety that should be achieved. Proponents of zero risk argue that no risk is acceptable though the attainment of zero risk in a complex technological society such as the United States has been challenged with respect to both feasibility and desirability. The rejection of zero risk leads, in turn, to the question of "how much risk" is acceptable. Unfortunately, the frequently used argument that any risk is acceptable as long as the expected benefits are greater than the expected costs neglects the costs of developing risk reduction strategies for a wide spectrum of consumption activities. The costs of obtaining such information may be far greater than the potential benefits.

The objectives of this paper were to develop a methodology for assessing risk and to apply the methodology to a selected consumption activity in order to demonstrate the feasibility and utility of risk-benefit analysis. The results should provide policy makers with a method for assessing risk. Risk assessment may then be used a) to obtain information concerning the level of risk to which consumer are exposed and b) to rank activities with respect to risk.

Need for Risk Assessment

Deaths and injuries involving consumer products pose serious social and economic problems in the U. S. It is estimated that approximately 20 million Americans are injured each year in the home as a result of accidents involving consumer products (National Commission on Product Safety 1970, National Safety Council 1978). The annual cost to the nation has been estimated at more than \$5.5 million.

The Consumer Product Safety Act which was passed in October 1972 was designed to protect the consumer from unreasonable risk of injury. A Consumer Product Safety Commission (CPSC) was established with jurisdiction over more than 10,000 consumer products. The Commission was granted authority to "develop, promulgate and enforce safety standards for consumer products and to inform the public concerning significant hazards associated with consumer products".

The number of consumer products which are subject to regulatory activities presents problems as the Commission acknowledges.

"It is not difficult to know when the need exists to ban an obviously dangerous or hazardous product.

But it is difficult to determine which of more than 10,000 consumer products are of the greatest risk to consumers all over the country and which of these products are the likeliest candidates for safety standards without undue cost to the consumer." (U.S. Consumer Product Safety Commission 1973)

In view of the impossibility of dealing simultaneously with all consumer products, it is necessary to establish a basis for ranking products with respect to unreasonable risk. One method for ranking products was the hazard index developed by the Consumer Product Safety Commission in 1973 and revised in 1975. The index was based on frequency and severity of injury. Accident frequency was obtained from NEISS data while severity values were based on type of injury and necessity for hospitalization. Severity values in the 1975 and 1976 hazard indices are given in Table 1. (U.S. Consumer Product Safety Commission 1976).

TABLE 1

SEVERITY VALUES USED IN CPSC HAZARD INDEX

Severity Category	Severity Value
1 = Mild injuries/small areas, dermatitis and sprains	10
2 = Punctures - fractures	12
3 = Contusion - scalds	17
4 = Internal organ injury	31
5 = Concussions - cell and nerve damage	81
6 = Amputations - crushing and anoxia	340
7 = All hospitalized category sixes	2,516
8 = All deaths	2,516

Categories 1 to 5 were increased by one severity value if the injury resulted in hospitalization. Similar values were used in the 1973 hazard index with the exception of category 8 where a value of 34,721 was assigned in place of 2,516.

A Frequency Severity Index (FSI) was obtained by multiplying the frequency of injuries in each severity category by the corresponding severity values. The Age Adjusted Frequency Severity Index (AFSI) differs from the FSI in that injuries to children under 14 are first multiplied by 2.5 in order to provide special consideration for this age group. The AFSI is the hazard index employed by the CPSC. In issuing the hazard index, the Commission noted that "a product does not have to be high on this list to receive Commission action but those high on the index are more likely to receive early attention".

¹University of Maryland Agricultural Experiment Station
Article No. A-2828.

The hazard index was criticized with respect to the particular severity values since there was no indication that the values were related to the economic consequences of a particular type of injury. As a result, the hazard index was replaced in 1978 by numbers of injuries involving various products. While the use of a simple numerical index avoids the bias associated with an incorrect severity scale, it provides less information to the policy maker. The new numerical index also has many of the same limitations as the discontinued hazard index.

First, neither index considers the number of products in use nor the degree of product usage by the consumer. Thus, products with the same number and types of injuries could be viewed as equally hazardous though hours of exposure might differ to a considerable extent. Both Lowrance (1976) and Rowe (1977) have discussed the need for including hours of exposure in any risk assessment.

Second, consumption benefits are ignored. However, the need for including product benefits in any evaluation of risk has been pointed out by Starr (1968, 1972), Clark (1969), and Dickerson (1968). Starr used consumer expenditures for an activity as a measure of benefits and concluded that the public was willing to accept a relatively high level of "voluntary" risk. Clark examined the conditions under which a product might be considered reasonably safe. His hazard index included injury severity, number of products used per year, costs of avoidable injury, costs of safety improvements and importance of product use. The first four terms in the hazard index represented the ratio of the costs of injuries avoided by a safety improvement to the costs of making the safety improvement. The fifth term - importance of product use - reflected the degree of product substitution since "a hazard is more grimly accepted as "reasonable" if there is little alternative to the use". Dickerson pointed out that "the mere fact that a product is dangerous is not enough; it must be unreasonably so". He also noted that it is not possible to achieve complete safety and that the need for and utility of the product should be considered in product regulation.

It is important, therefore, to consider both the costs and benefits from a particular consumption activity in evaluating risk. Risk-benefit analysis is a technique which may be employed to assess the costs and benefits of a given activity, which involves risk. Risk assessment includes both the probabilities of various outcomes and the consequences of such outcomes expressed in dollar terms. Benefit assessments measures the benefits to the individual and society from the given activity.

Interest in risk-benefit methodology as a decision-tool for evaluating risks with respect to public health and safety was evidenced in two conferences which were held in 1971 and 1975. The first conference was organized by the Committee on Public Engineering Policy, National Academy of Engineering who noted that there "had been neither extensive public discussion or formal attention devoted to the subject or the emerging technique of benefit-risk analysis" (National Academy of Engineering 1972). Topics discussed at the conference included data requirements for decision-making, the process of risk-benefit analysis and the problems of implementing good analyses.

The second conference was part of a National Science Foundation funded study at UCLA entitled "A General Evaluation Approach to Risk-Benefit for Large Technological Systems and Its Application to Nuclear Power" (Okrent 1975). The major emphasis of the conference was risk assessment and two large technology areas were considered - nuclear reactors and the shipment and storage of liquified natural gas. Risk assessment utilized probabilities of various outcomes and the consequence of such outcomes to estimate

the expected loss from a particular activity. Consideration was also given to the determination of acceptable levels of risk. Besuner and Gibson focused on risk per hour of exposure and concluded that the risk associated with a product or activity was acceptable if it fell at the lower end of the scale. Wiggins noted, however, that several factors might be responsible for discrepancies in risk per hour of exposure including benefit differences which would warrant a higher risk for some activities. In the case of man-made hazard, he emphasized that benefits must be weighed against the risks. This was also the opinion of Oberbacher who concluded that it was important to assess both the risks and benefits from a given technology.

Risk assessment was also the focus of a recent symposium which was held at the National Meeting of the American Chemical Society (American Chemical Society 1977). The introductory paper by Lowrance included a discussion of acceptable risk and procedures for determining acceptable risk. Lowrance defined safety as a judgement of the acceptability of risk but noted that "it is not often clear who should decide the acceptability of what risks, for whom and on what terms and why". Lowrance also stressed the need for "adequate socio-political decision-making tools" commenting that while the concept of "safety" is poorly understood, the concepts of "efficiency, cost, benefit, and other decisional attributes may be even less well understood".

The advantages of risk-benefit analysis with respect to risk evaluation are as follows:

- a) It serves as a basis for comparing products since it includes both the costs and benefits of a consumption activity. In contrast, hazard analysis ignores the need for and the utility of the product to the consumer.
- b) Risks and benefits pertain to the same period of time so that it is not necessary to estimate hours of exposure. Benefit analysis is based on consumer expenditures per unit of time (hour, day, week, year). Risk analysis is also based on the same unit of time. Thus, the number of hours of exposure per unit of time is immaterial. While risks and benefits pertain to product use per unit of time is not necessary to estimate hours of exposure since it affects both risks and benefits equally. In contrast, hazard analysis is confined to risk so that hours of exposure are important. Lack of information concerning consumer product usage may limit the employment of hazard analysis in risk evaluation.

Risk Assessment Model

The following assumptions were used for the risk assessment model proposed in this paper.

1. Accident probabilities and economic consequences of accidents vary by accident severity, e.g., fatal injury, major injury, minor injury.
2. Each product in a consumer product category (e.g., bicycles, ovens) has an equal probability of being involved in an accident of a given severity and will incur the same accident costs. However, this probability may vary between product categories.
3. The value attached to a consumption activity is equal to its ownership costs.
4. Risks and benefits from ownership pertain to the time of consumption, i.e., only risks and benefits are incurred during product use.

Relative risk is then given by $w'x/v$ where x is a column vector of increases in various types of injuries due to the activity, w is column vector of the costs of injuries and v is the value attached to the activity by the consumer. The term $w'x$ may be considered the expected loss from a particular consumption activity. Ownership costs reflect the willingness to pay for a consumption activity and include both acquisition and maintenance costs. In contrast to ownership costs which are incurred by all consumers, accident costs are borne by only a small group of consumers. Expected loss is a measure of this uncertain prospect.

In the derivation of risk-benefit ratios, the term $w'x/v$ may be re-written as follows:

$$w'x/v = (P_f C_f + P_n C_n) / V \quad (1)$$

where P_f = increase in probability of fatal injury
 P_n = increase in probability of non-fatal injury
 C_f = Cost of fatal injury
 C_n = cost of non-fatal injury, and
 V = ownership cost

The above equation may be re-written as

$$\frac{(N_f/Q)(C_f) + (N_n/Q)(C_n)}{V} \quad (2)$$

$$\frac{N_f C_f + N_n C_n}{VQ} \quad (3)$$

where N_f = number of fatal injuries
 N_n = number of non-fatal injuries
 Q = number of products in use, and
the other terms are as defined earlier.

The numerator in equation (3) is the total costs of accidents involving consumer products while the denominator is the total ownership costs associated with such products.

Application of Model

The risk-benefit model was applied to seven categories of adult clothing. The seven items selected were based on their consideration as possible candidates for flammability standards. (Product Safety and Liability Reporter 1974, National Cotton Council of American 1974, Simon et al. 1975).

The seven categories examined were: a) women's robes and housecoats, b) women's nightgowns, c) women's pajamas, d) men's pajamas, e) women's dresses, f) men's shirts, and g) men's pants.

Ownership costs and accident costs were derived for purchases in 1976 and all cost estimates were expressed in constant 1976 dollars.

Accident Costs

The direct costs of accidents were the medical costs while the indirect costs were the earnings foregone due to accidents (Dardis 1978). The present value of foregone earn-

²Market prices are used to represent the value attached to the last unit purchased of a good or service. Such prices reflect "value in exchange" as opposed to "value in use". However, the two are inter-related since the consumer's willingness to pay is based on the utility from the product or the perceived value in use.

ings was used in the case of death. Two discount rates - 5% and 10% were used to obtain present value estimates.

This measure neglects the pain and suffering component associated with accidents. While some agencies such as DOT have used court awards for pain and suffering to reflect such costs, this measure has generally been regarded as unreliable due to the extreme variability of court awards and the fact that only a small proportion of accident cases are decided in court (Dardis 1978). The omission of pain and suffering costs need not invalidate the ranking of products with respect to acceptable risk if it is assumed that this cost component is proportional to the sum of direct and indirect costs. Under this assumption, all risk-benefit ratios will be increased by a constant factor leaving product rankings unchanged.

Ownership Costs

It was assumed that the various clothing categories were non-durable goods with an expected life of one year. Ownership costs were based on total consumer expenditures for the particular clothing category in view of lack of data concerning maintenance costs for clothing. However, maintenance costs for most clothing items are likely to be small in view of the importance of easy care clothing in 1976. In addition, specific clothing items comprise only a small portion of total clothing consumption so that their contribution to total maintenance costs is likely to be small.

Extension of product life does not have a significant impact on risk-benefit ratios. For example, if the expected life is assumed to equal two years, then a first approximation of the present value of costs from purchases in 1976 is given by

$$0.5C_{1976} + (0.5C_{1977}) / (1+i) \quad (4)$$

where C = costs of accidents due to the activity and
 i = discount rate.

If the number and severity of burn accidents is similar in 1976 and 1977, then the present value of costs from purchases in 1976 is given by

$$0.5C_{1976} + (0.5C_{1976}) / (1+i), \text{ or } 0.95C_{1976} \quad (5)$$

for a 10% discount rate. The assumption of an expected life of one year when the average product life is greater than one year will thus serve to underestimate accident costs. However, such underestimation is likely to be small in the case of non-durable goods.

Provision for Imports

Consumer expenditure data were based on U.S. value of shipments. However, accident costs pertained to total U. S. consumption which included imported garments. Accident costs pertaining to U. S. shipments were based on the relative importance of U. S. shipments. According to a recent study by the Council on Wage and Price Controls (1978) domestic production accounted for approximately 90% of domestic consumption in 1976. Thus, 90% of U. S. accident costs were attributed to U. S. production.

Results

Consumer expenditures on U. S. merchandise in 1976 were based on U. S. value of shipments and retail mark-ups for the different clothing categories (U.S. Department of Commerce 1977, National Cotton Council 1974). Expenditures ranged from \$713.46 million for men's pajamas to \$3,735.22 million for men's pants. Based on the assumption that garments have an expected life of one year and zero maintenance costs, total consumer expenditures in 1976 are equal to total ownership costs in 1976. Ownership costs are given in Table 2.

TABLE 2

RETAIL VALUE OF U. S. CLOTHING SHIPMENTS IN 1976^a
(\$ Million)

Category	Value of Shipments
Women's Robes and Housecoats	577.08
Women's Nightgowns	710.53
Women's Pajamas	209.29
Men's Pajamas	173.46
Women's Dresses	3,198.13
Men's Shirts	2,366.70
Men's Pants	3,735.22

^aWholesale value of shipments increased by retail markups (National Cotton Council 1974)

Accident Costs, 1976

The number of injuries for each category was based on a total burn injury estimate of 60,000 for all ages in 1976 (U. S. Department of Health, Education and Welfare 1976). Data from the National Center for Health Statistics was then applied to this estimate to obtain the number of adult burn injuries, ages 13 and above (U. S. Department of Health, Education and Welfare 1977). The number of adult clothing burn injuries was based on a low estimate from the New York State Department of Public Health (1977) and a high estimate from the National Burn Information Exchange (U.S. Department of Health, Education and Welfare 1971). The resulting low and high adult clothing burn injury estimates range from 5,213 to 17,798. It should be noted that the high estimate from the National Burn Information Exchange (NBIE) reflects the fact that most cases from this data source are characterized by severe burns and hence are more likely to involve clothing. The New York State study includes all types of burn injuries and probably presents a more realistic picture of clothing involvement.

Adult clothing death estimates were based on data from the National Center for Health Statistics (U. S. Department of Health, Education and Welfare 1977) and the National Fire Protection Association (1969). The number of deaths ranged from a low of 459 to a high of 801.

The distribution of injuries and deaths for each adult clothing category was based on data from flammable fabrics investigations conducted by the Consumer Product Safety Commission (1975). The results are given in Table 3. The number of injuries is considerably higher than the number of deaths in all instances. The men's shirt category has the highest number of burn injuries while men's pajamas have the lowest number of injuries. The women's robes and housecoat category has the highest number of deaths while women's pajamas have the lowest number of deaths.

TABLE 3

NUMBER OF CLOTHING BURN INJURIES AND DEATHS
ATTRIBUTED TO U. S. SHIPMENTS IN 1976^a

Category	Injuries		Deaths	
	Low	High	Low	High
Women's Robes and Housecoats	460	1570	92	159
Women's Nightgowns	346	1179	43	76
Women's Pajamas	258	882	16	28
Men's Pajamas	104	355	21	37
Women's Dresses	255	870	27	49
Men's Shirts	683	2332	79	138
Men's Pants	339	1158	35	60

^aBased on the assumption that domestic production equals 90% domestic consumption (Council on Wage and Price Stability 1978, p.58).

The direct costs of burn injuries and deaths were based on length of hospital stay, which varied according to burn severity. Length of hospital stay ranged from 32-124 days which included an allowance for readmission and retreatment while a weighted average of 17 days was used for deaths (Dardis 1978). Hospital costs for flammable fabrics victims were estimated at \$333.00 per day and served as a basis for estimating total medical costs. Data from Rice (1966) and the Social Security Administration (Gibson and Mueller 1979) indicated that hospital costs accounted for 59% of total medical expenses for injuries.

The indirect costs of injuries were derived from the probability of working or housekeeping, number of days lost from working or housekeeping, and mean earnings. In the case of death, the present value of future lifetime earnings was obtained using 5% and 10% discount rates. Total direct and indirect costs of burn injuries and deaths are given in Table 4 for a 10% discount rate. Injury costs based on low injury estimates range from \$4.35 million for men's pajamas to \$27.94 million for men's shirts. Injury costs for high injury estimates range from \$14.84 million to \$95.41 million for the same two clothing categories.

TABLE 4

COSTS OF CLOTHING BURN INJURIES AND DEATHS
ATTRIBUTED TO U.S. SHIPMENTS IN 1976
(\$ Million)

Category	Injuries		Deaths ^a	
	Low	High	Low	High
Women's Robes and Housecoats	19.66	67.14	2.04	3.47
Women's Nightgowns	13.98	47.74	1.36	2.45
Women's Pajamas	9.55	32.60	0.70	1.12
Men's Pajamas	4.35	14.84	0.75	1.40
Women's Dresses	10.93	37.33	0.61	1.26
Men's Shirts	27.94	95.41	4.02	7.03
Men's Pants	13.58	46.39	2.17	3.73

^a10% Discount rate.

The costs of burn deaths are considerably lower reflecting the small number of burn deaths relative to burn injuries. As a result, the use of a 5% discount rate in place of a 10% discount rate had little impact on the total costs of burn injuries and deaths.

Risk-Benefit Ratios: 1976

The ratio of total accident costs and total ownership costs is given in Table 5 for each of the seven categories. In the case of low cost estimates, the ratios range from 0.004 for men's shirts and pants to 0.049 for women's pajamas. This means that every dollar spent on men's shirts or men's pants has an expected loss of less than half a cent. In contrast, an expected loss of approximately 5 cents is associated with every dollar spent on women's pajamas. If one wishes to consider the expected loss as a type of risk tax, then the risk tax for sleepwear is the same order of magnitude as a sales tax while the risk tax for daywear is considerably lower. However, an essential difference between the risk tax and the sales tax should be emphasized. All consumers pay a sales tax while no consumer pays the specific risk tax. Some consumers (those involved in accidents) pay considerably more than the risk tax while other consumers pay nothing. For society as a whole, the risk tax is as meaningful as a sales tax since it indicates the total costs of accidents associated with a particular consumption activity.

TABLE 5

RISK-BENEFIT RATIOS FOR VARIOUS CLOTHING CATEGORIES

Category	Risk-Benefit Ratio	
	Low ^a	High ^a
Women's Robes and Housecoats	0.038	0.122
Women's Nightgowns	0.021	0.071
Women's Pajamas	0.049	0.161
Men's Pajamas	0.029	0.094
Women's Dresses	0.013	0.043
Men's Shirts	0.004	0.012
Men's Pants	0.004	0.013

^aPertains to low and high estimates of the number of burn injuries and deaths.

In the case of high cost estimates, the risk is higher as might be expected. The risk tax for sleepwear ranges from 7% to 16% while the risk tax for daywear ranges from 1% to 4%. However, risk taxes based on high cost estimates are probably overstated since they are based on data from the National Burn Information Exchange which are biased in favor of clothing burns.

It is also of interest to compare the data in Table 3 and 4. Absolute costs of accidents in the case of daywear are highest for men's shirts followed by men's pants and women's dresses. However, when risk-benefit ratios are examined, women's dresses emerge as the highest risk category followed by men's shirts and pants. Similar reversals occur with respect to sleepwear with women's pajamas replacing women's robes and housecoats as the highest risk category.

Discussion

The results of this study indicate that considerable variations exist with respect to risk benefit ratios for the various adult clothing categories. Risk-benefit ratios for sleepwear are far higher than risk-benefit ratios for daywear. If low cost estimates are accepted, intervention in the case of men's shirts or pants is unnecessary. In contrast, the data for women's sleepwear provide support for intervention. This intervention may be a flammability standard similar to that used for children's sleepwear or it may be an educational program. Both types of intervention could be undertaken by the Consumer Product Safety Commission. An alternative strategy might be the voluntary marketing of more flame retardant garments by the apparel industry. Such marketing would have to be accompanied by an educational program since consumers, in many instances, are unaware of the hazards from flammable fabrics or the need for protection.

Other results of the study are also of interest. First, the proposed method for assessing risk appears feasible. The assignment of economic consequences to various types of injuries permits comparison between products with more than one type of injury. Ownership cost data may be obtained from consumer expenditure data, product life estimates, and maintenance cost data.

Second, risk-benefit analysis provides insight concerning the level of risk to which consumers are exposed. The issue of prevailing risk is of particular importance since a society that is not risk-free must decide what level of risk requires intervention. If there is no basis for determining when intervention is necessary then risk reduction activities may be ineffective, i.e., we may concentrate on low risk areas and ignore high risk areas.

Finally, it should be noted that risk-benefit analysis is only part of the risk reduction process. This type of analysis serves to indicate prevailing levels of risk and those areas where intervention may be desirable. Once the necessity for intervention is perceived, the selection of an appropriate strategy requires additional analysis. The main advantage of risk-benefit analysis pertains to its identification of risk levels and, in turn, those areas where intervention is necessary. This type of screening is important in view of resource limitation which preclude the development of risk reduction strategies for all consumption activities. Thus, in the case of adult clothing, alternative strategies should first be investigated for women's sleepwear. This investigation would, in turn, indicate if intervention were justified and the optimal intervention strategy.

SCIENTIFIC PROGRESS AND RESEARCH TRADITIONS IN CONSUMER RESEARCH

Liisa Uusitalo, International Institute for Environment and Society, Science Center Berlin
Jyrki Uusitalo, University of Helsinki

Abstract

This paper takes up some programmatic points related to the question of scientific dynamics in the field of consumer research. The article first takes a few steps in the direction of general conceptual analysis concerning the notion and problematics of progress in the field of social science, and then proceeds to discuss specific themes of present dominant research traditions in consumer research. Finally, it is argued that scientific progress in this area presupposes the development of new theories by comparing and weighting the relative merits and demerits of various traditions. Progress is not attainable merely by applying traditional models of consumption to new areas of phenomena. Alternative traditions and concepts should be proliferated on the field; this demand is also supported by the emergence of new societal problems pertinent to the field.

Scientific Progress and the Study of Social Science

Presently, the analysis of cognitive growth and progress discernible in various fields of scientific enterprise has become one of the key themes in the general philosophy of science. The "blockbuster" opening up this discussion was, as is generally known, the study by the American historian of natural science, Thomas S. Kuhn (1970). His study deals with so-called scientific revolutions, that is to say, global changes in the "paradigms" of natural science. These are changes in the scientific community's conceptual and methodological commitments that underlie scientific practice and that concern the subject matter and the methodology.

Kuhn's work itself brought about (or triggered off) some sort of "revolution" in the arena of science studies. Until then, in the wake of logical empiricism, the phenomenon of scientific progress itself had by no means been denied. However, it had been taken to consist mainly in a stepwise cumulative factgathering, and in the extension of previously well-confirmed theories, to cover new empirically observable phenomena. (For a good summary of this standard view, see e.g. Nagel 1961). Kuhn's dynamized vision of science also drew attention to the significance of the scientific community by stressing that the paradigm facilitates the professional communication and judgments. Kuhn's idea was also supported by a newly arisen interest in Kantian philosophies of science that stressed the dependence of scientific observation on some conceptual structure and emphasized the "theory-ladenness" of empirical facts and findings. (Such a philosophy is advocated by e.g. Popper 1965, ch. 3.)

All these arguments called the standard view forcefully into question. The new approaches also differed from one another in some significant points. For instance, Kuhn was stressing the significance of cumulative "normal-scientific" stages of work between the conceptual revolutions, whereas Popper and his disciples laid emphasis on a continuous active "proliferation" of several potentially falsifiable theories and the scrutinization of them against one another. (See Lakatos and Musgrave (eds.) 1970.) At any rate, nowadays at least, in the domain of natural sciences, a generally accepted view is that the philosophic work on foundational questions takes place in "dynamized" frameworks of some kind or another.

(For recent documentations of discussion, see e.g. Suppe 1978 and Niiniluoto & Tuomela (eds.) 1979).

One of these foundational issues is the problem of scientific progress. The new dynamic views of scientific activity have effectively helped scientists realize that progress in science is not necessarily guaranteed just by sticking to theories or theoretical structures that in the past have yielded the greatest number of successful predictions of phenomena. The new contributions in the philosophy of science have rather drawn general attention to the aspect of doing science which one might call, following Wartofsky (1976), "rational hopefulness" - that is, one's being able to choose on good grounds between rival research traditions and picking out those ones that most effectively helped one to tackle with the most important problems which the domain is facing. This precisely has been the background motive for some recent dynamic models of scientific activity that sharply dissociate themselves from the time-old empiricist tradition (Lakatos 1970, Laudan 1977).

Since the beginning of the above-described wave of discussion, attempts have also been made to thematize the field of social or "actional" sciences in a corresponding way. (For the case of sociology, see e.g. Friedrichs 1970 and Gouldner 1971; for economics, see Latsis 1976; for psychology, see Herrman 1976.) However, it seems that the overt plausibility of most of these studies (but not all of them) has often regrettably turned out to be illusory. Instead of first dealing with the important issue about the possible differences and contrasts between natural and social sciences, some authors have rather tended to pick out a priori some dynamic model of science and impose it on the discipline under study. Consequently, some of these studies have been inadequately treating the crucial question - that is, what kind of scientific knowledge is involved when the domain of human action is being studied.

For instance, Kuhn's dynamic model of science has frequently been used to describe paradigm change in social sciences mainly in terms of external factors (e.g., societal goal-settings and interests) affecting it. It is interesting to note, however, that Kuhn himself obviously did not intend his model of science to be understood in this sense only. Rather, he wanted to draw attention to the fact that science essentially is an activity of solving specific kinds of cognitive problems and always take place in a more or less well-established context of beliefs and assumptions about the disciplinary subject matter shared by the community of scholars in the field.

However, the notion of problem solving as a criterion of paradigm choice should not be understood in a straightforwardly "sociopragmatic" sense. For example, in the case of social science, it does not suggest the simple idea that science has just to solve externally determined "problems", but rather that cognitive activities in science also contribute to the structuring of the problems themselves.

In Kuhn's opinion, as is well known, the periods of stable "normal science" activity consist of attempts at making freshly observed phenomena intelligible in terms of the generally adopted set of beliefs about the subject matter of inquiry. Now, this idea of Kuhn's is obviously not directly applicable in constructing a "dynamized" model of

social sciences. In these sciences, we are not dealing with a stable domain or reality which determines the research in the same way as "nature" does for the natural sciences; the social reality is always essentially constituted by human actions as well. (On this criterion demarcating between natural and social science, see Krüger 1979.) And, this is why it is hardly conceivable that one single "normal scientific" tradition could be reigning in any particular social-scientific discipline.

Social sciences would also seem to dispose over normative criteria of theory choice that are themselves continuously changing. The overall idea here, then, is that in social science, especially when a newly emerging and largely interdisciplinary field like consumer research is at stake, the choice of the most promising - i.e. progressive - research traditions is not a matter of arbitrary decision but must itself be grounded on rational appraisal concerning the long-term problem-solving efficacy of various theoretical alternatives as well as their capability of initiating inquiry in new fields.

Research Traditions in Consumer Research

Consumer research, as a newly emerging discipline, consciously thematizes itself in terms of a specific, even restricted sub-area of social behavior - that is, consumer behavior. Here, we meet a rather clear-cut case where a previously unknown area or subject matter has been repeatedly shaped up more or less by analogy with the practices of some already well-established social science, be it economics, psychology or sociology. For the theory formation and the choice of consumer theories taking place within any of the thus constituted traditions, different and often extensive lists of criteria have been suggested. (see e.g., Zaltman et. al. 1973, Bagozzi 1976a). An empiricist philosophy of science has often been dominating these texts. Also, some ideas from more recent, so-called realist philosophy of scientific explanation have been utilized in some cases, but the perspective has been mainly on a rather general programmatic level (e.g. Bagozzi 1976b).

When it comes to the consumer theory appraisal internal to some tradition, the term 'theory' in this context, is taken to mean various systems of propositions or models that explain certain given phenomena, i.e., a given subject matter. (For instance, Zaltman et. al. 1973 compare the consumer models presented by Howard & Sheth, Nicosia, and Engel & Kollat & Blackwell, all of these describing the decision processes of individual consumer choices.) In all, scientific criteria have been used predominantly in evaluating theories within one consumer research tradition, rather than in evaluating different research traditions or paradigmatic belief systems.

Actually, one might venture to suggest that in this discussion, the famous Kuhnian view of one dominating "paradigm" at a time has been taken for granted, even though rather implicitly, and consequently, consumer research has been treated as being constituted by a single paradigm. However, the Kuhnian idea of the sequential development of a given discipline between the stages of stabilized "normal science" has also been explicitly disputed even by authors active in this area, maintaining that consumer research as a field, in fact, consists of several simultaneous and competing "paradigms" or research traditions. (For example, Bagozzi 1976b presents this view by analyzing competing paradigms in "macro marketing". All macro paradigms, in turn, seem to compete with the prevailing micro approaches which unfortunately have not been discussed in detail.)

In fact, the view of several competing traditions in explaining different kinds of consumption phenomena appears

also in the critique of psychological reductionism in present-day consumer research as well as in several calls for a different research approach that would allow an analysis of social phenomena which the psychologically oriented models never do bring into focus (e.g. Glock & Nicosia 1964, Levy & Zaltman 1974, Zaltman & Sternthal 1975, Angelmar & Pinson 1975, Arndt 1976, Mayer & Nicosia 1977, Bagozzi 1978, Jacoby 1978).

In a cross-scientific discipline like consumer research, it is, in fact, obvious that more than one research tradition will be present simultaneously rather than sequentially. As the situation now is, it seems, however, that these research traditions develop rather isolated from one another, and there seem to be very few integrating links between them. Therefore, it would seem to be more motivated to talk about a multi-disciplinary rather than an interdisciplinary discipline.

While some of these research traditions have been and still are very dominating, some others, in their turn, have for some reason or another been receiving less emphasis than they would obviously earn if certain criteria would be adopted which evaluate scientific progress based either on the potential problem-solving efficacy or on the capability of initiating theories for new fields of scientific inquiry.

When one takes a look back in time at the proceedings of all the ACR conferences or a look at some of the principal scientific journals where consumer research and its findings have been documented over the last ten years or so, one easily gets an impression of the overwhelmingly strong position of psychological research tradition in consumer research. In addition, most of the social-psychologically oriented research, say, research on social group influence or personal influence and its impact on consumption, is classifiable under this heading.

The subject matter of this tradition is constituted by individual product choices or decision processes leading to a choice. Among choices, the brand choice has been given an astonishingly strong emphasis in empirical research. The rapid development of the psychologically oriented research tradition - in a close connection to marketing research - is associated with the expansion of consumption in the 1960's and 1970's and the corresponding needs of competitive marketing. The formal development in cognitive psychology, from which the most significant models were taken, and the development of experimental research methods and multivariate analysis techniques, of course, have also contributed to the cumulative efforts and relatively high consensus on the constitution of the subject matter in this research tradition.

The approach being basically more or less predictively - and often even manipulatively - oriented in its workings, the realism of its background assumptions about the nature of human behavior has not been much of a problem to the advocates of this school.

The stronger a tradition becomes institutionally, the more difficult it often seems to be to bring up alternative research traditions that do not rely on the methodological individualism or readily received quasi-natural-scientific or positivistic view of science, cherished by the psychological paradigm and its underlying concepts of human action.

Actually, here, even the basic scientific terminology has been "psychologically biased". For example, if one presents the idea that consumption should be studied more than it has been hitherto in association with social factors or in itself as a social phenomenon, one easily meets the objection that such things already have been taken into account. Now, social, cultural and institutional factors, are, however, in these psychological or "social influence"

models frequently reduced to an individual level and often presented in a more or less ad hoc fashion as so-called situational micro-level factors. Social factors associated with any macro-level social theory do not appear, with the possible exception of some eclectic studies concerning the significance of certain separate variables (like social class).

In fact, it is somewhat ironic that the defenders of present-day dominant psychological or social-psychological approaches in consumer research, who in their work implicitly accept this as the only legitimate research, do not seem to take into account that this tradition was originally started as (and still is) a competing tradition to the "pure" neo-classical economic consumption theory which was then considered to make too strong assumptions concerning consumer rationality and to lay too little emphasis on the changes in consumer preferences. The idea of the formation and change of preferences - however, mainly applied to brand preferences only - became, for pragmatic reasons, one of the main subjects of interest in the marketing-oriented consumer research during the 1970's.

There seems to be only a few connections between the psychological "behavioral" consumer research and the neo-classical economic consumption theory, which both have developed in separate scientific surroundings - the former among marketing-oriented researchers and the latter among economists. However, some models within the two traditions seem to lend support to one another very clearly. For instance, Lancaster's model of the maximization of utility received from different product characteristics is in accordance with the cognitive attitude or brand preference models. Basically, all "psychological" brand preference models are based on the same neo-classical idea of individual utility maximization as is the economic theory of consumption functions. (Therefore, there must also be more or less institutional, external reasons which could explain the divergence between economists on one hand and behavioral consumer researchers on the other.)

A Challenge for Alternative Research Traditions

A positivistically modelled view of science seems to be common to both the neo-classical economic theory of consumption and the psychologically oriented research tradition. For example, the use of empirical findings and empirical research dealing with tendencies of human behavior on a societal scale as an aid to developing concepts or testing their construct validity is strikingly unusual in these approaches. And, empirical research is more often being considered just a case of hypothesis testing even in situations where there do not yet exist any theoretical concepts or propositions grounding the formation of hypotheses.

Now, a first step towards evaluating the merits and demerits of these discussed traditions is to take their ideas about the subject matter of consumer research under a critical scrutiny. The domain of economic activity seems to have been in fact treated in a quasi-naturalistic way here, and by means of a methodology modelled on natural science.

The quasi-naturalistic character of economic and behavioral models can be seen to consist primarily of two inter-related tendencies: (1) First, the tendency to stress that the basic task of economic science is to work out predictions of future observable phenomena and not bother about the possibly lacking realism of theoretical assumptions, i.e. the tendency to adopt an instrumentalistic philosophy of science. (2) Second, the tendency to make particular ontological and metaphysical assumptions, about the behavior of economic agents. In these

assumptions, the laws of rational economic activity are modelled on the idea of laws of nature in physical science. (For a critique of related ideas about the "plastic man", see Hollis 1977). Naturally, one here also should point out that the particular view of natural science adopted by the "quasi-naturalists" in social science is a through-and-through positivistic one, and that there are philosophies of natural science that sharply dissociate themselves from the above-mentioned basic tendencies (see e.g. Harré 1970).

Moreover, the dominance of individualistically and psychologically oriented models have in fact excluded many questions from the problem-solving field of the established traditions. Such questions obviously deserve consideration in light of recent work in social science generally - i.e., research in the general field of social studies that has contributed to a deeper understanding of societal processes which obviously have an influence on consumption activities (for example, studies on structural change in society, the emergence of so-called post-industrial life patterns).

Recently, in this connection, the qualitative aspects and consequences of consumption have emerged as a new subject matter about which we still possess relatively little scientifically grounded information. An analysis working to explain these features of consumption activity must include variables that deal with the institutional conditions and surroundings of consumption. Without resorting to such variables, for instance, a historical analysis of consumption does not seem to be possible; and moreover, these variables are apt to prove fruitful for an investigation of differences in existing consumption and life-style patterns.

Naturally, one must also add here that a mere aggregate-level analysis (in the spirit of the traditional pure economic approach) is not sufficient in analyzing the qualitative features and social consequences of consumption in modern societies; the study of consumption features typical of the different segments of society and its population is also necessary.

All of this would seem to signal the emergence of a fresh research tradition in consumer research, the historical-institutional tradition, which lays emphasis on the interrelations and interdependencies between consumption, economic structures of society, and the prevailing value and belief systems of human agents and groups. This approach is by no means totally new, as there have been several schools of thought since the last century that emphasize these interdependencies. (Most well known are perhaps the historic school in Germany, the Marxian school and the North American institutionalists, e.g. Veblen 1899. See also Seckler 1975.) Some other efforts to integrate the views of the economic and social sciences are exemplified in the works of Pareto 1935, Weber 1947, and Parsons & Smelser 1956. Thus far, however, these approaches have seldom inspired consumer research.

A cognitive choice in favor of any newly "budding" tradition, in contemporary circumstances, obviously cannot be grounded on only the quantitative appraisal of the number of significant empirical problems this tradition can solve or on phenomena it is able to explain by generating appropriate theories in the domain. The implementing of scientific progress in the presently discussed field involves, rather, the interesting task of finding a way of weighting the significance of empirical questions posed or, perhaps, even successfully answered by this approach, against the significance of problems posed or solved by the other traditions. Laudan (1977, p. 32) has put this general point in the following way: "If a philosophy of science, or a model of scientific progress, is going to be satisfactory, it must provide some guidelines not only for counting, but also of weighting, scientific problems on a scale of relative importance and cruciality."

One can easily see that the problem types of different traditions are not by far similar, which of course may make comparisons more difficult. However, even then it may be possible to measure and weight the efficiency of different traditions in the field by looking at the number of problems they solve and also the number and significance of problems they leave anomalous, that is, to be solved by some competing tradition. (On the role of problem-weighting in general, see Laudan 1977, 31-40.)

Ultimately, the weighting obviously also involves the comparison of the merits and demerits of the quasi-naturalizing and largely empiricist traditions on the one hand, and an interdisciplinary tradition enabling one to formulate several sorts of research tasks dealing with the social phenomenon of consumption, on the other hand. And, in dealing with a discipline that concerns itself with aspects of the human domain - i.e., consumption activities and their societal context - one might do well in opting for traditions that are most likely to do justice to the peculiar subject matter of social reality. The significant aspects of this reality can hardly be captured in terms of the utility-maximizing assumptions of established theories of economic rationality, even though the work done by these research traditions, when measured purely in terms of the quantitative magnitude of problems solved by them, may be impressive. After all, these research traditions are likely to leave many empirical problems about consumer behavior in its societal context unanswered.

The Challenge of Solving New Social Problems

The above presented criticism concerning the two most dominating theoretical research traditions in consumer research, economic consumption models and psychologically oriented consumer behavior models, is not to deny their obvious advantages in solving a number of research problems in the future as well. But, one cannot avoid seeing that they - bound to their specific type of models and methods - have also very much influenced the idea of what kind of problems have been considered to be "important" and "worthwhile" as a target of research in consumer science. Moreover, in both established traditions, a danger exists of treating existing theories as capable of solving all new problems too, and of explaining all new empirical social phenomena as well. That would mean sticking to the old, non-dynamic view of progress in science.

As an example of new social phenomena which call for new theory building, we can mention consumption-related environmental problems. It is true, for example, that economic demand functions or consumer attitude models can be applied in predicting consumers' reactions to certain parameter variables in affecting the environmentally relevant choices. The explaining and understanding of the causes of ecological damages, however, is possible neither in the pure framework of economic theory of consumption functions nor in any psychological information processing or group influence models. Neither do some eclectic middle range theories, borrowed from social science, prove very satisfactory as a basis of explanation.

What in fact are needed in this case are theories that lay emphasis on historic-institutional, cultural and economic development of societies or theories that describe the intermitting mechanism by which this development is reflected in micro-level consumer behavior. Of course, new concepts and theories do not emerge out of nothing. Therefore, they essentially have to integrate existing knowledge from different research traditions.

This integration work, at the same time, should be based on the motive of working out a methodology and philosophy of consumer research that dissociates itself from the research practice modelled on a purely positivistically

understood idea of natural science. If this point is not stressed clearly enough, the misunderstanding would easily emerge that the call for theoretical innovation in consumer research actually were a call for increasing what is already a high level of eclecticism in consumer behavior studies.

What is really desirable and necessary, in our view, is the breakthrough of a new metascientific way of thinking and the subsequent proliferation of new theoretical approaches and research methods that are at present not generally accepted. Often, new theories must also start from the basic level of theory building, that is, from the level of heuristic theorizing and the development of theoretical frameworks that subsequently can be expected to give rise to fruitful hypotheses.

TOWARD A REPLICATION TRADITION IN CONSUMER BEHAVIOR:
CROSS-CULTURAL REPLICATION OF BENNETT AND MANDELL'S
STUDY OF THE LEARNING-INFORMATION SEEKING HYPOTHESIS

Abstract

Two replications of Bennett and Mandell's classic study of the effects of prior product/brand experience on the information-seeking behavior of new car buyers are reported. Bennett and Mandell found significant support for the notions of classical learning theory but only non-significant evidence for a hypothesis drawn from the Howard-Sheth theory. Here none of the hypotheses were supported in the first replication conducted in the Mid-West. However, the results of the second replication in Norway conformed with the findings of Bennett and Mandell.

Introduction

The purpose of the study reported here is to conduct a cross-cultural replication of the often-quoted study of Bennett and Mandell (1969) on the relationship between learning and information-seeking.

As pointed out some years ago by Kollat and his colleagues (1970, p. 329), progress in consumer behavior research is hindered by the lack of a strong replication tradition. Many propositions have shaky empirical foundations as they are based on findings in a single study conducted at a special time, on a special location, in a special research setting, and by a special researcher. Nevertheless, despite their humble origin, such single-shot findings often take the form of "generalized knowledge" as they are quoted and requoted. Reservations as to the generality of the results tend to be leveled out.

Objectives of Replication

In general, a purpose of replication is to isolate universals from phenomena which are merely idiosyncratic to particular populations or methods of measurement.

More specifically, the role of replication may be discussed in terms of Campbell's distinction between internal and external validity of empirical findings (Campbell, 1957). Internal validity relates to the impact of the experimental manipulation on the set of independent variables. Hence, the validity may be threatened by lack of controls for extraneous variables producing spurious effects. Replication studies concerned with internal validity would emphasize rigorous design, particularly better controls and allowance for other explanatory variables.

The replication study to be reported here, however, focuses essentially on the external validity of the findings in the original investigation. Therefore the critical issue is the generalizability of the findings. It is true from the philosophy of Hume that induction or generalization can never really be justified logically. However, it is possible to approach the problem pragmatically by examining the sensitivity of the findings originally uncovered to variations in population, physical setting, and different operational definitions of

the variables.

All replication studies involve a dilemma. To simplify, the situation is as follows: If the replicator is too "conservative" and the design of the new study is too similar to the original one, the findings risk being only trivial reconfirmations of what is already known. Such research is unlikely to be interesting to the scientific community. If on the other hand the replicator yields to the temptation of extending the study too far, deviating too much from the original design, such "radicalism" may produce non-comparable data. In this case, a middle road was chosen.

Choice of Study for Replication

At least three important criteria should be used in the choice of study to be replicated. First, it is imperative that the study has addressed a substantial and central theory area within the field of interest. Second, there should be some minimum of consensus among researchers in the area that the particular study is a significant contribution. These two substantiality criteria are needed as safeguards to avoid the risk of having the journals flooded by trivial, quick-and-easy replications. A third (and practical) criterion is that the methodology should be reported in sufficient detail to allow the desired comparability of design.

The study chosen for replication was Bennett and Mandell's (1969) investigation of the effects of learning or prior product/brand experience on the information-seeking behavior of new car buyers.

Learning theories have lodged themselves firmly in marketing and consumer behavior as explanations of brand choice and information-seeking and handling (Alderson, 1952; Kotler, 1965; Ray, 1973). The models employed have ranged in complexity from Watson's (1913) simple Stimulus-Response formulation to the elaborate Howard-Sheth model (Howard & Sheth, 1969). In addition to being more complex, the Howard-Sheth model differs from the main body of learning theory in a major way which is of importance here.

Howard and Sheth argue that all experience with a class of objects, whether positively or negatively reinforced, are instructive. The consumer's information requirements and the intensity of his search efforts decline as experience in buying and using the generic product accumulates.

In classical learning theory, learning is portrayed as a function of the number of reinforced trials or the number of successive reinforced trials with a specific stimulus object (brand) (Hall, 1966, Hilgard and Bower, 1966).

The Bennett and Mandell (1969) study was chosen as it appears to be a classic in its own light. It was one of the

first major studies addressing the Howard-Sheth theory. As such it is routinely quoted in standard textbooks such as Hansen (1972, p. 333), Howard (1977, p. 141), Engel, Blackwell, and Kollat (1978, p. 239), and Berkman and Gilson (1978, p. 409-10) and comprehensive reviews of consumer information-seeking behavior, such as Newman (1977). A third point was that the methodology seemed to be basically sound.

Fourth, the reporting of the method was detailed enough for the purposes of the present study.

Bennett and Mandell's Study

In their study Bennett and Mandell formulated the following hypotheses:

- H₁: The buying experience itself is instructive, whether or not the choice is positively reinforced. As this experience increases, evidenced by the total purchases in the individual's history, the amount of effort expended on information search will decrease.
- H₂: As the total number of reinforced purchases of a brand increases, the amount of information-seeking before purchase of that brand will decrease.
- H₃: As the number of sequential reinforced purchases of a brand increases, the amount of information-seeking before purchase of that brand will decrease (Bennett and Mandell, 1969, p. 431).

The first reflects the Howard-Sheth model. The other two were drawn from the nations of classical learning theory.

Bennett and Mandell tested the hypotheses with self reports of information-seeking collected from 146 recent new car buyers chosen from new car registrations in the Spring of 1967 in Harrisburg, Pennsylvania. The respondents were requested to reconstruct their entire car ownership history, were given ample time, and were also encouraged to examine any legal or financial records that might assist their recall. The independent variable, "number of trials", was defined in three ways. The first (T₁), which was used to examine H₁, was simply the total number of cars the respondent had owned. For T₂, the total number of purchases of the brand currently owned were counted. T₃ was the length of the current sequence of purchases of the brand currently owned.

To illustrate, consider the history COOCCOCC where C is the brand of automobile currently owned and O is any other brand. The values for this individual would be T₁ = 7, T₂ = 4, and T₃ = 2.

The second set of critical data was related to the extensiveness of information-seeking. The measurement instrument was a structured questionnaire specifying ten classes of information sources, see Table 1. Responses were weighted on a judgmental basis (by a panel of experts) according to a scheme believed to reflect the effort involved in consulting various information sources (Table 1). The first hypothesis was not supported ($\chi^2 = 4.46$, $df=6$, $p<.62$).

Strong support was found for H₂ ($\chi^2 = 17.80$, $df=6$, $p<.007$) and H₃ ($\chi^2 = 22.12$, $df=6$, $p<.001$), the relationships being monotonic and in the predicted direction.

Replication

As previously mentioned, an objective of this replication was to test the robustness of the original findings to variations in the operational definitions and to changes in physical setting or culture.

The first replication study which was also conducted in the U.S. (St. Louis) introduced some variations in field design.

To test the spatial validity of the results, analysis was also performed on a second set of data collected in Norway. As far as we can judge, the design of the Norwegian study coincided with the Bennett and Mandell study in most respects, the only main difference being the one of location. It should be noted that at that time, Norway was lagging somewhat in national income per capita as compared with the U.S. Because of high fiscal taxes making cars very expensive, the incidence of car ownership was smaller, while the length of ownership for each car acquired was much longer. Hence Norwegian consumers were expected to have experienced less learning as car buyers than American counterparts.

St. Louis Study

The first replication study which used data collected from a cluster probability sample of 130 St. Louis households during the Spring of 1966, introduced some variations in the measurements made.

Bennett and Mandell employed a structured questionnaire, while the data in the St. Louis study were derived from responses to a series of open-ended questions. Bennett and Mandell sampled current new car registrations. In the St. Louis replication randomly selected households were asked about their most recent new car purchase.

Responses indicating that the buyer had consulted any of the information sources in Table 1 were recorded. Two different summated measures of information seeking were developed for each subject. In the first, the effort weights reported by Bennett and Mandell were applied. In the second score, no weights were employed; all sources were given an equal value. Bennett and Mandell recorded the total amount of information-seeking for all cars considered combined. The first replication, however, only obtained measures of information sources used for the car bought.

The measures of prior product/brand experience were identified to those employed by Bennett and Mandell.

Bergen Study

The source of the data in the second replication was personal interviews conducted among a sample of 96 recent new car buyers, selected by random sampling among all new car registrations in a given time period in the late Fall of 1969 in Bergen (the second largest city in Norway).

Like in the original study a structured questionnaire was used, and the buyers were asked about their information-seeking for all the brands considered. Also other parts of the procedure paralleled the Bennett and Mandell investigation. The only main difference was that auto shows (see Table 1) was not included as a possible source of information (owing to the absence of this source in Bergen at that time).

Therefore, while the three data sets are contemporaneous, there were certain differences in procedure. These differences are summarized in Table 2.

Table 1

Sources of Information and Importance Weights

Information Source	Weight ^a
<u>Consumer Reports</u>	18
Dealer visit	18
Expert opinion ^b	12
Friends' opinion	10
Reading brochures ^c	10
Discussion with spouse	9
Auto show	7
Advertisements	7
News articles	6
Discussion with children	3
Total	100

Source: Bennett and Mandell (1969).

^aWeights indicate the relative amount of effort required to use the particular source.

^bExpert could be mechanic or "purchase pal" with special knowledge of automobiles, either of a technical or economic nature.

^cIndicates the actual reading of brochure, usually picked up at "Dealer visit".

Table 2

Summary of Main Differences in Design in the Three Studies

Study	Design			
	Location and Time	Sample Frame	Method of Measurement of Extent of Information Seeking	Range of Information Seeking Included
Bennett and Mandell	Harrisburg, Pennsylvania Spring, 1967	New car registrations	Structured questionnaire	Information seeking for all brands (cars) in the evoked set
First replication	St. Louis Missouri, Spring 1966	Most recent new car purchase of households	Open-ended questionnaire	Limited to information seeking for the brand chosen
Second replication	Bergen, Norway Fall, 1969	New car registrations	Structured questionnaire	Information seeking for all brands in the evoked set

Theoretical Expectations

At this point it is appropriate to indicate the theoretical expectations for the replications and to comment on the meaning of confirmation and disconfirmation in this respect.

Since the procedure was practically the same (and since there was no reason to believe that the Harrisburg and Bergen car buyers would differ significantly in terms of relationships among the variables of interest), the Bergen replication was expected to produce findings supporting the original results.

For the St. Louis replication the expectations were less clear. In this case it is necessary to speculate about the impact of the variations in procedure introduced. The use of open-ended questions (instead of a structured questionnaire) in the St. Louis replication would seem to mean a downward bias in reported information seeking and more error due to inaccurate recall. Hence, the correlations obtained would be suppressed. Limiting the measure of extent of information-seeking to information gathering about the car actually bought (rather than about all cars in the evoked set) was believed to have similar effect. Therefore, the St. Louis study was expected to show weaker relationships for the two hypotheses (H_2 and H_3) supported by the original study.

In this case, confirmation of the results originally found would strengthen the belief that there is a relationship between learning and extent of information seeking. Spatial validation by the Bergen data would make it more likely that the Harrisburg findings did reflect an underlying behavioral law, and that the findings were not a chance result of some idiosyncrasies of a given setting. Disconfirmation of the findings by the St. Louis study would imply that the underlying "true relationships" were not strong enough to withstand major variations in procedure weakening the measures.

Findings

The correlations of the measures of product/brand experience with the information seeking indices for the St. Louis and Bergen samples are shown in Table 3.

As seen in Table 3, the St. Louis and Bergen data were analyzed by computing product moment correlation coefficients instead of the Chi Square statistic as in the original study. This did not affect the conclusions, but was done to simplify reading and easing comparison. As shown in Table 3, all the signs for the St. Louis data, with the exception of one, were as predicted. However none of the correlation coefficients were significantly different from zero. There was clearly no compelling evidence for any of the three hypotheses.

For the Bergen sample, on the other hand, the results showed a remarkable similarity to the Bennett and Mandell findings. While no support was obtained for H_1 , the data conformed with the theoretical expectations for H_2 ($p < .05$) and H_3 ($p < .05$).

Discussion

The main finding common to all three studies was the lack of support for the H_1 hypothesis based on the Howard-Sheth formulation that all buying experiences in the product category are instructive. A possible explanation is that the development of learning theory as applied here has mainly been concerned with low-involvement or low complexity issues, such as repetitive buying or frequently purchased convenience goods. It may be that for a big-ticket items such as cars (being presumably higher

in importance, complexity, and involvement) there is a non-monotonic relationship between learning and information-seeking. At low levels of learning there may be little search for information because consumers, though objectively "needing" information, lack ability to process and evaluate information.

Table 3

Correlations of Product/Brand Experience with Information Seeking

(Product moment correlation coefficients)

Product/Brand Experience	Information Seeking			
	St. Louis Sample (n = 130)		Bergen Sample (n = 96)	
	Weighted	Unweighted	Weighted	Unweighted
T ¹	-.02	+.04	+.12	+.12
T ²	-.05	-.03	-.24 ^a	-.20 ^a
T ³	-.07	-.07	-.24 ^a	-.20 ^a

^aSignificant at the .05 level or better

A second finding was that the weights assigned to the sources of information did not make any difference.

The main difference in results in the two replication studies was that the Bergen study as expected did support the patterns uncovered in the original study. However, also in line with our expectations, there was no relationship for H₂ and H₃ in the St. Louis replication.

Hence, it appears in conclusion that the Bennett and Mandell findings were not sensitive to change in physical setting and culture but very sensitive to changes in the operational definitions and way of measurement. The fact that the previous findings were reproduced in a different setting, increases our confidence in the generality of the original results.

The findings of this attempt to replicate the Bennett and Mandell study underscore the need for a replication tradition in consumer research. Further replications should bring in more variables and/or alternative hypotheses to establish under what conditions the original effects found exist. Hence, comprehensive systematic replication is necessary before it is possible to obtain a high degree of confidence in a lawlike generalization.

One solution is to carry out what Lykken (1968) calls "constructive replication", letting second and third researchers start from the conclusion of the original researcher using only the fact or law that the former claims to have established and then let the replicators formulate their own conceptualization and methods for sampling, measurement, and data analysis. To illustrate, instead of using a cross-sectional design, the Bennett and Mandell findings could be put to a more fundamental test by designing a longitudinal study. A panel study could follow a sample of persons over time through several car purchases.

METHODOLOGY AND META-METHODOLOGY IN CONSUMER RESEARCH: A COMMENTARY

Peter D. Bennett, The Pennsylvania State University

When asked to serve as a discussant in a session such as this one, there is a tendency to search for a common thread that holds it all together. That thread is there, though it's weak. In these brief comments, I will try not to stretch that thread to its breaking point.

All three papers plea for creative insight into new or revised methodologies, or in one case an even more fundamental plea to open our attention to new or different approaches to consumer research--our philosophies of science. All argue, more or less persuasively, for consumer researchers to not only look hard at our methodological biases and proclivities, but to develop new methodologies to fit unique problems which are beyond the evaluation of individual choice behavior.

But there the similarities end, so it seems the better part of wisdom to look at the three papers separately.

Hutton and McNeill

As a case study in the almost overwhelming difficulties of the evaluation of the impact of social programs, the paper is enlightening on the one hand, but frightening on the other.

While the paper really adds little in a methodological sense, it demonstrates a well conceived application of appropriate methods to the special problems of evaluation of a public domain program of some complexity. The contribution, then, lies in its treatment of the special problems of such public program evaluation. By that, I mean, were this research associated with a test market for a new brand of some existing product class, or even a new product, the "end-result" (how much did we sell?) as well as what Hutton and McNeill call "diagnostic" and "formative" issues would surely have been included by most sophisticated industrial researchers.

The authors point to a few of the special problems of the research domain. For one, they say that there are special problems of researcher/decision maker interaction because, "The policy maker does not have adequate training to judge research methodology and policy makers are, at the very least, hesitantly supportive of evaluation." How serious a problem this is, and how much it differs from the interaction between researchers and, say, brand managers, probably varies. In any case, it's not really a methodological issue, but a political one. In short, while it may be a problem, it doesn't really need to be one.

They also key on a problem of the timing of both the placement of evaluation as coming late in the program design, and decisions needing to be taken before the results are available. This is also not a methodological problem, but one of planning. Third, the problem they point to of the "orientation" of evaluators being toward survey and single measure research is not methodological, it is really a problem of education.

Having been involved myself in a research where the users were in the public sector, I sympathize with the authors' problems, and am grateful for their strong argument that these kinds of problems need to be overcome. We should also be grateful for their public report of an example of a real program evaluation study which tries to overcome some of these problems. Their research, insofar as the "end-results" portion is concerned, is well designed and executed. The "diagnostic" part of the research is perhaps

as well as could feasibly be done in the field setting of such a quasi-experimental design. All alternative explanations, e.g., some inherent differences between New Englanders and New Yorkers, might have been more thoroughly explored, given of course, adequate time and resources.

Dardis and Stremel

The paper on risk/benefit analysis in relation to product safety is, on the one hand, both extremely interesting and methodologically "tight." On the other, it is sufficiently marred with unsupported (perhaps unsupportable?) assumptions that it is frightening if it were to be actually used for making public policy decisions. The authors argue irrefutably for both the need for a risk assessment methodology, and that such a methodology consider benefits as well as risks.

The methodology suggested in the paper is intriguing, and I hope it will stimulate considerable comment and debate, because the topic is one of such critical importance. Dardis and Stremel conclude that, "the proposed method for assessing risk appears feasible." Whether or not it will eventually emerge as meaningful and operational requires answers to a number of questions. Let's take as given that:

$$\text{Risk/Benefit} = P_f C_f + P_n C_n / V, \text{ and}$$

$$\frac{N_f C_f}{VQ} = \frac{N_n C_n}{VQ}$$

where each term is as defined in their paper.

Since both P_i are really N_i/Q_i , we need to examine the assumptions underlying this relationship. The value of Q is rooted in dollars spent on product i , (not actually quantity of items) during one year. This assumes each product has a life of one year (or that the durability of the products are equal). Our own experience leads us to question this assumption--nearly always my pants outlast my shirts and my wife's robes seem always to outlast her gowns. I have no solid empirical evidence which speaks to the differences in the clothing turnover rates, but the assumption of equal life seems questionable.

Since N_i is the incidence of consumers being burned, it would appear to include burns received in a fiery auto accident or home fire, neither of which seem to have anything at all to say about the safety of the garments the victim is wearing, though they are here lumped together with burns received which are so related.

The serious problem with V is that it treats benefits as value in exchange rather than value in use, and the footnote doesn't adequately deal with the problem. It is the use of a product, not its ownership, that exposes one to risk. One may own a large number of shirts, each one of which is used, say, once every two weeks, while one's robe is used almost daily. Again, we are without data, but the assumption built into the operationalization is open to serious question.

Finally, and perhaps of greatest concern is the proposed operational treatment of the cost constructs. Such an oversimplified, purely economic, approach is flawed on both logical and political grounds. The openly stated assumption is that the rankings of products is not invalidated by ignoring "pain and suffering" costs if they are proportionate to the sum of direct and indirect costs. Since one major component to economic costs is the present value of future

earnings, this view assumes that the widow of a \$100,000 per year ad agency executive is greater than that experienced by the widow of a \$25,000 per year consumer researcher, and infinitely more than the widower of an unpaid housewife. It is an assumption that is hard to swallow on logical grounds, and is one that the NAACP and NOW organizations are likely to see as untenable.

Perhaps what we have in this proposed methodology is a way of comparing the relative risks/benefits across products to society, or more coldly to the economy. However, the whole purpose behind product safety intervention is to protect individuals, not the economy. It seems to me that a major contribution of this paper is to make it clear to us that the methodology that should eventually be used is one that is not likely to rest on readily available secondary data sources. The contribution lies in identifying those constructs for which we will need data in order to do risk/benefit analyses. The challenge will be to develop the appropriate operationalizations, which will no doubt be extremely complex and arduous tasks. That is why I said earlier that I am pleased this paper is here, and that hopefully it will stimulate comment and debate leading to those badly needed research efforts.

Uusitalo and Uusitalo

The final paper calls us to task at a much more fundamental level. The authors argue cogently for researchers in our young discipline to slip the bonds of a philosophy of science with roots in the physical sciences. I can remember when it was next to impossible to study the philosophy of science without using texts written by physicists, and for someone who knew nothing about physics, that was no easy task.

The authors have prepared some truly challenging suggestions with which I find myself largely in agreement. To the extent that researchers in our discipline are wedded to the tenets of logical positivism, we are losing opportunities to explore approaches to research questions which might be very fruitful.

Uusitalo and Uusitalo also suggest that we have continued to be wedded also to research approaches that are "traditional" to either economics or psychology. If they were saying that we were guilty of borrowing theories and concepts from those mother discipline and applying them blindly to consumer behavior phenomena, our reaction could legitimately be "ho-hum." But that's not what I hear them saying. What I hear is something much more fundamental. I have a friend who is a very fine consumer psychologist. When faced with a research issue of interest to him, he will study it, analyze it, and conceptualize the research in terms of the results as they would appear in an ANOVA table. What I hear the authors saying is that there are other, some radically different, ways to conceptualize both the problem and the entire approach to the research the problem calls for. Let's open ourselves up to those alternative approaches.

I found the paper very difficult to read, and I think the reason is that it says so much in so few words. Had the authors had the opportunity to expand their arguments and illustrations to three or four times the paper's current length, it would no doubt be much clearer. I hope that this fact does not stand in the way of lively debate and response to these proddings. For instance, would following this advice lead us to a research tradition in consumer behavior which is even more eclectic than we have now? and would that be functional or dysfunctional? Many of us could take either side of that question and have a debate that would shed more light even than the "debates" between presidential candidates. While some may find these authors poking at their sacred cash cows, I think we should thank them for doing the poking.

AN EVALUATION OF SEX ROLE THEORIES: THE CLASH BETWEEN IDEALISM AND REALITY

Susan Hesselbart, Florida State University

Abstract

This paper describes how different sex role theories can create new or perpetuate old myths about women and men. Research evidence is used to evaluate how well these myths fit reality.

Many consequences of contemporary feminism are now part of our daily lives. As with other social changes, theories are devised to explain new realities. This paper explores some new and old theories about gender and society, and the potential these approaches have for gender mythology.

We have discarded old and created new myths about the sexes during the past 15 years. Largely discarded myths include: the dire consequences to the offspring of employed women; that only men enjoy sex; or that sex discrimination vanished years ago. New myths include: the spectre of men as "emotional cripples"; that successful employed women now acquire men's "stress diseases"; or that both sexes are now converging in role demands and behavior.

Social myths serve functions for those who hold and promulgate them. Myths can be used to block or to foster social change. By "mythology" I mean that either: (1) data exist to invalidate the myth; (2) at best biased data support the myth; or (3) the mythological structure is illogical or inconsistent.

I will examine sex role theories along two dimensions: (1) postulating many versus relatively few sex differences; and (2) the attribution of similarities or differences to mainly biology ("nature") or to culture ("nurture"). Although each dimension is a continuum, for simplicity here I will treat each as a dichotomy.

Major Approaches to Gender

The Extent of Sex Differences

Most past and current sex role theories assume that there are many sex differences in character and social position. These differences correspond to common stereotypes held by laypersons. Men are generally portrayed as dominant, aggressive and stoical while women are viewed as warm, nurturant, cooperative and sensitive. The social positions resulting from these perceived differences assign men to "instrumental" task and leadership roles, taking an active part in major societal organizations, e.g., the economic and political. Meanwhile, women play "expressive" roles emphasizing nurturance, e.g., nursing or child care. Some claim that these are universal patterns. Approaches postulating many sex differences include most sociobiologists (e.g., Barash 1977, Goldberg 1974, Wilson 1978); recent work on men's roles (see the collections in Lewis and Pleck 1979 or Pleck and Brannon 1978); functional sociologists (Parsons and Bales 1955); and those advocating "crossover" or convergent sex roles (e.g., Giele 1978).

A theorist could believe that these sex differences are mainly shaped by "nature" or "nurture". Virtually all theorists believe that women's part in reproduction powerfully influences sex roles. Beyond this, theories diverge widely in terms of how much can be attributed to biology and why biology is important.

Far fewer theorists see relatively small sex differences. Those in this category focus generally more on social roles than on personality characteristics. Not surprisingly, most favor "nurture" over "nature". They place the greatest emphasis on how social change--technical, demographic or ideological--influences both sexes (e.g., see Huber 1976).

Nature Versus Nurture

Sociobiologists believe that traits are selected for "evolutionary fitness". Those enabling an organism to survive long enough to reproduce are passed to offspring. Many of these theorists believe that females have more "investment" in offspring than males. Females bear and nurse their young and are certain that a child is theirs, whereas males cannot be certain. This "investment" difference puts males in a "seller's market" competing to be found attractive by females. Economic provision and protection are two assets males can use to increase their attractiveness. Thus traits such as aggression or mental acuity were "selected for" in men. Since humans have a long, dependent infancy, traits such as nurturance in caregivers increase offspring survival; thus these were "selected for" in women.

Sociobiologists do not explicitly say that "anatomy is destiny". Rather biological sex is a predisposition or potential. Nevertheless, sociobiologists are also those who claim near universality of certain patterns, e.g., men's economic productivity or women as caretakers of children.

"Nature" theorists believe that biology shapes individuals who then shape society. In contrast, "nurture" types see the role of the sexes in reproduction as shaping societal institutions which then shape personality. To survive, any society must keep fertility at least at replacement levels. Societies with high mortality also need high fertility. In labor-intensive societies, children are also an economic asset.

All this implies that in earlier societies women bore and attempted to rear many children. Survival past reproductive ages was rare for both sexes until this century. Average longevity is below age 50 for many nations today. Thus, until recently, women spent most of their adult lives as mothers. Women's productivity was constrained by maternal mobility.

Changes influencing both sexes occurred with the industrial revolution. Productive labor moved from the home to the factory. Given women's maternal constraints, this largely meant that men left the home to take part in an increasingly cash monetary system. Home crafts that formerly had been women's work also moved to the factory. At the same time, improved living conditions led to less mortality. Children were less often seen as economic assets.

These changes have been viewed as leading to the devaluation of women. Productive "women's work" shifted outside the home or (in the case of childbearing) was seen as less valuable. Wage-earners in a cash economy have more power than those with little cash income. Thus, men as a class have been hypothesized to gain power over women as a class.

This view suggests that sex differences respond to the condition of larger society and are mainly the result of socialization. During childhood, the sexes are trained to appropriately fit into adult roles. If men earn their living in an industrialized culture stressing achievement, then boys are trained to be competitive and ambitious. If women remain within the home tending to children and adult men, they need training instead in forms of emotional expressivity (e.g., Hoffman 1977, Huber 1976, Oakley 1974, Parsons and Bales 1955, Stockard and Johnson 1980.)

Many "nurture" theorists are especially interested in adult socialization. For example, Kanter (1977a) stresses how adults are shaped by occupational hierarchies within corporations. Persons of either sex low in the hierarchy behave in stereotypically "female" ways, for example, stressing sociability on the job or having low aspirations for promotion. If the job is a dead-end one, these may be realistic responses.

Those taking a "nurture" stance also stress how demands made by different institutions shape individual behavior. Role incompatible demands can occur among both sexes, but they are especially pronounced for women--particularly for mothers in the paid labor force. These women face two jobs, one outside the house and one within. This "role overload" means that women have less leisure time than men. For example, employed married men in 1975 averaged 36 hours a week leisure time compared with 32 hours a week for employed married women (U.S. Department of Commerce 1977: Table 10/1). These types of differential demands may produce "sex differences" rather than biology or personality traits.

Finally, a few theorists perceive relatively small sex differences but attribute these mainly to "nature". The most famous example is Maccoby and Jacklin's *The Psychology of Sex Differences* (1974, but also contrast Bardwick 1979 with Bardwick 1971). These perceived sex differences mainly center around greater male aggression.

Theories of Gender and Social Science Mythology

These theoretical approaches have implications for the creation and perpetuation of social science mythology. Such myths extend beyond the academic community. They can shape perceived social reality, and can define whether social change is possible or desirable, the kinds of changes sought and the benefits and costs of change. For example, the distinction that Freud made between vaginal and clitoral orgasm influenced research, therapy and women's self images for decades.

The Case of "Fear of Success"

A more recent case is the "motive to avoid success" (M_{as}), sometimes called "fear of success" (Horner 1968). M_{as} was conceptualized as a stable, internalized motive, learned early, held by bright women who had the greatest chances for success. High M_{as} women fear the consequences of succeeding in male-typed professions such as medicine. Social rejection is seen as the "reward" for these accomplishments. When high M_{as} women are placed in a competitive or male-typed achievement situation, they will tend to lower their performance.

"Myth" may seem too strong to assign to "fear of success". However, most data do not replicate the patterns that Horner predicted. Indeed reanalyses of Horner's dissertation data do not support her hypotheses. Tresemmer (1976) found that high M_{as} women in Horner's data had the highest performance scores of all women in five out of six conditions. With more sophisticated research designs, what was categorized as an internal motive among women may turn out to be negative stereotypes about achieving women held by both sexes (e.g., see Levine and Crumrine 1975, Zuckerman and Wheeler 1975).

Let's consider some implications of the "fear of success" example. It implies that women's actual performance is below men's because women are hampered by M_{as} . In an economy that claims that merit is the most important determinant of reward, this suggests that women's lower rewards (e.g., income) result from their own performance. It should be noted, however, that many studies have found that the identical performance is rated lower when a woman's name is attached rather than a man's.

The "fear of success" perspective also specifies the remedy: women must change through therapy; "assertiveness workshops"; remedial education; or self-help books teaching one office politics. Finally, hidden in "fear of success" and many other individual differences approaches to gender is the idea that major traits and motives are instilled in childhood and adolescence and are very difficult to change during adulthood. This means we will need to wait many years for a new, strong generation of women to grow up before substantial social change can occur. The generational change remedy contrasts with suggestions by those stressing social structure (e.g., Kanter 1977a 1977b) and the short-term changes that organization changes can produce.

"Fear of success" became popularized during the early 1970s. Ironically, better designed later research which does not support the M_{as} has remained cloistered in academia. I suspect that a social science approach stressing individual differences is probably more acceptable than a social structure approach to Americans, who are told that it is individual merit that "really counts". A structural approach is also obviously more costly to existing organizations than one stressing individual change. "Fear of success" serves the needs of business and government far better than potential myth stressing massive social change.

The Seeds of Mythology

Different approaches to gender and society have differential susceptibility to mythology. In the preceding example, I pointed out that an approach stressing individual differences will try to locate motives and traits to explain social phenomena such as the lower economic rewards to women than to men. In general, I believe that approaches that either (1) stress relatively large numbers of sex differences or (2) attribute most perceived sex differences to biology have the greatest probabilities of creating or perpetuating mythology. Theories assuming relatively few differences with a nurture approach may be less susceptible to myth creation.

This does not mean that there are no sex differences in reality or that biology plays no role in gender differentiation. For example, cross-cultural work strongly suggests that pregnancy (rather than physical strength or personality traits) has influenced the gender differentiation of labor. Jobs that are predominantly male involve mobility: hunting; fishing; soldiering. Women's productive labor is closer to home: domestic agriculture; infant care. With low birth rates, highly predictable contraception, medically safe abortion and safe substitutions for mother's milk products of the last century, it is not surprising that much of women's roles had centered around the care of young children. Cross-cultural and time series data also imply that greater physical activity (which does not necessarily mean aggression) is more characteristic of males than females (e.g., Boserup 1970, Huber 1976, Maccoby and Jacklin 1974, Oakley 1974, Stephens 1965).

Thus, a theory need not stress that there are no sex differences at all. What I am saying is that approaches that a priori assume large sex differences or that biology strongly influences sex differences in "personality" are more open to social science myth creation. A priori assumptions constrain which topics are studied, how topics are studied, and

how results are interpreted. Research using true "null hypotheses" would assume at first that there would not be sex differences. To confirm or reject such hypotheses, we need to ask similar research questions about both sexes. In most cases, this is exactly what has not been done and our research accordingly has often contributed to mythology.

Consider again "fear of success". Horner a priori emphasized the importance of personality traits over, say, social structure in academic and economic achievement. This meant that effects from, for example, the hierarchical organization of corporations and the roles of each sex within these were not considered. Horner also assumed that the achievement conflicts within women would be reflected in the stories college students told about Thematic Apperception Test cues. Given that TAT responses were assumed to reflect internal conflict (rather than social stereotypes), Horner saw little need to present cross-sex cues. Thus, women responded only to a female referent and men only to a male referent. When later research did use cross-sex cues, men reacted with higher "fear of success" imagery to successful women cues than women did--hardly confirming the M_{AS} as an internal personality motive.

Instrumental and Expressive Role Mythology

In another current myth, many functional sociologists assumed a priori that sex differences result in a certain evolution of social structure. Men's instrumental or task oriented role was to "represent" the family to the outside world. His employment sets the social status for the entire family. Women play an expressive, socio-emotional role within the home. This efficient division of labor prevented spouses "competing" with each other for status were both to have an engrossing "career" (Parsons 1942, Parsons and Bales, 1955). The nearly wholesale buying of this myth continued until the late 1960s.

The "expressive/instrumental" mythology resulted in the neglect of many research questions even though existing data did not support it. For example, Parsons himself (1942) noted that this differentiation was mainly true only of the upper middle class. Working class families usually needed both spouses in the labor market (but see Oppenheimer 1977 on middle and working class data). Even in 1979, only 30 percent of employed men were in professional or technical occupations, i.e., those with the greatest chances to become upper middle class. The majority of men have blue collar jobs which are neither "engrossing careers" nor the route to upper middle class status. Thus, relatively few Americans can afford the "expressive/instrumental" differentiation.

The functionalists' division of roles assumes that a man's top priority is his work and a woman's is her family. This is particularly mythical when applied to men. While the largest allotment of time for married men may be to their job, whenever the question has been asked, men rank their families as their highest priority and greatest source of satisfaction. Survey data have been consistent on this since at least the 1940s, and such results have been obtained from all strata of men (see a review in Hesselbart 1978 and also Pleck and Lang 1978). Because of the functionalist approach, we have largely ignored men's family roles and treated women's employment as a "social problem" (Feldberg and Glenn 1979, Lewis and Peck 1979).

Perhaps because social science has rarely explored the family for both sexes with parallel questions, functionalist though has precisely reversed the roles of each sex within the family. A correlated myth is that full-time housewives do not "work". Housework was hardly examined until the middle 1970s, and it is made clear that

the major role women play within the home is instrumental (Berk 1980, Glazer 1976, Oakley 1974, U.S. Department of Commerce 1977: Table 10/1). It is hard to define the average 44 hour housework week for fulltime housewives and the 25 hour housework week for wives in paid employment as "expressivity". It is also usually the wife who represents the family to institutions other than paid employment, e.g., churches, PTA meetings, kin contact, or tradespersons. In contrast, husbands enjoy more expressive family relations, such as playing with (rather than routine care for) children or recreation. In comparison with wives, married employed men spent only 10 hours a week in family care in 1975.

"Nature" and Myth Perpetuation

Those who postulate many sex differences due to biology often end up either apologists or strident defenders of the status quo. Many sociobiologists argue that most sex differences in social structure and social institutions are inevitable universals. Male dominance in politics, culture or the economy are proposed as true of virtually all societies. Man's greater physical strength and logical character cause male dominance (e.g., Barash 1977, Goldberg 1974, Wilson 1978).

In proclaiming these universals sociobiologists exaggerate cross-cultural similarities. These are used to justify the relative lack of change in Western gender stratification. Even if large changes were possible, they would be so costly, change would not be worth it. Sex differences appearing dysfunctional now (e.g., norms encouraging women to have large families) were adapted in "99 percent" of our evolutionary history and would take generations to change. These assertions ignore the great variability in women's contributions to society, especially in economic productivity (e.g., Aronoff and Crano 1975, Boserup 1970, Rosaldo and Lamphere 1974).

Sex differences treated as biological or universal can also betray a curious sense of history. For example, women's greater longevity is a phenomenon of the twentieth century and may be due more to living habits (e.g., lower accident rates) than to biology (Harrison 1978). Such "universal" assertions are also contradicted by research that finds that sex differences appearing in early childhood during the 1950s or 1960s now do not emerge until adolescence during the 1970s (e.g., male superiority in math skills, Maccoby and Jacklin 1974). Even the most determined sociobiologists do not argue for spontaneous mutation and evolution over a 20 year period.

Nurture, the "Feminine Principle" and "Role Crossover"

Those subscribing to many sex differences instilled by culture can fall prey to other mythologies. In particular, they are susceptible to the mythology of the "feminine principle". Women's lives and "women's traits" are seen as healthier, more flexible and more useful to modern society than traditionally "male traits". These theorists argue for and perceive a society in which both sexes are becoming more alike or are "crossing over" into roles or traits that embody the "best" of both gender stereotypes. Thus, women gain more interests in paid employment or politics while men become more familial oriented. The healthiest persons are those showing the strengths of both sexes: "masculine" competence and "feminine" nurturance (e.g., Bem 1975 or Giele 1978).

Derivations from the "feminine principle" caution women against becoming "too masculine". "Executive stress" diseases once confined to men now strike the women entering "men's professions" or managerial roles. Related to "executive stress" is the belief that men suffer because they are not allowed women's emotional expressivity. A

theme of "how my life as a man has been crippled because I am not allowed to cry" repeatedly appears in those theorizing about male roles. Yet another spin-off is the role of "society's housekeeper" a myth that is the societal analogue to women's Victorian housekeeper role. Once women share power more equally with men, women will clean up the "messes" that men, like little boys, leave behind; war; ecological waste; inflexible life timetables; and hierarchical organizations (e.g., Bardwick 1979, Ciele 1978, Kenzer 1978, Lewis 1978).

There is a common core to these myths. Researchers creating and perpetuating them hold highly stereotyped views about the sexes. Men really are much more aggressive, repressed and hierarchical than women; women really are much more nurturant, emotional and cooperative than men. The problem is that men and women neither describe themselves so differently nor behave so differently to support such myths (Maccoby and Jacklin 1974). What are sometimes called "sex differences" by those unfamiliar with research on social structure may result from playing superior and subordinate social roles (e.g., Henley 1977, Kanter 1977a). Unfortunately, occupying a subordinate social position does not imply greater mental health or flexibility but instead a possible legacy of self-doubt, anxiety or depression (Deaux 1976, Dohrenwend and Dohrenwend 1976, Pearlin and Johnson 1977). Finally, women's roles are changing more than those of men suggesting that "role crossover" is quite a way into the future.

How well are these recent myths supported? Let's first look at "executive stress". Relatively few women are employed as managers--six percent in 1979 (14 percent of employed men). Most, of course, are not at the upper echelons where ulcers and heart disease reputedly strike. Comparisons of health rates over time fail to suggest that women were starting to suffer from "executive stress" more during the late 1970s. Age-adjusted death rates on cause of death showed lower not higher ratios in 1976 than in 1970 for women on heart disease, cirrhosis of the liver and suicide. These ratios were slightly higher for women in 1976 than in 1970 on respiratory diseases, homicide and ulcers--but women's rates were under half of men's. Life expectancy tables favoring women's longevity increased by a tenth of a year between 1970 and 1977. Death rates for heart diseases among young adults fell steeply for both sexes between 1950 and 1977. Five percent fewer women in the early 1970s said they had had or were near a "nervous breakdown" than in the early 1960s (men's comments fell by less than one percent). Age adjusted rates of acute illness dropped on respiratory illness very slightly for both sexes and rates of digestive illness and injuries rose for both sexes between 1970 and 1977. Rates of increase were nearly identical for both sexes (U.S. Department of Commerce 1977: Tables 5/8 5/39, U.S. Department of Commerce 1979: Tables 2/1 2/3, U.S. Department of Commerce 1980: Tables 100 112).

What is apparent is that more young women are smoking cigarettes. In 1974 among 17 and 18 year olds, 31 percent of boys and 26 percent of girls smoked cigarettes. The rates were identical for boys in 1968 but only 19 percent of girls smoked then (U.S. Department of Commerce 1977: Table 5/27). This is taking its toll in converging rates of respiratory illness. Of course, the inferential leap from increased smoking among teenage girls to the dire prophecies of "executive stress" is large and other data here do not support this leap.

There is little systematic research examining how social reactions to emotional expression differ across subgroups or situations. However, it is interesting that so many recent theorists on men's roles seem to believe that women's crying receives social approval. Women's supposed greater emotionality is frequently cited as a

reason to exclude women from political office or executive suites--hardly a sign of social approval. Further, men may be allowed to express anger more frequently than women. Some psychologists (e.g., Chesler 1972) believe that anger turned inward instead of out can result in depression, and it is the case that women in the United States generally show a higher incidence of depression than men (e.g., Dohrenwend and Dohrenwend 1976).

The role of "society's housekeeper" is actually a partial resurrection of the "female purity" myth used in the early 1900s when women sought the right to vote. Women are portrayed as more humane, opposed to war or to the sufferings of poverty than men. In public opinion polls there is some substance to this myth, but sex differences are relative rather than polarized. For example, if 53 percent of women and 66 percent of men support a military draft (Gallup Poll February 1980), just how humane could we expect a government of women to be? Both sexes are usually on the same sides of the issue even when sex differences in public opinion occur (see "The Polls" in the Public Opinion Quarterly or the Gallup Opinion Index for more examples).

Despite stereotypes among both managers and laypersons, women do not seem to bring unique humane contributions to business either. Women and men in similar jobs have similar values and personalities (Kanter 1977a, Reif, et al. 1975) whether through self-selection or adult socialization. It is possible that with more women in management larger sex differences might appear, but this is really conjecture at this time.

If sociobiologists and functionalists seem to serve the status quo, many of those arguing that large sex differences occur because of culture hold out a beacon of social change to benefit everyone. If androgyny becomes more prevalent, both sexes will gain. However, evidence supporting the "feminine principle" myths does not seem any more compelling than those supporting "gender universals".

I suspect that the "feminine principle" is a lure to sweeten the problems of social change. Shifts in gender and society influence us all, especially if these shifts involve a rebalancing of social power. Scanzoni (1979) suggests that women's negotiations to change men's roles in marriage may involve self-interest and/or altruism to effect greater role sharing. For example, it can be argued that a wife's employment (which seems to give her more power in marriage) makes her "more attractive" or a "better companion" than if she is not employed. A similar phenomenon of a "self-interest sell" may be occurring among social scientists who want more gender equality.

Socio-technical Models and Social Change

Socio-technical and structural models of gender have been left until last because I believe these models offer the least fertile ground for myth creation. Most theories of gender, these included, are "middle range". A larger theory should be grounded in tentative assumptions about both sexes that allow the greatest possible comparisons about sex differences and similarities over time and space. Socio-technical and structural models at this time come closest to this goal but systematic research using "null hypotheses" is just beginning.

We must begin to study the roles of men as parents, spouses, friends or lovers and women's labor whether cash compensated or not. "The family" seems to be a high priority for both sexes but we don't yet know how or whether the familial concept differs for women and men (the data on housework and men's expressivity do give some clues here). Survey data do not suggest that men's interest in the family is a recent one. Changes

that we see now, such as child custody in divorce may reflect old values activated by the recent women's movement. The connections between women's and men's value priorities and changes in social structure need a good deal more research.

Socio-technical theories appear to better explain the dramatic shifts that have occurred in women's labor force participation and the implications of these shifts for other institutions. The rise of married women in the labor market and rising divorce rates preceeded rather than followed contemporary feminism. A combination of low birth rates in the 1930s, high birth rates in the 1950s and an economy increasing in the service sector drew married women into the job market. By 1979, 49 percent of all women, 57 percent of the married mothers of school age children and 42 percent of the married mothers of preschool children were in the labor force. Accordingly, changes occurred in attitudes toward the acceptability of employed wives.

With more permanence in the labor market and with legal changes against discrimination, women's academic aspirations have changed. In 1977, women received 46 percent of bachelor's degrees, 47 percent of master's degrees and 25 percent of doctorates compared with 42 percent, 40 percent and only 14 percent respectively in 1971. In 1977, 12 percent of women receiving bachelor's degrees majored in business, engineering or physical science, double the 1971 percentage. Nearly 20 percent of new physicians were women in 1977 and 23 percent of new lawyers compared with eight and five percent in 1971 (Digest of Educational Statistics 1972: Table 114 U.S. Department of Commerce 1980; Tables 281 282 283).

With greater chances for self support (even with 59 percent of a man's income), more women seem to be electing to stay single. In 1978, 48 percent of women in their early 20s and 18 percent of those in their late 20s had never married, compared with 28 and 11 percent in 1960. Live birth rates plummeted from 118 per thousand women aged 15 to 44 in 1960 to 68 in 1977. Of ever married women, 25 percent were still childless in their late 20s in 1978 compared with 13 percent in 1960 (U.S. Department of Commerce 1980; Tables 54 83 91). Thus, the demographic and socio-technical factors which helped bring married women into paid employment in the 1950s and 1960s have probably "spilled over" indirectly into other forces of social life.

These sociocultural issues have not been postulated to cause large changes in men's roles, and, indeed men's lives seem not to have changed as much as women's over the last 20 years. Husbands do not generally do more housework when wives are employed, although they may now be spending a little more time in the 1970s than 15 years earlier (Pleck 1979). While women opted for more "masculine" college majors in the 1970s, men did not "cross-over" into fields such as nursing or childcare (see Hesselbart and Bayer 1978). At least one recent study (Margolis 1979) suggests that the "corporation man" is still wedded to his company with its attendant geographical mobility. Possibly it is the changes in women's work roles juxtaposed with the lack of changes in men's family roles that have led young women and men to marry and have children less frequently.

Even changes in the roles of one sex, women, have brought about substantial debate, legal change and scholarly research. Perhaps it is a measure of the anxiety caused by changes in basic roles that has laid the ground for new social science mythology on gender and the revival of old myths. It seems time to stop creating mythology and to do basic, unbiased research that is decades overdue.

HOUSEWIVES, BREADWINNERS, MOTHERS, AND FAMILY HEADS: THE CHANGING FAMILY ROLES OF WOMEN¹

Janet A. Kohen, Institute for Social Research, University of Michigan and San Diego State University

Abstract

Delayed age at marriage, decreased fertility, higher employment rates, and increased family headship indicate a major change in women's attitudes and relationships to family roles. Review of recent research findings suggests that women have redefined their relationship to the family so that their personal goals and interests can be met.

Only a generation ago, most young women planned their adult lives around marriage and full-time homemaking. Barbie dolls, Seventeen magazine, and Father Knows Best fed their dreams of a home in the suburbs, a white picket fence, and several loving children. Women's participation within the family has shifted dramatically since then. Women are delaying marriage; planning whether, when, and how often they will be mothers; entering the labor force before their children leave home, often before their children enter school; and, a great many are taking the responsibilities of heading their families for some part of their adult lives. They are participating in their families not only as wives and mothers but also as breadwinners and family heads.

In the process, family forms and domestic relationships have been transformed. New issues have arisen around marriage and family organization. Such questions as whether to live together before marriage, what should be included in the marriage contract, whether to have a second child, when the kids are old enough to stay by themselves after school, and, who does the laundry or changes the oil in the car are becoming common family decisions. The impact, however, extends beyond individual families to virtually every institution in the society. Volunteer work in schools and hospitals; fringe benefits of part-time jobs; social security, pensions, and insurance benefits; child custody and child support; even census classifications have come under scrutiny.

The response to these changes has not been entirely positive. Some social commentators fear that the family is failing. A closer examination reveals that it is not the family which is being threatened but the traditional ideas about how families should be organized. Families continue to function but women no longer participate in them in the same old ways. Delaying marriage, planning fertility, participating in the labor market, and heading families indicate women's increasing desire and ability to control the conditions of their lives, including the conditions of their relationship to their family. Such increasing control challenges pre-existing ideology of women's tie to wifehood and motherhood. Beliefs that women want and emotionally prefer self-sacrificing behavior, particularly for their husbands and children, or what Barbara Ehrenrich and Deidre English (1978) have labeled "masochistic motherhood," are no longer consistent with women's consciousness or behavior. Neither are theories which attribute a "culture of narcissism" to changes in the form of husband and wife roles (Lasch 1979). Instead, current statistics and recent research in the four major areas I've listed above suggest not selflessness, nor selfishness, but increasing autonomy of women.

Delayed Age of Marriage

Young women are approaching marriage today with a perspective that includes other roles besides family roles. Not long ago, women suspended self-commitments to their futures until marriage, expecting to build their lives according to their husband's interests and careers (Bardwick and Douvan 1972). Marriage occurred for some women even before high school graduation, although for most it occurred soon after. In comparison, young women are now waiting longer before they become wives. In 1977, 45 percent of young women between 20 and 24 years of age had never married. This represents an increase of 17 percent since 1960 (U.S. Bureau of the Census 1978). Instead of cooking, cleaning, and taking care of infants, almost one out of every two young women in their early twenties were accumulating advanced education and work experience for futures that most expect will include both family and employment. In a recent study by Cherlin (1980) enrollment in higher education and the expectation of being employed rather than a full-time housewife at age 35 were associated with delay of marriage.

Since most young women expect to marry, these findings demonstrate an increasing awareness of the eventualities of marriage--financial pressures, divorce, widowhood, and, 20 years or more of employment eligibility following their children's departure from home. Rather than a passive awareness though, these women's actions imply self-conscious planning both in relationship to the roles they expect within the family and within the labor market.

Other evidence suggests an equally rational approach to marriage among young women. In the 1976 replication study of Americans View Their Mental Health, a study with which I've been associated as a post-doctoral fellow over the past year, Elizabeth Douvan's analysis supports a significant shift in the way young women view marriage. In 1957, the year respondents were interviewed for the first study, single women were the most positive toward marriage of all marital status groups of women. They were even more positive than single men, a noteworthy difference since overall men were more positive about marriage than women. In comparison, the 1976 single women showed the greatest decline of any group of women in the number who placed a positive value on marriage. They were much more accepting of women who chose to remain single and were substantially more likely than their 1957 counterparts to view marriage as restrictive and burdensome (Douvan 1978). Instead of the idealistic and perhaps over-conformist stance of single women in 1957, the 1976 single women appeared to be more critical of the options provided by marriage.

The consequences of young women's shifts in marital timing and in attitudes toward marriage raise questions about these women's future marital roles. Delay of marriage could mean a swing to alternative family arrangements, or it could mean that marriage will be embraced with greater awareness of problems and greater commitment to their solution. Young women are bringing more psychological and social resources to family formation but the type of family that results in the future is not clear. Whatever the family arrangements that get negotiated, there are hints from the 1976 replication study of Americans View Their Mental Health that young women will take part in those negotiations with a greater sense of personal identity. More married women than married men viewed their marriages as composed of two separate people rather than being a couple and married women were also less

¹The work on this paper was funded by National Institute of Mental Health Grant MH-14618 to Elizabeth Douvan, Joseph Veroff, and Richard Kulka.

likely to view marriage as the basis for their social validity (Douvan, Veroff and Kulka in press).

Fertility

One of the major factors enabling women to modify their family roles has been their control over fertility. Young women can explore relationships and decide on the form they will take without the perils of pregnancy. Once a relationship is established they can plan their parenthood around a variety of events including hers as well as his employment career, family income needs, child care supports, and a variety of other marital and family specific events. Such events, hers, his, and theirs, have had an impact on fertility. Married women are currently having 1.8 children. This lowered fertility has been associated with increased formal education, planned employment, and actual employment (Stolzenberg and Waite 1977).

While on the surface lowered fertility might imply a rejection of motherhood for career, a more thorough examination indicates the opposite. According to the Bureau of the Census, lowered fertility appears to result from a reduction in family size rather than a reduction in the number of women who become parents. Instead of three or four children, women are now completing child-bearing with one or two children (U.S. Bureau of the Census 1976). While the replication study of Americans View Their Mental Health indicated a significant relaxation of pro-natal forms with an increasing acceptance of childless couples (Douvan, Veroff, and Kulka in press), and the number of young women who say that they expect to remain childless is increasing (U.S. Bureau of the Census 1977), still childless women constitute about 5 percent of the population of young women and the number of women who are still childless by the age of 45 has remained relatively constant since 1960 (U.S. Bureau of the Census 1979). The decline is more likely the result of the ability of women to control their fertility to match their desired family size rather than having to adapt to unwanted fertility as they did several decades ago. Even though the decline has been associated with women's employment, there is reason to argue that the increasing financial costs of raising children may stimulate both women's employment and their lowered fertility.

A recent estimate of the costs of the first year of a child's life is over \$3,000 (Ann Arbor News, July 6, 1980). Given both this initial cost and the continuing ones in raising children, women's wages become important contributions to the expenses of children both prior to birth and thereafter. According to the Bureau of Labor Statistics Studies, much of married women's income gets earmarked for the children whether it is basic survival needs, college educations, or certain luxuries. Thus fertility and employment are doubly tied. Having children increases the need to work; work tends to reduce fertility.

Furthermore, the mere ability to plan children may also promote both women's employment and their limited fertility. Having children when they are wanted makes each child more important and valuable than when children were simply a contingency of marital sexuality. In turn, the increased value of children increases the assessment of the goods and services that seem necessary for successful child-rearing. In a study of the value of children, Hoffman and Thornton report that American parents want children for the love and relationship they add to the parents' lives but they also found that these parents report financial cost as a predominant disadvantage of parenthood (Hoffman, Thornton and Manis 1978).

Equally important in fertility plans are the problems of managing and arranging parental responsibilities within the financial, social, and emotional demands of the family. For the most part, these problems have remained a women's issue. Thus, number of hours in the labor force and the

availability of child care have been associated with women's fertility behavior. For example, a recent study indicates that child care restraints are related to reduced fertility among mothers of young children who want to enter the labor market or increase their hours of employment (Presser and Baldwin 1980). Since time-use studies indicate that husbands' contribution to child care does not substantially increase when their wives enter the labor market (Robinson 1977; Berk and Berk 1979), employed wives' concern with the availability of child care seems to be a realistic consideration in their fertility plans. In most cases, mothers have more intimate awareness of their children's abilities than fathers. They, rather than their husbands, are more likely to experience the conflicts between employment to secure the children's needs and the quality and quantity of time necessary for rearing additional children.

From a research perspective, women's fertility behavior raises a number of questions. Studies of fertility have usually been within the field of demography. As a result, the mapping of fertility change and its correlates has been informative of large populations. Few studies have focused on fertility decision making that occurs within the context of family events. Partially this is because panel studies are needed and panel studies require commitments of time, energy, and money. Partially this reflects the recency of fertility control on a mass basis. Not enough time has elapsed to estimate the affects. Partially, too, this indicates a neglect or bias against studies which focus on women's issues. We know that most women, and men too, have plans for eventual family size. We don't know how these plans get negotiated between husband and wife, how spacing gets determined, what family events precede fertility decisions of when or whether to have a child. Is having a baby a way of leaving a routine and monotonous job? On the other hand, is getting a job promotion or receiving tenure a career plateau that makes the possibility of having a baby more likely? Is the experience of having the first child--the medical experience, the post-partum family organization, the availability of support following childbirth--an important experience in fertility decisions? Oakley's recent study of childbirth would seem to suggest the answer is yes (Oakley 1980). Her extraordinary research has located fertility decisions within the events that surrounded women's experience prior, during, and after having a child. Since women do control their fertility, hopefully, Oakley's research will provide a new model which focuses on women's experiences as the context for those decisions.

Employment

One decision that has become as commonplace in women's lives as fertility, particularly among young women, is employment. According to results from the 1976 replication of Americans View Their Mental Health, attitudes toward both housework and paid work have shifted since 1957. Housewives are less positive about housework and an increasing number plan to seek jobs. At the same time employed married women express a much higher level of job commitment, saying they would work even if they didn't need the money. Leisure is no less important to them than it is to full-time housewives but for many it is less important than work in fulfilling their major life values (Douvan, Veroff and Kulka in press).

These attitudes have been translated into labor force participation. For mothers of schoolage children, employment has become the norm. Even among mothers of preschoolers it has become increasingly common with 42 percent in the labor market (Hoffman 1979). Housework, childcare, and husband-wife interaction have been adjusted to the job demands of wives and mothers.

Time use studies have indicated that one solution to the multiple demands incurred when women enter the labor market is to put less time into housework (Berk and Berk 1979). Since the fewer hours put into housework by employed married women is not made up by contributions from other family members, the amount of housework which gets done within the family declines absolutely. Regardless of the decline though, a large portion of employed women's week still gets devoted to it. Besides getting up earlier to do housework before work and devoting weekends to laundry, shopping, and cleaning, working wives also spend part of their wages for time-saving foods and appliances, although rarely for paid household help. Thus, employment gets translated into lowered household production--less complicated meals, less ironing, less sewing--and higher household consumption--microwave ovens, dishwashers, and meals from fast food restaurants. Although to my knowledge we have no longitudinal studies on when, how, and what part of household production gets translated into household consumption, it seems evident that when family complaints arise during the process of household reorganization that accompanies entry into the job market, women assume the responsibility and adjust their lives accordingly.

While housework may lend itself to some reorganization, child care is more of a problem. Purchasing childcare replacements is limited both by availability and by costs. Working mothers often have to put together fragile packages of childcare from two or three sources. When these arrangements break down, as they invariably do, women assume the responsibility and adjust their lives to the crisis (Presser and Baldwin 1980). Despite these and other problems that employment brings into the lives of working mothers, the children rather than the mothers have received the most research attention.

Until the last two decades, researchers often hypothesized that being an employed mother was bad for children. As a result, the Nye and Hoffman volume, Employed Mother in America (1963), was a ground-breaking contribution to the study of the effects of employment on children. Their comprehensive review of research indicated that employment of mothers was not necessarily bad for children and even had benefits. Since then a variety of studies have indicated that children with employed mothers have more androgynous sex-role attitudes and that girls, in particular, have higher achievement aspirations than those from families without employed mothers. The implications for sons are less clear (Hoffman 1979).

If the children of employed mothers are somewhat different from those of full-time mothers, then the mothers' child-rearing activities must have changed as well. Obviously employed mothers spend less time around their children, although not necessarily less time in mother-child interaction (Hoffman 1977). What about the standards and expectations they hold for themselves and their children? Little research has been devoted to this question yet it seems more than likely that such change has occurred. If so, then some problems that have been attributed to the effects of maternal employment may, in fact, be the result of a lag between non-familial institutional expectations and those of parents. In my collaborative study of divorced mothers,² the mothers frequently felt that they expected a more mature and responsible role from their children than did the children's teachers and that classroom problems sometimes resulted. These mothers may or may not be correct in their evaluations but what this emphasizes is the intersection between changing family

roles and the responsiveness of other institutions to these changes.

A more common concern of researchers has been with the impact of women's employment on marital happiness. Loxley's (1980) recent analysis of the 1976 replication of Americans View Their Mental Health suggests no significant differences in overall marital happiness by wife's employment. However, when age is considered, younger employed women report lower marital happiness than full-time housewives. The complications introduced by balancing child-care and housework with employment apparently dampens marital satisfactions. Since women shoulder most of the burdens of adjusting family to work demands, such findings are not surprising. On the other hand, among older employed women who no longer have such burdens, employment apparently increases marital happiness (Douvan, Veroff and Kulka in press). Thus, in some cases, women's employment may give rise to family tensions, in others, contribute to the overall emotional climate of the family.

Women Heading Families

Nevertheless, expanding employment opportunities have often been cited as a reason for the increase in female headed families. Today, one out of every six families is being headed by a woman. Six out of ten divorces in 1975 involve children (Norton and Glick 1979) and Bane (1976) has projected that 40 percent of all children will spend some time before they are 18 in a female headed household. Almost 70 percent of the women who currently head these families were employed during their marriages, a rate much higher than among married wives (Bane and Weiss 1980).

For a variety of reasons, though, employment opportunities alone are unlikely to explain the rise in female headed families. First, both employment rates and divorce rates are higher among younger women. Second, women may enter the work force just prior to divorce in anticipation of heading their families. Third, women may leave marriage because their husband fails to earn money forcing them to hold a job despite their desire to be full-time mothers. In the divorced mother study mentioned earlier, the latter situation was common among young mothers. Having supported the family until their first child was born because their husband would or could not do so, they realized that the birth of their child did not change his earning ability. Nor, for that matter did he take on greater responsibilities by caring for the child. As a result, being a divorced mother meant the same responsibilities they had as a married mother but with one less person to care for.

Finally, the economic and social situation of divorced mothers who head their families can hardly be described as an inducement to leave marriage. The end of the marriage for the women in the divorced mother study meant a drop of over 50 percent in family income, residential mobility, and, reliance on used or second-hand goods to meet family needs (Kohen, Brown and Feldberg 1979). While welfare and child-support stipends are a resource for female headed families, usually they are inadequate to support a family. As a result, whether the mother wants to be employed or not, she comes to depend on employment to provide for her family. Consequently, almost 90 percent of divorced mothers are employed (Bane and Weiss 1980). Yet, many women who head their families receive such low wages that they also qualify for welfare assistance. Thus, the picture of a married wife getting divorced because of the self sufficiency engendered by being employed appears to be a myth.

Certainly, employment opportunities enable women to head their families, but it is unlikely that divorces would occur if there were not changes in role expectations within families that produce tensions and conflicts. Returning once again to the divorced mother study, the analysis

² This study was done by Boston Women's Research Center and supported by a grant from Russell Sage. Co-researchers include Carol Brown, Roslyn Feldberg, Elizabeth Mawry, and Ruth Brandwein.

indicates that women choose single parenthood to escape such problems as alcoholism, violence, and continual marital disputes. If employment plays a role, it may do so by encouraging a sense of competence and self worth that enables a woman to end a marriage and head a family when either hers or her children's needs are threatened. In the divorced mother study, the women often had trouble finding jobs and worried about making ends meet, but they valued the independence and control that resulted from heading their families. These women were less likely to be self-sacrificing victims of unhappy marriages than women were several decades ago. Loneliness, fatigue, and poverty were balanced with a new sense of self identity (Kohen in review).

Summary

Each of the major areas I've addressed, delaying marriage, planning children, taking on jobs, and heading families, indicate changes in the way women are relating to marriage, to family, and to themselves. Women no longer accept or expect the traditional family roles of their parents. Marriage and motherhood continue to be part of women's lives but women are remaking these family roles without giving up their self-identities. They are developing a sense of autonomy and are no longer uncritically responding to traditional patterns and institutions.

PSYCHOLOGICAL AND SOCIOLOGICAL PERSPECTIVES ON
WOMEN'S PAID AND UNPAID WORK CHOICES

Ruth B. Ekstrom, Educational Testing Service

Abstract

Working women are not a homogeneous group. The decision to work is related to situational, experiential, psychological, societal and opportunity factors. These factors interact in different ways for working class vs. middle class women and for wives vs. women who are the sole support for themselves and their families.

Introduction

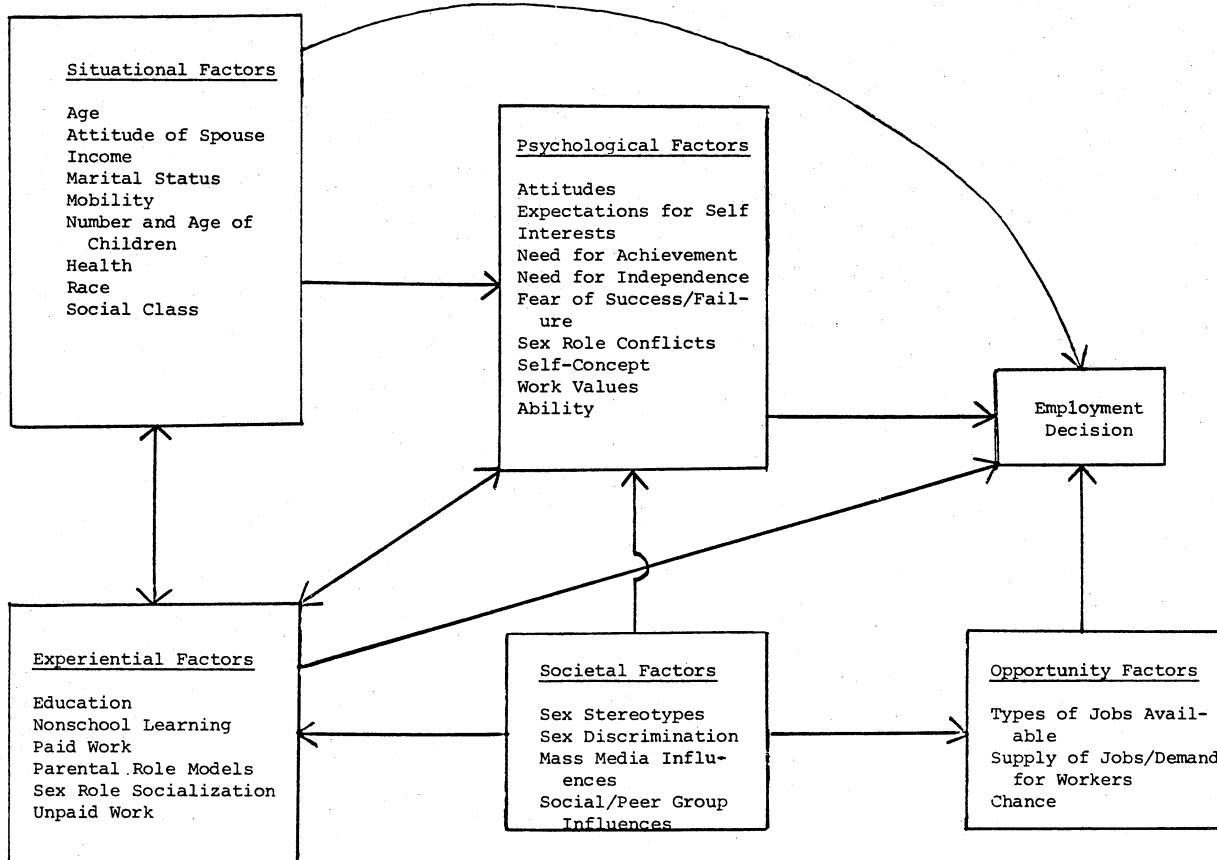

Today more women than ever before are working for pay outside of the home. Data for 1979 show that 51% of all females age 16 and over are in the labor force (the comparable figure for males is 77%). There has been a 10% increase in women's labor force participation rate in the past decade. As Hafstrom and Dunsing (1978) have pointed out, this affects not only the level of consumption but also the types of goods and services purchased. Therefore it is important to understand the factors that enter into women's employment decisions.

What Are the Factors Affecting Women's
Employment Decisions?

I hypothesize that there are five major factors which determine women's decisions about paid work (see model in Figure 1). Three of these factors are personal, specific to the woman herself. These include: (1) situational characteristics, such as age, race, social class, marital status, and number and age of children; (2) experiential characteristics, such as education, parental role models, sex role socialization, and previous paid work; and (3) psychological characteristics, such as ability, attitudes, expectations, interests, needs, and sex role conflicts. Each of these three personal factors can affect the employment decision directly. In addition, the situational and experiential factors affect the decision indirectly by modifying the psychological variables.

There are two other factors which affect the employment decision but which are external to the woman herself: (4) societal factors, such as sex discrimination, sex role stereotyping, mass media influences, and social/peer group

FIGURE 1
Model of the Factors Affecting Women's Employment Decisions

influences; and (5) opportunity factors, such as the types of jobs available, the supply of these jobs and the demand for workers to fill them, and, finally, chance--that is happening to hear about a job or being in the right place at the right time. The opportunity factor affects the employment decision directly while the societal factor affects it indirectly through the opportunity, experiential, and psychological factors.

A detailed discussion of the opportunity and societal factors is outside of the main scope of this paper but I would like to comment on them briefly. When the society at large accepts certain sex stereotypes (such as women lack mechanical aptitude) it not only limits the job opportunities available to women but it also affects women's feelings about themselves and leads them to believe that it is unfeminine or inappropriate to do certain kinds of work. This, in turn, leads women to narrow their job search to sex stereotyped occupations or, if they enter nontraditional occupations, to fear success and have sex role conflicts. Perceived support from both male and female peers is an important component of the societal factor and affects career aspirations (Angrist and Almqvist 1975; Parsons, Frieze and Ruble 1978). The availability of societal support through institutions, such as day care centers, women's groups, and other community institutions is also important in career decisions (Nye and Hoffman 1963).

It is important to point out that women's work choices are often not a single decision but a group of decisions. Many of the research studies have divided women into different experience groups or patterns of paid work. One common differentiation is between career-oriented and homemaking-oriented women; this may involve determining if the women are currently working and if they plan to work in the future. Thus, one can conceptualize women as falling into four groups: (1) those currently working who plan to continue; (2) those currently working who plan to leave the labor force; (3) those not currently working who plan to re-enter the labor force; and (4) those not currently working who plan to remain homemakers. Another common differentiation is between women who are homemakers, those in traditionally female occupations, and those in occupations that are nontraditional for women (pioneers). Still another differentiation is between women who are "career-oriented," as defined by intention to pursue a specific profession or occupation (or a group of hierarchically related occupations) and those who are "work-oriented" but not career oriented, as defined by intention to be in the labor force for much of their adult life but without a commitment to a specific occupation.

How Do Situational Characteristics of Women Relate to Employment Decisions?

Working women are not a homogeneous group. Situational characteristics of women are clearly related to differences in labor force participation.

Age cohort data on women's work is shown in Table 1. As can be seen, labor force participation increased between 1960 and 1978 in every age group except for women over age 65. The 1960 and 1970 pattern shows that women decreased their labor force participation during the child-bearing and childrearing years; this is no longer evident in the 1978 data.

One of the fastest growing groups of working women is mothers with children under the age of 14. In 1979, 41% of women with children under age 3 were in the labor force, as were 52% of women with children ages 3 through 5, and 62% of women with children ages 6 through 13.

Another rapidly increasing group in the labor force is women age 20-24. This is related to the trend toward

TABLE 1
Labor Force Participation Rates, by Age Cohorts
1960, 1970, and 1978

Age Cohort				Increase
	1960	1970	1978	1960-1970
20-24	46%	58%	69%	23%
25-34	36%	45%	63%	27%
35-44	43%	51%	62%	19%
45-54	50%	54%	58%	8%
55-64	37%	43%	41%	4%
65+	11%	10%	9%	-2%

later marriage. In 1970 approximately one-third of women in this age group were single; today approximately half are single.

Another rapidly growing group of working women, sometimes called displaced homemakers, are the middle-aged women who have been widowed or divorced. The data shows that the labor force participation rate is higher for divorced women (74%) and for single women (63%) than for married women (49%).

There are also racial differences in labor force participation. About half (51%) of all White women work for pay outside the home. This figure is slightly higher for Black women (53%) and slightly lower for Hispanic women (47%).

Most women make the decision to work for the same reason as men do--they need to provide for themselves and their families. Of all women in the work force in March 1978, 25% were self-supporting single individuals and 19% were self-supporting widows or divorced individuals; 18% were married to men whose 1977 income was below \$10,000, 15% were married to men whose income was between \$10,000 and \$14,999, and 23% were married to men whose income was \$15,000 or more.

The research on situational factors affecting women's employment reinforces these data. Miyahira (1976) found that women are most likely to work if they are single, if they have no children, and if financial need exists; they are least likely to work if they have children under age 6, if there is adequate income, and if the husband disapproves of the wife's working. Heckman (1978) found that the major variable leading a married woman to seek employment was the unemployment of her spouse; the major variable keeping women working in the home was the presence of children. Tang (1976) found that husband's positive attitude about wife's working, husband's low income, and few or no children were the major situational variables affecting women's employment.

Mobility, on first consideration, would appear to increase the probability of employment since migration can be to areas where the opportunity factors are better. This is true for single women. However, married women may lose job opportunities when they move. Data from a national longitudinal study (Parnes et al. 1975) found that migration led to the improvement of earnings for the family unit as a whole but earnings of the wife deteriorated as a result of the move.

There has been very little research on working class women for whom paid employment is more often a necessity than a choice. Studies by Walshok (1976) suggest that this group, which does not have the resources for the "elaborative" aspects of homemaking (such as, interior decorating or gourmet cooking), or a tradition of participating in unpaid work in voluntary organizations, may

find paid work a major source of personal satisfaction as well as providing additional income for family well-being. For the married middle class woman with adequate income paid employment is a choice; it is in this population that differences in the experiential and psychological factors have their greatest effect.

Stroud (1977) identified four patterns of work experience: (1) the career to homemaking pattern in which the woman leaves the work force after the birth of her children; (2) an unstable, intermittent pattern of labor force participation; (3) double-track women with high family orientation but who are in the labor force; and (4) work-committed women, with high career involvement who may or may not have families. She found that socioeconomic status significantly predicted career decisions in all groups. Family and personal characteristics were significantly related to work commitment for women who had attended college but there was no relationship between these variables and work commitment for women who had not attended college. College educated women with double-track or intermittent careers were unhappy in their marriages and in their role as homemakers.

How Do Experiential Differences Affect Women's Employment Decisions?

Education and other forms of job training have a large influence on employment decisions. As Mott and his colleagues (1978) have shown in their longitudinal study of the educational and labor market experience of young women that "women capable of earning higher salaries are more likely to maintain their work ties. Conversely, women with the least economic bargaining power--the less educated and the less skilled--are least likely to find and maintain employment at a reasonable wage level." The higher a woman's educational level and the greater the amount of occupational training, the more likely the woman is to be committed to a career rather than being home or work oriented.

The nature of women's unpaid work experience, especially their experience as homemakers, may lead them to seek paid employment. Early studies of homemakers (Weiss and Samuelson 1958) found them happy and content. More recently Ferree (1976) found that full time homemakers, compared to employed working-class women, are more dissatisfied with the way they spend their time (26% vs. 14%), feel that they have not had a fair opportunity in life (47% vs. 38%), and want their daughters to be different from them (35% vs. 22%). Ferree concludes that housework does not lead to a sense of competence, social connectedness, or self-determination to the same extent as does paid employment. Iglehart (1979) found a significant decrease in positive feelings about housework between 1957 and 1976. She also found a significant increase in the proportion of full-time housewives who plan to work at some time in the future. A study by Segre (1978) suggests that the happiest homemakers may be those who perceive that they have a choice between remaining at home and entering the work force; she also found that women who were part-time returnees to the work force were happier than either homemakers or full-time workers because they felt they had exercised a choice of position.

Several studies have indicated that there is a "chicken and egg" problem in studying the relationship between work experience and psychological variables, such as attitudes. For example, Macke, Hudis and Larrick (1978) found not only that attitudes affect the decision to work but also that work experience has a strong effect on attitudes. These authors believe that early sex role attitudes influence initial employment decisions and that the nature of this paid work experience affects later sex role attitudes and work decisions.

The early sex role socialization experience of young women affects their adult work decisions. Nickerson and Pitochelli (1978) describe how feminine sex role socialization often involves learning to be passive and dependent, what Lipman-Blumen (1972) calls "learned dependency." In later life this can lead to reduced feelings of control and reduced self-confidence when entering the labor force.

It has been generally acknowledged that parental role models, especially the mother, play a major part in the development of career aspirations in young women (Angrist and Almquist 1975, Nye and Hoffman 1963, O'Leary 1974). In general, daughters whose mothers worked during their childhood have higher career aspirations than daughters whose mothers were not in the labor force. More recent analyses have suggested that this relationship is somewhat more complex. Data from a national longitudinal study of working women (Mott 1978) shows that women who grew up in two parent families were more likely to work if they had a mother who worked during their childhood. This finding did not hold for women who grew up in single parent households. This suggests that when a mother makes the choice to work, she provides a positive model for her daughter but when the work decision is forced on the mother by circumstances, such as poverty or widowhood, it may be perceived by the daughter as a negative model. Parsons, Frieze and Ruble (1978) found that both mothers with careers and homemakers who were dissatisfied with their lives had daughters with high career aspirations but mothers who were satisfied with their role as housewives had daughters with lower aspirations.

How Do Psychological Factors Affect Women's Employment Decisions?

Much of the literature on the psychological factors affecting women's careers is based on research with college educated women. It seems likely that it is in this group, with a high investment in education and high income husbands, that ambivalence about paid work may be the greatest. However, it is unwise and unrealistic to over-generalize from college educated women to women in general.

Women often express conflicting feelings about their wish to enter the labor force and the fears they hold about the consequences their employment may have in their marriage and for their children. As the number of roles increases (from worker to wife and worker to mother and wife and worker), a woman feels increasing role conflicts. Home pressures appear to be the most important contributors to role conflicts (Hall and Gordon 1973). The absence of a supportive male, as is the case with displaced homemakers and other women who are self-supporting, increases the perception of role conflict and is a factor limiting interest in higher-level careers and inhibiting the movement of working women into positions of greater responsibility (Jerdee and Rosen 1976). O'Leary (1974) has suggested that at the point in the life cycle where women face multiple responsibilities, employing organizations should focus on helping women cope with role conflicts rather than on how to motivate them to achieve in the occupation.

Three psychological factors that inhibit women's occupational aspirations have been identified by DiSabatino (1976). These are sex role conflicts, poor self-esteem, and fear of failure.

The psychological literature shows that, in general, females have a poorer self-concept than males and that females of lower socioeconomic status may have poorer self-concept than middle class females. Thus, women are likely to have more doubts than men about their ability to compete in the work force successfully.

Mendelsohn (1979) compared the personality and characteristics of career-oriented and homemaking-oriented college

educated women. He separated these women into four groups: (1) those currently working who plan to continue working until retirement; (2) those currently working who plan to leave the labor force; (3) those not currently working who plan to re-enter the labor force; and (4) those not currently working who plan to remain homemakers. For all groups except the nonworking women who plan to remain at home, the opportunity to use skills was rated as the most important reason for working; this difference reached statistical significance between women now working who plan to continue and women not now working who do not plan to work. This finding and my own research with re-entry women (Ekstrom, Beier, Davis and Gruenberg, In press) shows that although homemakers have many skills they view themselves as having fewer skills than women in the labor force. The other significant difference between Mendelsohn's four groups was that women now working who plan to continue rate need for money more highly than women who are not now working but who plan to return to work.

Fear of success is a concept originated by Horner (1972). She has shown that women perceive a conflict between societal expectations for women to be noncompetitive and dependent and the competent, achievement-oriented behavior needed for success in many occupations. These findings have not been consistently replicated. Some researchers think that fear of success comes into play only when women are employed in occupations that are predominantly male.

Women choosing nontraditional careers tend to be more independent, more committed to their careers, and to hold more nontraditional sex role attitudes than are women who choose traditional occupations (Farmer 1979).

Walshok (1976) has identified the work values important to women in nontraditional blue collar occupations. These women are, first of all, concerned with the economic rewards of work, not only as a means of obtaining money needed for support and as fair compensation for contributions made, but also as a means of becoming self-sufficient and independent and of achieving an enhanced sense of self-worth. They also view paid work as a way of escaping the boredom of the home, of obtaining outside communication and friendship, of obtaining recognition and a sense of achievement, and of being challenged by the opportunity to learn new things and prove oneself capable.

The women in the Walshok study were, as a group, quite liberal in their sex role attitudes. For example, 93% felt that it was all right for women to compete with men for jobs; 93% also felt that most jobs can be done as well by women as by men. They showed little problem with sex role conflicts; 86% felt that a woman could have a career and still keep her femininity. These women also felt that husbands should take an active role in the family; 93% expected husbands to help in the kitchen and in doing other housework; 87% expected husbands to share actively in raising children. In contrast to this group, women who are homemakers have more traditional attitudes about sex roles (Segre, 1978).

A number of researchers have used Eyde's Work Values Scale to identify differences in the values held by working women and homemakers. Wolkon (1972) found that college educated women who were homemakers and who were in traditional occupations ranked independence as their highest value but women who were pioneering in nontraditional occupations ranked economic rewards as their highest value. In general, there were larger value differences between the traditional and pioneer working women than between the traditional working women and homemakers.

Summary

In summary, the vast majority of women make the decision

about whether or not to enter the work force on the basis of need and other situational factors, such as marital status, presence of children, and husband's attitudes about women and work. Opportunity factors not only affect the decision to work but also play a large part in the job choice of women with limited education and/or job training. College educated women appear to have higher expectations for their careers but feel greater sex role conflicts in their decision to enter the labor force. Women who elect the unpaid work of homemaker may do so because of traditional sex role attitudes, because they perceive high conflict between femininity and success, or because they feel they lack the skills needed in paid work. Married women in paid work, whether by choice or necessity, report problems arising out of their multiple roles as worker, wife and mother.

WOMEN IN PAID WORK: SOME CONSEQUENCES AND QUESTIONS FOR
FAMILY INCOME AND EXPENDITURES

Hila Kahne, Wheaton College

Abstract

The paper examines consumer preference and expenditures in relation to women's market work and income. Working women's participation rates, family forms, and income patterns are analyzed. Identification of research needs emphasize consumer expenditure studies at moment of time and studies of market responsiveness to changes over time in working women's lives.

Now that the social revolution in women's roles has become a settled way of life, analysis has begun of the economic consequences of these changes both for individual lives and for the economic life of the society. This paper looks at one aspect of these consequences which result from changes in numbers, characteristics and income of women engaged in paid work. It is concerned with how consumer preferences and expenditures are altered by women's labor force participation and by the income earned.

I will begin my discussion by reviewing the changing trends in women's work force participation and their family characteristics occurring over the past decade. I will then present some data on income patterns that have resulted from the influx of women into paid work. The section will conclude with brief comments on expected future trends related to working women, which have consequences for consumer needs and demands. The final section discusses three broad questions which require research attention if we are to understand more fully the relationship between working women and consumer behavior.

Trends and Characteristics of Women in the Labor Force

World War II and its aftermath speeded up a process of women's entry into paid work earlier given impetus by the dramatic population shift from farm to city, a shift which made it feasible for women to take paid jobs in place of unpaid labor on the family farm (Waldman 1976). Between 1950 and 1965 the proportion of women in the civilian labor force increased from 29.6% to 35.2%. More than one-half of the net addition of 7.8 million women workers were accounted for by mature middle-aged women, most of whose children, if they had any, were grown.

Since 1965 the social revolution in women's paid work has moved to a different age group. In this period, it is young women, particularly young married women and mothers of pre-school children who have experienced the most marked shifts of entry into paid work. During the decade of the 1970s, 58.8% of the 20.2 million person increase in the civilian labor force was due to the influx of women with the result that by 1979 43.4 million women, more than double the 18.4 million in 1950, were working or looking for work. They represented 42.1% of the paid civilian labor force of 103 million persons (29.5% of the labor force of 62.2 million in 1950). Fifty-one percent of all women 16 years and over were in the labor force. Between 1970 and 1979 women aged 25-34 accounted for nearly one-half of this increase in the number of female workers, despite the fact that almost three-fourths were married with a husband present and had young children at home (Norwood and Waldman 1979). By the end of 1979, almost two-thirds of all women aged 25-34 and 54% of mothers in this age group were working or looking for work. Overall, between 1950 and 1978, although the labor force participation rate

of women increased by 50%, that of married women, husband present doubled, reaching 47.6% in 1978, and that of married women, husband present with children under age 6 increased by more than three times, being 41.6% in 1978. Just as for mature women in the earlier period, the rate changes were mostly due to continued rising participation rates of women with similar characteristics, not to demographic changes in the female population itself. Paid work discontinuities, associated with marriage and child rearing in the past, are today strikingly diminished as important causes of women's life cycle work pattern.

One of the most important consequences of these changes in women's labor force participation rates has been the increased prevalence of the dual-worker family, now 60% of all married couple families (36% in 1950). The group, now numbering 28.4 million persons, has increased by 3 million since 1970, due almost entirely to the increase in the number of working wives (Hayghe 1976).

But other important changes in family forms are also taking place. Since 1970, the increase in the number of never-married women has risen significantly, an outgrowth of the coming of age of the "baby boom" generation and of the greater prevalence of postponed marriages. The rise in their labor force participation rates between 1970 and 1978 was greater than that for women in any other marital status, reaching 60.5% in March 1978, with the result that single women now comprise about one-fourth of the working woman population, a proportion not reached since 1957 (Johnson 1979). At the same time, the number of divorced women in the labor force has doubled between March 1970 and March 1978 as a result of a dramatic rise in the divorce rate, from 2.5 per thousand population in 1965 to 5.2 per thousand population in May 1978. The labor force participation rate of divorced women is higher than that for women in any other marital status (Johnson 1979).

Largely due to the rising incidence of separation and divorce (and also somewhat due to an increased number of never-married women who head families) the past eight years has also seen a significant rise in the proportion of families maintained by women. One in seven families in 1979 fits this description; their numbers are up 48% from 1970. Their 1979 labor force participation rate is 59.3%. Their earnings are extremely low.

How can we relate these trends in family characteristics of women in the labor force to our interest in consumer behavior? We have shown that although the numbers and proportion of working women have increased markedly, the increase is different for different marital groups. In the 1970s, increases in labor force participation are being felt most strongly among young married women, among women with young children, and among single women. At the same time there are marked shifts in the relative prevalence of family forms. Although the norm among women workers continues to be that of married status, there has been a sharp increase in the number of never-married women, a doubling of numbers of women in divorced status and a rapid rise of families headed by women, about 60% of whom are in paid work. By March 1979 30.1 million children had mothers in the labor force, almost 20% more than in 1970. Family lifestyles and incomes interact in their effects on consumer behavior. We must be alert not only to this contemporary experience with evolving family forms and labor force participation, but also to the rewards of paid work for women.

Together they impact on available income and on the kinds of consumer demands for its use.

Income of Women in the Labor Force

The income derived from women's paid work reflects a number of influences including the economic reward structure for particular occupations, continuity of work histories, training and education, the degree of part-time and part-year work, and at times still, the extent of discrimination. Because of the wide variation in influence of these factors among working women, a variation which is not diminishing over time, earnings distribution among women shows considerable range, larger than that experienced by men. Large earnings differences between women and men workers also continue, even when both work full time, year round (Henle and Ryscavage 1980). For many women and their families, an adequate standard of living is still contingent upon the existence of another income in the family.

Women's employment, as we know, is concentrated in a relatively few occupations, many of which have low status, little career progression, and limited economic reward. It is true that in recent years the proportion of women in some male professional fields has been growing -- e.g. accountancy, medicine, law. Professional, managerial, and sales jobs have expanded for women in a number of industries -- in the Federal government, in transportation, public utilities, finance, and insurance (Davis 1980). A recent survey of over 250 corporations documented considerable progress in the kinds of training and promotion opportunities offered to women at higher managerial levels in the private sector, particularly in female intensive industries (Schaeffer 1978). There is some indication that, spurred on by economic need and supported by affirmative action policies, blue collar women are finding jobs in construction trades and as miners, although in each division, employment is still under 10% (Davis 1980). The employment of black women as private household workers has dropped dramatically and an increasing proportion have become employed in clerical work. Among white women, the proportion in white collar positions have risen somewhat, while that of operatives have declined (Young 1980). Yet, despite such advances in women's proportionate representation in higher paying and more career-oriented occupations, the numbers of women so involved are still not large. Women have yet to reflect in their employment the full range of occupations in which men engage and for the most part have yet to achieve vertical career mobility once entry on a career track has been gained (Reubens and Reubens 1978). Women's median full-time earnings continue to be about 60% those of men, a relationship that has prevailed for the past 20 years (Norwood and Waldman 1979). The data on occupational distribution and earnings explains why income in families headed by women, even when working, continues to be so low. Occupational disadvantage reinforced by earnings disadvantage related to lack of training or experience, or opportunities, or discontinuities, or discrimination, affect both aggregate and specific consumer expenditures that would otherwise be generated by earnings from the work that women do.

Working women who are family householders and those in dual-worker families provide an interesting contrast of the characteristics that prevail among working women. Families with female householders numbered 8.2 million in 1978, and constituted 14.4% of all families. About 60% were in the labor force. They are a group who have grown sharply in relative importance as the divorce rate has spiraled upward (an increase of 47.7% in the past eight years). They are more likely to be black than are other families. They are more likely to have dependent children under age 18. Their labor force participation rate (58.9%) is higher than that of married women living with husbands (47.6%). Among women who head families, labor force participation is highest for divorced women (77.6%) and lowest for widows (39.4%). Their level of education

is considerably less than that of married women, husband present, and indeed of working men, and this affects their occupational work and income. Except for a small movement into non-traditional occupations, the overwhelming majority of female family householders work in traditionally female occupations. Second workers in families headed by women are much less common than in families headed by men (31% and 56% in first quarter, 1977). In 1979, 53% of families where the husband was unemployed had at least one employed family member; only 17% of families maintained by an unemployed female householder, had an employed family member. Responsibility for family maintenance rests heavily on the shoulders of female family householders. What can we say about income of these families?

Because of low average earnings, lack of steady employment, and absence of supplementary income from other earnings or asset sources, median income of these families is low. In 1977, it was \$7,700, or only 44% of the \$17,720 total for husband/wife families. Women family heads earned about \$6,370 or \$8,850 if they worked at full-time jobs all year. (Men earned an average of \$13,600 or \$15,600 for full-time-year-round jobs.) Consistently during this decade, about one-third of all families headed by women had money income below the poverty level, compared with about 5% of husband/wife families. Consumer behavior for individuals in this family form is strongly influenced by the absence for many of even a basic minimum income.

Dual-worker families provide contrast in both their composition and income level. They are about 60% of all married-couple families; in one-half of such families, both the husband and wife have jobs. Such families tend to be not only with higher income, but also younger, more mobile, and of greater educational achievement than single-earner families (Rawlings 1978). Despite the fact that only about 17% of husband/wife dual-worker couples both hold full-time jobs (1976 figure), the pay of working wives contributes about one-fourth of the family income, a figure that has remained constant over the past two decades (Johnson 1979). Wives who worked year-round full time in 1977 (41.7% of working women in dual-worker families) had a median income of \$8,600 and contributed 38% to the family income. Median income for families with the husband as the only earner was \$15,796 in that year compared with \$20,723 when both husband and wife worked (Johnson 1979). In general, wives' earnings were lower than husbands' earnings, although in one of every three married couples in which the wife had earnings, they were in the same or a higher class interval than that of her husband (Rawlings 1978). The contribution of the second family earner to the family standard of living is significant. In 1954, 57% of all families with incomes of \$25,000 or more had two incomes; in 1974, the year of latest available data, in 80% of households with the same high real level of income there were two earners. In recent years a rising proportion of these higher income level households have come into being because of women's entry into paid work.

In terms of societal income distribution, the implications of the two-paycheck families are more complicated, for they cause a marked division in income between families with a single earner and those with two or more earners. In 1977, as in 1970, the income of husband/wife families when only the husband was an earner was about three-fourths that of families when both husband and wife were earners (Johnson 1979). Moreover, 60% of working wives who entered the labor force in the 1960s and 1970s came from families with husband's income in the upper middle and upper ranges (Ryscavage 1979). If this trend continues, the gap between above-average income families and below-average income families could widen further, increasing the inequality of income distribution and causing problems for maintenance of economic well being for those families still in a single earner mode.

There is no reason to believe that present trends will be reversed in the near future and in fact they may be reinforced by additional factors we have not discussed. Family forms may develop further variety -- we did not refer to forms of communal families or those in non-married family status, both two sex and single sex partners. Nor have we discussed the greater variability than in the past of movement into and out of family forms over the life cycle, a seemingly permanent pattern that also has a bearing on consumer behavior. Similarly, not only is the rate of growth of women's labor force participation expected to continue to increase, though perhaps at a slower rate, but the percent of women holding two jobs may continue to grow -- 2.3% of women workers in 1969, 3.5% in 1979. Estimates of labor force participation of women in 1990 range between 53.8%, if the number of children born to each woman turns upward again, to 60.4%, if participation continues to rise at its present rate of growth. It is expected that the proportion of the labor force accounted for by women may reach 45-46% of the total by 1990, increasing the potential influence of working women on consumer behavior. Married women are expected to account for a larger proportion of the female labor force by the end of the 1980s than today (due both to an older population and to continued increasing participation rates) and a sharp rise is expected to continue in the numbers of working mothers with pre-school children. By the end of the 1980s, two-thirds of all married women under fifty-five may be working, including over one-half of all mothers of young children (Smith 1979).

The increase in the number of households and the greater prevalence of the smaller household, partly related to the decisions of young working women to postpone marriage, will further influence consumption patterns. During the past decade, the number of households increased 26%, three times faster than the population growth. One-person households increased 40% between 1970 and 1976 compared with an 11% increase in multi-person households. There is some uncertainty about the rate of continued growth during the 1980s. Rising unemployment and inflation are beginning to cause elderly persons to move in with children and young married couples to reside with one set of parents. Estimates of household growth in the 1980s range from 16% to about 23%, depending on the assumptions made about life-style trends of marriage, divorce, fertility, and residence preference. The pattern of future household formation will further strengthen the influence which working women's decisions have on the consumption of goods and services.

Working Women: Implications for Consumer Behavior

Having described some of the recent changes in the characteristics and income of women who work for pay, we come to the critical question of what difference changes in women's labor force participation and income will make in consumer needs and expenditures? By asking the question in this way, we seek to focus particularly on those changes related either directly (through earnings, e.g.) or indirectly (through changes in living styles such as smaller households or in consumer needs associated with larger numbers of working women of middle age) to the numbers and characteristics of women in paid work.

I suggest three general areas which need research attention if we are to understand more fully the influence of the particular factor of working women on consumer behavior. Economic research is not yet extensive in this area. But the studies that exist not only provide important information about the relationship between income of working women and expenditures, but suggest a context for thinking about the issues raised and about next questions for investigation. As we review the evidence, we must keep in mind not only the changes as they affect individual family units but also the relative importance of those units in the societal structure. We must remember, too, that consumer needs can be translated into

effective demand either by spending of personal income or income generated by social programs.

1. What do we know and what do we need to know about the new directions in consumer needs and choices that reflect changes in the numbers and characteristics of working women and the family forms in which they live?

With the recent dramatic changes in family forms and in women's labor force participation it is important that there be available a descriptive comparative picture of the expenditure patterns of each of these family groups which are of continuing growing importance in the society. What are the budgetary allocations -- and needs -- of families with female householders? What are the needs and expenditures of single working woman households which have grown so rapidly in recent years? What is the consumer expenditure experience -- and unmet needs -- of families with working mothers, whether male- or female-headed? On the other hand, what can we learn if we hold family form constant and compare consumer behavior of working-woman families by age (life cycle phase), by race, by occupation or blue collar/white collar status?

Some of this information is provided in a recent paper by Clair Vickery (1979). In her discussion, which focuses particularly on husband/wife families with and without a working wife, she addresses two issues. First, how do family expenditure patterns differ if the wife is a homemaker from those of a family with the wife in the labor force? In the absence of a wife's paycheck, Vickery states, expenditures on clothing, transportation, recreation, and retirement are as much as 50% lower, and expenditures on the basics of food and shelter are slightly lower as are savings and financial assets. Except for work-related expenditures, these differences reflect the different expenditure patterns of a 30% difference in income. When a wife enters the labor market, there is both some replacement of a housewife's time with market produced goods and services (e.g. restaurant meals, laundry and dry cleaning services) and some additional work-related expenses.

The second issue studied by Vickery in her own research, relates to these work-related expenses. Using data from the 1972 Consumer Expenditure Survey, she analyzed spending patterns of middle-income families with similar household characteristics (number and age group of children, life cycle stage of family head) and assets, and with the same income, to see the differences in spending for families with and without a working wife. Her analysis revealed several items of working-wife expenditures not incurred by nonworking wives which reduced the equivalence of full income between the two kinds of families who had the same money income. Working wives spent substantially more for transportation, for social security and pensions, and for clothing than did families with non-working wives. These work-related expenses (about 14% of the wife's earnings before taxes), reduced the value of the family full income and may account for the lower estimated savings and market value of financial assets, and lower rates of home ownership found for a working wife than a homemaker family. Other expenditures did not vary much between the two kinds of families except that working-wife families seemed partly to balance the work-related expenditures by allocating a lesser proportion of income to shelter. Interestingly, child care expenses did not show up as a significant quantitative expenditure for the average working wife. Whenever possible, family members appear to care for children within the home.

Vickery has provided us with a beginning understanding of budgetary patterns that result from having a working wife. But as we have seen, not all working women are part of two-earner families. Nor, even if they are at the moment, are they necessarily continuously so throughout their lives. We need to study this. We also need studies of

budgetary allocations of working women -- white and minority -- in other family forms, reflecting a range of socioeconomic levels. We need to know more of the trade-offs involved in making consumer choices and of the unmet needs not registered by income allocations.

2. To what extent are consumer choices -- either particular purchases or amounts spent -- influenced by the fact of women's participation in paid work or by the amount of additional family income generated? Is there a different decision-making process about consumption -- and outcome -- when women are the income earners?

Theoretical conceptualization and empirical research on this question, again focuses particularly on wives' economic behavior. Economists have suggested a number of alternative hypotheses to explain purchases made with wives' earnings: Mincer suggests (1960) that working wives spend more on durable goods (a form of saving) than nonworking wives because their earnings have a transitory component which is likely to be saved; Galbraith states (1973) that they spend less on durable goods than nonworking wives because of less time available for consumer administration; Drucker claims (1976) that they use income for "extraordinary purchases" because their earnings are transitory (reported in Strober and Weinberg 1977). Strober and Weinberg (1977), using data from the 1968 Michigan Survey Research Center 1967-70 panel Survey of Consumer Finances, have compared purchases of consumer durables of TVs, dishwashers, washers, dryers, stoves and refrigerators, for a sample of married couple non-farm families under age 65 with and without working wives, holding income, net assets, life cycle stage and other factors constant. They found that size of family income and whether the family had moved recently, but not the wife's labor force behavior per se, were important factors in determining the purchase of specific goods and services. Moreover, income and assets, but not wife's labor force behavior were significant in determining how much was spent for such items. The findings do not imply that wives' earnings are unimportant; rather, they stress the fact that it is the income and not its source that is the determining factor in purchases. If family income, assets, and several other variables are held constant, there is no significant difference between working and nonworking wife families in family expenditures on durable goods. A more recent study by the same authors (1980) using 1977 data from a consumer marketing panel of husband/wife families designed by Needham, Harper and Steers, extends their investigation to consumer purchases of microwave ovens and freezers. Again, holding income and life cycle stage constant, they found no greater purchase of these "time saver" consumer durables among working wife than nonworking wife families, reaffirming their hypothesis that wife's income, like husband's income, is treated as a permanent component of family income. Even the time-saving quality of the items did not alter the expenditure preference for time-pressured working wives.

The findings, not inconsistent with those of Vickery, suggest the complexity as well as the need for currency in study of these budgetary issues. We need now to extend analyses to categories of nondurable consumer goods and services (where there is some evidence of higher expenditure for working-wife families) to identify these consuming patterns. We need to study families with working women in different socioeconomic groups and family settings where tastes and pressures of time may have different effects on the outcome. Experience of families with working women in different life cycle phases, of working women who experience changing family forms over time, and of working women in a non-continuous paid work pattern within one-family form must each be examined to test the consistency of findings in different settings.

3. How do economic conditions of unemployment and inflation affect consumer needs and expenditures of working women and their families? Are studies of consumer behavior based on 1972 experience outmoded by these recent conditions? Will the affluent buying behavior wrought by the two-earner family give way to a standard of living crisis when unemployment strikes one earning member? Is the seeming work flexibility, made possible for the two-earner family, over-ridden by the rigid financial requirements established by a standard of living that requires both incomes? How do female householders with lower income and fewer second earners cope with needs and expenditures when unemployment or inflation strikes the household? For these, and for other working-women groups, how are expenditures adjusted when there are uneven and significant price rises in some essential categories such as energy?

In this area I have no research answers; only questions. They are critical ones for us to begin to address.

We live in a world where women now share with men responsibility for the production of goods and services of the economy and where their incomes comprise permanent and critical components of family income. Working women live in a variety of family forms. Their standard of living ranges from one of poverty, particularly prevalent among elderly, widowed and female householders, to one of affluence, often existing because both husbands and wives work. Their consumer behavior is also influenced by their roles, values, and tastes, which reflect both societal movement over time and individual change over the life course.

Research and marketing analysis has only begun to inform our understanding of this aspect of women's economic behavior. We need to study further consumer expenditures in relation to age, race, life cycle phase, socioeconomic situation of working women so as to learn more about the potential market for such items as luxury condominiums for two-worker small families, microwave ovens for working wife/mothers, sophisticated maternity clothes for the woman professional, or a new range of services for the traveling woman business executive. We need more expenditure studies for working women in all family forms. We need to know how economic conditions impact on their choices.

But in addition to a concern with effective consumer demand at a point in time, we need a better grasp of the responsiveness of the market to the changes taking place over time in the lives of working women. These have both to do with changing social mores and changing social roles. They sometimes take place because of movement among family forms in which working women live over the course of their lives and sometimes have to do with changes in women's paid work status over time that occur within a single family form.

Needs may be covered by effective private demand. They may be unmet needs that require social expenditures. Both kinds should be analyzed in research inquiries.

If research can extend and enhance our understanding of these aspects of consumer behavior, we will perhaps get a more complete grasp of the totality of consumer needs in relation to the flow of individual lives. My hope is that all these aspects, and not only individual product preference, can be addressed by our studies, so that we will be better able to assure that improvement in the quality of our lives proceeds apace with increased sales and marketing returns.

WOMEN'S CHANGING ROLES -- A CONSUMER BEHAVIOR PERSPECTIVE

Mary Lou Roberts, Boston University

Abstract

The multiple, and often conflicting, roles of women today pose significant challenges for marketers and researchers. This paper discusses actual and anticipated changes in women's consumer behavior on the basis of issues raised by studies of women's roles in non-marketing disciplines. Implications for research, marketing strategy, and public policy are discussed.

Change brought about by the continuing evolution in women's roles have affected, and will continue to affect, all aspects of our society. The purpose of this paper is to analyze the actual and anticipated effects of these changing roles on women's consumer behavior. The issues treated herein are those raised by the other five participants in this session. Underlying the multi-disciplinary approach taken in this session is a strong belief that we can better understand and anticipate the effects of women's changing roles on consumer behavior if we make use of knowledge available in the behavioral sciences and economics.

As an organizing framework, I will first treat issues directly observable in current demographic trends and then treat some interpersonal issues.

Four major factors which are evident in demographic data - delayed age of marriage, the decreasing fertility rate, women's employment, and women-headed families - have potential for causing important changes in women's consumer behavior. These factors have both individual and interactive effects.

Delayed Age of Marriage

One implication of this phenomenon is that women (and men, too) are spending more post-school years as single adults than have past generations. As young adult singles they may continue to live with their parents, live alone, live with one or more persons of the same (or with increasing frequency, opposite) gender, or live under the arrangement euphemistically described as co-habitation. Whichever living arrangement, or combination thereof, is chosen, delaying marriage implies a longer period of independence for the young adult.

The individuals who have experienced this protracted period of social and financial independence will bring to their eventual marriages a broad array of consumer skills. These consumer skills will be the result of both their own experience and of exposure to the life styles of other young adults including roommates, co-workers, and friends. Singlehood tends to force the acquisition of non-traditional consumer skills for both genders. For instance, the woman is likely to have purchased and maintained one or more cars and the man is likely to have prepared meals, maintained an apartment, and done the shopping associated with the performance of traditionally-female tasks.

Upon marriage, these persons are less likely to model their consumption patterns and decision-making processes upon the, probably traditional, patterns of their parents than are couples who lack this lengthy exposure to diverse and, often non-traditional, life styles prior to marriage. Both the nature of consumption-related decisions and the processes by which they are made will be affected. Kohen's statement that "young women will take part in

these negotiations with a greater sense of personal identity" is likely to apply in consumer decision-making as well as in family formation decisions. This sense of identity, reinforced by dual incomes, is likely to result in more autonomous decision-making by these couples.

Extensive pre-marital experience as single consumers may, over time, result in a more flexible approach to the division of household and other consumption-related tasks. Change is unlikely to be rapid, however. The most non-traditional attitudes and behavior should be exhibited by cohabiting couples, since they have chosen a relationship which is not sanctioned by a large proportion of our society. Still, a study of the division of household labor which included cohabiting couples (Stafford, Backman and Dibona 1977) found that even these couples were dividing tasks in the traditional, gender-linked manner. Even so, some change is becoming apparent. In earlier research dealing with meal preparation by husbands, Wortzel and I speculated that couples today seem increasingly inclined to perform at least the more creative tasks on the basis of personal preference as opposed to traditional gender roles (Robert and Wortzel 1979a). This is likely to become increasingly true as more young persons experience protracted periods of singlehood. While this is promising from the viewpoint of the demands on time of the working woman - and admittedly an over-optimistic one from the viewpoint of current time use research - it is a perplexing one for marketers. It has been difficult enough to select target segments, determine appeals, and accurately portray women as their roles have multiplied. Men's assumption of multiple, non-traditional roles will further complicate the situation. The best approach to take will be a cautious, research-based one, since change is not likely to occur simultaneously either across product categories or across market segments.

Since higher education is related to delayed marriage, another implication is that both partners will bring increased financial resources into the initial years of marriage. This will clearly allow for a more rapid accumulation of a stock of high-quality durable goods as well as for continued high expenditures on personal consumption goods, services, travel, and leisure pursuits.

Fertility

While the social implications of women's ability to control their fertility cannot easily be overstated, there are also important implications for consumer behavior.

One might start with the proposition that for the majority of American families having a child is now a conscious decision reached jointly by husband and wife. In her introduction to a special issue of the Psychology of Women Quarterly which deals with determinants of fertility, Russo states that "there is overwhelming scientific evidence that we value what we perceive ourselves to have freely chosen" (Russo 1979, p. 12). Therefore both necessity born of women's employment and positive attitudes toward nurturing of children should lead to greater male involvement in child rearing. Marketers should question whether fathers react similarly to mothers with respect to attributes of child care and entertainment products. Will they be more, less, or equally concerned about convenience in use, health and safety aspects, and educational benefits of products, for instance?

It seems clear that promotional activities for child-related products should reflect increasing male involve-

ment. Advertising themes, media selection and role portrayals may all be affected. Current television advertising for a new brand of disposable diapers can be cited as an example of portraying equal involvement of both parents in infant care.

The high educational level of these parents is likely to increase the size of the market segment which is extremely critical and demanding with regard to child-related products. Their expectations for quality in all types of products will be high. They will expect toys to provide developmental and learning experiences as well as entertainment. The increased financial resources they have accumulated as a result of delayed marriage, coupled with few children as a result of decreased family size, will allow sizeable expenditures on each child. The impact of large numbers of first births as well as many single-child households will increase the economic impact of this "echo baby boom" since higher per-capita expenditures are typical for first-born children (Cardozo and Haefner 1969).

Since many women may be delaying the birth of the first child until careers are well established, most of them are likely to return to the labor force very quickly, if they leave it at all. The resulting segment of well-educated and affluent two-worker families may choose to spend as little time as possible on activities that represent merely "custodial care" of the home or the children. Instead, they will try to devote as much time as possible to activities that provide rewarding family interaction. Products and services which promote interaction between parents and children that is both enjoyable and intellectually stimulating should be especially attractive.

Employment

In examining the effects of women's employment, Kohen points out that, while leisure is important to the working woman, it is frequently less fulfilling of them than is their work. In terms of their basic life priorities, this seems quite reasonable. Yet, it also seems reasonable to expect that changes in women's role-related attitudes will be reflected in their leisure pursuits. There is limited support in the literature for this hypothesis (Gentry and Doering undated). There is also the suggestion that women, like men, consider work and leisure to be inter-related and that women, even more than men, enjoy competitive leisure pursuits (Hawes, Blackwell and Talarzyk 1975).

In view of the limited amount of research available, some research questions seem to be in order. It seems clear that the scarce leisure time of the working woman should be highly valued. How does she approach the use of that leisure time? Does she see it as an end in itself or as an integral part of a well-rounded life, *i.e.*, as a way of keeping herself mentally and physically fit to cope with her work and personal activities? If she is married, does she reserve her leisure time for family activities or does she feel that she is entitled to some "time of her own?"

The theme of lack of time for the working woman to call her own recurs frequently in the more popular current literature on women's issues (see Bird 1974, for example). It seems that a majority of working wives correctly perceive themselves to be not only contributing to household income but also spending more time on household and child care than do other members of the family. They may, therefore, be very open to appeals related to doing something, either active or passive, for their own personal benefit and enjoyment.

In terms of the household consumer behavior that results from women's employment, marketers have more experience, but are not really much closer to developing useful

generalizations. The easy hypotheses have tended not to be confirmed by empirical data. Kahne points out that, although economists have hypothesized that purchase patterns for durable goods will be affected by women's employment, Strober and Weinburg (1977, 1980) have not been able to support this hypothesis with empirical data. The seemingly reasonable hypothesis that working women will tend to rely more on convenience foods than non-working women has fared similarly (Anderson 1971, Anderson 1972), although there is contradictory evidence (Editor and Publisher, 1972). Pointing out that sales of one convenience food, frozen vegetables, have actually declined in recent years, Wells sounds a warning that is widely applicable across product categories when he says, "Remember that frozen vegetables represent only one of a number of acceptable ways (emphasis mine) to shorten meal preparation time. The link between the desire to make meal preparation easier and the use of frozen vegetables is neither necessary nor direct (Marketing News 1980). Understanding the various possible approaches to task performance (see Roberts and Wortzel 1979b for an example), will shed considerable light on product and brand choice behavior. Again, a careful research-based approach is necessary, because there is no reason to believe that approaches to task performance will be consistent either across tasks within the same household or across households.

We should not overlook the fact that women's employment is creating for them another role -- customer for business goods and services. There is an easily observable tendency for marketers to fall back on the prevailing mythology about sex differences when dealing with women in business decision-making roles. Hesselbart sounds an important warning when she notes that "women and men in similar jobs have similar values and personalities." We should therefore not expect to find decision criteria and processes differing a great deal between male and female managers. Even in a situation where women do have a special set of problems (business travel is a good example), proprietary research has found no major difference in decision criteria between men and women. This type of woman, however, does appear to be very easily offended by two extremes of marketing behavior. At one extreme is blatant sexuality, usually in promotion, which is counter to her own role-appropriate behavior. At the other extreme is anything which bespeaks a patronizing attitude toward "the little woman." Actually, it may be that marketers of business goods and services have an easier basic task where women are concerned than do marketers of consumer goods and services; they should simply treat every role incumbent in the same manner.

Women-Headed Households

Both Elkstrom and Kahne point out that single women are disproportionately represented in the labor force and Kohen adds that one out of every six families is headed by a woman. Given current rates of divorce and of chosen singlehood, these trends seem likely to continue.

Expected differences in consumer behavior suggest that we should be looking at three different groups of currently single women:

Single women without families who are less than 55 years old (3 million in 1978).

Single women without families who are 55 years or older (7.3 million in 1978).

Single women who are family heads (5 million in 1978) (U.S. Department of Commerce 1978).

From 1970 to 1978, the most rapidly growing group of never-married women was the 25-34 age range (14% of all never-married women). Age alone makes them a prime

market for consumer goods, as does the fact that they are the best-educated of the women in this age bracket. In spite of the size of this market, only media catering to the young, single woman have published information which examines it specifically. It is clear that these women have a great deal of buying power, but how are they spending it? Are they buying condominiums or making other types of investments? Do they spend heavily on non-durable goods including clothing and personal care items? Are they especially heavy consumers of travel and entertainment services? The answer to all of these questions is undoubtedly "yes" but we need to understand the budgetary allocations of this segment. We also need to understand their shopping attitudes and habits. Are they part of the shrinking group of consumers who regard shopping as a pleasurable activity, perhaps because their free time is not constrained by family responsibilities? Are their shopping attitudes product specific - i.e. they like to shop for clothing and other personal items but dislike to shop for food? Do they mix shopping and entertainment? The basic hypothesis would be that the consumption patterns of this segment differ as a result of their relatively high level of "truly discretionary" income and that their shopping attitudes and behavior also differ from those of other women as a result of their life styles.

The segment of women living alone aged 55 and older presents a very different picture. They are less well educated and have lower incomes than other groups of employed women. In addition, women aged 55 to 64 are less likely to be employed than are any other group under age 65, although it is uncertain whether or not this is true for the single women in this age group.

Because elderly consumers make up a large portion of the market for many goods and services, there are several studies available. However, they tend not to cross-classify their data so that female responses can be distinguished from those of male respondents. One study (Martin 1976) studied fashion shopping behavior among young, middle-aged and elderly women. He found numerous differences between the three age groups with elderly women using more information from both media and sales clerks, shopping fewer stores, and shopping in specialty boutiques less frequently than either of the other two groups. Although there was little inter-group difference, elderly women perceived themselves as being fashion conscious and said they enjoyed shopping. While it is true that one might expect fashion-related behavior to differ widely between generations, different shopping patterns as well as the different information processing patterns discussed by Phillips and Sternthal (1977) suggest that different marketing strategies would be appropriate for the elderly female consumer. Single elderly women, an apparently unstudied group, should continue to increase in importance as a market segment, since a woman's life expectancy continues to exceed a man's by almost eight years and the differential is predicted to increase. (U.S. Department of Commerce 1978, p. 11).

The final group of single women is those who are family heads. As Kahne points out, the vast majority of these families are composed of children, a few include a male who is not defined as the household head, and still others are composed of other adult family members. While there are other similarities, the single most unifying aspect of these families is their low income level. It is not surprising that Kohen's research has found them to be an especially good market for used goods.

The low level of discretionary income does not make this a particularly appealing market target for most goods. The exception is products specifically designed to stretch the consumer's dollar, such as generic products in the supermarket. Even here, we may be missing out, because a recent study of the market for generics cites greater usage by the upscale customer (Murphy and Laczniak 1979).

This highlights the need for consumer information programs which will effectively reach this and other low-income segments. While this is a difficult task, it is one that deserves the attention of both marketers and researchers.

There is, however, another aspect of women-headed families that may prove to be of even greater long-run significance to consumer behavior. It is the consumer socialization of children from woman-headed households. If the alarming projection quoted by Kohen that 40% of all children will spend at least a portion of their formative years in such a household turns out to be true, we may see differences in socialization practices and the resulting behavior of adolescents and young adults.

It is clear that a great deal of learning about sex-role-appropriate behavior occurs in early childhood. However, the literature on single-parent families headed by women (see Herzog and Sudia 1973 for a literature review) indicates that, while absence of the father tends to delay this learning, other role models are used so that by young adulthood there is no discernable difference in internalization of sex roles between children from two-parent and single-parent families. It is not absence of the father per se that causes developmental and social problems in the children of single-parent families. Rather, it is the stress and fatigue engendered by the long hours, lack of dependable child care, and the low salaries of most of these women that lead to problems in the family.

The research to date does not seem to provide strong evidence to suggest that children from woman-headed families will be more sex-role egalitarian than children from two-parent families. It is more important to note that sex role stereotyping is less prevalent among children of all working mothers (Del Boca and Ashmore 1980), so maternal employment appears to be the key factor.

Kohen's finding that divorced mothers expect a more mature and responsible role from their children does suggest differences in consumption-related behavior in single-parent families with older children and teenagers. These children may shop for themselves and do routine shopping for the family at an earlier age. Time pressure in all families with a working mother, and especially in those with a single parent, suggests that more research attention should be given to assumption of household tasks and to shopping behavior by older children and teenagers.

Household Task-Sharing and Decision-Making

When considering the effect of changing sex roles on consumer behavior, one of the first concerns of marketers is changing patterns of household task performance. This concern seems to be based on the premise, which to the best of my knowledge has yet to be empirically tested, that persons who are involved in the performance of household tasks will be more influential in product and brand choice for task-related products.

There is ample evidence that both men and women hold increasingly egalitarian attitudes towards women's roles, and as a result, feel that household tasks should be shared. Unfortunately, egalitarian attitudes have not been readily translated into wholesale male assumption of household tasks (Lopata et al. 1980, p. 128). However, there is limited evidence that males are performing some traditionally female tasks (Roberts and Wortzel 1979a). When one of these tasks is grocery shopping, the results, in terms of brand choice, may be quite different than if the wife had done the shopping herself (Newsweek 1979, Progressive Grocer 1980). With the dramatic increase in two-wage-earner families in recent years, the topic of task sharing has relevance for marketers of a wide range of goods and services.

Various theories have been advanced to explain male-female roles in household decision making. Chief among them are the relative power, cultural role expectations, relative investment (Davis 1976) and time-available (Stafford and Dibona 1977) hypotheses. While all provide useful insights, none appears to provide consistent explanatory power with respect to household task sharing (See Wortzel and Roberts forthcoming for an extensive review of the literature on household task sharing).

Both observation and descriptive writing on the subject of household task sharing suggest that there are a variety of processes used in arriving at a, hopefully satisfactory, allocation of household tasks. They range from the marital contract which may specify duties in great detail, through recommended processes for arriving at allocations (see Seiden 1980, for an example) to the ad hoc arrangements which probably exist in the majority of households. The strategies used to allocate household tasks should provide insight into a broad range of family decision-making processes and are therefore well worth study.

At the risk of oversimplifying a complex situation, I would like to propose a paradigm which may be useful in studying household task allocation (Figure 1).

		Standard Relative to Task Outcome	
Attitude Toward Performing the Task			
	High	Low	
Positive	Individual likely to perform task	Individual likely to perform task 'when convenient'	
Negative	Individual likely to try to shift task performance to another person	Individual unlikely to care if task performed at all	

Figure 1.

As traditional roles become blurred, attitudes - whether actually positive toward task performance or just less negative than the partner's - are likely to become increasingly important. At the same time, perfectionist standards toward housework may be less important to women, especially working women, who have other inputs to their evaluation of their own self-worth. It is quite possible that a husband may have higher standards than his wife with regard to one or more specific task outcomes. This paradigm, then, applies separately to husband and wife and also to children old enough to assume general household tasks. Task allocation will be the result of the mix of attitudes and standards present within the family.

Other things equal, a positive attitude coupled with high standards should predict that the individual will perform the task. If two individuals in the family fall into this cell, they may share the task, perhaps on a time-available basis. The person(s) who perform(s) this task may actually prefer the type of product that requires more effort (materials to cook or bake 'from scratch' or non self-polishing floor wax, for example). On the other hand a person with a negative attitude but high standard, if (s)he must perform the task, would look for a product which achieves good results with minimal effort. The individual who falls into the positive attitude/low standard cell may be relatively indifferent to the attributes of the product used. The cell which couples negative attitudes with low standards, especially if it is prevalent throughout the family, suggests that the task may not be performed at all. There are two key warnings for marketers: not to assume that standards are uniformly high across the population and not to assume that they are gender-linked.

Hesselbart's distinction between expressive and instrumental tasks is also worth noting. Research has found that child care is the task husbands are most likely to share (Lopata 1971). Recent interest has centered on other activities such as cooking, which can also be expressive in nature. If husbands are most willing to share tasks which have expressive aspects and if women are less eager to find recognition or self-fulfillment tasks that are essentially instrumental, it suggests a more pragmatic approach to the promotion of products used in routine tasks.

It is also worth returning briefly to the problem of power versus time in the two-wage-earner household. If power is conferred by contribution to the family's income, then working women should indeed have more power in family decision-making. It is easy to hypothesize that women will exercise this power with the result being more joint decision-making. However, we must realize that time spent in income-producing activities is, for most women as well as men, time not spent at home. The trade-off between more power and less time may result in less assumption or sharing of previously male-dominated decisions than one would at first suspect. In fact, one study found more male participation in shopping and financial decisions that had previously been handled solely by wives (Pralle 1980).

Investigating how couples handle two incomes can also give useful insights into more specific consumption decisions. A study of more than 15,000 couples conducted by Family Circle magazine in 1976 and 1977 and quoted by Bird (1979, pp. 155-164) identifies four types of couples based on the manner in which they handle the wife's income:

- Pin money couples in which the wife's income is hers to save or spend as she chooses
- Earmarker couples who designate the wife's income for a specific purpose (children's college expenses, down payment on a home, etc.)
- Pooler couples who combine both incomes, usually in a joint checking account, and spend it without regard to its source
- Bargainer couples who treat income as the property of the person who earns it and negotiate the division of household expenses.

Preferred decision-making strategies are implicit in these categorizations. In addition, the freedom, or lack thereof, which the wife has in spending "her" money is likely to affect both product and brand choice behavior.

Working-Class Women

One large segment of women has been almost entirely overlooked in our discussion thus far. That segment is the working class woman. This is not surprising. Ekstrom notes that there has been little research on employment decisions of the working class woman. This is true of research on working class women in general with the classic studies (Rainwater 1959, Komarovsky 1962) predating the women's movement and therefore having limited applicability today. Major studies through 1974 are listed in an annotated bibliography (Samuels 1975), and a journalistic-type study which contains useful insights was published in 1977 (Howe 1977). However, research which explicitly deals with the consumer behavior of working-class women is virtually non-existent. The most recent study was published in 1973 (Social Research Inc. 1973).

Some of the salient findings about working-class women are:

- o Working-class women have been slower than middle-class women in breaking with traditional roles, and have tended to react negatively toward changes which appear to threaten established values.
- o For ethnic working-class women, especially, religious institutions tend to reinforce traditional values.
- o The working-class woman tends to be part of a tightly-knit social group composed primarily of female kin.
- o Although the necessity of working has expanded the social horizons of many working-class women, the traditional female jobs which most of them hold are not intrinsically rewarding.
- o These expanded horizons are reflected in the decreasing propensity of working-class women to define family responsibilities, especially child care, as the central focus of their lives. (Peters and Samuels 1976).
- o Working class husbands and wives tend to adhere to traditional household roles and to engage in sex-segregated leisure activities, even if wives work.
- o Wives' employment is often viewed as threatening by the working class husband whose ability to provide for the family is often the major source of his sense of self-worth (Samuels 1975).
- o While feelings of lack of self-worth and competency in dealing with the world outside the home have decreased among working-class women, they have decreased more slowly than have the same feelings among middle-class women. The result is an increasing disparity in feelings of self worth and self-confidence between the two social class groupings.
- o Working-class women are more likely than their middle-class counterparts to feel that their adult life is better than their childhood. Since part of the perceived improvement is due to acquisition of desired material goods, working-class women are more positive toward business in general and specific products, and toward the media in general and advertising in particular, than are middle-class women. (Social Research, Inc. 1973).

Taken together, these points emphasize the fact that most of our data about women come from middle-class respondents and is based on middle-class values. Working-class women make up an important market segment for many products and brands. In addition, they may react to some types of advertising appeals very differently from middle-class women (Johnson and Satow 1978). If we could believe that they are soon likely to adopt middle-class attitudes, values and patterns of behavior, their absence from most consumer behavior studies would not be an important omission. However, the S.R.I. study (1973) also indicates that working-class emphasis on upward mobility into the middle class appears for many to be giving way to an emphasis on achieving desired goals within the working-class milieu. The attention of researchers to the working-class market is therefore important and overdue.

Implications

For Research

The opportunities for research that are inherent in issues surrounding women's changing roles are so numerous that I shall make no attempt to enumerate them. However, there are some general issues that should be considered.

One of these is indiscriminate borrowing of concepts from other disciplines. The patterns of work experience described by Ekstrom are a good example of potential use and misuse. These patterns - career to homemaking, intermittent labor force participation, double-track women, and work-committed women - would seem intuitively to have potential in studies of family financial decisions. However, I see no reason to believe that they would be useful predictors of product or brand choice decisions.

A related problem is indiscriminate borrowing of methodology. Several years ago Green and Cunningham (1975) used Arnott's Feminism scale in a study of husband-wife decision-making and, citing this work, marketing researchers have continued to use it. This scale, which is about ten years old, is composed of ten attitudinal statements. Although the scale appears reliable, attitudes of the general populace continue to shift toward the "liberated" end of the scale, with the result being that the scale does not discriminate well. Since we know that role-related behaviors are not changing as rapidly as are related attitudes, role-orientation scales which have behavioral components should provide more ability to discriminate.

Another possibility is that we should move away from the idea than general role orientations will be good predictors of consumer behavior. Perhaps the concept of androgyny, infrequently used in marketing research to date, will be more useful.

The best solution of all, however, may be to focus on task and product-specific attitudes. They should not only be more powerful predictors of related behavior but will also enable us to avoid the troublesome problems of defining concepts such as "traditional" and "contemporary." Asking parallel questions of all family members will help us to understand the real nature of decision making within the family group.

And finally, all research, whether basic or applied, should recognize the inherent bias toward the middle class view of the world that is apparent in most of our work. Removing this bias will help us to understand the diversity that exists among American women today.

For Marketing

Those who market goods and services to women will be well advised to look beyond the "outputs" of consumer decision-making -- product and brand choice -- and to investigate in depth the processes by which those final decisions are made. The life style choices available to women today are many and varied. Products and services are sought both to implement these life style choices and to reflect them. Understanding how products and services fit into chosen life styles is a necessity if they are to be marketed effectively.

On the basis of research previously cited, it seems clear that we should expect to find few major differences in the purchase of consumer durable goods between families with working and non-working wives. Differences, however, may exist in buying behavior relative to frequently purchased goods and services, which have received less research attention to date. We should look for variations in product quality expected or preferred, in shopping patterns including outlet choices and timing of purchases, and in attitudes and family practices with regard to shopping.

In developing, as well as marketing, products and services we should look at the incompatible demands which often result from women's multiple roles. Any working wife or mother could assure us that these role-incompatible demands are legion. Take, for example, services of all kinds. Every provider of services -- from the washer

repairman to the orthodontist -- prefers to work from nine to five on weekdays. Obtaining services at these times is highly incompatible with the demands of most employers. Offering services at times and places convenient to the consumer could be a major coup. The same type of reasoning can be applied to the development and distribution of products which ease the time pressure brought about by the demands of multiple roles.

As marketers we should also look more clearly at the budgetary allocations and decision-making process of non-traditional families, especially the dual-income and the woman-headed family, two rapidly-growing groups. In this respect, we should also carefully evaluate the composition of households in the U.S. over the coming years. The number of households is expected to increase rapidly. Will the increase come primarily from affluent singles and dual-income families or will a large part of it be less-than-affluent woman-headed households? The demand for all types of goods and services, including consumer durables, will be greatly affected by the composition of households.

In effect, marketers should not look for easy answers to marketing strategy problems based on whether women work or not. The diversity of working, as well as non-working, women is too great for generalizations that will prove useful across broad groups of people and of products. Approaches centered around life styles, decision processes and task orientations should replace a simple working/non-working dichotomy.

For Public Policy

The papers in this session have also raised numerous issues which have public policy implications. Neither time nor the objectives of this session allows for a full discussion of these important issues, many of which relate to the job satisfaction and income-producing ability of women. Only a few can be highlighted here.

Ekstrom noted that numerous women lack the necessary skills to obtain employment that pays well enough to compensate for their absence from the home. Women in families where husbands or other adults are present may be able to generate worthwhile income by adjusting hours so that the husband or other adult can assume child care and other household tasks. Such arrangements can be economically and personally viable, but the behavioral science literature frequently refers to the strains on the marital relationship caused by such arrangements. The group affected most by lack of skills and low income is single mothers. If businesses can upgrade the skills of these women and assist them in finding satisfactory, low-cost child care, they will increase the level of effective demand emanating from a significant segment of our population. In this context, businesspeople may wish to consider the implications of Kahne's statement that consumer needs can be translated into effective demand either through spending of personal income or through social programs.

The possibility of an increasing gap between the incomes of one- and two-wage earner families is interesting, although its implications are less clear. It does seem worthy of continuing attention, however, both from the standpoint of marketing and of employee relations and for its potential in generating public policy issues.

Conclusion

It seems that, both as marketers and as researchers, we have overcome the notion that all women are or should be homemakers, even though some of the mythology concerning sex differences still pervades many of our activities. We have also come a long way toward understanding that working women do not make up a single, homogenous group,

nor are all non-working women alike. It is to be hoped that this session has taken us one step further toward a genuine understanding of women's multiple roles. That step would be the realization that, while change in women's role-related attitudes and behavior is pervasive, it is not occurring with equal speed on all the same dimensions throughout our society.

Only when we, as marketers and researchers, recognize the diversity that exists among women and their families in the way they interpret their work, family, and consumer roles will we be able to effectively cope with the changes that are occurring.

SEPARATING AGE, COHORT AND PERIOD EFFECTS IN CONSUMER BEHAVIOR

Joseph O. Rentz, University of Virginia,¹
 Fred D. Reynolds, University of Georgia²

Abstract

Traditional research designs for the study of consumer aging confound the effects of age, cohort and period. Cohort analysis is a group of methods designed to separate the three effects. Problems with conventional designs are discussed and cohort analysis methods critically reviewed.

Introduction

Our purpose in this paper is to point out to consumer behavior researchers some advances in research designs and methods for the study of aging. Generally called cohort analysis, these methods attempt to separate the effects of age, cohort and period. Use of the methods over the past decade has resulted in an increased understanding of the aging process. Researchers have found that some phenomena once thought to be related primarily to the aging process are instead related primarily to the cohort membership of the groups studied.

In this paper we critically review the cohort analysis methods. First the relationships between age, cohort and period are discussed and some shortcomings of traditional research designs for the study of aging are pointed out.

Relationships Between Age, Cohort And Period

Figure 1 graphically illustrates the relationships between age, cohort, and period. The figure represents the concomitant processes of aging and succession of four selected cohorts and reveals cross-sectional differences among age classes at any given point in time (Riley, Johnson and Foner 1972).

FIGURE 1
 Aging, Cohort Succession And Age Differences
 Source: Riley, Johnson and Foner (1972)

Johnson and Foner 1972). Each cohort is comprised of people born at approximately the same time. People within each cohort age over time.

Specifically, a cohort is an aggregate of individuals within a given population who experienced the same event(s) within the same time interval (Ryder 1965). In Figure 1 the defining event is birth although numerous types of cohorts can be identified including marriage cohorts, divorce cohorts, retirement cohorts and education cohorts. The word is typically used without a modifier to refer to birth cohorts. Cohort succession refers to the immutable process whereby cohorts of people are born, live out their life courses and die, being replaced by other cohorts (Riley 1973).

Cohorts can be expected to differ from one another on a variety of dimensions for a variety of reasons. Each cohort occupies a unique interval in time. Since society is constantly changing over time, each cohort experiences unique events or experiences events differently because each cohort is at a different stage in the life course when the events occur. Cohorts also differ in initial size and composition (Ryder 1965). The problems faced by members of the post-war baby boom cohorts -- crowded schools and limited job opportunities, for example -- are examples of the effects initial size can have on cohorts. Thus we might expect cohorts to differ from one another in many respects.

Age differences in the population at a given time are revealed by a cross section of the population at that time -- see the vertical line at 1980 in Figure 1. These cross-sectional differences can be important in their own right since they have implications for current marketing practice, public policy, etc. However from a developmental perspective, the important issue is what accounts for the current differences.

Figure 1 shows that there are two interpretations for cross-sectional differences in the age classes (Riley 1973). The "aging interpretation" is that the 1980 age class differences are due to the development (aging) of consumers. This is the interpretation that is nearly always given by consumer researchers to age differences. The alternative interpretation, the "cohort interpretation," is that the 1980 age class differences are due to the different cohort memberships of the age classes. If the cohort interpretation is correct then the characteristic of interest will remain relatively stable over the life courses of people in the cohorts and the characteristics of the age classes in the future (say in the year 2010 in Figure 1) will change as new cohorts occupy each of the age classes. For example, elderly consumers in the future will be different from today's elderly consumers. When aging is producing the age class differences, the characteristic of interest will change over the life courses of people in the cohorts and the characteristics of the age classes in the future will be similar to the characteristics of the current age classes. For example, the elderly of the future will be similar to the elderly of today.

The clearest example of a variable which is related to cohort membership rather than aging is education. At any point in time, elderly people report having completed fewer

¹Joseph O. Rentz is Assistant Professor of Marketing, McIntire School of Commerce, University of Virginia.

²Fred D. Reynolds is Professor of Marketing, University of Georgia.

years of formal education, on average, than young people. Clearly the number of years of education completed does not decline as an individual ages. Rather, age class differences in education are a function of cohort membership and we can expect the average educational level of the elderly, for example, to increase as more educated cohorts age into the elderly age classes and replace less educated cohorts.

Cohort membership accounts for a significant portion of age class differences in political party affiliation (Cutler 1970; Glenn 1972; Glenn and Hefner 1972; Knoke and Hout 1974), cognitive performance (Baltes and Reinert 1969, Schaie and Strother 1968a; Schaie and Strother 1968b; Schaie and Parham 1977), and consumption of a product class (Rentz 1980) as well as other variables.

Clearly the effects of aging are confounded with the effects of cohort membership in the cross-sectional design. Unless one has evidence that cohort effects are minimal, errors of interpretation can occur by attributing age class differences to the aging process.

A second research design, the longitudinal design, has also been employed by consumer researchers to study aging. For example, in Figure 1, one might measure a sample of individuals in a particular cohort at two or more points in time. The same individuals might be followed over time or an independent sample from the cohort might be taken at each time point. The longitudinal design also has weaknesses. In longitudinal comparisons the effects of aging are confounded with "period effects." Period effects are environmental influences which affect aging cohorts at one point in time (between two times of measurement). They include marketing efforts, public policy, and social change in general. Because it is impossible to employ control groups who do not age, one cannot separate period effects and age effects in longitudinal comparisons. Thus age effects and period effects are confounded in longitudinal comparisons.

A third research design, the time-lag design, is sometimes used to study differences among cohorts (or among generations). The same age class is compared at two or more points in time. For example, in Figure 1, youth in 1980 might be compared to youth in 1950. Differences are typically attributed to differences in cohorts (or generations.) However the comparisons are made over time so cohort effects are confounded with period effects in time-lag comparisons.

The confounding of age, cohort, and period effects in empirical measures led Baltes (1968, p. 153) to conclude: ". . . the conventional methods are in no way adequate research designs for the assessment of age effects."

How, then can consumer researchers separate the effects of age, cohort and period? A group of methods which fall under the general heading "cohort analysis" has been developed in an attempt to separate the effects of the three variables. The method can be used in studies of aging, in inter-cohort-studies, and in the forecasting of consumer behaviors. Reynolds and Rentz (1980) illustrate the use of cohort analysis in forecasting changes in women's roles. In the next section we discuss the basics of cohort analysis and then we discuss several cohort analysis methodologies.

Cohort Analysis: Separating Age, Cohort, And Period

Cohort analysis refers to any study in which one or more cohorts are measured on some variable at two or more points in time (Glenn 1977). Either panel data or cross-sectional data may be used. Cohort analysis normally begins with the construction of a "standard cohort table" (Glenn 1977). Tables 1, 2 and 3 are examples of cohort tables and illustrate the pattern of variation resulting from "pure" age, cohort and period effects. Normally a series of cross-sectional studies comprise the columns of the table.

TABLE 1
Cohort Table Showing Hypothetical Data (Percentages)
In Which All Variation Is Due To Age Effects

Age	Time of Measurement (Period)			
	1950	1960	1970	1980
20-29	40	40	40	40
30-39	45	45	45	45
40-49	50	50	50	50
50-59	55	55	55	55
60-69	60	60	60	60
70-79	65	65	65	65

The tables are constructed so that the interval between any two times of measurement (periods) is the same as the intervals used to delineate age classes. In such a table cohorts are represented in the diagonals of the table. Trends in an aging cohort can be traced by reading down the diagonals of the table as illustrated for one cohort by the underlined measures in Table 1. Nine cohorts are represented in each of the cohort tables presented here.

Age	Time of Measurement (Period)			
	1950	1960	1970	1980
20-29	70	60	50	40
30-39	70	60	50	40
40-49	70	60	50	40
50-59	70	60	50	40
60-69	70	60	50	40
70-79	70	60	50	40

Unfortunately, the interpretation of a cohort table is not straightforward. We have seen that age and cohort effects are confounded in cross-sectional comparisons (comparisons within any column in Table 1), age and period effects are confounded in longitudinal comparisons (comparisons within any diagonal in Table 1), and period and cohort effects are confounded in time-lag comparisons (comparisons within any row of Table 1). Comparisons between mean values for rows, columns, or diagonals does not eliminate the confounding. For example the difference between the means of the first two rows in Table 1 is the same as the mean of the four cross-sectional differences between the two rows. In each of the four differences, age and cohort effects are confounded so the mean of the four differences also contains confounded effects.

To further complicate matters, there is a formal linear

dependency between each of the independent variables of interest (age, cohort, and period) and the other two. That is, when age, cohort and period are indexed by chronological age, year of birth, and year of measurement respectively, then age equals period minus cohort, cohort equals period minus age and period equals cohort plus age.

Mason, et al. (1973) present a lucid discussion of the implications of the linear dependency and show that parameter estimation becomes impossible in most statistical models. Thus traditional techniques such as analysis of variance or regression are not appropriate without modification. The nonindependence of the variables is a case of the "identification problem" discussed by Blalock (1966). Identification of the operative variables is possible only through a priori assumptions.

Cohort Analysis Methods

Several methods have been proposed for separating age, period and cohort effects including "visual inspection" methods, methods to correct for period effects (Agnello 1973; Crittenden 1962; Klecka 1971), Schaie's (1965) sequential strategies, Baltes (1968) bifactorial model, the constrained multiple classification method developed by Mason, et al. (1973), and an approach developed by Palmore (1978). We prefer the methods of Mason, et al. and Palmore although there is by no means a consensus in the literature concerning which method is most appropriate.

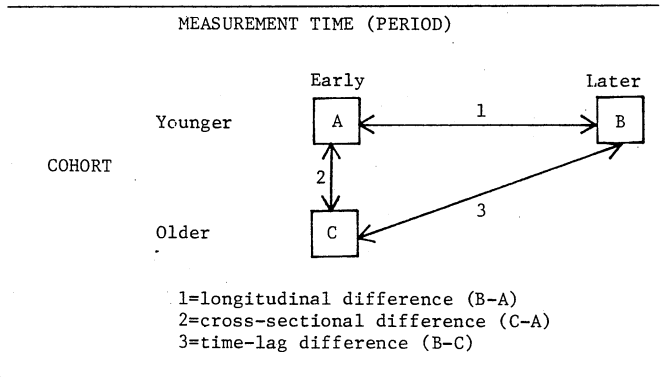

In this section we critically review four of the methods which we feel merit the consideration of consumer behavior researchers. For a complete review, see Rentz (1980). Palmore's method is presented first because his approach clarifies much of the conceptual and terminological confusion which exists in the literature.

Palmore's Method

Palmore (1978) points out that much confusion surrounding the age-cohort-period problem has arisen from a failure to distinguish between three necessary levels of analysis: computing observable differences, inferring effects, and determining the theoretical causes of the effects. Cohort analysis involves inferring effects from observable differences. The causes of the effects can only be decided on the basis of evidence outside the cohort table.

Observable differences are those differences which are calculated from empirical data. Three types of differences are observable (Figure 2). Cross-sectional differences (cell C - cell A) are differences between younger and older cohorts (and younger and older age groups) at one point in time.

FIGURE 2
Observable Differences
Source: Palmore, 1978

Longitudinal differences (cell B - cell A) are differences between early and later measurements on the same cohort (at different ages). Time-lag differences (cell B - cell A) are differences between two groups of the same age, one from the older cohort measured at the early time and one from the younger cohort measured at the later time. Computation of the observable differences is not a difficult process once relevant data are collected.

Palmore's second level of analysis is inferred effects. Age, cohort and period effects are inferred from the three observable differences. Each observable difference is composed of the effects of two and only two variables:

$$\begin{aligned} \text{Longitudinal Differences} &= \text{Age} + \text{Period Effects} \\ \text{Cross-Sectional Differences} &= \text{Age} + \text{Cohort Effects} \\ \text{Time-Lag Differences} &= \text{Period} - \text{Cohort Effects} \end{aligned}$$

The effects of age, period, and cohort can only be inferred from the observable differences. Since any one difference is composed of two effects one cannot equate any one effect with any one difference without further analysis or assumptions. For example, if one has other evidence or makes the assumption that cohort effects are zero, then cross-sectional differences can be equated to age effects.

One triad of data of the form shown in Figure 2 is the minimum number of cells necessary to compute the three observable differences. Palmore works with one triad of data at a time, inferring effects from observable differences in each triad. Each of the differences is tested for statistical significance. Three patterns of significant differences are possible: no significant differences, two significant differences and three significant differences. Because the three differences are related (the longitudinal difference is the sum of the cross-sectional and time-lag differences) one cannot obtain one significant difference except when sample sizes are markedly different.

We will illustrate Palmore's inference process using a pattern of two significant differences. The following data illustrate the pattern:

		Period	
		Early	Later
Cohort	Younger	10	20
	Older	20	

Here the longitudinal difference is ten, the cross-sectional difference is ten and the time-lag difference is zero. There are three possible interpretations of this pattern.

The first interpretation is that the age effect is ten and cohort and period effects are zero:

$$\begin{aligned} \text{Longitudinal Difference} &= 10 = \text{Age} (10) + \text{Period} (0) \\ \text{Cross-Sectional Difference} &= 10 = \text{Age} (10) + \text{Cohort} (0) \\ \text{Time-Lag Difference} &= 0 = \text{Period} (0) - \text{Cohort} (0) \end{aligned}$$

The second interpretation is that period and cohort effects are exactly counterbalancing one another in the time-lag difference and age effects are zero:

$$\begin{aligned} \text{Longitudinal Difference} &= 10 = \text{Age} (0) + \text{Period} (10) \\ \text{Cross-Sectional Difference} &= 10 = \text{Age} (0) + \text{Cohort} (10) \\ \text{Time-Lag Difference} &= 0 = \text{Period} (10) - \text{Cohort} (10) \end{aligned}$$

The third interpretation is that a complex combination of all three effects is producing the differences. Palmore argues that in the absence of other evidence the principle of parsimony favors the first interpretation over the other two. We have found that by making a priori assumptions about the directionality of two or three effects one can often rule out one or two interpretations. For example if one assumes that period and cohort effects are in opposite

directions then the second and third interpretations in the preceding example can be ruled out since period and cohort effects could not counterbalance one another in the time-lag difference.

Palmore offers similar interpretative guidelines for the patterns of no significant differences and three significant differences. Once the effects are inferred in each triad of the cohort table one can summarize effects over groups of triads.

Palmore notes that the major advantage of his method is that it is not necessary to assume some systematic pattern of effects. Some methods require the assumption that effects are additive or that the effects are unidirectional and positive. Palmore's method provides a way of determining whether systematic patterns exist and what they are. However the method also has weaknesses. Often directionality assumptions do not allow a choice of alternative interpretations and one is forced to rely on the principle of parsimony. Also the method is oriented toward finding one main effect and works best when no differences or two differences are significant. The typical situation may be that all three effects are operative and three differences are significant.

Schaie's Sequential Methods

Recognizing that only two of the three independent variables of interest (age, cohort, and period) can be varied independently, Schaie (1965) proposes three bifactorial designs in which different combinations of the three variables are represented two at a time. His cohort-sequential method is an age by cohort design, his time-sequential method is an age by period design and his cross-sequential method is a cohort by period design. The analysis of variance is used as the test of significance in each case.

Schaie recognizes the confounding of the variables in each of his three methods and does not advocate using any one of the methods alone to estimate age, period, and cohort effects. Rather he advocates using two or more of the methods in conjunction. He presents a set of decision rules for inferring effects using the time-sequential and cross-sequential methods in conjunction or the cohort-sequential and cross-sequential methods in conjunction.

Schaie's decision rules require the assumption that age, period, and cohort effects are unidirectional and positive, that is, "an incremental progression exists from a younger to an older age, from an earlier to a later measurement time, and from a younger to an older generation" (Schaie 1965, p. 103).

Essentially, the estimates provided by the analysis of variance are estimates of either mean longitudinal, mean cross-sectional or mean time-lag differences. Schaie's decision rules follow a logic similar to Palmore's. For example the estimate of the period effect from the cross-sequential method is actually an estimate of the mean longitudinal difference (which contains age and period effects). One of Schaie's decision rules states that if this estimate is zero then variation in the table is a result of cohort effects. Since both age and period effects are assumed to be positive, (or zero) if the mean longitudinal difference is zero then both age and period effects must be zero and all variation must be due to cohort effects. Similar logic can be employed to verify Schaie's remaining decision rules.

Variations of Schaie's methodology have been employed by others and especially by Riley, Johnson, and Foner (1972). Their "period analysis" is the same as Schaie's cross-sequential strategy, their "cohort analysis" is the same as Schaie's cohort-sequential strategy and their "cross-sequential analysis" is the same as Schaie's cross-

sequential strategy. They do not employ Schaie's decision rules but rather emphasize the need to make assumptions and use outside evidence in order to untangle age, cohort, and period effects.

The usefulness of Schaie's methods is limited by the necessity to assume that all effects are unidirectional and positive. However, Schaie's general approach of specifying the type of slope assumed for each of the three effects and developing decision rules based on the type of slope assumed is certainly valid when theory or outside evidence supports the assumptions.

Constrained Multiple Classification Method

Mason, et al. (1973) develop an approach to estimating age, cohort and period effects using multiple classification analysis. Multiple classification analysis is essentially a multiple regression analysis using dummy variables (Andrews, Morgan, and Sonquist 1967).

Mason, et al. employ a model of the following form:

$$Y_{ij} = \mu + B_i + \gamma_j + \delta_k + \epsilon_{ij}$$

where the effect of the i -th age group is given by B_i , the effect of the j -th period by γ_j , the effect of the k -th cohort by δ_k ; where μ is the grand mean of the dependent variable and where ϵ_{ij} is the random error. They show that the parameters of a model of the above form are not estimable because only one cohort exists for any given age and period (i.e., any one variable is linearly dependent on the other two). Mason, et al. also show that by constraining the above model such that any two ages, periods, or cohorts have identical effect parameters, linear dependency is eliminated and the parameters of the model are estimable. Mason, et al. proceed to show that when only two ages or two cohorts or two periods are constrained to be equal, the fit of the model to the data does not vary but the estimates do vary with different equality constraints. Thus one cannot judge the suitability of the many possible constraints. To remedy such a situation, Mason, et al. advise that the analyst place constraints on more than one dimension. For example, we have used the method by fitting three models with different sets of constraints: one with two ages and two cohorts set equal, one with two cohorts and two periods set equal and one with two ages and two periods set equal. The model that best fits the data is chosen as providing the best estimates of the effects.

The method of Mason, et al. is appealing since the assumptions involved appear to be minimal compared to other methods. Most investigators would be untroubled by assuming two ages, periods, or cohorts are equal. In many cases strong a priori reasons might exist for making the assumptions. In any case the model and assumptions are clearly specified. Another advantage of the method is that other independent variables can be included in the analysis along with age, cohort and period. (See, for example, Knoke and Hout (1974) and Hout and Knoke (1975). However, Glenn (1976; 1977) argues against the constrained multiple classification method because the model assumes that age, period, and cohort effects are additive, i.e., do not interact. The additivity assumption implies that age effects are the same for all cohorts and periods, that cohort effects are the same for all ages and periods, and that period effects are the same for all ages and cohorts. Glenn presents examples of theoretical and empirical evidence which suggest that the additivity assumption is unrealistic. For example, theory and empirical evidence suggest that attitudes tend to become less responsive to change as the individual ages. Thus Glenn maintains that period effects should not, as the additive model assumes, be the same for all age groups. Glenn concludes that for many additional and behavioral dependent variables, the

additivity assumption is unrealistic.

We feel that, given the alternative methods, the additivity assumption is not unrealistic. Rather than reject the method we attempt to incorporate likely interactions in our interpretation of the effects.

Visual Inspection Method

The "visual inspection method," advocated primarily by Glenn (1977)³ centers around the researcher being familiar with the patterns of variation produced by age effects only (Table 1), cohort effects only (Table 2), and period effects only (Table 3). The researcher should then be able to recognize the effects which produce the pattern found in his own data. However, Glenn stresses that there are two explanations for the pattern of variation in any cohort table. For example, the pattern shown in Table 1 could have been produced by age effects alone. There is no variation across periods or across cohorts in the table. However, the pattern also could have been produced by a combination of period and cohort effects. An increase in the percentages with each successive period combined with an offsetting decrease in the percentages with each successive cohort would produce the pattern of variation in Table 1. To further complicate interpretation, the pattern of variation also might result from a complex combination of all three effects.

Glenn maintains that the correct interpretation cannot be made by examination of the cohort table alone. He advocates the use of theory and evidence from outside the cohort table to choose the correct interpretation. For example, if one can assume on the basis of theory or other evidence that period and cohort effects result from the same causal influences, then period and cohort effects would tend to reinforce one another in the cohort table and one could rule out the interpretation of period and cohort effects offsetting each other in Table 1.

Glenn offers other interpretive aids to the visual inspector of cohort tables and concludes that by relying on theory and evidence from outside the cohort table, "there usually is only one plausible explanation for a pattern of variation predicted by pure age, cohort, or period effects" (Glenn 1977, p. 52).

The visual inspection method requires that outside evidence be employed when interpreting a cohort table. Usually assumptions about the direction or magnitude of the three effects must be made. The necessity to use outside evidence and/or assumptions is not unique to the visual inspection method. However the visual comparison between one cohort table and another is unique to this method and is not analytically appealing. When reasonable assumptions can be made, more rigorous methods of cohort analysis are available.

Summary

The validity of the various cohort analysis methodologies depends on the validity of the assumptions necessary for their use. While we prefer the Palmore method and the constrained multiple classification method, we urge consumer researchers to make their own judgments based on the nature of the problem at hand and the assumptions required for the use of the methods.

While cohort analysis has its limitations, it has much to offer to the student of consumer aging. Recognition of

³The term "visual inspection method" is the authors' and is not employed by Glenn.

the confounding of age, cohort and period in empirical measures and attempts to separate the effects using cohort analysis should produce more accurate descriptions and theories of consumer aging.

A Long-Term Solution to the Age-Cohort-Period Confounding Problem

The confounding of age, cohort, and period effects in empirical data is the result of the way researchers measure the three variables. Age is measured as chronological age, i.e., the number of years since birth. Cohort is measured as year of birth and period is measured as the year of measurement. The three operational measurements are formally dependent.

Each of the three measures is only a surrogate for more fundamental and meaningful variables. For example, chronological age is a surrogate measure of more meaningful dimensions of aging: biological, psychological, and social age (Glenn 1977; Maddox and Wiley 1976).

Maddox and Wiley (1976) and Mason, et al. (1976) point out that if we could measure these more fundamental and meaningful variables then the confounding problem would not exist. For example, Maddox and Wiley point out that replacing "period," indexed by time of measurement, with appropriate measures of environmental variables would be sufficient to remove the confounding since "there is no reason to suppose that age, cohort, and 'environment' are linearly dependent" (Maddox and Wiley 1976, p. 21). Similarly, cohort, indexed by date of birth, could be replaced by direct measures of environments which impinge on successive cohorts, and age, indexed by number of years since birth, could be replaced by direct measures of biological, psychological, and social age.

Unfortunately measures of biological, psychological, and social age are not well developed. Also, our understanding of the environmental conditions contributing to cohort and period effects is limited for many types of dependent variables. Because of these limitations, the direct measurement of the three basic dimensions of aging and the direct measurement of environments is not practical in most instances (Rosow 1978). However, as our understanding and measurement capabilities increase, it is certainly desirable to replace measures of age, cohort, and period with the more basic variables which they index. As Mason, et al. (1976, p. 905) point out, "The replacement of proxies by the variables they index is a universal goal of research." Thus a long-term solution to the age-cohort-period confounding problem is to replace the confounded variables by the unconfounded variables they index.

COGNITIVE AGE: A NONCHRONOLOGICAL AGE VARIABLE

Benny Barak, Rutgers--The State University of New Jersey
Leon G. Schiffman, Baruch College (CUNY)

Abstract

The determination and measurement of self perceived age as an alternative to chronological age has received almost no attention in consumer behavior and marketing research. This paper discusses a newly developed self-perceived age measure entitled "cognitive age", and presents some results concerning its reliability and its response patterns.

Introduction

While demographic variables have been a mainstay of marketing and consumer behavior research, this group of variables is typically selected and operationally defined quite automatically and usually without much imagination. Moreover, there has been a general lack of attention given to the development of new forms of demographic and "demographic-like" variables. Within a consumer behavior context, Roscoe, LeClaire and Schiffman (1977) have been sensitive to this problem when they suggested the need to refine existing demographics and develop new ones. In particular, they proposed that the age variable, the variable of concern in this paper, should be broadened so that it reflects such age-related factors as: the age of the household, age at birth of first child, age of siblings, birth order, age at first awareness of a product (or brand), age at first trial of a product and perceived age (i.e., youthfulness).

In the spirit of the Roscoe, LeClaire and Schiffman (1977) recommendations, this paper is concerned with the need for both refined and new measures of age, especially non-chronological measures of age. More specifically, this paper will endeavor to: (1) set out some of the major limitations of chronological age, (2) review the major types of nonchronological age variables, (3) propose a new perceived age variable, "cognitive age," and present some initial results pertaining to its reliability and response patterns in comparison to chronological age, and (4) offer our thinking on the future use of this age variable in various types of research, especially consumer behavior research.

The Limitations of Chronological Age

Chronological age is usually defined as either the number of years lived (Hendricks and Hendricks 1976), or as the distance from birth (Jarvik 1975). As a demographic variable, chronological age stands out from all other variables in terms of frequency of its use. In consumer behavior research it is often employed in descriptive consumer behavior studies, or in efforts to segment consumer markets.

Despite its great popularity, the use of chronological age is problematic for researchers interested in age-related research, particularly research that examines the attitudinal or behavioral patterns of the elderly. More precisely, chronological age does not lend itself well to functioning as a dependent variable; that is, it is exceedingly difficult to justify employing almost any behavioral variable of interest to consumer researchers as a predictor of chronological age. Stated differently, the unique antecedent character of chronological age restricts

its usefulness to being employed as a predictor variable.

Still further, from the perspective of the present paper, and consumer behavior research in general, the overriding shortcoming of chronological age would seem to be that it does not take into account the fact that people frequently perceive themselves to be at an age other than their birth age, and that this self-perceived or cognitive age seems to influence purchase behavior. There have been few references in the marketing and consumer behavior literature to the influence of self-perceived age on consumer behavior. A noteworthy exception is the Ford Motor Company's eventual recognition of the importance of self-perceived age in positioning its Mustang automobile:

The car was designed to appeal to young people who wanted an inexpensive sporty automobile. Ford found to its surprise that the car was being purchased by all age groups. It then realized that its target market was not the chronological young, but those who were psychologically young (Kotler 1976, p. 147).

Following this line of thinking, it might be expected that consumers would tend to consume many products according to their perceived age, and not according to their chronological age. This suggests that an individual's identity (and behavior) may depend, as much, if not more, on perceived or felt age than upon chronological age. Thus, a flexible and versatile perceived age measure would provide consumer researchers, marketers and public policy makers with an attractive alternative to relying on a chronological measure of age; and more importantly, it might provide greater insights into the patterns of aging and the consumer behavior of the elderly.

Nonchronological Age Variables

Gerontological researchers have suggested a variety of non-chronological age variables. The three broad categories of nonchronological age which are most frequently championed are briefly considered here, i.e., biological age, social age and social-psychological age.

Biological Age

Biological age is an estimate of an individual's present position with respect to his or her potential life-span (Birren and Renner 1977; Jarvik 1975). The measurement of biological age is difficult to accomplish and tends to take the approach recommended by Bell (1972); namely, the measurement of biochemical age through assays of blood serum and urine. Moreover, in discussing biological age, Bromley (1974) has pointed out that the body's organs are made up of different types of cells, so that an estimate of the biological age of any particular organ is extremely difficult to establish. In addition, the overall effectiveness of a human body is determined by the least efficient part of the system required to keep the body functioning and this varies among humans.

Social Age

Social age is the age of an individual as defined in terms of social roles and habits (Birren and Tenner 1977). It implies that age expresses an individual's place in the

social structure; which is indexed by such variables as socioeconomic status, occupation, education, race and sex (Bengston, Kasschau and Ragan 1977).

Social aging is also concerned with the different roles a person takes while passing through the life cycle. There is a continuous role change that takes place and the patterned sequencing of these roles reflects some of the changes in an individual's life (Blau 1973). Tied to this role alteration is a subjective perception of appropriate and inappropriate age-specific, society-determined norms that are an integral part of the varied roles (Bengston, Kasschau and Ragan 1977).

Social-Psychological Age

Three major types of social-psychological age measures have received special attention: (1) subjective age, (2) personal age, and (3) other-perceived age.

Subjective Age

Subjective (or identity) age measures an individual's self-perception in terms of reference age groups, i.e., "middle-aged," "elderly," or "old" (Blau 1956, 1973; Peters 1971; Rosow 1967, 1974; Ward 1977). It subjectively establishes how a person feels about such reference age groups.

Several conclusions can be drawn from the findings of research examining subjective age:

1. The majority of elderly have a strong tendency to see themselves as considerably younger than their chronological age (Blau 1956, 1973; Peters 1971; Rosow 1967, 1974).
2. The self-identification with a younger age group varies in terms of social class standing (Bengston, Kasschau and Ragan 1977; Peters 1971; Rosow 1967).
3. Women are more sensitive to the negative stereotypes associated with "elderly" and "old," and tend to see their age differently from their male counterparts (Bengston, Kasschau and Ragan 1977; Peters 1971).
4. Loss of critical roles and status also have a differential effect on subjective age perception; specifically, Neugarten (1977) suggests that especially "off-schedule" crises causing adaptational problems bring about change in the subjective perception of age.
5. Elderly who perceive themselves as younger are more likely to be innovative (Blau 1973).
6. Elderly voters who perceive themselves to be younger tend to have a more liberal and less traditional outlook on life (Bengston and Cutler 1976).
7. Those who perceive themselves to be younger are more likely to have had more education than those who perceive themselves as older (Rosow 1967, 1974; Peter 1971).
8. Finally, research indicates that subjective age is related to subjective well-being (i.e., life satisfaction or morale) and self-confidence (Bengston, Kasschau and Ragan 1977; Peters 1971).

A major problem with the subjective age construct has been the ambiguity surrounding how it has been defined and measured. Subjective age has been measured through self-

rating scales, expressed in terms of some form of nominal age-reference categorization (i.e., "young," "middle-aged," "elderly," "old"). This kind of rating is suspect since one is never sure just what such a nominal age-reference categorization means to the respondents in terms of commonly accepted units such as years.

Personal Age

Personal age is a different type of self-perceived age than subjective age. It is established by means of a self-report of an individual's age perceptions measured in terms of units of years. As operationalized by Kastenbaum, Derbin, Sabatini and Artt (1972), personal age consists of four major age dimensions: (1) feel-age (how old a person feels), (2) look-age (how old a person looks), (3) do-age (how involved a person is in doing "things" favored by members of a certain age group), and (4) interest-age (how similar a person's interests are to members of a certain age group).

In addition to the four age dimensions, respondents are also required to answer questions dealing with their individual feelings about age in general and how the four personal age dimensions compare with the respondents' chronological age. Thus, personal age is measured as a basic part of a complex procedure designed to investigate people's feelings about age. In the format employed by Kastenbaum, Derbin, Sabatini and Artt (1972), the personal age measure requires lengthy personal interviews that do not lend themselves to the types of survey research normally conducted by consumer and marketing researchers. Even though Kastenbaum's personal age measure has these limitations, it nevertheless provides a cornerstone-framework for the development of the cognitive age measure to be reported on here.

Other-Perceived Age

This final social-psychological age measure is concerned with the subjective evaluation of the age status of an individual as assessed by others. The measure is especially appropriate for examining stereotyping of age groupings and seems to be largely based on perceived physical looks and the perceived social roles of the individual(s) being observed (Lawrence 1974). This type of perceived age, while not as yet dealt with in the consumer behavior or communication-mass media literature, would seem especially ripe for exploring how consumers' perception of another person's age (e.g., a model in an advertisement) interacts with the product or brand, the usage situation, and other relevant environmental or situational factors.

An Exploration of Cognitive Age

In this section we will: (1) discuss how we operationally defined our nonchronological age measure, (2) describe the sample of elderly consumers that served as the subjects for the initial examination of our self-perceived age measure, (3) present the results of our effort to examine the reliability of the measure, and (4) contrast some of the basic characteristics of our survey results to the findings reported by Kastenbaum, Derbin, Sabatini and Artt (1972).

The Measurement and Analysis of Cognitive Age

Our self-perceived age measure, which we have labelled "cognitive age," was operationally defined in terms of four questions which were designed to correspond to the four dimensions of personal age suggested by Kastenbaum, Derbin, Sabatini and Artt (1972). The introductory statement which is either read by an interviewer, or read directly by the respondent, and the questions and response

mode for the cognitive age variable are displayed in the Appendix. To prepare survey results for analysis, responses to each of the four age dimensions (i.e., feel-age, look-age, do-age and interest-age) can either be scored separately, or an overall or composite score can be derived. As a first step, each respondent's score, for each of the four dimensions, is assigned a midpoint value (e.g., a response of "50's" was recoded to be "55"). This procedure provided an opportunity to set a numerical value (in terms of years) for a person's cognitive age (either for each of the four dimensions or a composite score), and it also allowed us to compare cognitive age and chronological age. In our preliminary research the composite score for each respondent was formed by the simple average of the midpoint values of the four age dimensions.

The Sample

The initial data gathered on the cognitive age measure was collected as part of a study that questioned some 324 elderly consumers who met the following qualifications: (1) they were female, (2) they reported their exact chronological age, (3) they were chronologically 55 years or older, and (4) they responded to all four cognitive age questions.

The respondents who were all residents of the counties that comprised a major Northeastern city, were all personally interviewed by specially trained interviewers. The questionnaire, which required about 45 minutes to be administered, focused on hair care product behavior and attitudes. Some of the major consumer behavior and consumer-related variables measured were: venturesomeness, self-confidence, dogmatism, opinion leadership, life satisfaction, club membership, a range of media habit questions, a battery of product/brand usage and experience questions, and a selected number of demographic items.

Estimation of Reliability

The cognitive age variable was subjected to three widely employed measures of reliability: test-retest reliability, Guttman's Lambda Test, and a split-half reliability test. The test-retest reliability was based on data collected during two interview sessions (separated by a three week period), conducted with the same small sample of 15 respondents. The resulting test-retest coefficient was .88. The Guttman Lambda and Spearman-Brown split-half reliability tests were respectively .86 and .85. On the basis of these three reliability estimates, it seems reasonable to suggest that the cognitive age scale has good internal consistency and is reliable.

Cognitive Age: Patterns and Regularities

In proposing that a nonchronological age variable such as cognitive age be employed along with, or in certain cases as a substitute for the traditional chronological age variable, it seems critical to attempt to ascertain the extent to which the cognitive and chronological age variables are measuring unique aspects of age. To this end, we elected to compare our findings with those reported by Kastenbaum, Derbin, Sabatini and Artt (1972) who undertook the original exploratory work which examined the four age dimensions.

Table 1 presents the percentage of our respondents who reported their chronological age in response to the four cognitive age questions. As Kastenbaum, Derbin, Sabatini and Artt (1972) found with their data, our results indicate also only a moderate degree of correspondence between the four cognitive age dimensions and chronological age. Specifically, none of the 16 percentages reported in Table 1 reach the 40 percent agreement mark. The greatest degree of agreement was 44 percent (i.e., look-age at chronological age 50's) and the least was 16 percent (i.e.,

interest-age at chronological age 80's).

TABLE 1

Decade	Percentage of Respondents Expressing Agreement Between Chronological and Cognitive Age			
	Feel-Age	Look-Age	Do-Age	Interest-Age
50's	42%	44%	28%	32%
60's	26%	35%	22%	18%
70's	35%	33%	17%	22%
80's	26%	32%	21%	16%

These results reveal that for the majority of our elderly subjects their chronological age does not adequately correspond to their perceived age as reflected by any of the four cognitive age dimensions. More importantly, the results can be interpreted as suggesting that the cognitive dimensions of age capture distinctly different aspects of age than is reflected by chronological age.

An important point that needs to be determined is the basic directionality of the decline in mean percentage of agreements that occur with advancing decades. What we want to know here is the extent to which our elderly subjects tend to view themselves as younger or older than their chronological age. In this regard, Table 2 shows the percentage of respondents who perceived themselves to be at a younger age grouping than their chronological age for each of the four dimensions of our cognitive age variable. The results reveal that our elderly respondents are considerably more likely to identify their age related feelings and actions with a younger age group than the one which is consistent with their chronological age.

TABLE 2

Decade	Percentage of Respondents Expressing A Cognitive Age That is Younger Than Their Chronological Age					Mean %
	Feel-Age	Look-Age	Do-Age	Interest-Age		
50's	54%	52%	69%	66%	60%	
60's	67%	63%	77%	71%	70%	
70's	63%	66%	80%	77%	72%	
80's	74%	68%	79%	84%	76%	

Also, the results indicate (i.e., the difference between the results in Tables 1 and 2) that the percentage of respondents who identify with an older age group than the one corresponding to their own chronological age was exceedingly small (zero for interest-age at chronological age 70's, and at the high end only five percent for feel-age at chronological age 60's).

Still further, the mean percentages appearing in the last column of Table 2 reveal that as our respondents' chronological age increases, they are more likely to identify with a younger cognitive age grouping.

It is also important to look at the degree of consistency between the four age dimensions that constitute the cognitive age variable. Table 3 reveals that the number of

cases in which each of the four cognitive age dimensions received the same decade-response as one of the other cognitive age dimensions ranges between a low of 45 percent (for interest/look age) to a high of 57 percent (for do/interest age). Performing a similar type of analysis, Kastenbaum, Derbin, Sabatini and Artt (1972) found somewhat lower levels of agreement (i.e., all were less than 50 percent -- the range was 28 percent for look/interest age and 49 percent for feel/do age). Nevertheless, the extent of inter-dimension agreement in our data is still quite low, suggesting that the four dimensions tend to reflect separate aspects of this perceived age variable.

TABLE 3

Consistency Percentage Among Cognitive Age Dimensions

	Feel-Age	Look-Age	Do-Age	Interest-Age	Mean %
Feel-Age		54%	55%	50%	53%
Look-Age	54%		48%	45%	33%
Do-Age	55%	48%		57%	53%
Interest-Age	50%	45%	57%		51%

Finally, the mean percentages in the last column of Table 3 reveal that when our respondents reported their perceived look-age, they were providing a response that had only a 33 percent mean correspondence with the other three cognitive age dimensions. In contrast, the other three cognitive age dimensions each have mean percentage agreement scores that clustered slightly above 50 percent. That the look-age had the lowest level of mean percentage agreement is consistent with the Kastenbaum, Derbin, Sabatini and Artt (1972) results. They found a 36 percent mean agreement score for look-age and the other three items that make up their personal age variable.

These results indicate that the four dimensions of our cognitive age variable are capturing aspects of age that are not adequately reflected in an individual's chronological age. Moreover, the analysis reveals the importance of examining each of the four cognitive age dimensions, for the composite measure that combines the dimensions is likely to mask some of the differences reflected by each of dimensions. Still further, the four age dimensions related to each other and to chronological age in a manner quite similar to patterns found by Kastenbaum and his associates (1972).

Conclusions and Recommendations

It is our feeling that the cognitive age variable, as well as other nonchronological age measures, will enrich the process of studying the impact of age on consumer behavior (and vice versa). Also, it is likely that nonchronological age variables will provide information not generally possible when chronological age is related to consumer behavior.

The present results also provide additional support for the increasingly popular view that the elderly should not be viewed as if they are a single group or market segment, with uniform attitudes and behavior. For instance, a consumer who is in her sixties might perceive of herself as being in her forties and identify with role models of that age. In such a case, the possibility exists that she really belongs to a different target market than indicated by her chronological age; that is, if she perceives herself to be younger, she actually might belong to a younger target market, even though her chronological age is older.

It would seem desirable that research be undertaken to examine the relationship between cognitive age (and chronological age) and a cross-section of different product categories (some likely to be age sensitive and some not) to see if the product category makes a difference in terms of age-related appeals and age-related role models.

Of course, the cognitive age variable should be employed in studies that do not solely focus on the elderly; that is, it should be used in studies that concentrate on other age groups, as well as a cross-section of age groups. For example, this research could include investigations of age perception among teenagers as compared to the elderly. (Teenagers might like to perceive of themselves as being older than their chronological age, while the elderly perceive of themselves as being younger than their chronological age.)

As a final suggestion, the cognitive age measure should lend itself to cross-cultural consumer behavior studies. Specifically, studies that explore the scope and nature of cultural differences in the perception of age, and how these differences influence various aspects of consumer behavior. It would also be desirable to assess the effect of subcultural and situational factors on the response to the cognitive age measure.

Appendix

Instruction and Format for the Self-Perceived Age Measure

Most people seem to have other 'ages' besides their official or 'date of birth' age. The questions which follow have been developed to find out about your 'unofficial' age. Please specify which age group you FEEL you really belong to: twenties, thirties, forties, fifties, sixties, seventies, or eighties.

	20's	30's	40's	50's	60's	70's	80's
I <u>feel</u> as though I am in my --	_____	_____	_____	_____	_____	_____	_____
I <u>look</u> as though I am in my --	_____	_____	_____	_____	_____	_____	_____
I <u>do</u> most things as though I were in my --	_____	_____	_____	_____	_____	_____	_____
My <u>interests</u> are mostly those of a person in her --	_____	_____	_____	_____	_____	_____	_____

LEISURE AND THE QOL CONSTRUCT:
A REVIEW AND SOME MODEST PROPOSALS

Lynette S. Unger, Miami University
Jerome B. Kernan, University of Cincinnati

Abstract

Consumer researchers have demonstrated an interest in the leisure construct both as a result of the broadened concept of consumer behavior and a specific interest in quality of life (QOL) assessment, with which leisure seems so closely to be associated. This paper reviews the voluminous literature of leisure, emphasizing construct definition and measurement, and develops a proposal for enhancing our understanding of this construct and hence that of QOL as well.

Background

Since the adoption of the broadened concept of consumer behavior (Jacoby 1976, Zaltman and Sternthal 1975), consumer researchers have addressed domains that extend considerably beyond those of traditional concern to marketing. Leisure is one of the domains considered germane under this expanded concept. The leisure experience is frequently associated with the acquisition of products/services and even more often requires that the person invoke a choice process--he/she must choose from among activities, uses of time or money budget alternatives. Perhaps most appealingly, leisure can generate satisfaction--a criterion most familiar to consumer researchers. While the for-profit leisure industry has long commanded marketers' attention, leisure's demonstrated contribution to life quality encourages research attention for social purposes as well.

The leisure domain is generally recognized as a significant component of life satisfaction across the total American population and particularly among certain segments. Leisure's importance to life quality has been noted frequently in non-empirical research across many disciplines: in psychology (Neulinger 1974), sociology (Dumazedier 1974, Riesman et al. 1950), philosophy (de Grazia 1962), anthropology (Huizinga 1950), communications (Stephenson 1967), and economics (Morgan 1962), and most empirical studies of life quality include measures of the leisure domain (Andrews and Withey 1976, Campbell et al. 1976, Cantril 1965, Canadian Minister of Supply and Services 1977, George 1979, Liu 1973, 1976, U.S. Department of Commerce 1977).

More importantly, in two recent subjective studies of life quality, satisfaction in the leisure domain was found to contribute significantly to global well-being. Andrews and Withey (1976) found that satisfaction with "how much fun you are having," a leisure domain item established by earlier perceptual mapping, was the strongest contributor to global satisfaction among twelve selected predictors. In a second subjective study (Campbell et al. 1976), satisfaction with "the ways you spend your spare time," designated as the leisure domain by the authors, was the individual domain which most strongly correlated with an index of global well-being. In multiple regression, the leisure domain was ninth in importance among twelve selected predictors.

Among certain segments of the population, leisure's contribution to perceived happiness is underscored. Because the elderly have more leisure time, satisfaction in this domain seems to have a greater impact on overall perceived well-being. The gerontological literature largely indi-

cates that there is a positive relationship between leisure participation and global satisfaction (Barfield and Morgan 1978, Edwards and Klemmack 1973, Graney 1975, Hepner 1969, Knapp 1976, Larson 1978, Lemon et al. 1972, Markides and Martin 1979, Szewczuk 1966, Toseland and Rasch 1978, Wolk and Telleen 1976). Finally, Neulinger (1974) has noted other specific groups of people with leisure-related problems (alcoholics, drug addicts and the urban poor) that seriously impair life quality.

Current trends also augur well for the continuing importance of the leisure domain. Innovative changes in work time such as flexitime, shared jobs, the four day/forty-hour week and three-day weekends will create larger blocks of time for leisure activities (Clawson and Knetsch 1966, Poor 1971, Roberts 1971). Total leisure spending (an estimated \$160 billion in 1977) has proved itself largely resistant to energy shortages and recessions, enjoying an average eleven percent annual growth rate over the past decade (Commerce America 1977). Demographic and social developments also point to growth. The sixty-five and older segment will increase dramatically over the next twenty years, the feminist movement will continue to expand leisure horizons for women, and Americans' heightened interest in health and physical fitness, now well beyond the fad stage, promises continued leisure growth.

Because it has been shown to contribute significantly to overall life satisfaction, accurate assessment of leisure quality becomes essential. Several researchers have warned against "rushing to the data" without sound constructs and measures (Churchill 1979, Reynolds and Barksdale 1978). The purpose of this paper, therefore, is to review the leisure literature, emphasizing construct definition and measurement. Based on that review a set of properties is proposed that adequate leisure domain/QOL measures would seem to require. Finally, some "next steps" toward achieving those measures are discussed.

Measurement of the Leisure Domain

Leisure has generally been measured in three ways: as time, as expenditures, or as activities. These are also used as surrogate measures of leisure quality, both as domain-specific items in QOL studies and in empirical leisure studies by psychologists, sociologists and recreation scientists.

Measuring Leisure as Time

Leisure is often equated with leisure time, and there are two common objective measures. In one method, leisure time is defined as time free from paid work (total time - work time = leisure time), a viewpoint rooted in the microeconomic labor-leisure analysis (Henderson and Quandt 1971, Robbins 1930). Trends in aggregate working conditions such as average workweek length, number of paid vacation days or holidays and length of average working life are used to trace longitudinal changes in the amount of leisure available. While the workweek has declined very little since World War II, researchers generally conclude that Americans are enjoying greater "blocks" of leisure time as a result of increased vacation/holiday time (de Grazia 1962, Moore 1971, Neulinger 1974, Wilensky 1961).

The second objective measure is the time diary or time budget. With variation among studies, respondents record their activities during short time intervals over the course of one day, and these data are aggregated. Alternatively, subjects might be asked simply to estimate how much time in a day or week they spend engaged in particular activities. The methodological problems of time diaries and budgets have been widely discussed (Bishop et al. 1975, Ennis 1968, Foote 1961, 1966, Holman and Venkatesan 1979, Szybillo et al. 1979). In these studies leisure time is generally defined as that time remaining after hours devoted to work and nondiscretionary activities are subtracted from total time. This is based on the tripartite model of time (total time - (work + nondiscretionary time) = leisure time), which has been described by a number of researchers (Bell 1975, Brightbill 1963, de Grazia 1962, Hendrix et al. 1979, Jacoby et al. 1976, Parker 1971, Voss and Blackwell 1975) and is based on a modification of the traditional labor-leisure analysis (Becker 1965, Mincer 1963, Voss 1967). Many early time diary studies were conducted during the 1930s, when the Depression's "forced leisure" generated interest in the use of free time (Lundberg et al. 1934, National Recreation Association 1934, Sorokin and Berger 1939). Renewed interest in leisure study during the 1960s and 1970s resulted in a number of new studies (Chapin 1974, Hawes 1977, Robinson 1977, Szalai 1972). In addition, most of the recent objective QOL studies contain at least one measure of leisure quality expressed as amount of discretionary time (Canadian Minister of Supply and Services 1977, Terleckyj 1975, U.S. Department of Commerce 1977).

There are three conceptual problems with measuring leisure as leisure time. First, it is often difficult to segregate work, non-discretionary and leisure time components (Bell 1975, Dumazedier 1974, Moore 1971, Murphy 1974, Schary 1971). There are many gray areas where the characteristics of each type of activity overlap. Where, for instance, does one classify time spent gambling or commuting or caring for children? Second, a priori classification of time spent pursuing a specific activity as "leisure" may be inappropriate. An activity typically categorized as a leisure pursuit may not be perceived at all as leisure by some individuals. Playing golf with friends, for example, may be a thoroughly enjoyable pastime for one person and a terrible chore for another. Even within the same person, a particular activity may shift from leisure to non-leisure, depending on situational context. A third problem with using leisure time as a surrogate measure of leisure is the question of direction. A "more is better" normative stance is implied when quite the opposite may be true, as in the case of too much leisure time among the unemployed, youth or the elderly. Inherent in all three problems is the fact that leisure has existential elements which extend beyond time constraints. Time diary researchers frequently suggested that subjective qualities differentiated leisure from other nonwork activities. Chapin (1974) and Szalai (1972) proposed categorizing activities according to their position along an obligatory/discretionary continuum. Robinson (1977) pointed to three criteria to segregate leisure from other nonpaid activities: enjoyment, discretion and spontaneity. Extensive empirical testing of subjective leisure elements was beyond the scope of these large-scale time diary studies, however.

Measuring Leisure as Expenditures

Researchers measuring leisure expenditures generally combine secondary data sources such as aggregate leisure sales data (U.S. Department of Commerce, Bureau of Census 1972a, 1972b, U.S. Department of Commerce, Bureau of Economic Analysis 1977) and aggregate leisure consumption data (U.S. Department of Labor, Bureau of Labor Statistics 1976, 1978a, 1978b). Several authors have used objective leisure indicators of this type (Canadian Minister of Supply and Services 1977, de Grazia 1962, Ennis 1968, Fisk

1963, Kaplan 1960). Measuring leisure as expenditures presents two problems similar to those encountered regarding leisure time. First, it is difficult to segregate leisure from nonleisure spending as, for example, in the case of gasoline (Eisenpreis 1971, Fisk 1963). Second, the validity problem reappears. One cannot assume direction, that more leisure spending means higher quality leisure.

Measuring Leisure as Activity Participation

Leisure is often defined as participation in recreational activities. This view of leisure grew out of the "recreation movement" of the 19th and early 20th centuries. The "classic" theories of play, prominent during this time, suggested that recreation served certain functions such as restoration or release of surplus energy (Ellis 1971). Because recreation was often viewed as a cure for social problems, it acquired a certain moralistic flavor. People were encouraged to recreate because it was good for them (Arnold 1980). There are two objective measures of activity participation. The first measure aggregates individual participation rates, association memberships, institutional attendance records or number of leisure facilities as gauges of leisure quality. Some researchers have indicated that these measures may underestimate actual participation (Ennis 1968). Indicators of this sort, however, are commonly used as leisure measures in QOL studies (Canadian Minister of Supply and Services 1977, Liu 1976, Terleckyj 1975, U.S. Department of Commerce 1977).

A second group of activity-based studies is generally not used in quality of life research, yet its prominence in the leisure literature warrants discussion. The theoretical basis is the same: activity participation frequency is used as a surrogate measure of activity enjoyment or leisure quality. In this body of research, however, activity participation frequency is used as a criterion variable. Four major types of predictors are used: socioeconomic variables, early leisure behavior, demographics or personality variables.

Socioeconomic Variables. Studies of this type use either occupational prestige/social class or occupational role to predict participation in leisure activities. Some researchers have found that differences in leisure activity participation are explained by differences in social class or occupational status (Clarke 1956, Dowell 1967, Reissman 1954, Romsa 1973, Settle et al. 1979, White 1955). This is based on the theory that leisure activities are economically determined. Others, by contrast, found these variables did not predict leisure activity (Burdge 1969, Defee, et al. 1974, White 1975). In a slightly different approach, some researchers have linked occupational role with activity participation (Bishop and Ikeda 1970, Gerstl 1961). Inconsistencies in findings using socioeconomic predictors have been explained as conceptual problems (Gerstl 1961) or resulting from the changing U.S. socioeconomic system (Settle et al. 1979).

Early Leisure Behavior. In leisure socialization studies, leisure activity participation early in life is used to predict frequency in later life. With few contradictions, studies have found that childhood leisure behavior can be used to predict activities pursued in adulthood (Burch 1969, Sofranko and Nolan 1972, Yoesting and Burkhead 1973), and that early adulthood activity is linked to later adult behavior (Kelly 1974, 1977). In studies attempting to relate pre-retirement leisure behavior with post-retirement activities, results are conflicting. Atchley (1971), Bultena and Wood (1970), Dye et al. (1973), Lambing (1972), McPherson and Guppy (1979), Peppers (1976), Pfeiffer and Davis (1971) and Szewczuk (1966) found post-retirement activity was strongly related to pre-retirement leisure. Others, however, found overall activity declined with age, as a result of health or mobility problems (Barron 1961,

Palmore and Cleveland 1976, Palmore and Luikart 1972).

Demographic Variables. In addition to age-related differences, other demographics have also been used to predict activity participation frequency. Sexual differences in leisure participation have been noted, usually as a part of larger studies (Duncan 1978). Family life cycle stage has also been used as a predictor (Landon and Locander 1979). Rural/urban residence effects on leisure activity have been demonstrated by Hendee (1969) and Knopp (1972). Some studies grouping several demographic and socioeconomic variables have isolated significant predictors of activity participation frequency (Tatham and Dornoff 1971), while others have concluded that demographics are not helpful in grouping leisuers (Romsa and Girling 1976).

Personality Variables. This genre of studies uses personality variables to predict leisure activity participation frequency. The theory of this research is that people tend to favor those activities which satisfy certain needs (Hawes 1978, London et al. 1977). Examples of this type of study include: McKechnie (1974), Procter (1962), Tinsley et al. (1977) and Weller and Brasch (1979). The amount of variance in participation frequency explained by personality varies widely across these studies.

In using leisure participation frequency as a measure of leisure quality, construct validity again comes into question. While the inconsistent findings in the four types of empirical activity-based studies may be due to theoretical problems peculiar to each area, it is also likely that the criterion variable, participation, lacks validity as a surrogate leisure measure. Some authors have stated (Meyersohn 1972, Murphy et al. 1973) that this measure assumes intrinsic enjoyment of an activity when situational/extrinsic motivation might better explain participation. Indeed, researchers have shown that situational variables such as antecedent conditions (Belk 1975, Markides and Martin 1979, Witt and Bishop 1970) and social situation (Cheek et al. 1976, Field and O'Leary 1973) can be used to explain participation.

Overall, the questionable construct validity of the three "objective" measures of leisure--time, expenditures, and activity participation--suggests a need for more subjective measures of leisure quality. While many authors have called for psychological investigation of the leisure experience (Mannell 1980, Murphy et al. 1973), objective measures remain the most widely used. The development of subjective measures of leisure domain life quality has begun in two directions: in QOL studies and in the empirical leisure literature. Among most QOL studies, the bulk of the "subjective" items are actually based on objective indicators. In the gerontological literature, for example, leisure activity is measured almost universally in objective terms: number of social contacts, organization affiliations, activity participation (Edwards and Klemmack 1973, Graney 1975, Knapp 1976, Larson 1978, Lemon et al. 1972, Wolk and Telleen 1976). Out of six "subjective" leisure indicators in the Andrews and Withey (1976) study, three are time-based: "the amount of relaxation in your life;" "your chances for relaxation - even for a short time;" "the amount of time you have for doing the things you want to do;" and one is activity-based: "the way you spend your spare time, your nonworking activities." Two measures, however, approach a subjective concept of leisure: "how much fun you are having," and "the amount of fun and enjoyment you have." Importantly, one of these items was also the leading predictor of global QOL, as discussed earlier. In a second direction, several empirical leisure studies have attempted to identify subjective experiences enjoyed during participation in specific activities (Hawes 1978, Hawes et al. 1975, Tinsley et al. 1977). These, however, are not designed to measure overall leisure quality. In summary, development of a subjective measure of leisure is needed, one that transcends specific activities and approaches leisure from a number of existential

dimensions.

Toward An Expanded QOL Measure: Subjective Properties of the Leisure Domain

As Churchill (1979) has stated, the first step in measurement development is to specify the domain of the construct in question. The literature should be reviewed, and the various dimensions of the domain should be assembled. Most definitional discussions of leisure compare it to three closely-related concepts: free time, recreation and play (Miller and Robinson 1963). As discussed, free time and recreation correspond to "leisure as time" and "leisure as activities," objectively measurable dimensions of leisure. Play, like leisure, however, is frequently described in more subjective terms. Some authors distinguish the two concepts (de Grazia 1962, Pieper 1952). Leisure is described as being restful or contemplative and is limited to adults while play is generally seen as the activity of children and animals and is characterized by its apparently "useless" nature. Conversely, other authors have suggested that it is impossible to segregate the subjective properties of leisure from those of play, and that the concepts are inextricably intertwined (Arnold 1980, Ellis 1971, 1973, Kaplan 1975). Some researchers use the terms synonymously, implying that leisure is simply the play of adults (Berlyne 1969, Smith 1980). All the major subjective properties of leisure described below have also been used to describe play, attesting further to the similarity of the two constructs. Because the concepts are so closely related, it appears appropriate to include both leisure and play in the construct domain.

There appear to be several major subjective properties of leisure discussed in the literature: intrinsic satisfaction, perceived freedom, high involvement, arousal, feelings of mastery and spontaneity.

Intrinsic Satisfaction

Most leisure definitions suggest that the leisure experience offers pleasure or gratification. Leisure is pursued for its own sake and is an end in itself rather than a utilitarian means to an end (Berlyne 1969, Caillois 1961, de Grazia 1962, Douglass 1960, Kaplan 1975, Kerr 1962, Lee 1929, Piaget 1962, Riesman 1963, Schary 1971, Smith 1980, Stephenson 1967). Because of its intrinsic rewards, leisure offers a means of self-expression and affirmation (Dumazedier 1974, Farina 1969, Murphy et al. 1973, Pieper 1952).

Perceived Freedom

Leisure is often described as "free," something one does voluntarily, without coercion or obligation (Caillois 1961, Douglass 1960, Ennis 1968, Huizinga 1950, Kaplan 1975, Stephenson 1967). At least two authors have maintained that perceived freedom is the single precondition of subjective leisure (Bregha 1980, Neulinger 1974). As noted earlier, many time-oriented researchers recognized this subjective leisure element and proposed an obligatory/discretionary continuum to segregate leisure from other nonwork activities (Chapin 1974, Hendrix et al. 1979, Robinson 1977, Szalai 1972).

High Involvement

Some have suggested that true leisure means high involvement or total absorption in an activity. When we leisure, we become so involved that we enter a microcosm distinct from daily life (Anderson 1961, Berlyne 1969, Douglass 1960, Dumazedier 1974, Erikson 1950, Foote 1966, Huizinga 1950, Kaplan 1975, Lee 1929, Piaget 1962, Riesman 1963, Stephenson 1967). Some have described this experience as a fantastic escape from reality while others simply call it an interlude from the ordinary. While the micro-

cosm may be relatively free from social control, it is governed by its own rules and order (Caillois 1961).

Arousal

Several researchers indicated arousal or tension are present in leisure (Berlyne 1969, Ellis 1971, Lee 1929, Murphy et al. 1973, Piaget 1962, Riesman 1963). Novelty-seeking, exploration and risk taking behavior have been noted. Also related to arousal is the repetitious or ritualistic nature of leisure activity (Huizinga 1950, Stephenson 1967).

Mastery

Feelings of mastery have been identified as another property of the subjective leisure experience. One has the opportunity to test one's self (Murphy et al. 1973) or conquer the environment in some way (Berlyne 1969, Erikson 1950, Piaget 1962, Riesman et al. 1950, Riesman 1963).

Spontaneity

Finally, several authors have noted leisure's spontaneous nature (Lee 1929, Piaget 1962, Riesman 1963, Robinson 1977).

It seems desirable to relate currently-used objective measures and the proposed subjective properties. Churchill (1979) stressed that bringing together widely varying definitions of a construct was a way to synthesize current knowledge and to avoid future confusion. Old measures of a construct should be considered along with new viewpoints in order to avoid "throwing the baby out with the bath-water." Importantly, QOL researchers also maintained that, while subjective measures may offer improved construct validity in measuring satisfaction, they must be tied in some way to objective conditions in order to contribute to policy making (Schneider 1976). Obviously, in terms of measurement development and policy application, it is necessary to relate the objective conditions and subjective properties of leisure.

The two-dimensional matrix in the Exhibit provides a framework for relating objective measures and subjective properties. The rows of the matrix represent the major objective indicators of leisure quality. The $E_{i,j}$ s equal the general evaluation of the objective conditions across subjective properties. For example $E_{2,1}$ would indicate how much amount of expenditures contributes to leisure quality. The columns show the major subjective properties of leisure, and the $E_{i,j}$ s indicate the evaluation of subjective properties across objective conditions. $E_{2,2}$ would measure, for example, how perceived freedom across all objective leisure conditions contributes to overall leisure quality. The grand mean ($E_{..}$) would provide a general evaluation of leisure quality "as-a-whole." It is important to note that the lists of properties and objective conditions shown are by no means complete, and that a general evaluation of leisure quality would optimally include as many measures as possible. Finally, on a more specific level, the $E_{i,j}$ s would measure leisure quality under a particular objective condition with respect to a particular subjective property. The relationship between each objective condition and subjective property could then be determined.

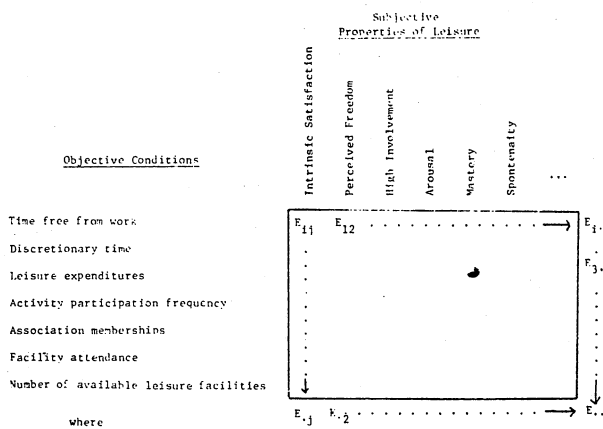

Next Steps

Next steps include the development and integration of subjective and objective leisure measures and the exploration of personal and situational antecedents of the subjective leisure experience. The development of subjective leisure measures should be continued, following the steps Churchill (1979) has enumerated. This would entail a more extended review of the leisure literature to add other properties not included above. The construct domain should be adequately sampled and items generated for each dimension. Following data collection within the proposed framework, the measures should be purified and reduced to a parsimonious set, and reliability should be assessed. Convergent validity of the measure might be evaluated by correlating an overall leisure quality measure developed from the various items with existing one-item leisure domain satisfaction measures such as those used in subjective QOL studies. Discriminant validity could be assessed by correlating the overall leisure quality measure with QOL study measures of other, theoretically unrelated domains (satisfaction with safety, home or money, for example). In assessing construct validity, one might expect the overall leisure domain satisfaction measure to contribute significantly to global satisfaction, as demonstrated in past subjective QOL studies. The matrix discussed above might be used to relate subjective properties with objective measures for policy purposes. This could be done using simple Pearsonian correlations or canonical correlation. Further, analysis of variance or multiple regression could be used to assess the subjective properties and objective measures as predictors of leisure domain satisfaction. Research could be conducted on an individual level of analysis or between communities, as done by Schneider (1976).

Further investigation of the antecedents of subjective leisure is warranted, paralleling similar studies of objective measures. As discussed above, socioeconomic variables, early leisure behavior, demographics and personality variables have been related to objective leisure measures, albeit often weakly. These same personal variables might be tested as predictors of subjective leisure properties as well. Further, the subjective leisure experience appears to be highly situational, varying across different experiences with the same activity or even within the same person. This situational quality of leisure also has been discussed by several researchers (Huizinga 1950, Stephenson 1967). Some have begun to investigate the effects of situational variables such as antecedent conditions or social surroundings on objective measures (Field and O'Leary 1973, Witt and Bishop 1970). Their effects on subjective properties might also be

EXHIBIT*

Dissagregation of the Leisure Domain

- $E_{i,j}$ = Affective evaluation (response) under a particular objective condition with respect to a particular subjective property
- $F_{i,j}$ = General evaluative response to an objective condition (across properties)
- $E_{.j}$ = General evaluative response to a property (across objective conditions)
- $E_{..}$ = General evaluative response to all objective conditions over all properties; i.e., to leisure as a whole

*After Andrews and Withey (1976)

explored.

Summary

Since there are many reasons for assessing leisure, there are many measures for it, each with its rationale and proponents. There seems little merit to arguing for subjective over objective assessment, particularly since the benefits of each can be combined. It should be recognized, however, that such a combination, although useful, is merely an initial step toward the systematic explication of the leisure domain and our ultimate understanding of its contribution to QOL evaluation.

THE CONSUMER AND THE HEALTH CARE PROCESS

Lynn Langmeyer, Wright State University
George Miaoulis, Wright State University

Abstract

A review of perceived past and current directions in health care delivery research is presented to set the stage for a paper on a suggested future direction in this critical area. Consumer data on attitudes toward health care is presented and discussed in order to reveal a relatively unexplored direction within which consumer research can make unique and important contributions: the interpersonal dimension of the health care consumption process. The paper concludes with suggestions for specific research of both a theoretical and practical nature.

Introduction

The focus of this paper is consumer behavior issues of health care consumption. It is generally accepted that many consumers are dissatisfied with the quality of health care they receive and, at the same time, feel unable to remedy the situation. In this paper, we suggest that the health care provider - patient interaction, the interpersonal dimension of the system, has often been neglected as an important source of these dissatisfactions. At the same time, the interpersonal dimension represents an important starting point for dealing with these dissatisfactions. The objective of the paper is to provoke consideration and exploration of health care consumption behavior and not, at this point, to provide a detailed analysis of consumer dissatisfaction with the health care process.

Health Care Delivery -- Where's the Consumer?

Zaltman and Vertinsky (1971) mention, rather briefly, in their article "Health Service Marketing: A Suggested Model," that one of the "perceived barriers to taking proper health action is the psychological distance between patient and physician." This distance, they suggest, "may cause patients to ignore the treatment prescribed by the physician." Health care professionals, particularly nurses, have been aware for many years of the inequality inherent in the physician-patient relationship (See M. Karmar 1972) and the negative effect of this imbalance on the patient. However, the physician component of the profession has changed little in the past ten years with respect to the interpersonal dimension, and little consumer-oriented research has been done in this critical area. Indeed, although the interpersonal dimension has been a relatively unexplored issue of health care research, we can find hints of its importance in health care literature.

For example, Hochbaum (1969) discussing consumer participation in health planning states:

We must recognize and accept the fact that it is the consumers of health services who are the final and proper judges of what kinds of services they want, how they want them delivered, what form they should take and in what setting they should be provided.

It is only on the medical and technical details that the health professions have any exclusive right to make decisions.

To further emphasize, support and underscore this issue, we found the majority of specific dissatisfactions that

the Wright State study panel members experience with health care (aside from cost) can be traced to what Zaltman and Vertinsky call "psychological distance," what Kramer calls "power imbalance" and what Hochbaum calls "inequity." As marketers, if we are to assist health care professionals in addressing these dissatisfactions, then we must begin to understand, explain, and eventually model general health care consumer behavior. We believe the first step in this research process is to examine the issues of health care consumption behavior with emphasis on the interpersonal dimension. We will identify and examine these issues by first discussing previous directions in health care literature and research, which suggest or consider but do not thoroughly explore consumption behavior and then, in the balance of the paper, directly address the issue of consumer attitudes and the consumption process.

Identified Research Issues (Directions?)

The literature and research in the area of the consumer and health care appears to address four major issues and one minor issue. These research issues are:

- 1) consumer participation in the planning and delivery of health care
- 2) consumer satisfaction with delivery systems
- 3) health care decision models
- 4) health promotion
- 5) health care facility location

Each of these is summarized below from the perspective of the role of and impact on the consumer.

Planning and Delivery

The passage of Public Laws 88-164, and 93-64 in 1963, 1966, and 1974 respectively, require that representatives of the consumers of health care facilities be participants in the planning and operating councils of such facilities. The conceptual literature and empirical research in this area, with respect to the consumer, focuses on issues such as, "The Whys and Why Nots of Consumer Participation" (Thomson 1973), "Community Health Planning or Who Will Control the Health Care System" (Brown 1972), "Consumer Participation in Health Planning: Toward Conceptual Clarification" (Hochbaum 1968) and "The Merits of Using Experts or Consumers as Members of Planning Groups: A Field Experiment in Health Planning" (Nutt 1976).

These articles have appeared in public health journals or management journals and emphasize the organizational ramifications and problems concomitant with consumer participation in the planning and delivery of health care. The discussions and research results are useful for educational, skill training and general managerial purposes. They are, however, relatively unuseful for exploring patient health care consumption behavior.

The issue of consumption behavior is not completely ignored. Nutt (1976), in discussing the role of consumers as members of planning groups makes the following observations: "people should have a role in articulating their needs"....yet we are "co-opting health consumers by giving them a voice in the decision process and not fundamentally altering the decision process itself (e.g. the criteria selected or criteria weightings used to make

decisions)." We would add that additional co-opting occurs when health consumers are given no role or voice in evaluating how well articulated needs are being met which raises the issue of consumer satisfaction with delivery systems.

Consumer Satisfaction Issues

The second major theme, appearing at this time almost exclusively in public health journals, concerns consumer satisfaction/dissatisfaction with specific types of delivery systems -- HMOs (Pope 1978), prepaid group practice (Weinerman 1954; Bashshur, et.al. 1967; Tessler and Mechanic 1975), health plan coverage (Gerst, et.al. 1969), etc. The results of these studies are somewhat confusing, perhaps, as Kramer (1972) suggests, due to the lack of differentiation between the "outcome of medical care as contrasted to the activities involved in obtaining or being given that care." She raises the issue of the interpersonal dynamics in health care consumption and Weinerman (1964) reports "disappointment with the degree of personal interest shown by the doctor" attributing this patient perception to conflict between lay and professional concepts of proper care.

This interpersonal theme is further suggested by others. Pope (1978) states his respondents are "more satisfied with the technical aspect of HMOs than the interpersonal components;" Friedman and Di Matteo (1979) mention "power differential," "the patient as an object," "the impact of health care professionals on patient's reactions," "satisfaction comes from treatment as a person," and "the needs and values of patients determines 'best' procedures;" O'Connor (1978) states "accurate and complete information about patients' needs and satisfactions" must be available. Weinerman (1964) summarizes these ideas in his statement, "the most neglected and least appreciated element in medical care planning and evaluation is overall perceptions of patients...the reactions of the consumer to medical care."

Generally, despite these selected comments, the satisfaction/dissatisfaction health care studies are concerned with the implications for health care organizations and not health care consumption itself. For example, Swan and Carroll (1980) conducted an extensive literature review to explore the possible conceptual and research contributions the patient satisfaction literature might provide for research on consumer satisfaction. It is clear from the reviewed research that "physician-patient interactions" are strongly related to patient satisfaction. However, explanations as to why this relationship exists or how it operates in health care consumption are not offered in the literature reviewed.

Decision Models

The contribution of consumer behaviorists to health care marketing, in the form of health care decision models, comprises the third major research theme. These studies have appeared in marketing journals and conference proceedings and have concentrated on modelling action/no action decisions with respect to illness (Zaltman and Vertinsky 1971) or exploring the demographic and psychographic factors associated with the decision to seek medical care (Wortzel 1976). The emphasis appears to be on social marketing and segmentation issues of health care rather than on identification and exploration of consumption behavior issues. As such these articles contain important implications and suggestions for preventive health care behavior changes. However, we feel it is also important to follow the consumer in this process beyond the initial action/no action state. Indeed, it is possible that action/no action decisions are tied inextricably to prior experiences in health care situations, particularly the interpersonal aspects of those situations,

and the existing models do not demonstrate this orientation.

Health Promotion

The fourth area, health promotion, addresses health educators attempts to increase utilization of health services, and to stimulate changes in health behaviors, and changes in health attitudes, knowledge, and values. The focus of Keyes (1972), Rosenstack (1966 and 1974) and most recently Green (1979) has been on those activities designed to increase consumer participation in the health care system and to reinforce consumers' positive health behaviors. Of the five areas being reviewed, health promotion comes closest to identifying and responding to consumption behavior issues. However, health promotion currently fails to consider the consumer's interpersonal needs as an integral element of the promotion and reinforcement process. Some recent research by Green (1979) and Miaoulis (1979) suggests that health educators are beginning to address this issue and we are suggesting that consumer behavior researchers do the same. There is substantial opportunity for marketers to assist in the development process as health educators have not historically recognized the importance of consumer decision processes.

Facility Location

The final theme, rather undeveloped at the present time and therefore somewhat minor, is the use of mathematical models to determine health care facility location. Parker and Srinivasan (1976) report on a modelling approach which incorporates consumer preferences in planning rural primary health care facilities. Their study indicates that the method, although elaborate and time consuming, has "substantial reliability and predictive validity" as well as viability. This aspect of health care delivery, however, is only tangentially related to our field of interest.

Consumer Attitudes

Consumption Process

The specific theme conspicuously absent (aside from passing mentions here and there) in the previous discussion of health care research (which is by no means meant to be exhaustive) concerns issues surrounding consumer health care behavior subsequent to participating in the location, planning, and operating of a health care delivery system and the decision to use it. In other words -- what factors affect the behavior of a consumer, negatively and positively, as he or she is in the process of consuming general medical care and/or local hospital services?

Imagine that you are a consumer in the examining room of your physician's office. You have just been informed that the results of the series of tests you underwent last week indicate surgery is necessary. Your physician says, "No, it is not really serious, but should be taken care of as soon as possible." This typical exchange between consumer and physician leads to some important consumption issues:

1. Does the consumer participate in the surgery decision making process?
2. Does the consumer question the physician as to the benefits of the surgery and its outcomes? Unfortunately, there is no money back guarantee or trial size.
3. If the consumer seeks a second opinion, how are opinions compared with respect to quality, cost, etc.?

4. If the consumer decides to undergo surgery, does he or she have the authority to determine the who, when, where and under what conditions it will be performed?
5. To summarize: Is the consumer a participant in the consumption process?

Now imagine that you have decided to undergo surgery and are seated in the waiting room of "your" hospital, filling out insurance forms since that is the necessary first step in your consumer/patient role. How do you feel? Is there a knowledgeable person available with whom you can share your feelings of anxiety and powerlessness? Are you being treated like "the patient" or "a case"? This scenario certainly suggests you have not been a consumer in the traditional usage of that term -- involved decision maker.

Illustrative Data

To illustrate the consumer's lack of involvement in the health care consumption process, we draw upon a 1978 Wright State University consumer panel study designed to assess the overall quality of medical care and hospital services in the Dayton, Ohio SMSA.* While the study was not specifically designed to analyze the health care consumption process, several open-ended questions illustrate the consumer lacks of involvement, and warrant reporting here.

The data from the panel study suggests that consumers are feeling helpless, depersonalized, uninformed and scared. Panelists were asked to respond to the question, "If you could change one thing about the general level of hospital services, what would it be?" The following are selected verbatim comments directed explicitly at the interpersonal component of services:

- Let the patient know more, explain more.
- Take more time to be sympathetic and explain what is happening and why.
- Improve education of personnel, especially to be more compassionate and devoted to patients.
- More caring doctors.
- Quicker more efficient personal attention.
- More communication between physician and patient.
- More individualized care.
- More personal concern.
- Be more aware of the family in regard to the truth of the conditions of the patient.
- More empathy with patients.
- Medical professionals should look past their income levels and more into what they're being paid to do.
- Quality of 'bedside' manner of professionals.
- More personalized service. Patients are scared humans, not just bodies.
- More concern, more interest in people than money.

The following summary to the question, "If you could change one thing about the general level of hospital services, what would it be?", indicates clearly the consumers' need for improving communication between the health care providers and the patients.

Suggested Improvements	Response
Cost containment	25%
Better communications with patients	20
Emergency room services	15
Better preventive medicine	15
Better food services	15
All other comments	10

*The Wright State University Consumer Panel is a randomly selected demographically cross sectional sample of 1,000 households in the Dayton, Ohio SMSA.

The results suggest that patients feel they are not active participants in the health care consumption process. They have little or no control and power within the system, and their expressed dissatisfactions (aside from cost) are with interpersonal and other non-technical aspects of the health care system.

Quality of Health Care

It is also evident from panel responses that quality health care is defined in terms of both technical aspects and interpersonal aspects. When asked, "How would you define quality care within a hospital?," panel members gave considerable attention to the non-technical, interpersonal dimension:

Quality of Hospital Care	Response
Technical aspects	
Qualified staff	24%
Efficient staff	16
Non-Technical aspects	
Patient concern	22
Patient care	9
Friendly personnel	7
All other comments	22

Panel members were asked a similar question regarding their perception of quality care by physicians. Their responses to "How would you define quality care by a physician?," also reflect concern for both the technical and interpersonal aspects of health care.

Quality of Physician Care	Response
Technical aspects	
Diagnosis	25%
Medical knowledge	15
Proper treatment	11
Non-Technical aspects	
Patient interest	17
Personal communication	11
Physician availability	4
All other comments	17

The interpersonal dimensions of health care are equally as important, and perhaps more important to consumers. To fully participate in the consumption process, and to have the opportunity to assess issues such as quality care, consumers require interpersonal attention and communication. The technical and non-technical aspects of health care cannot continue to be treated as separate elements of the delivery system. Illness is an inherently anxious condition and hospitals are scary places. If consumers' health care are to be met satisfactorily then we must design human systems to meet them and not simply buildings and support facilities.

Implications

The data strongly suggests that the non-technical, interpersonal dimension of health care consumption, generally ignored or given cursory attention in health care consumer behavior studies, must be considered and studied regardless of the "major themes" being investigated. The issues of lack of active participation, lack of communication, feelings of helplessness, powerlessness and depersonalization not only influence but perhaps determine health care behavior.

If, as consumer behavior researchers, we are to contribute to the understanding and explaining of health care behavior, and provide genuinely useful information to health care professionals, then we must address and systematically investigate the issues of the consumer and the health care consumption process. To this end, we recommend that the following research be undertaken:

- Examination of the formal and informal communications networks in various health care settings.
- Patient oriented research to identify and investigate the role inequities of the interpersonal patient physician relationship.
- Physician oriented research to identify mechanism through which physician (and medical students) can be taught to emphasize the interpersonal dimensions of health care delivery.
- Broader conceptualization and integration of the health care process through more interdisciplinary research.
- In-depth research on consumer motivations and attitudes toward and benefits sought from health care interactions.

The research studies outlined above will contribute to understanding consumer attitudes and the health care consumption process.

ATTITUDES TOWARD PUBLIC POLICY ALTERNATIVES TO REDUCE AIR POLLUTION*

David A. Aaker, University of California, Berkeley
Richard P. Bagozzi, Massachusetts Institute of Technology

Research into public concern with environmental quality has mainly attempted to identify causes or determinants of environmental concern. Although there have been exceptions (Koenig 1975, Kinnear, et. al. 1974), the evidence suggests that concern is associated with higher levels of education and socioeconomic status, younger age groups, urban dwellers and nonminorities (see, e.g., Erskine 1972, Tognacci, et. al. 1972). With respect to political orientation, the evidence indicates that Democrats, liberals and those less politically alienated are more concerned with the environment (see, e.g., Tognacci, et. al. 1972, Dunlap 1975, Koenig 1975, Buttell and Flinn 1978). There is also evidence that concern is related to perceived consumer effectiveness in influencing environmental quality (Kinnear, et. al. 1974).

This article will attempt to extend this research stream in several directions. First, the study will focus upon a specific domain of concern: concern for air pollution. Past research has tended to use a much broader definition of concern which would generate constructs like concern for the overall environment, ecology, or pollution. When the constructs consist of multi-item scales, the individual items are often quite diverse (e.g., Weigel and Weigel 1978). The problem with the use of such a general concern construct is that people can hold a variety of attitudes and beliefs toward the many components of the environment. If these components are combined, especially when they are combined in an unspecified way, the meaning of, and attitudes toward, the resulting construct may be unstable. Second, and perhaps most important, the research will study not only the antecedents of concern but also the impact of concern and other constructs upon the advocacy of a set of public policy alternatives such as closing freeways or adding additional pollution control equipment on automobiles. Previous research with few exceptions has been content to consider generalized concern as the sole dependent variable of interest. However, concern is more properly treated as an intervening variable. Inquiry should be extended to the link between concern and various public policy alternatives. The practical question is whether concern becomes translated into support for public policy alternatives that will be costly, inconvenient, or both. It is this link that is really important to understand the process by which an issue such as pollution gets addressed in our system of government.

Among the few studies that have looked beyond concern in order to investigate possible action that might be taken are several which use a "willingness to pay" construct (cf National Wildlife Federation 1969 and 1970, Schuller and Ervin 1972). Although such a construct is somewhat artificial and therefore less useful than more realistic public policy alternatives, the results of these studies are suggestive. Basically, they indicate that, although a majority of people are willing to pay something to ameliorate problems like pollution, the amounts are likely to be quite modest. Thus, we might hypothesize that a

concern for problems of pollution may not necessarily be transmitted into support for public policy programs if those programs have associated costs. More particularly, the link between concern and support for public policy alternatives should be related to the costs of those alternatives for the respondents. A natural alternate hypothesis is that concern will indeed generate support for public policy alternatives.

Third, this study will introduce a variety of constructs which normally have not been considered in past investigations but which will act as important control variables, add useful exogenous variables, and introduce intervening variables enriching the model building process. The determination of the link between concern and support for public policy alternatives is potentially confounded by many factors which can be controlled. Thus, in this study, a liberal-conservative construct is included to control for individuals' inclinations toward governmental solutions; and a miles driven construct is included to control for each respondent's attachment and reliance upon the automobile. Useful exogeneous variables included are objective measures of actual pollution levels. The few studies that have used pollution variables have found that these can influence attitudes (Degroot et. al. 1966). Several endogenous variables have the potential to increase our understanding of the attitude formation process. One such variable is the attitude toward the efforts of automobile companies to improve air pollution and another is beliefs as to the change of air pollution. Instead of the conventional two-way analysis, these variables are explored in the context of a structural equation model.

In sum, this study hypothesizes that whether people will advocate certain policy recommendations affecting themselves, industry, and government will depend upon (1) their beliefs that the problem in their immediate environment is getting worse, (2) their concern as to the seriousness of the perceived problem, (3) their political orientation, (4) their demographic characteristics, (5) their use of the automobile, and (6) the amount of actual pollution in their region. The particular sequence of relationships among these variables is developed below.

Method

In May of 1973 (before the OPEC oil embargo), a total of 521 respondents were interviewed in their homes as part of the regular California Poll conducted by the Field Research Corporation. A cluster sampling design was used with over 100 randomly selected starting points for each cluster. Interviewing was conducted late afternoons and evenings on weekdays and all day on the weekend. Up to four call-backs were employed. One adult per household was selected systematically to provide a representative age and sex distribution. The sample was divided on a random basis into an analysis sample (n=348) and a validation sample (n=173).

Exhibit 1 describes the eight endogenous variables and the eight exogenous variables developed from questions in the survey. The first five variables can perhaps be considered behavioral predispositions or policy variables in that they reflect respondents' positions on public policy legislative alternatives to combat air pollution. These include the installation of anti-pollution devices, gasoline rationing,

*The authors are grateful to the Field Research Corporation which originally collected the data used in this study, the University of California State Data Program which provided access to it, and the Institute of Business & Economic Research at the University of California which supported the study: Of course, these organizations are not responsible for the analysis or interpretation of data appearing herein.

EXHIBIT 1

VARIABLES EMPLOYED IN THE RESEARCH

Endogeneous Variables

1. DEVICE All cars and trucks to install anti-pollution devices that could cost up to 300 dollars. (Four point disagree (1) to agree (4) scale.)
2. RATION Ration gasoline. (Four point disagree - agree scale.)
3. FREEWAY Sum of two questions proposing to reduce freeway driving by closing of freeways or slowing freeway construction drastically. (Four point disagree - agree scale.)
4. TRANSIT Sum of two questions proposing to buy busses with gasoline tax and set aside exclusive bus lanes and to build a rail rapid transit system. (Four point disagree - agree scale.)
5. AIR Sum of three questions on whether the auto air pollution standards are too strict. (Three point scale from too strict (1) to too lenient (3) and a two point scale from easing up some (1) to standards should be met (2).)
6. CONCERN How serious is the air pollution problem? (Not at all serious (1) to extremely serious (4).)
7. BELIEF In the last year has air pollution become worse? (Not as bad (1) to worse (3).)
8. AUTCO Are auto companies doing all they can to reduce the air pollution problem? (Doing all they can (1) to could be doing more (2).)

Exogenous Variables

9. MILES Approximate number of miles driven in an average year. (Five point scale.)
10. LIBERAL Do you consider yourself a conservative or a liberal. (Five point scale from strongly conservative (1) to strongly liberal (5).)
11. NO2 The amount of NO2 air pollution in the area in which the respondent lives. (The state was divided into ten areas.)
12. OZONE The amount of ozone air pollution in the respondent's area.
13. DUST The amount of dust air pollution in the respondent's area.
14. INC Family income. (Seven point scale.)
15. AGE Age. (Twelve point scale; 18-20, 21-24, 25-29, etc.)
16. ED Education. (Seven point scale.)

restricting freeway use, encouraging rapid transit, and reducing automobile air pollution standards. Three alternatives were among those being seriously considered by state and local governmental units throughout the country who were under a mandate from the Clear Air Act of 1970 to submit plans for meeting the Environmental Protection Agency's air quality standards.

The CONCERN variable, a central variable in previous research, is based upon a question asking how serious is the air pollution problem. The BELIEF variable indicates the degree to which the respondent thinks that pollution has become worse during the past year. Finally, the AUTCO variable reflects the respondent's judgment as to whether the automobile companies have done all that they could to reduce air pollution.

The first exogenous variable represents the miles driven by the respondent, and the second reflects a liberal/conservative self disclosure. It was felt that these variables should explain people's position with respect to public policy issues. Someone who drives more than average might feel that legislation is unnecessary or inconvenient. Further, a liberal orientation should lead toward a tendency to look to the government for solutions. These variables are not only interesting in themselves, but serve as important control variables when trying to determine the predictive ability of demographic variables.

The next three variables reflect the main types of air pollution in California. One interest is to see if one seems to be more dominant in the analysis than the other. The final three variables are the demographic variables of income, age, and education. The highest correlation among the exogenous variables was .34 (excluding the correlations among the three types of air pollution measures).

A Recursive Model

Stepwise regression was run upon the analysis sample for each of the endogenous variables. A recursive structure was used. The BELIEF regression used only the exogenous variables. The CONCERN regression also included the BELIEF variable as an independent variable. In addition to the exogenous variables the AUTCO regression included the CONCERN and BELIEF variables and the remaining "behavioral" predisposition variables included the BELIEF, AUTCO and CONCERN variables as independent variables. The recursive structure is shown in Figure A.

The results of the stepwise regressions are shown on the top line of each row in Table 1. Each variable coefficient reported has a beta weight of close to or exceeding 0.10 and each was at least significant at the 0.10 level. Also shown are the mean values for each variable and the R² values.

The resulting model obtained from the stepwise regression was fitted to the validation sample using ordinary least squares. The results are presented on the second line of each row in Table 1. The numbers in parentheses are the t-values of the validation run. The results are summarized in Figure A. Only paths are included that have a beta weight of at least 0.15 on one of the data sets and were "confirmed" by the other. Stepwise regression with a validation sample is appropriate here since the prior theory is strong enough to support the model structure but is not strong enough to provide a priori specification of the paths. In fact, a purpose of the research is to identify paths. The low correlations among the exogenous variables and the use of a validation sample reduce the classic dangers of stepwise regression.

TABLE 1

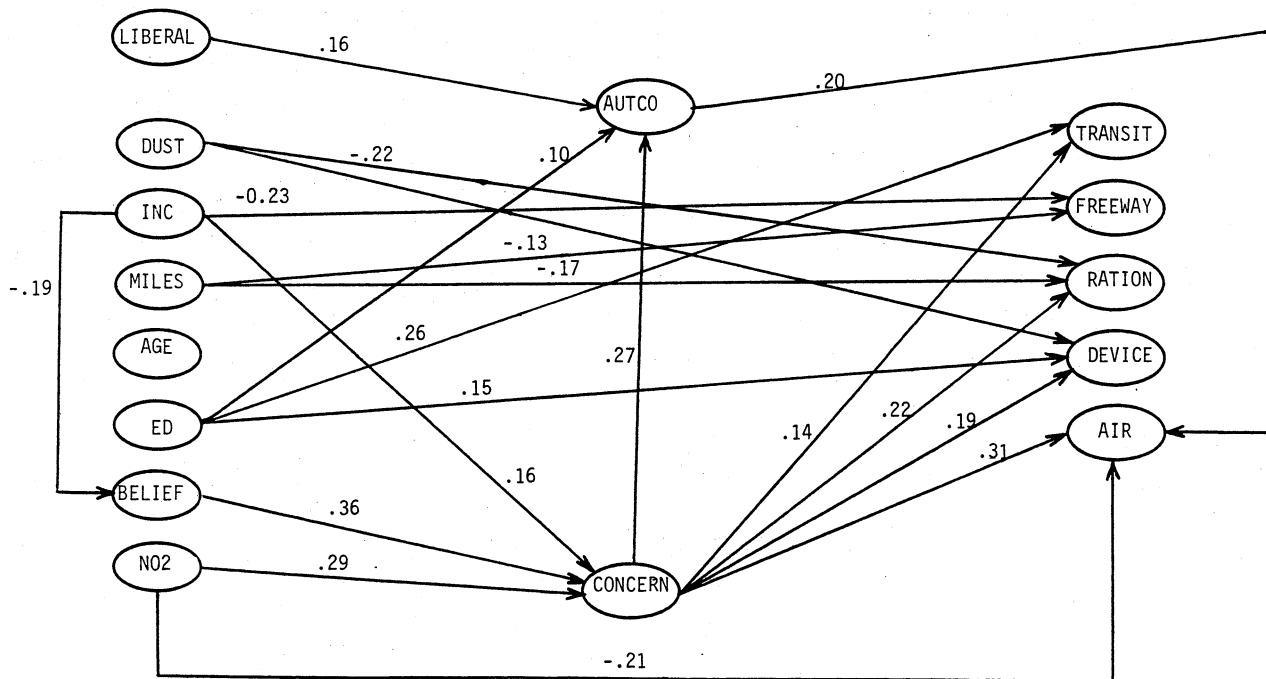

THE ANALYSIS AND VALIDATION RESULTS: BETA WEIGHTS

FIGURE A

Discussion

The Means

The means on the first four variables are directly comparable. A 2.5 rating indicates a neutral position. Two of the proposals, DEVICE and TRANSIT, obtained a neutral score and the other two were regarded negatively.¹ Actually, the TRANSIT variable included a bus system proposal with exclusive bus lanes which was not supported (2.2) and a rail rapid transit system which was supported (2.8). During this time some exclusive bus lanes were tried in Los Angeles and proved to be unpopular. About 40 percent of the probability sample was from the Los Angeles area. Thus, the anti-pollution device and the rail rapid transit were judged neutral or favorable and the rest were judged unfavorably. Clearly, attacks on freeways and gasoline rationing are not popular among Californians who are heavily dependent on the automobile for transportation.

With respect to the AIR variable, respondents felt that the automobile standards were a bit too lenient but a small majority felt that they would still be relaxed if car performance were affected. The CONCERN variable indicated that respondents exhibited attitudes between feeling that the pollution problem was very serious (2) and somewhat serious (3). They further felt that the problem was (a) worse than it had been in the past (BELIEF) and (b) by a wide margin that the automobile companies could have been doing more (AUTCO).

The Intervening Variables

BELIEF. BELIEF is a cognitive construct indicating whether air pollution is perceived to be worsening. It is hypothesized to be influenced by the pollution variables. In fact, the effects of the pollution variables were actually negative, although they were too small to be included in the table. Two qualifications need to be mentioned. First, the pollution variables did not reflect the change in pollution, only the absolute magnitude. Further, with minor exceptions, the areas had about the same levels of pollution level. Thus, the pollution variables are confounded with the "Los Angeles area effect." This interpretation problem is probably inevitable when dealing with pollution on an area basis as opposed to a neighborhood basis.

Those believing that air pollution has worsened tended to be younger as expected, but with lower income, which was unexpected. Perhaps the income variable served as a surrogate for neighborhood pollution levels. In any case, the R^2 values were relatively low.

CONCERN. The CONCERN construct has been the focus of many of the reported studies and is a central intervening construct here. Note that the R^2 value for both data sets is over 0.20, an impressive level considering that disaggregative data are involved and that the dependent variable consists of a four point scale. If the respondents had been grouped, the R^2 would be much higher. Bass, et. al. (1968) provide a discussion why R^2 values are low for disaggregated data, and Aaker (1972) provides an illustration of what effect grouping can have on R^2 .

The two most significant coefficients have the expected sign. The pollution variable is large and positive as expected. Again, it should be noted that this variable

¹The differences between the means of the first four variables are statistically significant except for the difference involving DEVICE and TRANSIT.

is somewhat confounded by the fact that to some extent it is an indicator variable for the Los Angeles area. However, it seems safe to assume that a causal link should and does exist between pollution levels and CONCERN.

The BELIEF variable also has a large beta weight in both samples. Thus, there is evidence supporting a causal link between a perception that pollution is increasing and CONCERN. It could be argued that BELIEF is simply another measure of CONCERN and therefore what is observed is that two indicators of the same construct are correlated. Such a conclusion is regarded as not persuasive for two reasons. First, BELIEF is a perceptual or cognitive construct, while CONCERN is affective in content. Further, an attempt was made to consider BELIEF and CONCERN as indicators of a latent or unobservable variable in a recursive structure similar to that of Figure A. The resulting model had an extremely poor fit to the data indicating that such an approach was simply not compatible with this data. For a discussion of the use and testing of unobservable variables in structural equation models, see Aaker and Bagozzi (1979).

It should be noted that NO₂ was only marginally superior to DUST and OZONE, so the evidence is very weak indeed that NO₂ is a more relevant pollution variable. In fact, the three variables have intercorrelations of .70, .86, and .93.

INCOME had a positive coefficient, although it was not significant in the validation sample. Still, it is of interest that income was included in the regression equation when such control variables as LIBERAL, MILES, AGE, and ED were also available.

AUTCO. The most significant explanatory variable in the AUTCO equation is CONCERN. The R^2 value with only CONCERN was nearly 0.09. Note also that the link between CONCERN and AUTCO is higher than the link between CONCERN and any of the behavioral predisposition variables except AIR. Thus, it seems that a concern about air pollution indeed seems to result in a tendency to "blame" the automobile companies for not solving the problem. The AIR variable also relates to this judgment since it involves the legislated automobile exhaust standards which would impose an automobile company generated solution. The other behavioral predisposition variables, on the other hand, involve more of a sacrifice on the part of the motorists.

The ED variable is positive, as expected, and the INC variable is also positive, though its influence disappears in the validation sample. The relatively weak performance of the demographic variables may, in part, be due to the existence of the LIBERAL variable which was significantly positive. To some extent, demographic variables might be simple surrogates for a liberal/conservative orientation.

The Behavior Predisposition Variables

Air. Among behavior predisposition variables, the AIR equation generated the highest R^2 value: 0.20 for the analysis sample and 0.12 for the validation sample. Again, it should be noted that these levels of R^2 values are relatively high considering disaggregative data are used, the fact that the relationships involved are nontrivial, and the findings of previous studies (cf., Sharma, Kivlin, and Fliegel 1975).

A tendency to advocate stricter automobile exhaust standards is explained in large part by CONCERN (concern about the air pollution problem) and by AUTCO (the belief that automobile companies should have been doing more about the problem.)

A third significant variable is a pollution variable, NO₂. However, the pollution variable has the wrong sign! Note

that pollution also appears with a negative sign in the DEVICE AND RATION equations. The explanation for this finding is that the pollution variable is acting as a surrogate for the Los Angeles area and that other characteristics of residents of the Los Angeles area dominate or override the influence of pollution itself. This is somewhat surprising in view of the fact that MILES (a control variable for miles driven) is also in the equation. Thus, the fact that Los Angeles area residents drive more is not the characteristic that is causing the negative coefficient of the pollution variable. Note also that the coefficient of the MILES variable is negative as expected.

The remaining two explanatory variables, LIBERAL and INC, are in the expected direction but are not confirmed in the validation sample. The failure of the demographic variables to have more explanatory value is somewhat surprising.

The Remaining Behavior Predisposition Variables

The equations for the four other "behavioral" variables had smaller R^2 values on the order of 0.10, and these values decreased in the validation sample. In the case of the TRANSIT and RATION variables, the drop in R^2 was substantial. Still there are some worthwhile observations that emerge even for these two equations.

Overall the most significant explanatory variable is CONCERN. This finding is expected. In fact, it is somewhat surprising that the CONCERN variable did not have more explanatory power in the validation sample. Note that the BELIEF variable did not appear in any of the equations. This fact lends support to the hypothesized recursive structure. BELIEF seems to influence the behavior variables indirectly only through CONCERN and not directly.

The pollution variables appeared in the DEVICE and RATION equations (they were essentially zero in the others), but again with a negative coefficient. The most plausible interpretation is probably that the Los Angeles area residents do not support performance degrading automobile emission devices and gasoline rationing even after controlling for miles driven.

ED was consistently a substantial explanatory variable with the expected positive sign. Of interest is the fact that the other demographic variables failed to contribute. An exception is the large negative INC coefficient in the FREEWAY equation. The higher income people are opposed to radical efforts to cut down freeways whereas the lower income people are more disposed to such a move. This finding is unexpected. The hypothesis was that income would be associated with concern and with support of the policy alternatives. Thus, the direct negative links between income and other behavioral predisposition variables are somewhat surprising.

MILES and LIBERAL both made modest contributions in three of the equations. As expected, a willingness to support three proposals to restrict (RATION and FREEWAY) or affect (DEVICE) driving are negatively associated with miles driven. The support of the more radical government imposed solutions (RATION, FREEWAY and TRANSIT) is positively associated with LIBERAL.

Combining the Behavioral Predisposition Variables

It can be hypothesized that the five behavioral predisposition variables can be considered as indicators of a single underlying construct. Thus the model with a single unobservable "behavioral" construct was used with various combinations of the five behavioral predisposi-

tion variables as indicators. The results of this analysis (not shown) supported the counter hypothesis that the five variables are sufficiently different in the context of the structural model that they should not be considered indicators of a single unobservable. Any combination that included the AIR variable had exceptional poor fits as measured by a chi square value that is a by-product of the maximum likelihood estimation that was used (Aaker and Bagozzi 1979). When AIR was excluded, the fit was still unsatisfactory and, in fact, would improve dramatically each time the number of indicators was reduced. Only when one indicator was used was the fit extremely good. Hence, a separate recursive model for each of the behavioral predisposition variables was judged to be the most realistic model of the situation.

Conclusions

The results lead to the following summary comments and conclusions. First, education was found to have a direct although modest impact upon the policy variables. Income had a modest indirect effect through the CONCERN variable. However, the impact of these variables was perhaps smaller than expected, and the reason can be traced probably to the inclusion of the various control and intervening variables. Of note is the lack of impact of the AGE variable.

Miles driven had a direct impact on the automobile-associated public policy alternatives. The liberal/conservative orientation variable had a direct impact upon the more radical alternatives involving substantial governmental actions.

The pollution variable did seem to have an impact upon the CONCERN variable. However, its direct impact upon the variables was negative due to other characteristics of Los Angeles area residents for which the pollution variables was acting as a proxy.

The hypothesis that the extent to which concern about air pollution generates support for public policy alternatives depends upon the cost of those alternatives is supported in this research. Concern about air pollution had a greater effect upon the AUTCO construct than upon the behavioral predisposition variables. This indicates that people were more ready to blame the automobile companies than they were to face certain alternatives involving sacrifices. Among the policy alternatives, the one with the strongest link to CONCERN was the proposal that the automobile air pollution standards should be stricter, a proposal that deflects the problem to the automobile companies and only indirectly affects the respondents. The DEVICE alternative, which also had a relatively strong link to CONCERN, was certainly much less extreme than the others. Of interest is the fact that TRANSIT, which was rated about as desirable as DEVICE, had a weaker link to CONCERN. Thus, the alternatives represented in the TRANSIT construct, although relatively palatable, were regarded positively in large part for reasons other than the fact that they represent a possible partial solution to the air pollution problem.

CONCEPTUAL AND METHODOLOGICAL ISSUES IN
RESEARCH ON THE QUALITY OF LIFE

William K. Zikmund, Oklahoma State University

Abstract

This paper discussed three papers on consumer research and the quality of life. Issues of theoretical development, research design and data analysis are considered.

Introduction

At the outset, it should be stated that each of these papers is conscientiously trying to investigate a relatively unresearched topic. While they may be grouped together under the heading, Quality of Life, the diversity of these papers illustrates that there are numerous dimensions and aspects of this issue from a consumer standpoint. Each of the three papers deals with the very distinct topic.

Two of the papers are empirical. Some standard cautions should be given. There are limits to the inferences that can be made when no measure of reliability or validity is given. This seems doubly important in quality of life research because one of the major empirical works indicates that quality of life measures had very low stability coefficients (Campbell, Converse and Rodgers 1976). Both empirical papers suffer because of the lack of these measurers. A second deficiency, typical of conference papers, is that the data appear to have been collected in a limited geographical region (i.e., in the state where the researchers reside). These limitations should be considered by those reading the papers.

The Papers

Unger and Kernan

The authors provide a comprehensive, if not exhaustive, review of the literature. Initially, a quick scan of the paper brings an awareness that the paper's references are absent. When I observe this in conference papers, I am somewhat skeptical. I often jump to the conclusion that the authors have not been concise in their presentation of the material. However, after receiving a copy of the bibliography I found that its length exceeds that of the paper. In this case, the proceedings space limitations should have been relaxed. The authors should be commended for their extensive search.

Some minor aspects of the literature review require clarification. When discussing the value of leisure for the various market segments, there seems to be a confusion between the perceived happiness construct and perceived satisfaction construct (c.f. Campbell, et. al. 1976, p. 32-36). A distinction is usually made between these two constructs in quality of life research. Second, although this issue might be the subject of a second review, no comments are made about the reliability and validity of existing measurers. It has already been suggested that this caution is more than the generalized statement of good research technique to provide true measurement because measures of the quality of life (Campbell, et. al. 1976) have lacked stability.

Beyond reviewing the literature, the authors' goal was to develop a subjective measure of leisure quality; "one that transcends specific activities and approaches leisure from a number of existential dimension." This subjective existential perspective seems to allow for a philosophical definition of leisure, somewhat similar to the classical Greek ideal of leisure as exposed by De Grazia (1964). According to De Grazia, "Leisure is not fully realizable, and hence an ideal, not alone in idea. Leisure refers to a state of being free from the necessity to labor, a condition of man, which few desire and fewer achieve" ... "Leisure is the state of being in which activity is performed for its own sake or as its own end." This view may be that of a philosopher, rather than a psychologist, sociologist or consumer researcher, but it does illustrate that the concept of leisure is somewhat elusive when subjective interpretations are allowed. To clarify the concept of leisure the authors attempt to identify the subjective properties of leisure: intrinsic satisfaction, perceived freedom, high involvement, arousal, mastery, and spontaneity. The question arises does this help us more precisely define leisure. This, to those of you who read Pirsig's (1974) Zen and The Art of Motorcycle Maintenance, may be reminiscent of Phaedrus' exploration into the meaning of the term Quality. "As he became involved in finding quality he singled out aspects of Quality such as unity, vividness, authority, economy, sensitivity, clarity, emphasis, flow, suspense, brilliance, precision, proportion, depth and so on; kept each of these as poorly defined as quality itself ..." And of course at one time before his madness he wrote, "But Even Though Quality Cannot Be Defined You Know What Quality Is!"

Take for example, "perceived freedom." Is it freedom from work? Or as Dumazebier (1967) suggest is "Contemporary Leisure ... Defined by contrast not just to one's job, but to all of the ordinary necessities and obligations of existence?" Is freedom any more concrete than leisure? Doesn't a subjective obligatory/discretionary continuum have the same definitional problems as leisure? Consider that the functions of leisure according to one view are relaxation, entertainment and personal development. It is not clear what empirical rules would be utilized so we can be confident that we should classify relaxation into "arousal" (its absence) or into intrinsic satisfaction. Of course, there may be some hope if the rules for specifying the subjective properties are clearly identified. However, they are not in this proposal.

It seems to me an inherent problem of a subjective measure is similar to the problems of objective measures. Of particular relevance is the situational content of leisure. The authors recognize that objective leisure measurers and subjective leisure experience appear to be highly situational. It is difficult to see how they will tackle this problem even though it is a recognized problem. In sum, the authors are dealing with an exceedingly difficult measurement problem, and while they shed some light on the issues they do not solve the problem.

The authors focus on a timely topic that is important to all of us.

The authors' begin the paper by identifying five research issues. The first three deal with understanding the behavior of health care consumers and the discussion of a normative prescription of the role consumers should have in health care planning and administration. For the most part, a satisfactory review of key articles is given. The authors do state that their literature review was not meant to be exhaustive, and they should not be severely criticized for this. However, it should be pointed out that there was an over-emphasis on the physician-patient interaction with almost a complete absence of the discussion of other health care alternatives. While there is a brief mentioning of health maintenance organizations, there is no review of the literature on physician assistant, nurse practitioners, or other forms of health care delivery. Research in this area (e.g., Zikmund and Miller 1979) indicates that there is a similarity between the underlying cognitive factor consumers hold toward nurse practitioners and those they hold towards physicians. Further, a clear-cut interpersonal dimension has been identified. The next two research issues reviewed deal with two marketing mix variables: health promotion and facility location (distribution). One might question if pricing issues (e.g., pricing strategies of denturists, medicaid/medicare, etc.) and other marketing mix questions should not be of concern to those interested in health care/satisfaction consumption issues. Only one citation from the literature related to facility location is given. Undoubtedly this issue has been dealt within proprietary research and as a regular business matter that has not generated substantial interests in the theoretical literature in recent years.

The main strength of this paper is to provide selected responses from several open ended statements. While the data base is composed of 1,000 Dayton, Ohio residents, there is no breakdown of the data by market segments to take advantage of this large sample size. One wonders whether dissatisfaction lies with a particular group, such as the aged, poor, or those who received healthcare in a particular location within Dayton? Further there is not any investigation of the different medical contexts that may create satisfaction or dissatisfaction. It is most surprising that no inferential statistical analysis is presented in the paper. One wonders why not. Surely the data permit some reasonably sophisticated analysis.

Aaker and Bagozzi

The paper by Aaker and Bagozzi has several strengths. The paper is well written. It reads with clarity in both the conceptual and methodological sections. The data analysis also has some strong points. The research divides the sample into an analysis sample and a validation sample. Certainly a very sound methodological technique; too often omitted in consumer research papers.

In general, the use of stepwise regression seems appropriate to identify paths. Of course, the normal caveat that the widespread use of assuming ordinal scales have interval properties is violated. For example, the 4 point agree/disagree scale seems to be ordinal. Shouldn't the authors know that "despite the widespread treatment of the total (Likert) score as an interval scale, there is no evidence it has no more than ordinal properties" (Aaker and Day 1980, p. 186).

Some questions may arise about the data base. The survey was conducted in 1973, and is obviously somewhat dated. As the authors suggest, things may have changed since the OPEC embargo. Things have changed! Car pooling has increased. People didn't even know what Kalaka was in 1973. BART (Bay Area Transportation) has been completed and many other things have changed including the OPEC oil embargo. Certainly attitudes towards gasoline rationing, restricting freeway use have changed dramatically, especially in California where the sample was taken. And, of course, California isn't like anywhere else on this planet. The sampling question is of particular relevance in this paper. To the authors' credit, "objective measurers of actual pollution levels were included in the study." This is important especially in L.A. where in the autumn the air turns brown and falls to the ground?

However, the paper addresses theoretical issues and perhaps these issues can be minimized. Lets turn our attention to this topic. It appears to me that this study is an example of theorizing with an existing data base in mind. Certainly other constructs (not examined here) could be considered as factors influencing attitudes towards air pollution. Further, a more important conceptual issue is that this study seems to assume that air pollution is an exclusive function of the automobile. Automobile companies are not the sole "villians." Steel mills, oil refineries, and other factories have for years been portrayed with large black clouds flowing from their smoke stacks. The domain of "concern" in this study apparently is a variable that should be labeled "concern for air pollution generated by automobiles." A person living next to an oil refinery may have a great concern for air pollution, but not attribute this to an automobile company. To make a public policy decision based on this logic and under these circumstances would be unwarranted.

Summary

Like most discussants I have mentioned the papers' strengths and dwelled on their shortcomings. I assume the readers will realize that each of these papers deserves some merit. Because of the diversity of these three papers it is difficult to summarize them taken together and make a universal recommendation. One common characteristic is the fact that quality of life constructs, whether it is pollution concerns, health care satisfaction, or leisure, all are relatively subjective concepts that will vary within situational contexts. This presents difficulty to researchers wishing to measure these concepts. Certainly measurement is the main issue to be addressed in future research.

TRADE-OFFS IN ATTRIBUTE LEVELS MADE BY ECOLOGICALLY CONCERNED
AND UNCONCERNED CONSUMERS WHEN BUYING DETERGENTS¹

Abstract

Environmental concern is less intense than it was a decade ago. Today when selecting products, consumers may be giving much greater weight to price than to ecological attributes of product. Whether this suspected trend holds for ecologically as well as non-ecologically concerned buyer segments is the principal focus of this paper.

Introduction

"During the past fourteen months we have seen a virtual storm of public protest and journalistic attention devoted to the nation's ecology. One of the prime targets of the environmental hue and cry has obviously been the business community and the role that it plays in our deteriorating environment." Times change. Written almost ten years ago, that opening paragraph of an article on ecological factors and buying behavior (Herberger and Buchanan 1971, p. 644) seems strangely out-of-step with public opinion today. No longer does environmental concern rank particularly high in national priorities (Jaroslarosky 1980). In the early and middle 1970's it did, and national policy favored a strong, regulatory approach to problems like environmental protection (Nixon 1973). As that decade drew to a close, national sentiment seemed to reflect greater sympathy for the problems of business, especially the regulatory burden it carries, which is widely considered to be an important cause of inflation (DeMuth 1980). And inflation seems to be on everybody's mind. More and more, consumers are shopping price and they seem to be less interested in buying products that are ecologically benign than they were at the start of the decade (Marketing News 1979).

This turn of events is critical to the credibility of a concept that has been referred to in the marketing literature as ecological marketing (Henion 1976). Both a suggested national policy alternative to increased regulation (Henion 1978) and itself a sub-discipline of social marketing, this concept has one central idea. It is that environmental protection and resource conservation can be better advanced through less regulation by the public sector and more enterprise in the private sector. This idea, in turn, is based on the premise that the ecologically concerned consumer is a legitimate but largely untapped market segment -- one that is identifiable, accessible and measurable (Henion 1976). Such a

¹The authors gratefully acknowledge the financial assistance of the Sperry and Hutchinson Company whose grant in ecological marketing helped make this study possible. The authors also express their appreciation to Professor Mark Alpert for many ideas for improving the analysis and discussion sections; also, to three blind reviewers for numerous helpful suggestions.

²Karl E. Henion is Professor of Marketing; Russell Gregory is a doctoral student in the Department of Marketing; and Mona A. Clee is Assistant Instructor of Marketing.

segment is a potential market for products that are environmentally benign (EN-products, for short).

But, clearly, no customer -- whatever his or her degree of ecological consciousness -- will buy EN-products on the basis of their ecological impact alone. The consumer obviously buys a collection of attributes. In the case of a detergent, the attributes would probably include price, cleaning ability and -- for some shoppers, such as the ecologically concerned consumer -- ecological impact. Just as for other products, a bundle of attributes is sought; and the EN-product bought will depend on trade-offs the consumer is willing to make among various levels of such attributes.

The Problem

What trade-offs in attribute levels then do consumers make today when choosing products that are particularly relevant from an ecological perspective? Only two studies in the marketing literature have addressed this question.

The earliest study, which took up the issue in indirect fashion, was based on a simulated shopping experiment whose data today are ten years old (Herberger and Buchanan 1971). In that study price and ecological information were experimentally manipulated for four brands of detergents. Ecological information was found to influence brand preferences across all three price levels studied. The effect was in favor of low-phosphate brands at the expense of high-phosphate brands. Yet, in the context of the extent of the change in preference, change was not as great when phosphate-free detergents were priced disadvantageously. Less conclusive results were reported for soft drinks.

In the other study, Kerin and Peterson (1974) considered the subject of trade-offs more directly. Responding to mailed questionnaires, housewives rank-ordered detergent and soft drink product configurations, each made up one of two levels of price, brand and ecological impact. Regardless of high or low level of environmental consciousness, respondents compromised ecological compatibility first, price second and most favorite brand third.

The aim of the present study was to make a current assessment of attribute level trade-offs for an EN-product. Former assessments reflected in the studies mentioned are dated and limited. For example, neither study reported results based on observed behavior. Also, in the earlier study ecologically unconcerned consumers were not distinguished from concerned consumers -- an important distinction. Although such a distinction was made in the later study, no information was supplied about either the scale used to measure ecological consciousness or its reliability and validity. Moreover, in the 1974 study, the only price levels studied were those below and above prevailing prices. Consequently, overlooked was the realistic and important situation in which products are priced the same.

In the present study the expectation was that ecologically concerned consumers would value attribute levels

of an EN-product differently from unconcerned consumers. This prediction is consistent with key findings in much of the ecological marketing literature. Numerous studies (e.g. 's, Anderson, Henion and Cox 1974, Kinnear, Taylor and Ahmed 1974, Webster 1975) have shown that these two segments exist and that consumers comprising them are inclined to believe and behave in different ways when buying products that are particularly ecologically relevant.

Method

As in the previous two studies, laundry detergents were also the **product** focus of the present study. The field setting was five stores of a supermarket chain situated in a medium-size city in the Southwest. They served shoppers living in middle to upper-middle class neighborhoods. Each store carried the same line of about 25 brands of powdered and liquid detergents. Several of them were phosphate-free: the powdered detergents Arm & Hammer, Purex, Trend, Topco Orange and Ivory Snow; and the liquid detergents ERA and Dynamo.

Trained interviewers, stating that they were conducting a survey on consumer preferences using a technique called conjoint analysis, administered a pre-tested five-minute questionnaire to a total of 188 in-store shoppers, mostly as they filed by the detergent aisles of the stores. Of this number 110 were observed and recorded, prior to the interview, as actually taking a particular brand of detergent from the shelf and selecting it for purchase. The three-part questionnaire was administered to the respondents in the following order: (a) trade-off tables of paired attribute levels; (b) an index of ecological concern (IEC) developed by Kinnear and Taylor (1973); and (c) several demographic questions, which are of no direct concern to the present study. Evidence of construct validity of the IEC has been reported by the above investigators (1973, pp. 192-193); additional evidence is provided elsewhere (Henion and Wilson 1976).

Data were collected by the trade-off method instead of the full-profile method (Green and Srinivasan 1978) for several reasons. Knowledge of the relative importance of the attributes was necessary for testing one of the hypotheses of the study; and this can be easily done by comparing utility ranges based on the information that respondents provide directly in the trade-off method (Johnson 1974). Also, the experience of one of the authors gained from other field experiments using both data collection methods resulted in a decided preference for the trade-off method because it was easier to apply and explain to busy shoppers in supermarkets. The issue of interactions, which cannot be estimated under this method, was not considered a potential problem; the attributes of the present study were viewed as independent and non-redundant and hence orthogonal.

Another issue that should be addressed arises from self-perception theory. According to that theory, some persons who bought low-phosphate detergents conceivably might have labeled themselves as ECCs and developed and registered an attitude on the IEC consistent with such behavior, both of which may have had low reliability if measured on a later occasion. However, disguiser steps were taken so that subjects would not be self-conscious about the fact that the ecological aspect of their buying behavior was being monitored. Moreover, the limited time shoppers were willing to take for the interviews did not warrant embedding the IEC in a lengthy battery of other measures.

The interviewer first explained to the respondent how to fill out a trade-off table in which pairs of attribute levels were to be rank-ordered; then the interviewer

had the respondent practice on two tables containing attribute pairs for unrelated products. These tables helped disguise the ecological interest of the study. Next, three 3X3 trade-off tables for detergents were separately presented. (Since only one of the three attributes was ecologically related, the disguise was further protected.) The three detergent attributes (and their three levels) were price (15¢ more than, 15¢ less than and same price as usual); cleaning power (somewhat cleaner, equally clean, and somewhat less clean); and phosphate content (high, average, and low). Choice of these attributes served the main purpose of the study, namely, to clarify their previous ambiguous role in the literature of ecological marketing. Other detergent attributes, such as softness or odor, while relevant for different purposes such as new product development, were not relevant for this study.

Hypotheses

Motivated by the studies of Herberger and Buchanan (1971) and Kerin and Peterson (1974), the following predictions were made:

- H₁: A low phosphate detergent has more utility for ECCs than for non-ECCs; and, conversely, a high phosphate detergent has more disutility for ECCs than for non-ECCs;
- H₂: A detergent's phosphate content will be considered by ECCs to be more important, and by non-ECCs to be less important, than other attributes.
- H₃: An EN-Product that is higher priced and/or less functional than its environmentally less desirable substitute will have less overall disutility for ECCs than for non-ECCs, e.g., a low-phosphate detergent priced higher and with less cleaning power than a high-phosphate detergent.

Results

From the sample of 110 respondents who were observed buying a detergent, 18 ecologically concerned and 29 unconcerned consumers were identified, as well as 63 neutral or inconsistent consumers. Identification of the first two groups (ECC and non-ECC) was based on two criteria: observed purchase of a detergent and score on the IEC, whose range was from 0 to 25 points. If shoppers bought a phosphate-free detergent and also scored above the third quartile (15) on the IEC, they were classified as ECCs. If they bought a phosphate detergent and scored below the first quartile (7), they were classified as non-ECCs. Interquartile scorers were considered neutral whichever detergent type was bought; there were only six respondents whose scores and purchase behavior were inconsistent.

From the rankings of attribute level pairs made by each of the 110 identified respondents, a parametric utility for each attribute level was estimated using conjoint analysis. The analysis was based on an additive model and was carried out using \$FTROFF (Nehls, Seaman and Montgomery 1976). This algorithm rests on the assumption that the dependent variable is, at most, ordinally scaled.

\$FTROFF prints out a badness-of-fit measure, ϕ , for each respondent. It is based on the extent to which the sums of the estimated utilities for each pair of intersecting attribute levels in a trade-off table have rank orders dissimilar to the input ranking that the respondent made of the sample pairs. This measure, which accounts for

both number and size of errors arising from the revealed dissimilarities, accumulates such errors across all of the tables that the respondent fills out. The average ϕ for the ECC group was .054; for the non-ECC group, .085. The average proportion of correct comparisons of utility sums in each cell for the ECC group was 87.5%; for the non-ECC group, 84.3%.

For each attribute level, an average utility was calculated from the utilities derived from the conjoint analysis of ranks at the individual level. The results for the consumers in the ECC and non-ECC groups are presented in Table 1. The algorithm forces the algebraic sum of each respondent's utilities for the three levels of each attribute to equal zero; hence the sum of the utility averages for each attribute at the group level approximates zero.

The utilities for the nine attribute levels (3X3) were cast as independent variables first in a multiple discriminant analysis, with the ECC vs. non-ECC vs. neutral and inconsistent group membership (utilities not shown) as the criterion variable. The results were not significant using the whole spectrum of subjects. However, the theoretical interest was in the ECC and non-ECC groups. Hence, the indifferent and inconsistent group was dropped from the model and a simple discriminant analysis was next run using the other two groups. Forty percent of the variance in the resulting discriminant function was explained by the group variable. The canonical correlation coefficient was .63; the Wilks Lambda of .60 was significant at .014 ($\chi^2 = 20.71$ with 9 d.f.).

The jackknife technique was used in cross-validating the results of a parallel stepwise discriminant analysis, owing to the small size of the sample. Correct classification and α -probabilities for the two groups were: ECC (78%, $p < .02$) and non-ECC (55%, $p < .28$). The rest of the paper focuses on findings for these two groups.

TABLE 1

Average Utilities For Three Levels of Three Attributes For Two Groups of Consumers

Attribute and level	Average utility (\bar{u})	
	Consumer group	
	Ecologically concerned (n=18)	Non-Ecologically concerned (n=29)
<u>Price</u>		
15¢ more	-.3398	-.3885
Same	.0501	.0748
15¢ less	.2891	.3075
<u>Cleaning Power</u>		
High	.2844	.3474
Average	.0866	.1225
Low	-.3710	-.4692
<u>Phosphate content</u>		
High	-.4669	-.2356
Average	.0569	.0394
Low	.4109	.1962

Within each attribute for each consumer group in Table 1, the pairs of correlated means (i.e., those in the vertical direction) were significantly different for each of the three possible pairs of attribute levels (t's had $p < .001$ or better in all cases but two, which had $p < .02$ instead: one in the ECC group, d.f. = 17, and one in the non-ECC group, d.f. = 28).

The direction and size of the utility means show that persons in both groups place higher utility on lower price and on higher cleaning power. This result one would expect to find. Of special interest, however, is the finding that not only ECCs but also non-ECCs place higher utility on low phosphate content than on average or high levels.

We turn next to a comparison of uncorrelated means across the two groups (i.e., those in the horizontal direction of Table 1). While there are 9 possible comparisons, only 6 are particularly relevant since values of the utilities for the 3 middle levels for the attributes will tend toward zero, owing to the logic of the \$FTROFF algorithm. Of the six comparisons, three revealed differences in mean pairs that were significantly different. The other three were not significant, although they were in the expected direction; the probability that three pairs would randomly be arrayed in the expected directions, given that each of them is equal likely to have been reversed, is .125, which approaches some statistical significance. Overall, strong support was found for H_1 .

The disutility of high phosphate content was significantly higher for ECCs than for non-ECCs ($p < .001$, d.f. = 45); and the utility of low phosphate content was significantly higher for ECCs than for non-ECCs ($p < .003$, d.f. = 45). In a similar vein, low cleaning power had less disutility for ECCs than for non-ECCs ($p < .05$, d.f. = 45); and, while not statistically significant ($p < .27$) high cleaning power had less utility for ECCs than for non-ECCs. Unfortunately, none of the price comparisons produced significant differences. It seems that price qua price (i.e., when not compared with other attributes) is about equally important to both groups of consumers. Nevertheless, numerically, the values of the means are in the expected direction. High price had slightly less disutility for ECCs than for non-ECCs; low price, slightly less utility.

Ranges

The relative importance of a set of attributes can be indexed by computing the range of utility values across the levels of an attribute and comparing it with the corresponding ranges for the other attributes. The greater the range the greater the importance. For each respondent the range of utilities for each attribute was calculated and the means of the ranges for the three attributes for the two groups are presented in Table 2.

The rank order of the attributes according to mean utility ranges is quite different for the two consumer groups. As mentioned earlier, low phosphate content had positive utility for both groups. However, ECCs considered this attribute to be of first importance (with the highest range of .9021), cleaning power next and price last. But non-ECCs considered phosphate content to be of least importance (with the lowest range of .5628), placing price and cleaning power ahead of it.

TABLE 2
Mean Utility Ranges for Three Attributes
For Two Groups of Consumers

Attributes	Consumer Group					
	Ecologically concerned ^a (n=18 ECCs)			Ecologically unconcerned ^b (n=29 non-ECCs)		
	Rank	Mean utility	%	Rank	Mean utility	%
Price	3	.6324	(28)	2	.7152	(34)
Cleaning Power	2	.7204	(32)	1	.8542	(40)
Phosphate content	1	.9021	(40)	3	.5628	(26)
		2.2549	(100)		2.1322	(100)

^aF = 3.39, p < .05

^bF = 5.74, p < .005

The one-way ANOVA of the mean ranges for each consumer group produced significant F-values. For the ECC group, the results of t-tests for the three pairs of correlated means were: no significance between price and cleaning power (p < .20); approaching significance between cleaning power and phosphate content (p < .10); and significance between price and phosphate content (p < .02). For the non-ECC group, the results for the same pairs were, respectively; approaching significance (p < .10); significance (p < .05); and significance (p < .005). Consequently, good support was found for H₂.

Amplifying these findings were the results of t-tests for two of the three pairs of uncorrelated means (i.e., those in the horizontal direction). For two attributes -- phosphate content and cleaning power -- significance (p < .005 and p < .056, respectively) was found between the ECC and non-ECC groups, but not for price.

Product Simulations

For each respondent, a composite utility was calculated for each product simulation or configuration. A configuration was made up of 3 attribute levels -- one from each of the 3 attributes. The utilities of the 3 levels were summed to form a respondent's composite utility for the configuration. The means of the respondents' composite utilities (\bar{u}_c) for the 27 possible product configurations are shown in Table 3 for the ECCs and the non-ECCs.

Direction signs, - 0 +, in Table 3 indicate whether a level for an attribute is desirable relative to the attribute's other two levels. These signs were employed in the following manner. Product configurations have been listed in Table 3 in descending order according to the sum total of the advantages or benefits that various attribute's levels in a configuration are judged to have. Thus, the first entry in the list is a detergent that has a low (L) price (i.e., 15 cents less), high (H) cleaning power and low (L) phosphate content. This configuration, symbolized by the ordered triple (LHL), is also represented by an ordered triple of signs (+ + +). Here a + indicates the most desirable level of an attribute; a 0, a middle level; and a -, the least desirable level. Let a + and a - be interpreted as +1 and -1, respectively. If equal weights (1 : 1 : 1) are then arbitrarily used as attribute weights for each sign in the triple, then the algebraic sum of the signs indexes the utility of a configuration. Hence, the first triple yields an index

of +3. Expectedly, for configuration 1 the \bar{u}_c obtained for each consumer group has the highest value; for configuration 27, the lowest value.

Abstracted from Table 3 and shown separately in Tables 4 and 5 are the mean composite utilities, respectively, for the nine detergent configurations with low phosphate content and the nine with high phosphate -- results on which H₃ principally depend.

Based on the composite utilities, support was found for this hypothesis. Considered first will be the "and" part of the "and/or" statement of H₃. For ECCs the mean composite utility (\bar{u}_c) for configuration 20 was -.299901 but only -.330226 for item 21, although the difference in the correlated means was not significant; whereas, for non-ECCs the corresponding \bar{u}_c 's were -.661557 and -.038328 (p < .001). Thus, a low-phosphate detergent priced higher (by one level) and with less (by one level) cleaning power than a detergent with a high level of phosphate content was considered by ECCs to have more utility (right direction); by non-ECCs, to have significantly less. However, these reversals did not hold if both the disadvantages of higher price and less cleaning power were at the extreme

levels, i.e., by two levels: for ECCs the utilities were -.299901 (again configuration 20) vs. .106660 (configuration 8) with $p < .01$; for non-ECCs, -.661557 vs. .419263 with $p < .001$. These last results however, are based on extremely strict criteria. The ECC is being asked to sacrifice for ecology not only price and cleaning power (function) but also to the extent of the most disadvantageous levels of these attributes.

It is noteworthy that in Table 4 the composite utility mean for the ECC group is higher than that for the non-ECC group for each of the nine product configurations with low phosphate content. The reverse is true in Table 5: the \bar{u}_c is lower for the nine with high phosphate content. The probability of either of these outcomes is less than .002 (binomial test). Obviously the ECC places greater value on phosphate content being at a lower level than does the non-ECC.

The utilities were next examined under criteria that were less strict, namely, the "or" part of the "and/or" in H_3 . Rather than both disadvantages, only one disadvantage of the other were considered -- again at one level and two levels. The results, which are broken out from Table 3 and summarized in Table 6, provide strong support for H_3 . In the case of these somewhat less unattractive configurations -- namely, a low-phosphate detergent with either a higher price (whether 1 or 2 levels) or less cleaning power (also whether 1 or 2 levels) -- the EN-product was still considered by ECCs to have higher utility than its environmentally less desirable substitute; by non-ECCs, lower utility. In six of the eight possible pairings of the \bar{u}_c 's of the EN-product with those of the substitutes, significant differences in correlated means were found ($p < .01$ in four cases and $p < .05$ in two); in the other two pairings -- both in the non-ECC group -- the one with configuration 25 approached significance ($p < .08$) while the other with 24 was not significant.

TABLE 6

Means (\bar{u}_c) Of Composite Utilities: Partially Disadvantaged EN-Product Detergent vs. Four Highest Phosphate Product Configurations For Two Consumer Groups

Product type and configuration for EN-product	Disad-vantage level	Direction signs of attribute levels			\bar{u}_c	
		Attributes			Consumer group	
		Price	Clean-ing power	Phos-phate con-tent	Ecologi-cally con-cerned	Ecologi-cally uncon-cerned
EN-pro-duct						
20		-	-	+	-.299901	-.661557
Highest phosphate product						
24	1	0	-	-	-.787805	-.629983
25	1	-	0	-	-.720103	-.501623
18	2	+	-	-	-.548762	-.397287
19	2	-	+	-	-.522259	-.276728

Discussion

These results, based on concomitant measures of observed behavior and attitude, help buttress the case of ecological marketing. Today inflation is driving consumers more and more to shop price, and yet concerned consumers in this study are at least implying -- by the trade-offs they registered -- that they would be willing to subordinate price to ecology. Unconcerned consumers, however, place price and function ahead of ecology. Therefore, our findings contradict those of Kerin and Peterson (1974) who reported both consumer groups as placing price

ahead of ecology. The strength of the present findings is our identification of the ecologically concerned consumer is more valid than theirs. One caveat is that these findings are applicable to consumers with middle to upper-middle socio-cultural background.

Given this caveat, these findings have relevance for a long-standing, unresolved issue in ecological marketing research. If consumers show greater concern for price, as is expected, will sales of an EN-product be adversely affected (Henion 1976)? That depends. Is a particular EN-product less or more expensive than the product for which it is a more ecologically desirable substitute? (Obviously the critical condition is when it is more expensive.) What is the cross-elasticity of demand for the two products? How do patterns of price inelasticity of an EN-product differ for ecologically concerned and unconcerned consumers? Based on the earlier studies, the presumption is that the patterns are the same for both groups of consumers, namely, little if any elasticity (and further that substantial cross-elasticity exists for an EN-product and its functional counterpart which is ecologically insulting). However, the present assessment of attribute levels trade-offs -- which were made by one sample of respondents for one EN-product and analyzed using a decompositional model of consumer preference -- suggest a different conclusion. Concerned consumers might possibly be willing to pay a premium for an EN-product, even during times of high inflation, although unconcerned consumers would probably not -- based on the results of the range analysis.

However, the external validity of the conjoint measurements taken is still an open question, making predictions of the degree to which consumers actually would trade-off higher prices against lower phosphate content quite another matter. As with previous studies, the design of this study may have increased the salience of the area. For we have presumed that buyers perceive phosphate levels as salient; further that such salience was probably augmented by labelling the levels for respondents in the trade-off tables. In the real world attribute levels compete for buyer recognition with other cues that may be more dominant, e.g., price; and in the case of detergents usually, phosphate content is merely registered rather than highlighted (although it was highlighted on the package of one of the six phosphate-free detergents in the present study). External validity would be more assured if phosphate content had been labeled prominently as it was in one study (Henion 1972); surveying instruments would then not differ much from the information available to buyers when shopping. At any rate, results from the present study can justifiably be compared with those of prior studies, since whatever cue bias exists in the present study was present in the others, too.

Accordingly, field experiments need to be conducted in which prices of EN-products are experimentally manipulated with phosphate content highlighted. If inelasticity of EN-products were found for the ecologically concerned consumer, then the suspicion of ecological lip service would be largely groundless for this group. Meanwhile, confirmation that concerned consumers value attribute levels of an EN-product differently from unconcerned consumers are encouraging from the policy perspective of ecological marketing, coming as it does five years after the 1974 study with its negative results.

A CAUSAL PATH ANALYSIS OF ECOLOGICAL BEHAVIOR RELATING TO MARKETING

Lawrence A. Crosby, University of Nebraska
James D. Gill, University of Nebraska

Abstract

A study of voter preference on the Michigan "Bottle Bill" provides new insights into the characteristics of the Ecologically Concerned Consumer and strategies for marketing to this consumer segment. A path model is developed to account for complex interrelationships among the predictors of ecological concern and behavior. The model is based on the environmental behavior literature and psychological theory. The survey results are found to be generally consistent with the model.

Introduction

The decade of the 1970's was a turbulent period in the history of the American marketplace. Major shifts in the economic, political and social climates significantly impacted marketers. During this period serious questions were raised about marketing practices and especially those affecting the natural environment. Many felt that "ecological concern" might pose a threat to marketing by stimulating the passage of more regulation. However, a few astute marketers argued that it was possible to convert this threat into an opportunity through Ecological Marketing. The premise of Ecological Marketing is that a segment of consumers exist who are motivated to buy environmentally safe products and who will respond to an ecological appeal (Henion 1976).

Research was undertaken in an attempt to identify the ecologically concerned consumer segment (see e.g., Anderson and Cunningham 1972, Kinnear, Taylor, and Ahmed 1974, Webster 1975, Murphy, Kangun, and Locander 1978). This research focused on the demographic, personality, and attitudinal correlates of ecological concern that might be relevant to the design of effective communications strategies. Unfortunately, the findings were not very encouraging. It appeared that the ecologically concerned consumer (ECC) could be identified but that the segment was small and hard to reach.

Consumer research pertaining to Ecological Marketing has been hampered somewhat by two problems. First, only limited phenomena exist for study because few consumers presently engage in ecological consumption behavior. This has forced researchers to increasingly rely on experimental choice situations that necessarily require some sacrifice in external validity (Murphy 1978, Lepisto 1979, Arndt and Helgesen 1979). The second problem concerns the lack of an appropriate methodology to account for complex interrelationships between the correlates of ecological concern. Multicollinearity among the predictors has generally been viewed as a methodological defect rather than an important source of information about underlying causal influences.

The Research Application

While consumer demand for ecological products may be limited (at present), consumers seem more willing to support the regulation of marketing activity affecting the environment. This is particularly evident in the case of the beverage container problem. Consumers have generally shunned returnable containers in favor of the convenience of throwaways, even though throwaways waste resources and

contribute to solid waste and litter. However, in apparent contradiction of this marketplace behavior, consumers in eight states have supported the passage of mandatory deposit laws (the states are Oregon, Vermont, Iowa, Maine, South Dakota, Connecticut, Michigan, and Delaware).

The present study focuses on the 1976 beverage container deposit law referendum in Michigan. In that election, Michigan voters approved by a substantial margin (64% to 36%) a proposal to require refundable cash deposits for soft drink and beer containers. This election was selected for study because: (1) individuals were acting in their roles as both voters and consumers, (2) a large number of persons were engaging in ecological behavior by supporting the law, and (3) the successful passage of the law was expected to provide some guidance for the marketing of ecological products.

The Methodological Approach

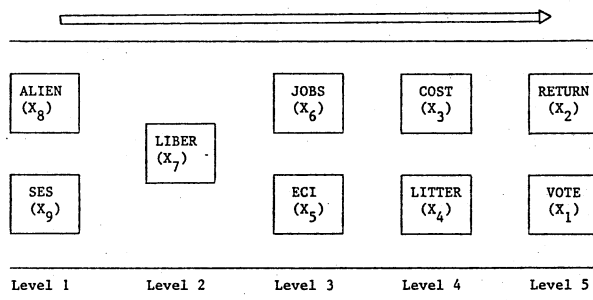

A generalized causal model was developed and tested for its ability to explain and predict deposit law voting preferences. It is suggested that the approach taken to developing and operationalizing the model can be applied to the study of various ecological behaviors. Although the model does not include all possible causal influences, it does include variables representing the most important classes of predictors. Furthermore, the model reflects causal influences among the predictors as well as those between the predictors and the criterion. Thus, both the direct and indirect effects of the predictors on the criterion can be assessed.

The Causal Model

The a priori causal model (see Figure 1) incorporates five levels of variables. The most basic level involves individual differences in demographics and personality. Included at Level 1 are the constructs of socio-economic status (SES) and alienation (ALIEN). The second level contains a political orientation measure of liberalism-conservatism (LIBER) which may reflect important differences in values. Level 3 contains general attitudes or opinion clusters relating to ecological concern (ECI) and concern about the unemployment consequences of environmental protection (JOBS). Level 4 contains more specific environmental and economic attitudes with particular relevance to the deposit law issue. Among these are concern about throwaway containers as a source of litter (LITTER) and concern about the effects of a deposit law on beverage prices (COST). The fifth level incorporates the behavior related variables. Included at Level 5 are variables dealing with voting preferences on the deposit law (VOTE) and previous habits regarding the purchase of returnable containers (RETURN). The criterion variable is VOTE.

The specific causal paths are not shown in the a priori model (Figure 1) because this would create undue complexity in the diagram. Basically, the a priori model assumes that causal influences move from left to right in the diagram and that each lower level variable has a causal path connecting it to each higher level variable. In addition, causal paths are assumed to exist from SES → ALIEN and from RETURN → VOTE while unanalyzed paths are assumed to exist between JOBS ↔ ECI and between COST ↔ LITTER.

FIGURE 1
A Priori Model

Model Justification and Hypotheses

The causal model was formulated on the basis of theoretical considerations and knowledge of the environmental behavior literature. The purpose of this section is to justify the choice of variables and their level of inclusion in the model.

Numerous researchers have tried to predict ecological concern from demographic and/or personality variables (Anderson and Cunningham 1972, Kinnear, Taylor, and Ahmed 1974, Webster 1975, Henion and Wilson 1976, Murphy, Kangun, and Locander 1978, Murphy 1978, Lepisto 1979). Demographically, the ECC's tend to be white and have higher incomes, higher status occupations, and higher socioeconomic status although the findings are not very consistent. Socio-economic status (SES) was included in the present model to determine how this variable influences an entire complex of environmental attitudes and behaviors, not just limited to ecological concern. It was felt this might uncover any countervailing effects tending to suppress the influence of SES.

Socioeconomic status was positioned at Level 1 as a basic causal influence in the model. It is assumed that individuals of similar social status have shared many of the same learning experiences and that these experiences serve to shape personality, values, attitudes, and behavior. For example, it is predicted the socio-economic status has a negative influence on feelings of alienation (ALIEN). Those who receive the rewards and respect of society and maintain positions of power and influence are less likely to experience feelings of powerlessness, meaninglessness, and social isolation.

Previous studies have produced contradictory findings about the relationship of alienation to ecological concern and behavior. Anderson, Henion, and Cox (1974) found the ECC to be more alienated than the non-ECC person. On the other hand, Nelson (1974) found the ECC to be less alienated. Anderson and Cunningham (1972) found that socially responsible persons were less alienated. It seems reasonable that alienation would exert some influence on environmental attitudes and behavior since alienated individuals tend to feel powerless in helping to solve social problems. Therefore, alienation (ALIEN) was included in the model with the expectation that it would relate negatively to the environmental variables.

The "alienated voter hypothesis" provides another reason for including a measure of alienation. Several studies in the political science literature have found that alienation is associated with political negativism and a tendency to vote against referendum issues like the "bottle ban" (Horton and Thompson 1962, Stone 1965, Aberbach 1969).

Alienation was also positioned at Level 1, as a basic causal influence in the model. Personality is thought to be a determinant of a person's political orientation (Adorno, et. al. 1950) and attitudes (Katz 1960). Also, personality is often tied to the concept of "consistent responses to the world of stimuli surrounding the individual" (Kassarjian 1971) suggesting a link to behavior.

There is some evidence in the literature of marketing (Webster 1975, Mayer 1976) and environmental behavior (Tognacci et. al. 1972, Constantini and Hanf 1972, Dunlap 1975, Koenig 1975, Buttel and Flinn 1976) to suggest that liberals are more ecologically concerned than conservatives. Such a relationship might be expected since most environmental programs involve some form of government intervention. Since this was also true for the Michigan deposit law, it justified including a measure of political orientation in the model (LIBER).

The LIBER variable was positioned prior to the other attitudinal variables at Level 2 on the basis of its "centrality." A belief, attitude, or opinion is said to possess centrality if it lies close to the person's values (Bem 1970). Also according to Bem "labels like liberal and conservative usually enable us to predict many of the individual's attitudes because these two terms refer to broad underlying values which are shared by large segments of the population." Since individuals attempt to maintain consistency with central values and attitudes, this implies a causal flow in the direction of decreasing centrality.

There is evidence that people can be arrayed in terms of the strength of their ecological concern (Maloney, Ward, and Braucht 1975) and that they exhibit consistency between their ecological attitudes and behaviors (Kinnear and Taylor 1974, Antril and Bennett 1979). Although the link between ecological concern and voting behavior has not been established, this seems to be a logical extension of these findings and is the reason for including ECI in the model.

It is clear academically that environmental protection can have serious economic consequences in terms of inflation, slowed GNP growth, reduced investment in productive facilities, and unemployment. It is suspected that members of the general public also see this environment-economic tradeoff to some extent, especially on such concrete matters as unemployment. A variable labeled JOBS was included in the model to represent an influence of economic concern that might run counter to the influence of environmental concern.

The variables ECI and JOBS were positioned at Level 3, indicating moderate centrality. These general attitudes and opinions are thought to represent the individual's orientation and affinity for certain social goals which serve to guide preferences and choices in specific situations. As such, these general attitudes may also be indicative of some of the individual's underlying values and motives.

The variables at Level 4, parallel those at Level 3, but with greater specificity to the question of the deposit law. Whereas the variable JOBS reflects a macroeconomic concern about environmental protection, COST reflects a microeconomic concern about the deposit law, namely its effect on prices. Likewise, the variable ECI reflects a concern about the environment in its many aspects while LITTER taps only a small part of that, namely concern about beer and soft drink container litter. It is expected that the attitudinal variables at Levels 3 and 4 will be associated. It is assumed that the causal flow is from the more general to the more specific attitudes (from 3 to 4). Finally, it is recognized that other potentially relevant variables dealing with the impact of the deposit law could have been included at level 4 (at the expense, of course, of greater model complexity).

The behavioral variables are represented at Level 5 in the model. They include not only the criterion VOTE but also the prior use of returnables (RETURN). Since both of these can be construed as ecological behaviors, an important question is whether they are influenced by the same variables in the same fashion. It is also assumed that the related consumption variable RETURN would causally influence VOTE since consumers are likely to resist changes in their consumption habits for convenience type goods like beverages. A good deal of support for this assertion exists within learning theory as applied to marketing (Howard and Sheth 1969).

Procedure

Data

The data utilized in this study were obtained from a telephone survey of 306 voting age adults in the State of Michigan. Interviews were conducted between October 23-30, 1976 with the last interview obtained three days before the election. Respondents were selected using a random digit dialing method similar to Waksberg's Two-Stage Procedure (Frankel and Frankel 1977). A randomization procedure was used to select from multiple eligible adults within the same household. The calling was done from a central location. The interview lasted about 25 minutes.

Interviews were completed with 61% of those who were contacted and determined to be qualified. The sample matched population estimates in terms of sex and area of residence. Some differences were noted on education, age, and income but not of sufficient magnitude to seriously affect the relationships under investigation. The survey results predicted the election outcome with a high degree of accuracy.

Measures

Both single items and multi-item indices were used to measure the theoretical constructs. Theoretically related items were combined whenever it was possible to form an index having satisfactory reliability for this type of research.

Socioeconomic status (SES) was measured as a three factor index including income, education, and occupation. As was the case for all the indices, each component received an equal weight. Cronbach's Alpha for SES was .48.

The alienation index (ALIEN) measures the extent to which feelings of powerlessness, meaninglessness, and social isolation are experienced by the respondent. High scores on the index indicate more alienation. This basic approach to measuring the construct is generally consistent with other research operationalizations (see: Aberbach 1969; Stone 1965). Cronbach's Alpha for ALIEN was .48.

A single item (LIBER) was used to measure the respondent's political orientation, with special reference to the role of government in economic affairs (i.e., whether government should force all products that pollute off the market). Because a large portion of regulatory activity in the 1970's concerned the environment, this seemed to be a meaningful way to ascertain feelings about government involvement. It is recognized that other dimensions of liberalism-conservatism exist. However, it is also true that the organization of political idea elements begins to breakdown as one moves from more to less sophisticated publics (Converse 1970), suggesting that the attitude domain should be more narrowly defined as was done here.

An ecological concern index (ECI) was formed to measure the respondent's concern about protecting the environment. The starting point for this index was an earlier version of the ECI developed by Kinnear and Taylor (1973), although

the current version is strictly attitudinal in nature. Higher ECI scores indicate more concern about the environment. Cronbach's Alpha for this index is .60.

A single item (JOBS) was used to measure the respondent's concern about the macroeconomic impact of environmental protection. The JOBS variable focuses on unemployment which is a concrete manifestation of the economic/environment tradeoff. Higher JOBS scores indicate more concern about the effects of environmental protection on unemployment.

A single item (COST) was used to measure the respondent's concern about a microeconomic impact of the deposit law, namely its effect on beverage prices. Higher COST scores indicate more concern about the adverse price effects of the law.

Concern about the degree to which beverage containers contribute to pollution and litter, an opinion highly specific to the deposit law, was measured by the LITTER index. Higher LITTER scores reflect the respondent's perception that container litter is a major problem. Cronbach's Alpha for this index is .72.

Prior use of returnables (RETURN) was determined by asking respondents whether they usually purchased soft drinks and beer in returnable bottles, non-returnable bottles, or cans. Responses to this question were coded: usually returnables = 1 and usually throwaways = 0.

To measure voting preference regarding the deposit law (VOTE), respondents were exposed to a statement of the law as it would appear on the ballot, and then asked "if the election was held today, would you vote yes or no on the deposit law?" Responses to this question were coded: yes = 1 and no = 0.

Analysis and Results

The causal model was analyzed by the method of structural equation analysis. Path analysis is a useful method to determine whether the data are consistent with the a priori model. However, consistency of the data with the model does not provide proof of the theory, but only lends support to it (Kerlinger and Pedhazzer 1973, p. 307).

The structural equations and path coefficients were estimated by ordinary least squares regression analysis. While this method of analysis assumes all variables are measured on interval scales, multiple regression is still the recommended procedure when ordinal scales are used, as in this study (Bohrnstedt and Carten 1971). Other assumptions underlying the application of path analysis appeared to have been met (see Kerlinger and Pedhazzer 1973, p. 309).

Table 1 shows how the a priori models were tested, trimmed, and how the path coefficients were estimated. The a priori models in this study were simply the regression models relating each variable to those variables preceding it in the causal flow of Figure 1. Table 1 shows the regression coefficients in unstandardized and standardized form. The standardized coefficients are referred to as "path coefficients."

Goldberger's (1970) approach to model trimming was used and a significance criterion of $p < .05$ was set as suggested by Duncan (1975). The trimming involves a reestimation of the regression equations with the predictors found non-significant in the first attempt eliminated. The regression and path coefficients for the trimmed models also appear in Table 1. A comparison of the coefficients of determination (R^2) for any of the a priori models and trimmed models indicates no significant loss in explanatory power resulting from theory trimming. Figure 2 is a diagram of the trimmed model showing the causal paths found

to be significant.

From an analysis of Figure 2, structural equations were developed that could be used to decompose the total association between the variables. Due to the complexity of the model no attempt was made to specify the nature of the noncausal association (i.e., to distinguish between spurious association and unanalyzed correlation). By substituting the path coefficients of the trimmed models appearing in Table 1, into the structural equations, it was possible to decompose the total association between each variable and those that causally precede it. These results are summarized in Table 2. This table shows the decomposition of the total association (i.e., the simple correlation) into direct, indirect, total causal, and noncausal association.

The VOTE Model

The test of the VOTE model indicated that RETURN, COST, LITTER, ECI, JOBS, and ALIEN all had significant direct effects on VOTE (p < .01) and, in the trimmed model, accounted for 40% of the variance in VOTE. The valences of the beta coefficients indicated that supporters of the deposit law were more litter conscious, were less concerned about the potential impact on either beverage costs or

unemployment, were more ecologically concerned, and were less alienated. Supporters were also more likely to have been previously purchasing returnables.

The magnitudes of the direct effects on VOTE generally decline as the causal variables become more remote. The variables with the largest direct influence on VOTE were assigned either to Level 4 (COST = -.40 and LITTER = .19) or Level 5 (RETURN = .15). Direct effects of less magnitude were obtained for the variables at Level 3 (ECI = .14 and JOBS = -.12), Level 2 (LIBER = N.S.), and Level 1 (SES = N.S. and ALIEN = -.09). These findings are consistent with the nature of the causal flow postulated in the a priori model.

An examination of the components of total association (Table 2) indicates that all predictors had some causal impact on VOTE. Several variables assumed greater prominence when total effects were computed because they had substantial indirect effects. This was particularly true for ECI which was second highest in terms of total effect (= .32). This finding provides additional support for the consistency of ecological attitudes and behaviors. Two of the variables that lacked significant direct effects were found to have notable indirect effects. This was the case for LIBER (= .12) and SES (= .07). The negative total association between VOTE and ALIEN (= -.14) supports the "alienated voter hypotheses."

Other Important Findings

Few of the variables appeared to exert much influence on the voluntary use of returnable containers (RETURN) and only 4.4% of the variance in RETURN was accounted for by the trimmed model. The total causal effect of ECI on RETURN (= .04) was much less than on VOTE (= .32). Apparently, returnables were being purchased for reasons other than ecological concern (e.g., habit, brand loyalty, etc.).

Contrary to the model, concern about the price effects of the law (COST) was unrelated to concern about the potential effects of environmental protection on unemployment. Instead, the general attitude of ECI was found to have a relatively strong direct influence on both of the specific attitudes: COST (= -.20) and LITTER (= .47). As might be expected, concern about the effects of the deposit law on prices was greater among alienated consumers and those of lower SES.

The general attitude of ECI was found to be related to LIBER and SES. As hypothesized by Mayer (1976), ecologically concerned consumers appeared to be more liberal. As he suggests, holding these opinions may offer the liberal a chance to express his or her progressive and humanitarian values. Ecological concern can be viewed as a relatively central attitude mediating these values.

A positive direct effect (= .14) was found to link SES to ECI. At the same time, however, those with higher SES scores tended to be more conservative. Greater conservatism implies less ecological concern. The total association linking SES to ECI was reduced (to .07) as the result of this countervailing tendencies. As expected, consumers of lower socioeconomic status were more alienated.

Interpretation

It should be re-emphasized that path analysis is not capable of proving causality but serves mainly to identify the logical consequences of the causal assumptions that are made. While the data in this study were generally consistent with the model, consistency itself does not establish causality. The data may also be consistent with other models not considered. Path analysis was found to be useful, however, in uncovering associations that would have been overlooked using conventional methods.

The substantive findings indicate that consumers perceived voting for the deposit law as a rather clear expression of their ecological concern. This points to a successful marketing effort on the part of the environmentalists. Prior to the election, however, consumers did not seem to associate buying returnables with ecological concern. Either that, or returnables were found to be unacceptable for some other reason (e.g., non-availability of favorite brands). This suggests that Ecological Marketing efforts by industry to sell returnables were either ineffective or non-existent prior to the election.

The success of the deposit law indicates there is sufficient ecological concern among the population to undertake Ecological Marketing programs. However, in marketing the "bottle bill" to Michigan consumers environmentalists did not rely solely on its ecological appeal. As part of their strategy, they successfully attached support of the law with the specific benefit of reducing litter. Also, they successfully overcame consumers' concern about the adverse effects of the law on prices and the economy.

Conclusion

Through the method of path analysis additional insight can be gained into the motivational basis of ecological behavior. The technique offers several advantages and should be used in future research dealing with the ecologically concerned consumer. One important advantage is that it forces researchers to make explicit their causal assumptions. A causal model employing demographic, psychological, and behavioral variables seems to have application to the study of the ECC. With additional elaboration, refinement, and testing a general model of ecological consumption behavior might be developed.

THE EVOLUTION OF DISTRIBUTION CHANNELS FOR SOLAR PRODUCTS:
CONSUMER DECISION MAKING IN PERSPECTIVE

Jerald W. Blakely, University of Oregon
Scott M. Smith, University of Oregon

Abstract

Consumer acceptance of solar products is examined from a distribution channel perspective. The current focus on the consumer as the central decision maker for solar products is criticized. New channels of distribution are presented, along with the variables that will facilitate their adoption. Future directions for solar consumer research and public policy decisions are given.

Introduction

The need to develop alternative energy sources has been widely accepted in this country. Solar energy is one of the alternatives being developed and its potential contribution is highly touted. The possible utilization of solar energy for heating and cooling of public, commercial, and residential buildings has gained considerable attention and support. Information on the application and viability of solar energy for heating and cooling buildings is being distributed by both public and private sources in an attempt to generate awareness and interest. Recognizing that information alone will not result in widespread adoption, both Federal and state governments are offering financial incentives to encourage interested consumers to incorporate solar options into their homes. To date, efforts directed toward increasing the rate of adoption of solar as an energy source have been relatively ineffective, thus blunting progress toward energy independence. Solar advocates have become concerned and frustrated about the sluggishness of the adoption process. This problem would be better understood and efforts more effective if it were viewed not as an isolated case, but rather placed in the larger context of diffusion of any new technology or innovation.

When a new technology or innovative product is developed, the basic question of how to get it diffused and accepted in the marketplace must be answered. The diffusion of technological innovations is often retarded by distribution problems. Difficulties are encountered in establishing new distribution channels or adapting to or changing existing channels. A product may be so different that established distribution channels or patterns do not exist, or the product class may have established channels but the new technology may be so different as to not be accepted by the channel members. The array of solar options, with its many variations, encounters both these difficulties.

The present discussion will examine some of the previously ignored problems encountered in the diffusion of solar products. These problems will be discussed in the larger contexts of technological innovations in general and heating and cooling products in particular. The discussion will focus on distribution problems and will further consider the implications of these problems for consumer decision making and public policy decisions.

Distribution Channels

Technological innovations generally fall into one of two basic product classes: consumer or industrial goods. Many components used in the manufacture of consumer durable goods are classified as "industrial" products. The normal distribution channel for industrial goods is shown in Figure 1-A.

There may be several component manufacturers in succession prior to the end use product, which duplicates and extends the channel. The end use product has its own distribution channel which is shown in Figure 1-B.

FIGURE 1
Traditional Distribution Channels

A. Industrial Products

B. End Use Products

It is important to consider the differences in purchase decision making between the manufacturer of an end use product who buys and assembles components, and a consumer who buys the completed product. Consumer evaluation of durable goods typically centers on the end use product which flows from the product manufacturer to the consumer as diagramed in Figure 1-B. Consumer decision making research would therefore be evaluated as constrained to the end use products model. While this is appropriate for consumer durable goods, it will be argued here that solar products are not an end use product, but rather an industrial good following distribution channel 1-A.

Distribution Channels for Residential Heating and Cooling Systems

The traditional distribution channels for residential heating and cooling equipment are more similar to those used for industrial products than for consumer durable goods. It may appear at first glance that the seller/installer is the retailer selling end use products, but he is more than that. In the case of residential heating and cooling, the seller/installer plays a critical decision making role. The installer is a "packager," or final manufacturer of the system. He is the system designer. He takes a number of components, frequently from different manufacturers, and assembles them into a system. Thus, it is not a final product which flows through the channel to the installer, but rather a group of components. Therefore, the installer could be thought of as the final manufacturer (of the heating and cooling system), while the other members of the distribution channel are industrial goods suppliers.

The installer could also be viewed as another industrial goods supplier, since the heating and cooling system is another component in the final end use product, which is the home. The consumer does not purchase the heating and cooling system as an end use product, and in the technical

sense, the seller/installer is a manufacturer more than a conventional retailer. Therefore, the relationship of the consumer to the seller/installer is not the same as the normal consumer-retailer relationship for consumer durable goods.

Consumers as Solar Decision Makers

The ultimate consumer of technologically complex products has traditionally had little or no input into the selection decision for components that make up the product. This holds for many products across industries including home computer systems, audio components, and home building. The decision as to the type of system components and their relative advantage has typically been made by the packager/manufacturer. Given the complexity and technical nature of such systems and related decisions, it should be recognized that most consumers have inadequate knowledge and experience for making such decisions.

It is important to recognize the difference between heating and cooling systems and other durable goods with respect to consumer use patterns and decision processes. For example, with automobiles and major home appliances consumers have considerable "hands on" experience and well developed use patterns, resulting in sets of salient attributes and evaluative criteria. What consumers lack in technical knowledge is not so critical because other attributes such as psychological appeal and user benefits tend to be adequate for decision making in the absence of technical knowledge. For residential heating and cooling, consumers have little experience with product attributes other than comfort level and costs of operation and maintenance. Unlike other durables there are no substitutes for technical factors which consumers can use for making decisions. The majority of heating and cooling equipment sales go into new construction. It is therefore the builder who typically makes the equipment purchase decision. The builder's choice of equipment is strongly influenced by the installer. The installer serves as a "final manufacturer," of the system. Installers exhibit control over equipment selection by assembling components from different equipment manufacturers into a functional system. The design of the home and general mode of construction do provide parameters for system design. However, the installer still has considerable latitude in component selection and system design even when the requirements for heat gain and loss and air flow are considered.

Homeowners are rarely involved in heating and cooling system decisions except when they are confronted with replacement decisions which arise from equipment failure. Until recently, equipment failure was the only real motivation for shifting fuel source. There was seldom reason to consider replacing systems which were performing well. Homeowners have normally not seriously considered changing fuel source in the replacement decision because of the high initial cost of replacement. Now the high cost of oil is causing many homeowners to consider other fuel sources.

Even in replacement decisions, homeowners have traditionally deferred to the experts in making decisions. System decisions are rather technical in nature, involving degree days, heat gain and heat loss calculations, comparison of relative efficiencies, air flows, and equipment design features, to name a few. The primary consideration for the homeowner has been price and soliciting bids from several installers. Homeowners have been forced to rely on the installer's assurance that the replacement system would offer the same level of performance as the previous one. In some cases brand name recognition becomes an influential decision variable for consumers in the absence of technical knowledge.

The decision process for heating and cooling systems is a complex one, involving multiple decision makers and deci-

sion roles. The consumer's role has been minimized by a lack of technical knowledge and competence to judge the critical decision variables. Yet, in the case of solar options, which are merely an alternative method of heating and cooling, the majority of information and incentives are being directed at the consumer. The consumer is being asked to become the principal actor in evaluating products and making purchase decisions for residential solar systems. This is being done without adequate educational preparation of consumers.

Solar Distribution: A Mismatch of Channel and Product

Channels for distribution and sale of residential heating and cooling systems are well established and functional. However, these traditional channels have been little utilized for the distribution of solar space heating products. Of twenty-five solar installers listed in the 1978 Oregon Solar Directory, only five were also sellers of conventional heating systems. Conversely, this also means that only five of the hundreds of Oregon heating and cooling contractors were selling solar equipment. Solar installers are typically new, small firms specializing in solar equipment.

The selection and/or development of distribution channels for solar products is a sticky problem. There is no single "product," but rather a vast array of different products many of which are distributed in different channels. The basic differentiation of passive and active systems exposes the difficulty in identifying appropriate channels of distribution for the divergent products.

Many solar proponents consider passive solar systems to be the most feasible and desirable alternatives to conventional fuel systems. However, formal distribution channels for passive systems do not exist. Passive systems are largely design concepts which do not require distribution of physical products. They do require dissemination of designs, engineering specifications, performance data, etc. to architects, engineers, and builders. Because this is not a normal physical product supplied by manufacturers for profit, distribution becomes quite difficult to organize and coordinate. It is not yet clear how this can effectively be done on a large scale.

In contrast, active solar systems are mechanical products, for which distribution channels are available. However, unlike most other new heating and cooling products, solar equipment has not come from standard industry suppliers. When central air conditioning and heat pumps were introduced, they were distributed through the same channels as other heating and cooling products. This was largely due to the fact that the manufacturers were the same as for existing products. When technological innovations come from manufacturers who are new to an industry, these new manufacturers do not have established relationships with existing channels of distribution. So the distribution difficulties being encountered with solar should come as no surprise; it is common to technological innovations.

Carrying the problem a step further, the different forms of active solar products may even require different channels. For example, water transfer systems may require plumber/installers, air transfer systems may require ventilation/installers, and photovoltaic cells may require electrician/installers. Such a pattern could preclude one channel of distribution from supplying all types of solar heating and cooling systems. It can further create problems for equipment suppliers, who may be forced to build and maintain relationships with multiple channels, which can be very costly. It can also create problems for installers who may have to build relationships with multiple suppliers. Finally, such a pattern could severely dilute the kind of concentrated effort which is generally needed to launch a new technology. Another major difference between solar and conventional heating and cooling equipment is

that of sizing, installation and maintenance. Existing installers are presently ill-equipped to handle these activities. A substantial investment in training and equipment is required to adequately prepare for handling these new and different products.

Non-Acceptance by the Channel

Solar options are merely another way of heating and cooling buildings. It therefore seems logical that regular heating and cooling contractors would be best equipped to handle sales and distribution. However, it appears that they have been generally less than enthusiastic to date. That is not to say they have no interest at all. From a profit perspective, market demand is insufficient to warrant the required investment in training and preparation. Solar equipment will not be marketed by distributors of conventional heating and cooling equipment until such time that it becomes profitable for them to do so.

However, the blade cuts both ways. Francis DeWinter, Chairman of the American Section of the International Solar Energy Society (1978), commented that "designers balk at marketing their products through existing networks."¹ The apparent lack of interest shown by the established channels has caused these channel members to be viewed as competitors and anti-solar, simply because they are carrying on business as usual. Thus, they are labeled as outsiders, and producers of solar components or systems look elsewhere for distribution. As solar equipment manufacturers are learning, it is very difficult and expensive to build new distribution channels from the ground up. If the installers are not existing businesses with years of experience and a good local reputation, they may have difficulty gaining either consumer or designer/builder acceptance. Thus, distribution of solar systems may be the classic "chicken and egg" situation. Conventional distribution channels may not handle them until they are successful and the systems may not be successful until they can be processed by existing channels.

Future Distribution Patterns for Solar Options

Distribution channels evolve just as consumer adoption evolves over time. Distribution channels for a new technology often change as part of an evolutionary process. The introductory stage of the product life cycle for solar products has been characterized by a select group of solar innovators. These innovators are generally homeowners who have designed and built their own solar systems. They are motivated more by their interest in the technology and lifestyle than by economic justification for the investment.

Solar distribution channels have evolved from a state of non-existence, where the consumer innovators designed and assembled their own systems to the current state where many solar specialty firms now sell and install solar products. These firms are the channel innovators. Like the consumer innovators, they are motivated more by their interest in furthering the cause of solar technology than by a profit motive. The widespread lack of business experience, operating capital, and economic rationale will result in a high mortality rate for this group of channel innovators.

Just as the mass market, or majority of homeowners, will differ in characteristics from solar innovators, so will the eventual seller/installer differ from the retailer innovators. There will be heavy capital requirements for inventories, installation and test equipment, and education for sizing, installation, and maintenance. This invest-

ment may be compounded by the increasing sophistication and diversity of solar products. Therefore, it may become increasingly difficult for new firms to assume the role of the seller/installer, and thereby force solar options to be distributed through existing channels for heating and cooling products.

There are differing views as to the future development of solar distribution channels. Some believe that new channels must be created because of the lack of interest exhibited by members of conventional channels. One scenario is that the "solar system packager" is the best distribution alternative, but this is merely a solar specialist who operates in the same manner as conventional heating and cooling contractors.

The more prevalent view reported in the literature is that conventional channels will be the primary outlet. This seems logical and there are numerous signs of such development:

1. Johnson (1976), in discussing policy options for solar, contended that the regular operation of the national building industry is the most reasonable method for integrating solar options.
2. Overtures toward the solar industry are being made by conventional channel members. Trade publications in the traditional heating and cooling industries are increasingly reporting on the solar industry.
 - a. Air Conditioning, Heating, and Refrigeration News is the major weekly information source for this industry. It runs many news reports as well as frequent articles on solar activities.
 - b. The primary trade publication for the oil heating industry has been for years Fuel Oil & Oil Heat. This monthly periodical not only includes regular articles and reports on solar systems, but it recently added and Solar Systems to the title of the publication. This appears to be a sign of things to come.
 - c. Many of the articles which appear in these and other industry publications are focused on the interface between these conventional channels and the solar industry. For example, fuel oil suppliers and installers are being encouraged to become involved in selling and installing solar systems. It is claimed that they are compatible and that the dealers' future livelihood may be dependent on such a transition.
3. One recent article predicted that if solar is to achieve the market share being predicted over the next five to ten years, conventional distribution channels will have to be utilized in order for solar to become a mass market item (Air Conditioning, Heating and Refrigeration News 1977).

Regardless of whether new or existing firms eventually assume the principal role of seller/installers, the traditional decision making structure for heating and cooling systems — including solar options — can be expected to remain unchanged. That is, the majority of the purchase decisions are made by builders, and the majority of the sizing and configuration decisions are made by the seller/installers. Therefore, the current focus of marketing research on the homeowner as the decision maker is both inadequate and short sighted.

Facilitating Distribution to the Builder and Seller/Installer

If solar heating and cooling is to meet growth targets, technology may have to take a back seat to marketing and industry organization. Channel members must see demand creation, manufacturer support, and profit opportunity if they are to adopt new technologies and incur the accompanying expenses. There are a number of facilitating factors which are critical to converting existing channel members to solar.

1. Involvement of conventional heating and cooling contractors could be enhanced by the development of packaged systems which could be more easily sized and installed by contractors.
2. Development of industry standards for comparison of solar system performance would dramatically reduce the frustration of explaining systems features and performance to prospective buyers, who are presently confused by conflicting information.
3. A substantial improvement in promotion and effective dissemination of technical information is needed. For the most part, solar manufacturers are underfunded and cannot afford adequate promotion. As yet, total industry sales are insufficient to provide the needed funds.

Directions for Consumer/Market Research

Three areas for future research appear promising using solar products. Decision making research has to date focused on the homeowner/consumer of the solar product. Future decision making is expected to shift from the homeowner to the builder and finally to the seller/installer, following the same pattern which presently exists for conventional heating and cooling products. The study of solar products offers a unique opportunity for research. Major product innovations that cause shifts in consumer decision making processes are rare. Suggested topics for study include causes of shifts in decision makers, and differences in the information acquisition process that occur at various points in the product life cycle for different decision makers. As consumer researchers we must explicitly recognize the different decision making segments and decision making roles as they shift over time.

Solar products are in search of a channel for distribution. As such, a longitudinal analysis of evolving distribution channels for a series of high technology innovations is possible. Worthy topics for investigation might include the modeling of variables that facilitate and enable shifts in the predominant channel decision maker. Channel conflict is another topic that is interesting in the study of traditional vs. new channel members.

Industrial marketing is a third area of research related to channel decision making. Multiple decision makers in the homeowner — builder — solar seller/installer triad permit the analysis of interaction both within and between channels distributing solar products.

Directions for Public Policy Decisions

It was pointed out earlier that homeowners/consumers have been the focus of promotion and incentives for solar products. This runs counter to the distribution and decision patterns for conventional heating and cooling products. Promotion and incentives for conventional heating and cooling products are primarily directed from the equipment manufacturer to seller/installers and builders, much the same as the pattern for industrial goods. In contrast to industrial promotion, consumer durable goods promotion is usually through or tied in with seller-installers. Solar,

promotion and incentives have come primarily from government and private sources — rather than existing channel members.

We have suggested that as solar products mature along the product life cycle, alternative distribution channels for solar products will necessarily unfold. This change in distribution, along with the associated shift in decision makers dictates that public policy programs and research be segmented. Information and incentive programs must eventually be shifted from the homeowner, and tailored for the designer/architects, builders, and retail solar sales and installation firms. Lastly, information and programs must be developed for conventional heating and cooling, plumbing, and electrical contractor channels as cost effective air, liquid and photovoltaic systems are developed. Again, both information and incentive programs are needed for the specific decision making segments as they develop to meet the changes in product technology and market demand.

A higher level of government involvement could accelerate the solar adoption process. For example:

1. Federal and state governments could carry the burden of "institutional" selling, or promotion of solar systems in general. Then the producers would only have to promote their own products, as the product class would be presold by public funds. This approach could, however, encounter opposition from competing industries.
2. A very strong impetus could be provided by government mandation of energy conservation or solar options. Two California communities have recently provided such a boost. The city of Davis has a performance standard for energy conservation which has resulted in the incorporation of solar options in new construction. San Diego County has mandated solar water heating in all new homes constructed in unincorporated areas of the county. These activities will obviously result in demand creation which will heighten the interest and involvement of conventional channel members.

Conclusions

When viewed in the larger context of developing technologies, it is obvious that the problems confronting residential solar heating and cooling are not unique. These adoption and diffusion problems are characteristic of most new technologies. When looking at the history of residential heating and air conditioning, it can be seen that similar problems have been previously encountered with new products in the same industry.

One of the primary causes of the slow rate of adoption of solar heating and cooling is inadequate and ineffective distribution of the products. This is often a problem with new technologies, but it is compounded by some unique aspects of solar technologies. The diverse array of solar products and complexity of application decisions create difficulties for both seller and buyer. There are many suppliers of solar products, most of whom are undercapitalized and are not traditional suppliers to the heating and cooling industry. A lack of product standards and slow accommodation of building codes pose problems for seller/installers. These factors combine to deter the type of demand pull and facilitation which normally help to develop functional and effective distribution channels. Solar heating and cooling products are presently at a very difficult stage in the evolution of distribution channels. Many of the current seller/installers are "innovators" who will eventually give way to more traditional heating and cooling operations. In the opinion of these writers, the conventional heating and cooling distribution channels are well equipped to handle solar products and they or similar outlets will eventually assume the role.

A separate but related problem is that solar products are being treated erroneously as consumer durable goods and marketed directly to consumers. This is in stark contrast to traditional distribution and marketing patterns for conventional heating and cooling products. They are treated more as industrial goods with technical decisions made by installers and most purchase decisions made by home builders. Prospective solar consumers are being asked to make product evolution and application decisions which they have previously not made for this product class. Research, information, and incentives for solar products have been directed at consumers. These efforts have, however, failed to adequately consider the critical decision roles played by the seller/installer and builder. In the future, both marketing research and marketing strategy development must address the multiple decision makers and their interactive decision roles if they are to be meaningful and effective.

PROVIDING REINFORCERS FOR ENVIRONMENTALLY UNCONCERNED CONSUMERS

Michael L. Rothschild, University of Wisconsin

Abstract

The marketing concept and behavioral learning theories both emphasize the need for positive reinforcement of behavior if repeat behavior is desired. In nonbusiness situations there is often a situation where there is individual cost and societal benefit but no individual benefit. The papers in this session show examples of this type of case in the area of ecological/environmental marketing and also suggest methods for dealing with this issue.

Discussion

Important new areas have been entered into by marketers and consumer behavior researchers in the past few years. These include public sector, nonprofit and public policy arenas.

In the public and nonprofit areas one deals with a complex set of issues including intangible products and prices, which translate to difficult to perceive benefits and costs. In public policy issues one tries to aid policymakers who may need to have an impact upon the knowledge and/or behavior of the general public. The area of environmental and/or ecological concern touches on both of these thrusts (i.e. public/nonprofit and policy) as can clearly be seen in the three papers presented in this session.

Two other recent papers consider issues parallel to those of environmental concern from a consumer behavior perspective. These papers deal with marketing communications in nonbusiness situations (Rothschild 1979) and a behavioral learning theory perspective of marketing (Rothschild and Gaidis 1980). Both relate to the three papers of this session; the three environmental papers serve as examples of the points made in the two theoretical papers.

As the tools of marketing develop uses in these areas of societal thrust, one can see a weakening of the marketing concept. The marketing concept offers the philosophy that success is achieved through meeting the needs of consumers. A parallel model is offered by behavioral learning theory and states that the probability of any future behavior is increased when that behavior has been positively reinforced in the past. These two models are essentially identical.

As marketers attempt to meet societal needs, though, they may lose sight of the exhortation to meet individual needs as well. Individual behavior which is not reinforced will not be maintained in the long run. Examples of this paradox abound in nonbusiness cases; the three papers presented here provide just such cases. It is clear that there are societal benefits to be derived from appropriate individual behavior; it is far less clear that the costs associated with the individual behavior will be offset by individual benefits. These cases are, then, removed from the *quid pro quo* type of exchange which typifies private sector marketing. The three papers provide insights into dealing with these unbalanced types of exchanges.

One can also consider the policy implications of unbalanced exchange situations. If there is a societal benefit and a societal need then perhaps policymakers should be called upon to provide sufficient incentives for behavior so that the individual cost benefit relationship is perceived favorably. From this perspective policymakers as well as

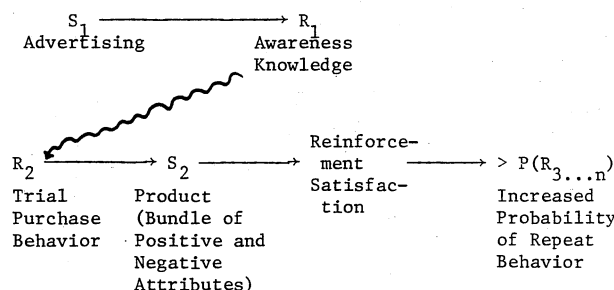

marketers are concerned with environmental issues.

Parenthetically, in the Henion, Gregory and Clee paper, reference is made to an earlier Henion paper (1978). In this paper Henion suggests that private enterprise is a viable alternative to governmental regulation in the area of environmental issues. That would seem to be a difficult assignment for a firm operating for profit. Perhaps sufficient individual reinforcers are only available through government subsidy; perhaps no individual firm or person has sufficient incentive to provide these reinforcers. An alternative to positive reinforcement which is available to government is brute force of law. Legislation may, by itself, provide adequate incentive for behavior. Again, the papers speak to this issue as well.

Figure 1 shows a model which combines education with positive reinforcement. Verbal learning theories can contribute to the top set of relationships; behavioral learning theories are necessary to the lower set of relationships. The three papers provide insight into application of this behavioral model.

Henion, Gregory and Clee discuss trade off analysis with respect to nonphosphate detergents and present a nicely done piece of research. An analysis of tradeoffs implies a search for reinforcers. One can see from their data that there are some individuals who will accept non-phosphates with their accompanying higher prices and lower cleaning power.

Figure 1
Learning Theory in a Marketing Context

Source: Rothschild and Gaidis 1980.

Given real world market shares it is clear, though, that most consumers do not see sufficient individual reinforcement in this product. Low phosphate detergents clearly provide a societal benefit but not an individual one. Low price and clean clothes help individuals; most individuals opt for these personal reinforcers.

The Henion, Gregory and Clee paper presents a useful method to show how consumers value the possible tradeoffs across attributes. Such a method would be useful in testing specific reinforcers and may also show that industry is unable to provide the necessary reinforcers. In this case the issue would become a policy one if society had a sufficient need for low phosphate detergents.

Crosby and Gill use path analysis to examine voting behavior with respect to a returnable bottle referendum in Michigan. Again a useful method is used well in providing

insights as to motivations and reinforcers.

In this case the events were more policy related since voting on the proposed policy was about to occur. The main issue of the paper, though, concerns which reinforcers to use to motivate the voter. In this paper, as in the previous one, one sees that the group of environmentally concerned citizens is quite small in the absence of reinforcers and that the private sector was unable to provide sufficient individual benefit to gain appropriate behavior. The referendum was a test of societal needs. Passage of the referendum was a mandate to policymakers to provide sufficient incentives and/or legal sanctions.

The data show that perception of cost is the main driving variable of vote; this is consistent with behavioral learning theory. Where there is less concern with cost, more votes result; where the perception of cost is low, more votes result. Secondly, behavioral variables are more important than attitudinal or SES variables. Again, individuals behave based on cost benefit relationships and reinforcers.

Later in their paper, Crosby and Gill state that the marketers of the bill marketed the benefits of reduced litter and minimized the perceived cost. Here a societal benefit (reduced litter) was transformed to an individual benefit and the individual benefit was minimized.

The third paper, by Blakely and Smith discusses the distribution of solar related products. Once again there is a case of insufficient reinforcement for consumers; demand for solar products is still quite low.

Blakely and Smith feel that a change in distribution systems (from a consumer directed to a builder/contractor directed system) would help to stimulate demand. Unfortunately the authors have no compelling argument as to why builders or contractors would be more reinforced than were consumers. These authors do, though, suggest a system of reinforcers. They point out the current lack of reinforcers and recommend a system of incentives and legislation. By doing so, they again bring a product class into the realm of public policy.

The three papers show commonality when considered within the framework of using reinforcers for nontraditional products. All too often private sector marketing tools are blindly applied to new situations. The profession is slowly learning that some nonbusiness problems are quite difficult and require new or modified marketing paradigms. The methods of path analysis and trade off analysis provide useful insights for dealing with these problems.

Researchers and practitioners in nonbusiness situations are urged to consider behavioral learning theory and the notion of reinforcement in dealing with these situations. Without reinforcers there will not be long-run behavior. The three papers in this session provide applications of this model.

INTEGRATION OF ECONOMIC GEOGRAPHY AND SOCIAL PSYCHOLOGICAL MODELS OF
PATRONAGE BEHAVIOR

Robert F. Lusch, University of Oklahoma

Abstract

This article develops a model of patronage behavior which incorporates key concepts from geography, social psychology and economics. The model is shown to be rich in explanatory power but its predictive power is not assessed.

Introduction

The study of retail patronage behavior is not new. Over fifty years ago W.J. Reilly (1929) in his now classic monograph developed a gravity based model of retail patronage behavior. This model postulated that a household's attraction to a community for shopping purposes was positively related to the size of the community and inversely related to the distance to the community. Some thirty years later David L. Huff (1962) transformed Reilly's law into an intrurban patronage model. Huff's model suggested that a household's attraction to a store was positively related to the size of the store (i.e., square feet) and inversely related to the distance from the household's place of origin to the store. At about the same point in time Bob R. Holdren (1960) in an elegant model of the structure of retail markets postulated that the buyer evaluates the store offering on three dimensions: (1) the distance the buyer is from the store; (2) the level of prices at the store; and (3) the level of non-price offer variation. All three of these authors viewed patronage behavior from an economic geographic perspective. That is patronage behavior was viewed as being determined by the structure of physical space. This spatial orientation to patronage behavior continues to be pursued. For example, recent work by David MacKay (1973), Dennis Lord (1975) and William Young (1975) is reflective of the spatial research orientation toward patronage behavior.

On the other hand some early pioneers in patronage behavior research attempted to explain shopping behavior in terms of social-psychological concepts. Utilization of these concepts resulted in researchers treating shopping behavior as being unaffected by physical space. Notable early examples of this approach include Gregory Stone's (1954) work on categorizing shopping orientations used to evaluate stores. Stone's shopper orientations fell into five categories: (1) economic, (2) personalizing, (3) ethical, (4) apathetic, and (5) a residual category of unique or indeterminate criteria. Another early example includes the work of George Fisk (1961-1962) in which the consumer's image of the store was postulated as the major latent guiding force in determining patronage behavior. The social psychological approach to explaining patronage behavior continues to receive attention. Some relatively recent examples include the work of Darden (1980), Granzin and Painter (1976), Monroe and Gultinan (1975), James et al. (1976), Miller (1976), and Marks (1976).

As far as the author is aware the only attempt to integrate the geography and social psychology approaches to studying patronage behavior is in the area of what has been labeled cognitive mapping. In this stream of research the consumer's perceptions or cognitions of store size and/or distance are utilized in traditional geographic patronage models rather than real distances or actual store sizes. This approach is relatively recent and includes the research of Maze (1974), Cadwallader (1975) and MacKay and Olshansky (1975). Findings from this stream of research suggest that cognitive or perceptual measures are better

predictors of behavior than physical or real measures.

The purpose of this paper is to provide further integration of the geography and social psychological approaches to the study and explanation of patronage behavior. In addition useful concepts from microeconomics are integrated into the proposed patronage model. Portions of the model are taken from a theory of retail structure recently developed by Ingene and Lusch (forthcoming).

Theoretical Development

As in microeconomic theory we begin by assuming that the consumer (i.e., shopper) is rational. It is however recognized that not all consumers have the same rationality. What may be rational from one shopper's perspective may not be rational from someone else's perspective, but, nonetheless rationality as the individual defines it does exist.

In addition it is assumed that shoppers don't have perfect information. Therefore shoppers must make decisions in the face of uncertainty.

The fundamental underlying proposition upon which the model is based is that shoppers will make rational shopping decisions so as to maximize their net consumer surplus. Consumer surplus is a concept borrowed from economics. Consumer surplus occurs when goods are sold at a price lower than the maximal demand price a consumer would be willing to pay for them. It is because goods are offered by retailers below the consumer's maximal demand price that consumers are enticed into expending effort to shop for goods.

When the price the consumer must pay for the product at the store plus the costs associated with acquiring the product, such as the cost of traveling to and from the store, exceeds the consumer's maximal demand price shopping will become uneconomic. The preceding implies that there are certain costs incurred in shopping. When these costs are subtracted from consumer surplus one arrives at net consumer surplus. It is net consumer surplus that the consumer attempts to maximize.

The Patronage Model

The model that is being proposed of patronage behavior can be formalized as follows:

$$E(W_j) = P_j (P_m - P_e) q - 2rt' - [(2r/m) + s]t'' - t''' \quad (1)$$

where:

- $E(W_j)$ = expected net consumer's surplus from shopping at store j,
- P_j = probability that if store j is patronized that the product being sought is in stock,
- P_m = maximal demand price per unit given quantity desired,
- P_e = expected price per unit,
- q = quantity desired,
- r = distance in miles from store to household departure point, and therefore $2r$ is equal to round trip distance,
- t' = cost per mile of travel,
- m = speed of travel in miles per hour,
- s = expected in-store shopping time,
- t'' = opportunity cost per hour of time,
- t''' = psychic costs (benefits) of shopping trip evaluated in dollar terms.

Appreciation and understanding of this store patronage model can be facilitated by an elaboration of its individual components.

The first term (P_j) is included in order to capture the degree of uncertainty that confronts the shopper. Once a consumer recognizes a need for an item it must assess the set of stores which may have the item and estimate the probability that the item is in stock at each of the respective stores. This probability is the P_j term and it captures uncertainty on the part of the shopper. In reality the product the consumer plans to shop for either is or is not in stock at the store. That is if the consumer knew the truth then P_j would be assigned a value of 0.0 or 1.0. But the consumer does not know reality (i.e., certainty) and therefore P_j is its estimate of the likelihood that the item will be in stock at the store.

The term P_j is itself a function of several managerial and behavioral variables that are not explicitly included in the model. Most important from a managerial and behavioral perspective is the information the prospective shopper has available. This information is a function of the quantity and quality of promotion on the part of the retailer and also of the information processing capabilities of the shopper. Theory and concepts from social psychology can therefore be used to empirically study the determinants of P_j .

The second term, the maximal demand price (P_m) captures the consumer's desire, need or want for the item and the consumer's ability to acquire the item. As the consumer's purchasing power increases the maximal demand price will rise. Purchasing power may increase due to rising income or more readily available credit. Thus the retailer can have some influence over P_m via its credit policies. In addition the retailer could advertise or promote the item to have certain unique and strong traits or benefits which could result in the consumer wanting or desiring the item more and therefore shifting P_m upwards. Behaviorally oriented theories of advertising could be helpful in shedding light on this matter.

The expected price per unit (P_e) reflects what the consumer believes the retailer will charge for the item being sought. Once again this term suggests the shopper faces uncertainty. A shopper seldom knows a priori what the precise price of an item will be. Therefore the shopper must estimate the price. As you might well expect the retailer's promotional efforts--especially its advertising--can aid the shopper in better estimating prices. In addition the process of learning will become important in establishing (P_e). Everytime the consumer shops at a store it learns more about its pricing policies.

The quantity (q) the shopper plans to purchase on any given shopping trip is basically an inventory decision if the item is a nondurable rapidly consummable item such as food. A household will tend to purchase nondurables in larger quantities when its income is higher; the cost of travel is high; time pressures are great; storage is available and household size is larger. Most durable items (e.g., cars, furniture, appliances) are purchased one at a time. If more than one is purchased on a single trip it is usually due to income or wealth factors.

Combining together the four variables we have discussed (P_j , P_m , P_e , q) will allow us to formalize expected consumer surplus. Expected consumer surplus is equal to $[P_j(P_m - P_e)q]$.

From this the costs of shopping must be subtracted. The major variables influencing the costs of shopping will next be discussed.

In traditional economic geography models the most important variable is (r) or the distance from the store to the shoppers point of departure--usually its residence or place of employment. Naturally this variable is a function of where

the retailer locates its store and the location of households or businesses surrounding it. But (r) is also a function of city planning of road networks. The straight line distance between the store and shopper may be short but if travel is to occur on existing roadways the distance could be considerably greater. From a behavioral perspective (r) is a function of learning, information availability and information processing. The more times one travels to the store the more they will learn the shortest route. Or in terms of a first trip the more the information the consumer has on how to get to a store the better it will be able to travel the shortest route and thus minimize shopping costs.

Travel costs per mile are also important in determining patronage behavior. In the model the cost per mile of travel is labeled (t'). This important variable is influenced by the availability and cost of public transportation and if private transportation is used the cost of operating an auto. Costs of operating an automobile will vary by region of the country due to varying rates for insurance, gasoline, and taxes in different parts of the country. The total round trip costs of traveling to the store are represented in the patronage model by $2rt'$.

The costs of shopping not only include travel costs but also the implicit cost of time. As families are increasingly facing a scarcity of time the opportunity cost of that time rises. In the model the opportunity cost per hour of time is labeled t'' . This variable is a function of the alternative opportunities an individual has for leisure or work. One would expect that some of the correlates of t'' would include: income, lifestyle, and social class.

The total amount of time spent on the shopping trip can be divided into two components: (1) travel time; and (2) in-store shopping time. Travel time is equal to $(2r/m)$ in the patronage model, where m is average speed of travel in miles per hour. In most part speed of travel is a function of the type of transportation used, speed laws, road networks, and road congestion. In-store shopping time is labeled s in the model. This time variable is a function of a variety of factors which include: (1) the amount of information the shopper has on where the item(s) is located in the store; (2) in-store congestion; (3) store layout; (4) degree of sales assistance available; and (5) merchandise availability.

The cost of time per hour (t'') when multiplied by the amount of time spent on the shopping trip $(2r/m)+s$ will determine the total cost of time devoted to the shopping trip.

The final parameter in the patronage model is t''' or the psychic costs or benefits of the shopping trip. The shopping trip cannot only cost in terms of direct monetary travel costs and the opportunity cost of time devoted to the shopping trip but also in terms of psychic costs. For example let us assume that in order for a shopper to travel from its home in the suburbs to a large downtown department store that it must maneuver its auto over 32 miles of congested freeway and then through 12 blocks of ghetto neighborhoods. In addition to the time and travel involved this trip may be very nerve wrecking and tension creating thus resulting in certain psychic costs.

In principle psychic benefits can also accrue during a shopping trip. That is the shopping trip may be viewed as an enjoyable experience and thus of value in and of itself. For instance assume that it has been a long cold Winter and with the arrival of Spring the consumer desires to load his family into the car and drive to a regional shopping center forty miles away in order to browse in the shopping mall and look at the new Spring fashions. This shopping trip may actually be an enjoyable experience thus creating psychic benefits vs. psychic costs.

Explanatory Power

The traditional patronage models in economic geography, such as the Huff model, have good predictive power but are lacking in explanatory richness. This is not the case with the proposed patronage model. Not only can the proposed model explain the impact on patronage of changes in behavioral, environmental and geographic variables but it is also capable of explaining well accepted theories such as central place theory, Reilly's law and the Huff model.

Behavioral Variables

There are at least several behavioral variables which can fit well into the model and increase its potential explanatory power. Some of these variables include information processing, attitudes and consumer certainty.

Lets briefly look at information processing. As a person obtains more and better information about a store they will be better able to make shopping decisions which will increase their net consumer surplus. Increased net consumer surplus via better informed decision-making will lead to consumers being more store loyal.

A second behavioral variable is customer attitude toward the store. If attitudes become more favorable then the store should become a more enjoyable place to shop which should reduce the psychic costs (t'') of patronizing the store. This in turn could increase the distance (r) a shopper would be willing to travel to visit a store.

A third behavioral variable regards the degree of certainty the consumer has that the product being shopped for is in stock. As certainty increases the number of patrons a store can potentially attract increases because the distance a consumer would be willing to travel (r) rises. At the same time existing patrons will become more loyal because their net consumer surplus will rise.

Environmental Variables

In terms of environmental variables we could investigate the impact of changes in things such as transportation costs and speed of travel. As transportation costs rise or the average speed of travel declines several things could happen. Consumers may purchase in larger quantities so they will not need to make as many shopping trips; they may try to gather more information to increase their certainty as to whether the product is in stock; they may decide to patronize more stores closer to their residences or places of work; or they may try to reduce the amount of time involved devoted to in-store shopping by more carefully planning their shopping trips.

Geography Concepts and Models

The proposed patronage model is not only capable of explaining the impact of changes in behavioral and environmental variables on patronage behavior it also helps to explain central place theory, Reilly's law and the Huff model.

Central place theory (Christaller 1966) tells us that there is a hierarchy of communities each of which is progressively larger and performs a larger group of retail functions representing an increased variety of product availability. The smallest communities perform the most basic functions and the larger perform more specialized functions. In addition each successively larger community performs all lower-order basic functions. The larger communities are spaced farther apart and are bordered by smaller communities. In terms of the proposed patronage model this suggests that the larger the community the greater the probability that an item can be found in a store within the community. The larger the community therefore the greater will be the distance (r in the model) people will be willing to travel to the community. This is in principle what cen-

tral place theory concludes.

Both Reilly's law and the Huff model postulate that patronage is inversely related to distance and positively related to size of store or size of community. In the proposed patronage model distance (r) is also incorporated in such a fashion that an increase in distance reduces net consumer surplus and therefore the likelihood of a patron shopping at the store declines. Size of store is not directly incorporated in the proposed patronage model. Importantly, however, what size of store is a surrogate for is included in the model. Size of store itself is not an attraction force but rather the increased width and depth of merchandise assortments which accompany large stores is the attraction force. When these assortments increase then the probability that a shopper will find the item(s) it is seeking will increase which will in turn increase consumer surplus. Increased consumer surplus will increase a store's ability to draw patrons. Thus we see that what the size variable is reflective of is more directly incorporated in the proposed patronage model. And importantly it allows for the same end conclusion to be drawn as the size variable in the Reilly and Huff frameworks.

Discussion

The patronage model as it has been presented is not complete in all respects. Further work and refinement is needed. For example the model assumes that only one product is being shopped for. This is unrealistic. To make the model more realistic multiple product searches should be included. If the shopping trip is a multi-purpose single stop trip then the model can be extended by summing across items to be purchased. However if the trip is a multi-purpose multi-stop trip then extension of the model is considerably more complex.

In addition the model could become richer if it not only explicitly included demand related variables but also supply and competitive variables. This would enable the retail manager to manipulate certain managerial variables in order to determine a profit maximizing strategy.

Finally the model is in need of rigorous testing of both its individual components and its total composition. It is believed that all of the variables in the model can be measured directly except the psychic costs or benefits of shopping. Since many of the correlates of the major constructs in the model are social-psychological in nature, indirect measures may be necessary for them.

To better understand the relationship between patronage behavior and each of the variables in the model several approaches could be used. First, calculus could be used to establish the impact of a change in each variable on net consumer surplus. Second, simulation could be used to investigate the magnitude of these effects. Third, empirical research could be used to test hypotheses derived from the two preceding approaches.

Conclusion

A model of patronage behavior has been presented which incorporates concepts from economics, social-psychology and geography. The model appears to be rich in explanatory power. With additional refinement its explanatory power should be further improved. Its predictive power, however, still remains to be assessed.

WOMEN'S SELF-ASCRIBED OCCUPATIONAL STATUS
AND RETAIL PATRONAGE

Elizabeth C. Hirschman, New York University

Introduction

Since the early 1970's there has been a steady research stream concerned with the increasing occupational diversity of women and the relationship of this occupational diversity to women's behavior as consumers (e.g. Bartos 1977; Lazer and Smallwood 1977; McCall 1977). Investigations conducted at the outset of this stream of research tended to dichotomize women into only two groups: employed and unemployed (e.g. Anderson 1972; Douglas 1976; Strober and Weinberg 1977).

Later studies, however, utilized a three member typology: housewives, "working" women and "career" women; where "working" women were defined as those who viewed their employment as a job and worked primarily for financial reasons, and "career" women were those who viewed their employment as a career and worked primarily for self-fulfillment (e.g. Joyce and Guiltinan 1978; Hafstrom and Dunsing 1978; Bartos 1977).

Based on empirical findings that support the validity of a three-member occupational typology for women, Bartos (1977 p. 37) writes: ... We must go beyond a simplistic comparison of working women with housewives if we are to understand these two kinds of markets. The contrast found in the ... behavior of career women and the "just-a-job" working women is dramatic evidence of the need to go beyond the perspective of (employed) women as a monolithic group."

Purpose

The present research has two purposes. The first is to explore the overlap between a woman's self-ascribed perception of her occupational status (i.e. housewife, working woman, career woman) and her externally-ascribed occupational status. For example, professional-managerial, sales-clerical and unemployed occupational categories are three externally-ascribed status categories into which many women are often grouped by researchers (Miller, Schooler, Kohn and Miller 1979; Greenberg, Straight, Hassenger, and Roska 1978; Tumin 1967). In consumer research on such externally ascribed occupational status groupings, professionally employed women often are implicitly assumed to view themselves as "career" women, while women having sales-clerical jobs are frequently assumed to hold "working" women self-perceptions, and 'unemployed' women assumed to view themselves as housewives (e.g. Joyce and Guiltinan 1978). One important research hypothesis, therefore, is whether this implied congruence between externally-ascribed and self-ascribed occupational status actually is present for women.

If this congruence is found, the second objective of the research will be to examine differences among the self-ascribed status groupings of women in terms of retail patronage variables. In this regard, the product area of apparel is especially important, because one of the primary ways an individual displays status to others is through apparel (Belk 1978, Holman 1980). Four areas of potential differences among Housewives, Working Women and Career Women will be investigated: (1) types of stores shopped for apparel, (2) times at which apparel shopping is conducted, (3) the dimensional structure of store attributes relevant to apparel purchases and (4) information source importance in apparel purchases.

Internal and External Status

It is important to gain an understanding of the occupational status concept and the perspectives from which it may be viewed. The term status refers to a social position; social positions may be defined along many dimensions. Wealth, educational attainment, sex, race, religion and occupation are some of the more common dimensions for defining status in Western society (Tumin 1967). Within a given society, some social positions are normatively valued more/less highly than others, and hence may be ordered hierarchically in terms of their prestige or social value. This normative, hierarchical ordering gives rise to status ranking.

One of the most important sources of status ranking in U.S. society is that of occupation (Tumin 1967). It is because of the predominance of occupation as a social ranking dimension and women's traditionally unemployed condition that women were often said to occupy a "low-status" position in society. As women acquired jobs outside the home, they altered their status and provided a means for differentiating themselves. That is, by acquiring occupations other than that of housewife, women generated greater within-group status heterogeneity. Occupational status became an additional dimension that could be used by researchers and by women, themselves, for differentiation.

Two perspectives may be used for studying women along this "new" differentiating dimension of occupational status: one which is externally-assigned and one which is internal to the individual. An example of an externally-assigned status system is that of labeling certain jobs as professional-managerial, sales-clerical, skilled labor and so forth. Such a labeling system is used as a social convention to ascribe status to occupations. These externally-ascribed statuses subsequently are often normatively ranked as to social desirability; for example, professional-managerial occupations are generally viewed as higher in social value than those based upon those based upon skilled labor (Tumin 1967).

A second perspective is to ask women to ascribe a status to themselves based upon self-perceptions of their occupations. Here, instead of labeling herself as (say) a 'sales-clerical worker', the woman would define herself as a "Housewife," a "Working Women" or a "Career Women." For present purposes we will define "Working" Woman as a self-perceived occupational status to describe an occupation that serves as "just a job" and which was acquired primarily to generate income; whereas the "Career Woman" self-perception refers to an occupation that was acquired mainly as a means of self-fulfillment.

It is expected that these two status systems will be generally consistent in actual practice. That is, that women who hold professional-managerial occupations will view themselves as career women; women who hold clerical-sales occupations will view themselves as working women, and women who are voluntarily 'unemployed' will view themselves as housewives. This expectation is based on the premise that the status ranking system characterizing the society in which the woman lives will be internalized by her as a result of socialization processes. In essence, we come to view and value ourselves as society views and values the positions that we occupy.

Because a professional occupation is highly valued in U.S. society, a woman would be expected to view it as a means for achieving self-fulfillment and recognition. Because a clerical occupation is less-valued in our society, a woman would be expected to view it, not as self-fulfilling in and of itself, but rather as a means for obtaining other objectives - for example, the generation of additional income to purchase desired products.

To the extent that externally- and internally-ascribed status systems overlap, they may be used interchangeably in examining the consumption behavior of women. That is, we may classify women either by a set of externally-imposed categories or by the self-ascribed classification scheme that they apply to themselves. Thus the first hypothesis advanced in this research is that self-ascribed occupational status and externally-ascribed occupational status for women will be consistent.

H1: Specifically, it is hypothesized that women who hold a professional or managerial occupation will view it as a career; women who hold a clerical-sales occupation will view it as a job; and women who are voluntarily unemployed will view their occupation as that of housewife or homemaker.

It was further hypothesized that income and educational differences previously found for women based on their externally-ascribed status will be consistent with those found for their internally-ascribed status (Joyce and Gultinan 1978). That is:

H2: Career women, housewives and working women will be ordered as high, medium and low in family income, respectively.

This hypothesis is based on prior descriptive research and also on the following reasoning. First, one reason why women who voluntarily choose not to work (i.e. Homemakers) are likely to do so is because there is no immediate financial need which forces them to seek employment. Thus, they are likely to be from moderate to high income households. Second, "Working Women" have already defined themselves as working primarily "for the income;" therefore there is reason to suspect that there is inadequate household income unless they work. Third, the fact that "Career Women" are seeking self-fulfillment as a primary reason for working presupposes that there is at least adequate household income; otherwise they would be employed mainly out of necessity and not out of desire. Further, empirical reality suggests that "career" occupations are typically the most financially rewarding. Thus, the combination of a high household income (e.g. a well-employed spouse) together with her own above average earnings should place the Career Woman in the highest income rank.

H3: Career women, housewives and working women will be ordered as high, medium, and low in educational attainment, respectively.

In addition to the earlier findings that gave rise to this hypothesis (Joyce and Gultinan 1978), there are some logical inferences upon which it may be based, as well. First, educational attainment tends to be linked to income and occupational status. Therefore, it is straightforward to reason that women who work of financial necessity (i.e. Working Women) are less educated. Women who can be Homemakers are likely to be married to well-educated men who hold financially-rewarding jobs. Women who have professional occupations are likely to be highly educated. A high level of education is generally a prerequisite for holding most professional-managerial jobs and, thus, is likely a prerequisite to perceiving oneself as a Career Woman.

Retail Patronage

The second objective of the research was to extend the examination of self-ascribed status rankings to an inves-

tigation of interpersonal differences in retail patronage. The patronage area of specific concern was that of apparel purchasing. Since apparel is one of the primary means used by the individual to create a self-identity and to communicate that identity to others (e.g. Belk 1978, Holman 1980), it stands to reason that there should be apparel purchasing differences among women based on their self-ascribed status. The specific hypotheses advanced in this portion of the research were:

H4: Women will display a different pattern of apparel shopping at various store types depending upon their self-ascribed occupational status.

H5: Women will display a different pattern of apparel shopping during various times of the day and days of the week depending upon their self-ascribed occupational status.

H6: Women will display a different dimensional structure for store attributes relevant to apparel shopping depending upon their self-ascribed occupational status.

H7: Women will display a different ranking of importance for information sources regarding apparel shopping depending upon their self-ascribed occupational status.

More specific rationales for these hypothesized differences are given in subsequent discussion.

Methodology

Sample

Data for the research were generated by mailing self-administered questionnaires to stratified groups of women. The aim was to obtain proportionately equivalent representation of self-identified Housewives, Working Women and Career Women. To accomplish this, mailing lists were obtained for New York Area PTA groups, clerical and sales worker associations, and professional and business associations. Names of women were selected at random from these lists and 75 questionnaires were mailed to each type of source (e.g. PTA, clerical associations, business associations). After three weeks, 48 questionnaires had been returned on which the respondent identified herself as a Housewife, 42 questionnaires were returned on which the respondent identified herself as a Working Woman and 35 questionnaires on which the respondent identified herself as a Career Woman. Follow-up mailings (n = 50) were sent to women on the three mailing lists; and enough questionnaires were received from this second mailing to bring the total self-identified Housewives to 51, self-identified Working Women to 52 and self-identified Career Women to 50.

Because of the stratified nature of the sampling design, the approximately equal proportions of the three types of women used in the research do not, of course, mean that these groups occur with equal frequency in the general population. The purpose here was not to define parameters for the Housewife, Working Woman and Career Woman status segments, but rather to examine intergroup differences. Hence group proportional equivalence rather than population representativeness was the dominant criterion.

The women composing each group in the sample are believed to be representative of the group, within the parameters imposed by use of the mailing lists. These lists restricted the sample frame to women residing near New York City and to women belonging to certain organizations (e.g. a PTA); hence the findings from the study must be generalized from cautiously both on a demographic and

sociological basis.

Criterion

The primary criterion employed in the research was a multi-part question that requested the respondent to identify herself as belonging to one of three possible occupational groups. The classificatory statement read:

Do you see yourself primarily as a:

- (1) Homemaker, that is, your principal occupation is taking care of your home and family.
- (2) Working Woman, that is, your principal occupation is a job whose major purpose is to earn income.
- (3) Career Woman, that is, your principal occupation is a career whose major purpose is self-fulfillment.

Based on their responses to this question, women were classified as Homemakers (n = 51), Working Women (n = 52) or Career Women (n = 50).

Results

Hypothesis 1. The first hypothesis expressed the expectation that a high degree of congruence would be found between a woman's self-ascribed status and the status externally ascribed to her occupation. To test this, a contingency table was constructed comparing the three self-ascribed groupings (Homemaker, Working Woman, Career Woman) with three levels of externally-ascribed occupational status (professional-managerial, clerical-sales, housewife/unemployed). These latter status groupings were formed on the basis of actual occupation as reported by the individual.

As can be seen from the data displayed in Table 1, there is a very high degree of correspondence between self-ascribed status and actual occupation for the women in this research. Approximately three fourths of women who considered themselves "Career Women" held professional-managerial occupations; and roughly the same percentage of women who classified themselves as "Working Women" held clerical-sales positions. There was complete correspondence between women who viewed themselves as "Homemakers" and those who listed their occupation as housewife. This correspondence between occupational self-perceptions and actual occupations was highly significant statistically ($p \leq .00001$).

TABLE 1

SELF-ASCRIBED VERSUS EXTERNALLY-ASCRIBED STATUS COMPARISON

	Professional Managerial	Clerical Sales	Housewife
Homemaker	0 0.0	0 0.0	51 100.0
Working Woman	14 27.0	38 73.0	0 0.0
Career Woman	39 78.0	11 22.0	0 0.0

$\chi^2 = 191.6$

$p \leq .00001$

$n = 153$

Hypothesis 2. The second hypothesis stated the expectation that Career Women, Homemakers, and Working Women would be ordered high, medium, and low, respectively, with regard to household income. This expectation is partially confirmed by the data in Table 2. As can be seen, the Homemakers in the sample have the highest average household income, Career Women an intermediate level and Working Women the lowest. The one-way ANOVA of group mean differences indicated that both the Homemakers and Career Women had incomes significantly higher than Working Women ($p \leq .05$ and $\leq .10$, respectively) based on the Scheffe' test for simultaneous comparisons. There was not a significant difference between the income of Homemakers and Career Women, although the general direction was opposite that anticipated.

Hypothesis 3. The third hypothesis expressed the notion that Career Women would be highest, Homemakers intermediate, and Working Women lowest in educational attainment. This set of expectations was partially borne out by the results shown in Table 3. The one-way ANOVA of differences in population means indicates that Career Women are highest in educational attainment, Homemakers are intermediate, and Working Women are lowest, as was anticipated. The Scheffe' test for simultaneous comparisons was significant at the $p \leq .05$ level for the difference between Career Women and Working Women. However, there was not a statistically significant difference between the educational attainment of Career Women and Homemakers or Homemakers and Working Women as had been anticipated, although the general direction was as expected.

Since testing the first three hypotheses generally confirmed the overlap between self-ascribed and externally-assigned occupational status for women, analysis was extended to an examination of retail patronage. Specifically, the relationships between self-ascribed occupational status and several variables concerning apparel shopping were examined.

Hypothesis 4. This hypothesis expressed the belief that patronage of various types of retail stores for apparel purchases would be related to self-ascribed occupational status. Five types of stores were examined: discount stores, chain stores, department stores, specialty stores and boutiques. Respondents were asked:

"In what type of store do you usually shop for your own daywear clothing?"

The responses given by Career Women, Working Women and Homemakers were analyzed using contingency tables and are shown in Table 4. As can be seen, for only one type of store - the specialty store (e.g. Saks, Lord & Taylor) - were differences found at a statistically significant level among status groups. For specialty stores, Career Women were found to shop for daywear clothing at a proportionately greater level than either Homemakers or Working Women ($p \leq .03$). Further, it is important to note that a majority of all women respondents reported shopping most often at department stores for their daytime apparel. Women's apparel has traditionally been the forte' of department stores, and it appears that this relationship still holds among the present respondents.

Hypothesis 5. It was hypothesized that differences in day and time of shopping for apparel would be present among women having different self-ascribed occupational status. More specifically, it was believed that Career Women and Working Women would shop more on weekends and during the evenings; whereas Homemakers would utilize the "traditional" weekday shopping hours (i.e. mornings and afternoons). This was tested by asking respondents:

"When (days and hours) do you usually shop for your own clothing?"

Response categories were:

Days: Weekdays, Weekends, or Both

Hours: Mornings, Mid-day, Afternoon, Early Evening, Late Evening

TABLE 2

INCOME DIFFERENTIALS BETWEEN CAREER WOMEN,
WORKING WOMEN AND HOMEMAKERS

Career Women	Working Women	Homemakers
$\bar{x} = 22.7$	$\bar{x} = 20.0$	$\bar{x} = 24.4$
Scheffé test of simultaneous comparison		
$p \leq .10$ C/W, $p \leq .05$ H/W, $p \geq .10$ C/H		
n = 153		

TABLE 3

EDUCATIONAL ATTAINMENT DIFFERENTIALS BETWEEN
CAREER WOMEN, WORKING WOMEN AND HOMEMAKERS

Career Women	Working Women	Homemakers
$\bar{x} = 17$	$\bar{x} = 13$	$\bar{x} = 15$
Scheffé test of simultaneous comparison		
$p \leq .05$ C/W, $p \geq .10$ W/H, $p \geq .10$ C/H		
n = 153		

Responses to these questions were arranged in contingency tables and tested using the Chi-square statistic. Data are given in Table 5. As can be seen from the figures, there are some significant differences among alternative occupational status groups in shopping time. As was expected, Homemakers did most of their apparel shopping during the weekdays (84%), whereas the majority of both Career Women and Working Women did their apparel shopping on the Weekends or during a combination Weekends and Weekdays. This difference in shopping pattern was highly significant ($p \leq .0001$).

As anticipated Career Women and Working Women reported shopping in the early evening to a significantly greater extent than did Homemakers ($p \leq .0001$); whereas Homemakers were significantly more inclined to shop during the morning and afternoon hours ($p \leq .02, \leq .007$). Thus, occupational status appears to directly relate to a woman's retail patronage habits, at least as far as apparel shopping is concerned.

These findings suggest that retailers may be attracting different occupational segments of women depending upon the time of day and the day of the week. Thus, shopping time may be a central dimension for segmenting women customers. Salespersonnel, for example, could be alerted to the differential probabilities of encountering women of each occupational status group at various time periods, and sales appeals and merchandise displays could perhaps be adjusted accordingly.

Hypothesis 6. This put forward the expectation that different dimensional structures of retail-relevant attributes would characterize women having different self-ascribed occupational statuses. The specific question used to obtain data to test this hypothesis was as follows:

"How important are the following characteristics to you in deciding where to shop for your own daywear clothing?"

- (1) Broad selection of merchandise
- (2) Good service; helpful salespeople
- (3) Convenient locations and hours
- (4) Reasonable prices
- (5) Fashionable merchandise

Each of the attributes examined has been determined salient in prior research on fashion apparel (King and Ring 1980). Responses were recorded on a four-point scale ranging from 'Very Important' (4) to 'Not Important' (1). To discern if different dimensional structures existed for these attributes among the three women's occupational status groups, scores for each group were input to factor analysis (principal components with varimax rotation).¹ The results given in Table 6.

As can be seen from the data in Table 6, there are substantial differences among the three groups in terms of attribute factor structure. For Homemakers two factors were obtained; the first factor is correlated highly with selection and fashion, while the second factor is related to service, convenience and prices. In contrast, Working Women displayed a simpler, one-factor structure in their attribute perceptions. All attributes tended to be evaluated similarly by Working Women, resulting in one, overall factor upon which each attribute loaded highly.

¹ Only factors having eigenvalues greater than 1.0 are discussed.

Career Women exhibited the most complex factor structure; three factors were extracted to represent their attribute perceptions. The first factor correlated highly with convenience and prices; the second with service, and the third with fashion. Thus it appears that for the respondents in this research, there is a substantial difference in the dimensional structure of salient attributes characterizing the three occupational status groups. This finding suggests that images of varied complexity may be perceived for apparel retailers depending upon whether a woman views herself as a Homemaker, a Working Woman or a Career Woman.

Hypothesis 7. This hypothesis expressed the notion that different rankings of importance for various apparel-relevant information sources would result depending upon the self-ascribed occupational status of women. This hypothesis was tested by asking respondents the following question:

"To get ideas about what to wear during the day would you:"

- (1) Shop in stores
- (2) Read fashion magazines
- (3) Read newspaper advertisements
- (4) Watch television and movies
- (5) Wear what your friends are wearing
- (6) Wear what your work associates are wearing
- (7) Ask family members
- (8) Wear what your superiors at work are wearing

Responses were arrayed on a four-point rating scale ranging from 'Very Important' (4) to 'Not Important' (1). Based on mean values computed for each occupational status group, these scores were transformed to rankings, which are given in Table 7. The Kendall rank order correlation coefficient, tau, was used to compute the correspondence between information source rankings for pairs of occupational status groups.

TABLE 6
 FACTOR STRUCTURES FOR RETAIL-SALIENT
 ATTRIBUTES BY STATUS GROUPS

	<u>HOMEMAKERS</u>		<u>WORKING WOMEN</u>	<u>CAREER WOMEN</u>		
Selection	.82	.37	.80	.51	-.18	.46
Service	.44	.70	.75	-.21	.92	.07
Convenience	.24	.60	.79	.79	.43	.12
Prices	-.11	.87	.50	.84	-.21	.19
Fashion	.93	-.02	.79	.17	-.07	.95
Explained Variance	71%		54%	75.2%		

n=153

TABLE 7
 COMPARISONS OF RANK FOR INFORMATION
 SOURCE IMPORTANCE BETWEEN
 OCCUPATIONAL STATUS GROUPS

<u>Information Source</u>	<u>Homemakers</u>	<u>Working Women</u>	<u>Career Women</u>
Shop in Stores	1	1	1
Read Fashion Magazines	2	2	2
Read Newspaper Ads	3	3	3
Watch TV and Movies	4	6	7
Wear What Friends Wear	5	5	6
Wear What Coworkers Wear	7	4	5
Ask Family Members	6	4	6
Wear What Superiors Wear	7	6	4

Kendall's tau: Homemakers/Working Women = .59; $p \leq .01$

Homemakers/Career Women = .37; $p \leq .01$

Working Women/Career Women = .70; $p \leq .01$

n=153

The calculated values of Kendall's tau ranged from .37 to .70, all of which were significant at the $p < .01$ level. Thus, contrary to expectations, there is significant correspondence between the rank-order importance of various apparel information sources among occupational status groups. This finding is readily apparent from visual inspection of the ranked information sources provided in Table 7. The highest correlation was between Working Women and Career Women (.70); the next highest was between Working Women and Homemakers (.59); and the lowest was between Career Women and Homemakers (.37).

Rankings of the three most important apparel information sources - shopping in stores, reading fashion magazines and reading newspaper advertisements - is invariant across status groups. There were some inter-group differences, however. Wearing what coworkers or superiors wear are somewhat more important information sources for Career Women. Homemakers placed relatively more importance on watching television and movies as sources of apparel information, than did either Working Women or Career Women, perhaps because Homemakers have more time available for this type of information-seeking. However, despite these dissimilarities, the overriding pattern is one of congruence among the women's occupational status groups as regards apparel information source importance.

Further, it is of strategic importance for retailers to note that the dominant source of apparel information for all three groups of women was shopping in retail stores. This, of course, is the "source" which is most directly under the control of the retailer. The fact that all three types of women studied are turning to the store as their most important source regarding apparel information provides a substantial degree of strategic maneuverability to retailers who take advantage of this role.

Summary

This research explored the congruence between externally and internally ascribed occupational status for women, and the relationship that internally ascribed status has on various aspects of women's retail patronage. It was found that, for the respondents studied, there was very great consistency between internal and external occupational status ascriptions.

With regard to the relationship between internal status ascription and retail patronage, the following conclusions were reached: First, Career Women shop at specialty stores more than do Working Women or Homemakers. Second, Career Women and Working Women tended to shop more in the evenings and on weekends than did Homemakers. Third, Career Women, Working Women and Homemakers displayed substantially different factor structures for retail relevant attributes. Finally, rankings of importance for apparel information sources were found to be largely congruent among the three occupational status groups.

CONSUMER SOCIALIZATION FACTORS IN A PATRONAGE MODEL OF CONSUMER BEHAVIOR

William R. Darden, University of Arkansas

Roy Howell, University of Illinois
Shirley J. Miller, University of Arkansas

Abstract

The paper proposes that patronage behavior is more strongly influenced by consumer socialization than is brand choice behavior. The paper draws upon theory from sociology and business to make this case. In conclusion it strongly suggests that patronage theory has much to offer strategic planners and is therefore a research area with great potential.

Introduction

Thomas Kuhn, in The Structure of Scientific Revolutions (1970), described the pre-paradigmatic state of a science:

"In the absence of a paradigm or some candidate for paradigm, all of the facts that could possibly pertain to the development of a given science are likely to seem equally relevant. As a result, early fact-gathering is a far more nearly random activity than the one that subsequent scientific development makes familiar. Furthermore, in the absence of a reason for seeking some particular form of more recondite information, early fact-gathering is usually restricted to the wealth of data that lie ready to hand. The resulting pool of facts contains those accessible to casual observation and experiment together with some of the more esoteric data retrievable from established crafts like medicine...." (Kuhn 1970, p. 15).

It is rather obvious that Kuhn has described the history of marketing science, just as his description applies to physics, biology, etc. Early marketing science was conducted largely by practitioners of a pragmatic bent. Their variables were the ones which seemed most obvious to them, and each seemed as important as the others.

In 1963 Howard presented what was to become the Howard-Sheth Model, the most extensive and well-known system model of consumer behavior (1969). In 1966 Nicosia presented his flow diagram-simulation of consumer behavior and suggested several areas of behavioral research for marketers. The "school phase" of marketing history was established with the presentation of the "multimediation" model of Engel, Kollat and Blackwell, the point at which we now find ourselves (1973).

"Under these circumstances, the dialogue of the resulting books was often directed as much to the members of other schools as it was to nature. That pattern is not unfamiliar in a number of creative fields today, nor is it incompatible with significant discovery and invention" (Kuhn 1970, p. 13).

Kuhn continues by showing that science does not proceed by accretion, the pattern once ascribed to science by historians, but by the production of revolutions in normal science which result in paradigms. "...it remains an open question what parts of social science have yet acquired such paradigms at all."

In the absence of such a paradigm, marketing can hardly afford to ignore the schools which have developed in the closely related social sciences, since their volume of received knowledge is at least larger than our own.

Paper Objectives

Socialization is not, of course, a new variable in the study of consumer behavior. In terms of "received knowledge," socialization receives attention in almost every consumer behavior text either explicitly or implicitly. Engel, et al., (1973) includes such variables as beliefs, attitudes, motives, personality, life style, normative compliance, cultural norms, reference group and family influences, etc., in their model, all of which are the result, in the individual, of the socialization process (Berkman and Gilson 1978).

Most large system models, however, focus on brand choice behavior. For example, Engel et al., use the socialization process to explain brand choice behavior. Yet little has been written on the influence of the socialization process on patronage behavior. In addition, the consumer behavior literature rarely addresses the influence of "adult socialization" on the consumer. There is evidence that adult socialization has great impact on patronage choice behavior under a number of life cycle conditions. Furthermore, there is increasing evidence that patronage choice behavior is a major factor in explaining consumer behavior. Thus the socialization process as it applies to adults may be relatively more important to decision makers than is understanding the socialization process as it applies to adolescents (Ward 1974 and Moschis and Churchill 1978).

The objective of this paper is to present some arguments for research in the areas of adult socialization and patronage choice behavior. In particular, the paper proposes that adult socialization impinges on shopping orientations and store choice criteria, and that this relationship changes as the consumer proceeds through the stages of the family life cycle.

Figure 1 depicts the Patronage Model of Consumer Behavior, which is to be used in this paper to help illustrate the relationships between adult socialization and patronage behavior (Darden 1979).

Theoretical Background

There are numerous approaches to the study of socialization. The major concepts of the social learning theorists include imitation, shaping, reward and punishment. The developmentalists include the Freudians who are concerned with social repression of psychosexual instincts and the Piaget school with the interactive maturational unfolding of innate mechanisms. The interactionists and phenomenologists are more interested in the interaction between the situation and the role or knowledge which the individual brings to the situation in order to act, rather than react within it.

All schools of thinking, however, are agreed that, no matter what the process of socialization involves, it is an ongoing process. While it is more dramatic to watch a human infant learning its culture, the adult, too, is continually interacting with its culture in a fluid process.

Perhaps one of the first to take note of the importance of adult socialization was Erik Erikson (1950), with his "Seven Stages of Man," in which he called attention to the

"It is doubtful that one comes on a role in later life without any fragments at all of relevant socialization; the inexperienced mother may seem to know little, but she knows something, and, even more, she has response elements for the role performance that are not manifest at the conscious level."

Both socialization and resocialization are important in most adults' lives. As Babbie (1980) points out:

"Every time you interact with someone, you are being further socialized by that person, and you are socializing him or her. When you buy something in a store, you learn a little more about being a customer, and the salesperson learns a little more about being a salesperson. You may not have noticed it, but your understanding of the role of customer probably changed a little in the process."

But Brim (1966) points out there are some important significant others which affect the adult at various points in the life cycle. Brim discusses four major sources of adult resocialization (our term, not his): (1) Mobility, geographical and social; (2) Variance in customs in society (social change); (3) Changes in the content of socialization, arising from passage into different stages of the life cycle and different institutions; and (4) Where childhood socialization was incomplete.

Geographical mobility is a highly relevant factor in American society today, although there are indications that people are moving less than they did a few years ago. With the great amount of homogenization which has occurred as a result of national chains and mass media (Where can you go in America and not be understood when you ask for a "Big Mac"?), this factor may become even less important, within the society. However, it is still important, as a look at such publications as the Sterns' Roadfood (1978) or Rice and Wolf's Where to Eat in America (1979) reveals.

Social mobility has perhaps been overstressed in American society, since statistics indicate that much less vertical mobility actually occurs than the American Dream would have us believe (Robertson 1977). However, as there are strong indications that we are becoming a nation of white collar workers (Robertson 1977), and as the number of people with some college education keeps rising (Robertson 1977), social mobility is obviously an important source of adult resocialization. Much resocialization demanded by upward mobility is perhaps accomplished through anticipatory socialization (Merton 1968), and some through the mass media (*Playboy*, for example, and *Mad Magazine*; see Winick 1962; and Darden 1976).

Variance in the customs in society, or social change, affects people much more evenly, since most members of a society are subject to these pressures at relatively the same time periods. Babbie (1980:147ff) gives as examples of such factors war and social movements. These kinds of changes are perhaps more dramatic and more obvious to the participants, although some are much more obviously accepted than others.

Changes in the content of socialization which arise from different stages in the life cycle affect every normal adult in American society, although not continuously. It is expected, for example, that every adult get married, entailing a transformation from one status to another, but this transformation is expected to be performed within a definite period of time (Ritzer 1977). Moreover, it is usually expected that one's peers are undergoing such transformations themselves at relatively similar times, so that they help and give support during the resocialization process.

Brim's fourth category of resocialization factors, those which occur where childhood socialization has been incomplete, are not normally expected of a member of society, and in most cases result in institutionalization.

Normal adult socialization, as Babbie (1980) points out, is a feature of every interaction with everyone. He points out further that the main sources of such socialization are such agents as formal schools (colleges, vocational and professional schools), on the job training, and the military. One's peers are, as in childhood, the most important agents of socialization for adults, as they are for adult resocialization.

Socialization: Patronage Theory vs. Brand Choice

Socialization involves learning the norms of one's society. All human behavior is said to be normative, socialized behavior. Socialized behavior must be meaningful to the individual, and it must be learned in interaction with the individual's environment. The environment includes other actors as well as props, or material aspects of the culture. Most learning is at least as abstract as the concept "many," according to linguists.

Thus, as the behavior becomes more meaningful, the symbolic and cultural aspects become more important in its determination. Marketers have demonstrated, for example, the greater importance of group influence on more visible product choices than on those less visible (Bourne 1956) (people see your choice in cigarette brands and in part define you by your use of filters or nonfilters, etc., whereas few people see your choice of underwear and shape your identity accordingly). It is our contention that store choice, i.e., patronage behavior, is more highly visible behavior than is brand choice, for many kinds of purchases. One does not simply choose the closest retail outlet, but rather chooses that outlet which fits his image of himself, a store where he is apt to meet other people who are "like him," who are apt to be his friends (Tauber 1972), and where he can find the kinds of products which people "like him" find acceptable. Massey (1973), for example, describes the behavior of many patrons of pornography shops as being furtive and secretive, because they do not want people "like them" to see them there, wishing probably to disavow this aspect of themselves as parts of their announced identities.

As related to Brim's three important sources of adult resocialization, patronage behavior would seem to be very important.

In terms of geographical behavior, it has been found (Andreasen 1968) that people who move to another area establish their patronage habits rapidly.

Social mobility obviously involves a great deal of change in patronage behavior, as people "on the move" try to determine where people "like them" or "like they want to be" do their shopping. Much of this behavior may be exploratory, at least initially.

Variance of customs in society as a result of social change need not have any marketing implications, but most likely does. Certainly, a war can cause disruption in patronage behavior, caused by the absence of products from the marketplace, etc. Social movements probably affect most adults' patronage habits very little, although those convention cities in states which have not adopted the E.R.A. may find a difference of some degree.

Probably the largest amount of patronage behavior to be explained by socialization and resocialization occurs as a result of status changes caused by entrance into different stages of the life cycle, and by different institutions.

Socialization and Patronage Theory

Although consumer research to date has virtually equated socialization with young people (as young people are the most common referent for socialization research), it is clear that consumer socialization can and does continue

throughout the entire adult life cycle (Brim 1966; Rose 1979; Riley, et al., 1969). We will be concerned here with both adolescent and adult consumer socialization, as it is perceived that socialization to the shopping task and the retail environment is a recurring phenomenon throughout the life cycle. As discussed by Sigel and Hoskin (1977), the relative importance of early socialization as compared to adult socialization is unclear. The persistence-beyond-childhood model of socialization would accord primary importance to the socialization acquired in childhood, while at the other extreme the constant change model, "...while not excluding childhood socialization, argues that adulthood brings the organism into contact with new experiences (new settings, novel events, new responsibilities, changes in biological and social status) which have a powerful socializing impact on the individual" (Sigel and Hoskin 1977, p. 262). The true position is assumed to be somewhere between these two extreme theories.

Values

Human values, operationalized in the patronage model through the Rokeach (1973) paradigm of terminal and instrumental values (reflecting the individual's perception of some end-states of existence and modes of conduct as personally and socially preferable to alternative end-states of existence and modes of conduct) are given a prominent role in the patronage model, reflecting their centrality as constructs in consumer behavior. Values, in the Rokeach (1973) sense, are highly central and quite general, conceptualized as forming the basis for judgments in more narrowly defined situations or with specific referents. Since, in the broad sense, socialization is defined as the transmittal of culture, and since the basis of culture is the norms and bounds of acceptable variations in value systems (Clawson and Vinson 1977), it follows that the development and maintenance of a value system is, for the individual, at least in part a socialization process (Simpson 1977). This socialization may be imparted through agents such as the family, school system, peer group, or mass media in early life, while adult value socialization may be the result of the work group (occupation), geographic or social mobility, or the mass media, in addition to other factors. Rokeach (1973) has found that values differ by age group, social class, gender, and occupation. Darden, et al., (1979) have similarly shown that values are related to shopping orientations, as are the above four variables. While direction of causation is difficult to ascertain for the relationships between social class and values and the relationship between occupation and values (as will be discussed below), it can be seen that values, and thus the socialization process, play an important role in determining shopping orientations, and thus patronage behavior, both in their direct effects and as intervening variables.

Sex Role

It is generally accepted that the acquisition of a sex-role orientation is a socialization process. While the socialization agent is typically the same-sex parent, both one's peers and the mass media play a part in the sex role socialization of the individual through the identificatory process. It is felt that, in this case, one is socialized to a sex-role early in life, although it is possible for an adult to be socialized to some degree by agents reflecting the current cultural sex-role norms (Bandura 1969). While we will strictly avoid the estrogen/androgen vs. socialization argument here, suffice it to say that at least some of the sex-role variation found between males and females is due to the internalization of social norms of behavior.

The sex-role orientation of the individual with respect to shopping is a strict and important subset of that individual's general sex role orientation; the implications of

the sex-role socialization process, given the traditional sex roles in U.S. culture, on patronage behavior are numerous. To a large extent, shopping is considered the woman's domain: men are neither exposed to a shopping role model nor encouraged by their peers to be a "good" shopper. Thus, shopping tends to be a less well internalized role for the male, resulting in major differences in patronage behavior from females, who have traditionally had a strong role model in the shopping context, and thus strong anticipatory socialization to the role.

In addition to placing value on the female's family role of being a "good" shopper, the traditional female sex-role stereotype tends to sanction shopping as a legitimate social/recreational activity in which wives/mothers can engage with their peers while at the same time being "productive." Similarly, the traditional wife/mother role for which females are prepared through anticipatory socialization embodies fairly narrow life space. Shopping may thus be viewed as a sanctioned vehicle for otherwise deprived social interaction. While both of these conditions suggest different shopping orientations for males and females socialized to traditional sex-roles, and thus different modes of patronage behavior, they also suggest that the female will be more susceptible to adult socialization in the shopping task through peer influence. While this discussion is not exhaustive of the potential impacts of sex-role socialization on patronage behavior, it does indicate the importance of socialization processes in this area.

Occupation

One key aspect of social learning is "anticipatory socialization" of children and adolescents for work roles in later life (Turner 1971). Similarly, adults tend to be socialized to the work environment by their peers and the organization of the work situation with this close interaction extending the realm of socialization in some cases to roles and orientations beyond the workplace (Lorence and Mortimer 1979).

As Turner (1971) notes, the father's occupation plays a large role in determining the roles to which the adolescent will be exposed, and the nature of the "anticipatory socialization" which will occur, noting the particular impact of having a father who is in an entrepreneurial occupation.

Of particular interest here is the impact of having a parent employed in retailing. Darden, Howell and Powell (1980) have documented the extent of retail work experience in the U.S., indicating that this is not an extremely limited phenomenon, with over 35% of each of three separate random samples reporting having worked in retailing. The effect of having a parent working in retailing on the socialization process would seem to be significant, as would the effect of this unique socialization experience on subsequent patronage behavior.

Even more significant is the socialization experience acquired from working in retailing. Darden, Howell and Powell (1980) produce evidence that retail work experience, viewed as a socialization factor, is related to shopping orientations, attitudes toward retailers and retailing, and retail patronage behavior.

Mobility

Geographic mobility is one of the primary forces bringing about adult consumer socialization. A move to a new community requires a high degree of resocialization to different customs, subcultures, shopping norms and retail structure. It means, perhaps, a new job with new peers and a new organizational structure. It may mean a new set of roles for which the individual may or may not be prepared. It means the search for new role models. The farther the move (especially culturally), the greater the degree of

socialization which must take place (assuming that the individual does not engage in "expedient" socialization, wherein one learns new specific norms and behaviors but fails to internalize them, maintaining primary orientation to former norms) (Bandura 1969).

As noted by Darden, French and Howell (1978), mobile consumers have different general and shopping specific life stages, perhaps as an adaptation to the recurring resocialization process.

Age

When age is employed as a variable in consumer research in general or patronage research in particular, it is recognized that it is in fact a proxy for a number of factors, some of which are reflective of social learning. The multiple influences subsumed under age may affect patronage behavior in different ways; it is thus useful to identify them such that they can, perhaps, be measured explicitly.

In one sense, age serves as a general indicator of accumulated life experience, reflecting the extent, if not the specific nature, of the socialization process.

Age is also a component of the family life cycle, carrying with it unequal probabilities of being married, having children in the home, and the other factors which comprise the FLC, as well as altering the probability of the geographic mobility of the individual.

Age also brings with it differing levels of physical prowess and agility, thus affecting the physical cost of shopping, as well as altering the information processing style of the individual.

Finally, age reflects a cohort with similar socialization experiences based on macro-environmental events and evolution. The age cohort is also likely to reflect similar patterns of socialization based on the role-models, educational philosophy, and media available at various stages of their socialization process. Thus, when one finds that a patronage variable increases or decreases with age, one cannot partial out the cohort effects from the other effects, making inference about what the "younger" people will do when as they grow older impossible from cross-sectional data (Outler 1977), unless socialization life cycle, individual, and cohort effects are measured separately.

Conclusions and Implications

The purpose of this paper has been to use the Patronage Model of Consumer Behavior to demonstrate the impact of consumer socialization on patronage behavior. Some conclusions are listed below:

1. Consumer socialization affects patronage behavior differentially at each stage in the family life cycle.
2. While age is important in the family life cycle, it has additional implications for consumer socialization and its relation to patronage behavior.
3. Modeling, reinforcement and social interaction have significant impact on the Patronage Model of Consumer Behavior shown in Figure 1. For example, Darden, et al., (1980) suggest that retail work experience provides consumer socialization of a technical nature that significantly effects select shopping orientations. For example, those with high levels of retail work experience are likely to be quality shoppers.

4. Darden, et al., (1978) show that instrumental and terminal values are related to shopping orientations. It seems likely that consumer socialization provides the raison d'être for much of this change in values. Thus if consumer socialization changes values, it may indirectly--as well as directly--affect patronage behavior.

The introduction to this paper presented Kuhn's views on the genesis of research direction in a discipline. He stresses that scientific disciplines develop using the data at hand, rather than addressing necessarily the most critical issues. From our discussion it seems likely that patronage behavior is a critical area in marketing that deserves more attention than it has received in the past. Darden (1979) presents several reasons for the neglect of patronage research, all of them supporting Kuhn's theory.

As suggested by Kuhn a discipline can benefit from placing research emphasis in critical areas. The current emphasis on "strategic planning" in marketing could benefit from a comprehensive knowledge of patronage behavior. Strategic planning requires an understanding of the process by which consumers choose stores. Manufacturers and large chain retailers can no longer afford the inefficiency of concentrating solely on brand choice behavior in planning their distribution and promotional strategies.

AN EXPLORATORY INVESTIGATION OF MEDIATING FACTORS IN RETAIL STORE IMAGE RESPONSES

Robert A. Peterson, University of Texas at Austin

Abstract

This paper proposes a general paradigm for investigating retail store images which takes into account the context of the research. An example illustrating several of the concepts set forth is provided.

Introduction

A considerable amount of research in the area of retail patronage has been concerned with the concept of store image. For example, research has been conducted regarding the role of store image in determining store loyalty and choice (e.g., Anderson and Scott 1970; Lessig 1973; Schiffman, Dash and Dillon 1977). Likewise, research has been conducted to investigate possible relationships between consumer self-images and retail store images (e.g., Bellenger, Steinberg and Stanton 1976; Dornoff and Tatham 1972), and differences between consumers' images and retailers' images (e.g., Pathak, Crissy and Sweitzer 1974-75). Indeed, an entire issue of the Journal of Retailing was devoted to store image research.¹ Finally, the importance of store image research as a managerial strategy was recently documented by King, Tigert and Ring (1979).

Moreover, because of its importance, a substantial amount of research has been dedicated to improving the measurement of retail store image. Empirical studies focusing on both validity and reliability issues have been reported in the literature (e.g., Hawkins, Best and Albaum 1975-76; McDougall and Fry 1974-75; Menezes and Elbert 1979), and several contributions made. In addition, progress has recently been made in determining the manner in which store images are formed (Reich, Ferguson and Weinberger 1977).

Purpose

The purpose of this paper is not to review and/or summarize the (ponderous) research on retail store image. Nor is it to offer new findings on store image determinants or methodological approaches to measuring store image. Rather, the purpose is more modest. It is to propose and illustrate a paradigm for more fully evaluating and interpreting retail store image data. While this paradigm can be applied in many research situations, it is particularly appropriate in store image research since there is a paucity of both physical and conceptual criteria against which to evaluate research conclusions.

Because of the desire to stimulate discussion as well as thought, no attempt is made to present an exhaustive documentation of appropriate literature. That task will be left to a later, more systematic exposition of the insights offered here. It is assumed that researchers interested in store images will already be thoroughly familiar with the appropriate literature.

A Paradigm

Investigating consumer images of retail stores is a relatively straightforward and standardized research activity. In the typical store image study a sample of consumers is selected, questionnaires administered, resulting data analyzed, and inferences drawn about image similarities and

differences among the stores investigated. Few researchers, however, are naive enough to believe that image differences observed to exist among stores---as reflected by one or more scale or question responses---can be interpreted at face value. Instead, differences must be considered within the context in which the data were collected.

In particular, image differences observed between retail stores may not arise solely as a result of perceived differences between the stores (the stimulus objects). Although the majority of the variance in consumer image responses may be due to differences between stores, other, frequently confounding, factors may account for some of the variance as well. Conceptually, responses to an image question can be thought of as reflecting a plethora of factors and influences, only one of which is stimulus object-related. Symbolically

$$R = f(SO, SC, MI, M, EN, E) \quad (1)$$

where

R represents an image response (in general or in particular);

SO represents stimulus object characteristics;

SC represents subject (consumer) characteristics;

MI represents measurement instrument characteristics;

M represents mode of data collection;

EN represents the data collection environment; and

E represents extraneous or error factors.

Subject characteristics consist of a wide variety of factors and influences. Many of them are relatively permanent and general in nature, such as demographic or personality characteristics. Others, like mood, are more transitory, while still others are specific to the research situation (e.g., response syndromes like haloing or yeasaying).

Three categories of factors are methodological in nature. Measurement instrument characteristics include type of question (open or closed end), nature of questionnaire, and so forth. Data collection mode refers to whether data are collected by means of telephone, mail or personal interviews, and whether questionnaires are self- or other-administered. Environmental factors include physical, social, and temporal (time of day, etc.) influences. The list of factors is nearly endless.

Factors within each category as well as the entire categories themselves interact and collectively result in an image response. Many of the nonstimulus object factors can be considered mediating factors in that they intervene between a stimulus and a response. Such factors can confound, bias, attenuate, or otherwise adversely influence an image response. In the extreme case an image response may actually be more an artifact of the mediating factors than be reflective of stimulus object characteristics.

In general, the above paradigm can be viewed as merely an application of concepts derived from SOR learning theory and environmental and gestalt psychology. Thus, underlying assumptions and axioms are well described elsewhere and need not be reiterated here. The remainder of this paper consists of an example illustrating, in a nonabstract manner, some of the notions expressed in the paradigm. Although the research is exploratory, it is hoped that insights will be obtained into, and an appreciation gained of, factors in store image research.

Illustration

Method

To collect requisite study data a 2X2X2 experimental design was employed. Two classes of undergraduate marketing students, 347 individuals in total, served as subjects.

Subjects were requested to complete a three-page questionnaire consisting of retail store image questions, shopping behavior questions, and several self-perception and demographic questions. The dependent variables investigated were 10 common retail store image dimensions. These dimensions were presented in the form of 7-point rating scales and addressed such characteristics as prices, merchandise quality, sales personnel, and physical layout. The specific scale content is irrelevant for the present discussion. However, approximately half of the subjects were administered the scales in a bipolar (semantic differential) format while the other half were administered the scales in a unipolar (stapel scale) format. This treatment, labeled V1, was designed to serve as a measurement instrument (MI) characteristic. In addition, half of the subjects evaluated Foley's Department Store, a large component of the Federated group, while the other half evaluated Penney's. This treatment was labeled V2; it served as a measure of stimulus object characteristics.

The third treatment was environment. About two-thirds of the subjects completed their questionnaires in a classroom with controlled conditions at one point in time. The remaining third were allowed to complete their questionnaires at their leisure, outside of a classroom environment, and return them at their convenience.² This treatment was labeled V3.

Four other variables in the subject characteristic category were also investigated. These variables were, respectively,
 ---sex (V4);
 ---shopping frequency at ___ department store (V5);
 ---general interest in department stores (V6); and
 ---mood at time of questionnaire completion (V7).
 Shopping frequency and interest were measured using 4-point rating scales. Mood was measured by means of a 6-item Likert-type summated rating scale. Scale scores ranged from 5 (good mood) to 30 (bad mood), with a mean of 16.2, and standard deviation of 3.5. Because of its temporary nature mood was deemed a "nuisance" factor.

Analysis

Initially relationships between the set of 10 dependent variables and the set of 7 independent variables were investigated through canonical analysis. This resulted in 3 canonical roots (functions) being statistically significant at the .07 level or greater. Canonical loadings for the 7 independent variables are given in Table 1. The first root was by far the most significant, with $p < .0001$; it accounted for 71 percent of the explainable variance. Together, the next two roots only accounted for 19 percent of the explainable variance.

Function I is clearly dominated by V2; 76 percent of its communality is accounted for by stimulus object characteristics. Function II is essentially an interest-frequency function since these variables load most heavily. The third function can be interpreted as reflecting the influence of mediating factors since all independent variables but stimulus object characteristics possessed

2

The low return rate of the latter group accounted for the size differences in the treatment levels.

significant canonical loadings.³ With regard to the variance explained by each independent variable, stimulus object characteristics accounted for the largest percentage of explained variance in the dependent variable set while mood accounted for the smallest percentage of explained variance.

TABLE 1
Independent Variable Canonical Loadings

Variable	Canonical Function		
	I	II	III
V1 (polarity)	.04	.13	.32
V2 (store)	.93	-.28	.08
V3 (environment)	-.02	.06	-.55
V4 (sex)	.29	.11	-.62
V5 (frequency)	.26	.52	.55
V6 (interest)	.34	.74	.39
V7 (mood)	-.02	.16	.40

To obtain greater insights into specific variable interactions an analysis of variance was conducted for each of the 10 dependent variables. However, to make each analysis more manageable, only four independent variables were retained for investigation:

---V2 (store)
 ---V4 (sex)
 ---V5 (frequency)
 ---V6 (interest).

Using a significance criterion of .05, only 27 of 150 possible effects were statistically significant. Of these 27 effects, 22 were main effects, broken down as follows:

Variable	Number of Main Effect Significant
V2 (store)	7
V4 (sex)	8
V5 (frequency)	6
V6 (interest)	1

There was no consistent pattern to the 5 interaction effects that were statistically significant. Moreover, the substantive significance of any effect was marginal at best.

Conclusion

This paper has suggested a paradigm for empirically investigating retail store images. By means of this paradigm a researcher can evaluate store image differences in a holistic sense, simultaneously taking into account perceived differences between stimulus objects and mediating (intervening) factors. This would allow, in turn, quantitative evaluation of the various factors influencing image perceptions apart from store perceptions per se.

While the results of the example are not extremely significant, they are sufficiently strong to both illustrate the concepts espoused and warrant further research. Other possible influencing factors need to be empirically explored and categorized as to their importance. Ultimately, a typology of influencing factors needs to be constructed so that store image data can be better evaluated with regard to the manner in which they are collected. The benefits of so doing are both widespread and obvious.

3

Terming a factor mediating or determinant is essentially a function of analytical purpose.

CONDITIONAL LOGIT VERSUS MDA IN THE PREDICTION OF STORE CHOICE

Stephen J. Arnold, Queens University
 Victor Roth, University of Toronto
 Douglas J. Tigert, University of Toronto

Abstract

When a research problem focusses on determinancy of choice rather than on classification or identification of a retailer's strengths and weaknesses, conditional logit analysis is clearly superior to multiple discriminant analysis. Too often, MDA is misused as a methodology for prediction of choice.

Introduction

The research described here was inspired by the recent paper of Gensch and Recker (1979) and by an earlier paper by Westin and Watson (1975). The Gensch and Recker paper provided a comparative analysis of the predictive power and diagnostic quality of conditional logit and regression analysis as applied to the problem of consumer choice of food stores. The paper raised a number of critical issues about the adequacy of a number of covariance choice models when the research question focusses on cross-sectional data rather than individual analyses and when the key research issue is determinancy of choice.

The Westin and Watson paper focussed on the issue of whether or not the population should first be segregated on the basis of "importance" characteristics before predictive models of choice are applied. In addition, the authors also raised the issue of the appropriate model for a choice framework rather than a classification framework. The research objectives for the study reported here were threefold and they build upon the key issues arising from the two papers cited above:

- i) to shed some light on the differences in the underlying assumptions of both the theoretical underpinnings and the quantitative structure of conditional logit and multiple discriminant analysis.
- ii) to test the key assumption of conditional logit related to the concept of a "common behavioural rule" (homogeneity of choice) expressed by McFadden (1974) and challenged by Westin and Watson (1975).
- iii) to examine the diagnostic qualities and predictive powers of conditional logit and discriminant analysis when applied to the same body of data.

The Multinomial, Multiattribute Logit Choice Model

Among the wide variety of competing choice models in the consumer behaviour literature, the logit model belongs to the general class of models described as covariance models. This class includes regression, MDA, logit and probit and is distinguished from other major classes such as Fishbein's (1972) learning-based model, lexicographic models, hierarchical models, multidimensional scaling and linear programming, etc. Some models incorporate individual beliefs about attribute importance while others attempt to derive such weights. The covariance models attempt to derive the weights and then use those weights in the prediction equation(s).

The logit model, which has its foundations within the psychological literature, is consistent with the theory

of sampling from a population of utility maximizing decision makers, and uses the attribute ratings of both chosen and unchosen alternatives in the choice set in order to reveal the determinant attributes. Briefly, the conditional logit model posits that when the n th individual in the population ($n = 1, \dots, N$) has a vector of measured attributes S_n and faces J alternatives which are described by vectors of attributes x_{jn} , then the individual has a utility function

$$U(S_n, x_{jn}) = V(S_n, x_{jn}) + \xi(S_n, x_{jn}) \quad (1)$$

where V is a nonstochastic function reflecting "representative tastes and ξ is stochastic and reflects the idiosyncracies of this individual in tastes for the alternative with attributes x_{jn} . If it is assumed that

$$V(S_n, x_{jn}) = Z_{jn} \theta \quad (2)$$

where $Z_{jn} = (z_{jn}^1, \dots, z_{jn}^k)$,

$$z_{jn}^k = v^k(S_n, x_{jn}), \quad k = 1, \dots, K,$$

$$\theta = (\theta_1, \dots, \theta_k),$$

a vector of unknown parameters, and that ξ is a function that varies randomly in the population with the property that in each possible alternative set $\{x_1, \dots, x_{jn}\}$, the values $\xi(S_n, x_{jn})$ are independently distributed with the Weibull (double exponential) distribution, then McFadden (1974) has shown that the probability P_{in} of the n th individual selecting the i th alternative is

$$P_{in} = \frac{e^{z_{in} \theta}}{\sum_{j=1}^J e^{z_{jn} \theta}} \quad (3)$$

Estimation of the unknown parameters θ is based on a maximum likelihood procedure i.e., finding the vector θ which maximizes the joint probability of observing the particular choice outcomes of each consumer. Mathematically, this procedure is equivalent to maximizing, by any of a variety of programs for unconstrained nonlinear optimization, the adjusted Log likelihood function

$$L = C - \sum_{n=1}^N \sum_{i=1}^J S_{in} \log \sum_{j=1}^J e^{(Z_{jn} - Z_{in}) \theta} \quad (4)$$

where Z_{in} is the vector of "ratings" by the n th consumer of the chosen i th alternative, and Z_{jn} is the vector of "ratings" by the n th consumer of the j th alternative. S_{in} is the value of the dependent variable.

The advantages of the conditional logit model over other methods of identifying determinant attributes are several-fold. The result of the maximum likelihood procedure is that the elements of θ are asymptotically efficient

and normally distributed under very general conditions and that an approximation is good even in small samples ($N > 50$). Also provided are standard errors of each of the elements of $\hat{\theta}$ thus permitting hypothesis testing and construction of confidence intervals. A determinant attribute can therefore be defined as an attribute where the null hypothesis that its coefficient is zero is rejected at the α level of significance.

The logit model can also derive the affect of a change in the choice probability as a result of a change in any of the attributes of any of the alternatives. However, the analyses of these elasticities and cross-elasticities is beyond the scope of this paper. Essentially, the programme requires that a reasonable model is one in which individuals compare all pairs of choice alternatives on the basis of their perceived differences in satisfaction on those attributes possessed by all alternatives. The programme allows for differential consideration sets across respondents so long as there is at least one pair of alternatives. Thus, the research instrument must generate the evoked set for each respondent and provide for a rating system for each alternative on all attributes. S_{in} is the value of the chosen/preferred store in each pair. It could be a dummy variable with the value "1" if the Z_{ij} pair includes the preferred store in which case all pairs of stores which do not include the preferred store are eliminated from the analysis. Alternatively, S_{in} could be the proportion of trips taken to a particular store in proportion of total dollar spending at a particular store, etc. Similarly, the $(Z_{in} - Z_{in})$ net difference scores could be based on semantic differential scales or simpler measurements such as dummy variables which express the extent to which a particular store either did nor did not possess a specific characteristic.

How Does Conditional Logit Differ From MDA

Multiple Discriminant Analysis is a fundamentally different type of model in that it is a classification rather than a choice model. The other techniques, including conditional logit, basically assume one population making choices based on their evaluation of the independent variables. MDA assumes several distinct populations (e.g., shoppers of the different chains), each having different patterns of scores on the independent variables. Discriminant analysis begins by pre-classifying respondents into market segments and then searching for a set of coefficients in n -dimensional space that will maximally separate the groups. Essentially, the discriminant programme examines across versus within group variances on the independent variables and develops a set of discriminant functions that will partition the groups in an n -dimensional space in the most efficient manner. MDA utilizes information only about the chosen alternative for each respondent and looks for patterns of differential scores on the attributes across the groups. There is no underlying relationship between attribute differentials and attribute importance in determining store choice. In conditional logit, it can be hypothesized that where large differences occur in attribute ratings between chosen and unchosen alternatives within the consideration set, then those differences should reflect determinancy of choice.

In addition, the preference probability function in conditional logit analysis overcomes several deficiencies in both discriminant and regression analyses. The computed probabilities are constrained to fall in the range of zero to one. More important, the shape of the logistic curve is theoretically consistent with the consumer choice literature. It assumes that the probability of choosing a given alternative is based on both the current position of that alternative relative to other alternatives

as well as on changes in that position based on improvements on determinant attributes. The logistic curve also recognizes the concept of "threshold" levels. Over certain portions of the curve, small improvements in market position might lead to only small improvements in the probability of choosing a particular alternative whereas at other positions on the curve, small improvements in market position might lead to large increases in the probability of choosing a particular alternative. Neither linear regression nor discriminant analysis incorporate those theoretical concepts. The following empirical section clearly demonstrates the diagnostic and predictive superiority of the multinomial logit model over MDA.

Methodology

The data analyzed were collected via telephone from a central WATS facility in Chicago, by a professional interviewing company. The market survey was conducted in the SMSA of Tampa/St. Petersburg in January, 1978 with all calling in the evening hours to insure the proper representation from working women. The sample of 903 respondents was drawn on the basis of a systematic random sampling procedure from the appropriate telephone directories covering the market area.

Questionnaire Design

The major section of the questionnaire asked respondents to name a single chain that was felt to best answer each of a series of 19 questions representing a fairly exhaustive list of grocery store attributes. Such attributes included dimensions as "lowest prices," "easiest to get to from home," "largest assortment/selection of food products," etc. The procedure, referred to as the associative technique, is simplistic in design and easy to administer by telephone. Its weakness lies in the fact that the attribute ratings on each chain by each respondent are all dummy variables. Either the chain is the best, the lowest, the cleanest, etc., or it is not. However, the diagnostic qualities of the associative technique in pinpointing strengths and weaknesses of the competitive chains in a market are well known (Tigert and Ma 1978).

In a separate section of the questionnaire, respondents were asked to specify both the most important and the second most important reason for choosing the store where they shopped most often. These "attribute importance" questions, generated by the direct questioning method, were not used in either the logit or MDA analysis but are used later in this analysis to help confirm or reject the logit and MDA results. In fact, one might argue that the logit coefficients and/or the MDA standardized discriminant function coefficients provide a measure of the validity of the direct questioning technique in uncovering determinant attributes.

The total set of outlet attributes was fairly exhaustive and included all the dimensions covered by the Lindquist (1974-75) review. They were based, however, on over 100 grocery shopping studies in Canada, the U.S., the Netherlands and the U.K. that have been completed by the authors. A summary of the development of that attribute list is reported in Arnold, Ma and Tigert (1977).

The dependent variable for the analysis was also a dummy variable represented by the specific chain at which the respondent shopped most often. For the MDA analysis, respondents were grouped into chain sets for each of the six largest chains in the Tampa/St. Petersburg market. Of the total sample of 1,000 respondents, 903 were shoppers of one of these six chains and this group forms the sample for the following analyses.

Definition of the Consideration Set

The logit analysis allows for differential consideration sets for each individual. For purposes of this analysis, a specific chain was included in an individual's evoked set if the chain received at least one mention on the 19 store attribute rating questions. Specifically, the chain had to be best on something. While it is hypothetically possible for a consumer to choose an outlet that is not perceived to be best on anything, no respondent was eliminated from the analysis on the basis of the screening criteria. As shown in the first column of Table 1, the average respondent had about 4 chains in the consideration set and therefore about 6 pairs of stores on which the net difference scores were computed. These results are consistent with the findings of Gensch and Recker (1979).

A Test of the Homogeneity of Choice Assumption

The logit analysis was first completed over the total sample of 903 respondents. Subsequently, three sub-samples of respondents were selected based on their responses to the direct questioning procedure on attribute importance. One sub-sample reported that "lowest prices" was the single most important reason for choosing the store where they shopped most often. A second group mentioned "assortment/variety of food products" and a third group rated "easiest to get to from home" as the most important attribute.

The logit model was estimated using for the choice object, the ratings of the store "shopped most often" rather than the store "shopped last" or a number of other shopping ratings included in the questionnaire. Previous work by Tigert and Arnold (1980) suggested that better predictions and higher logit coefficients result when using store shopped most often.

The strength and diagnostic quality of the logit model versus MDA was examined by comparing the hit ratios in the prediction results as well as the size and signs of the coefficients relative to the results of the direct questioning procedure on attribute importance.

Results

Table 1 reports on the results of the logit analysis and presents a series of logit coefficients for the total sample and for the three sub-samples described earlier. The coefficients are reported only for the most significant attributes from two different computer runs. In the top half of the table, only five attributes are reported. These five dimensions, covering location, price, assortment and service (2), have consistently appeared in the retailing literature as key determinants of store choice and they generated an 80 percent correct prediction in the logit model.

To investigate the improvement that could be achieved by expanding the attribute set, a second run was made with the same five attributes plus the next best three attributes. The logit coefficients for the original five attributes changed only marginally and the predictive power of the logit model improved only slightly to 81 percent correct prediction.

By far the most powerful store attribute was location/convenience ("easiest to get to from home") with a logit coefficient of 1.48 for the total sample. In the MDA analysis, this dimension was not significant at all in discriminating between the six shopper groups. The rationale for this major difference in results is directly traceable to the use of net difference scores versus absolute ratings on the chains. Table 2 sheds some light on this key concept.

TABLE 1

TAMPA/ST. PETERSBURG SUPERMARKET DATA: LOGIT COEFFICIENTS FOR MULTINOMINAL MULTIATTRIBUTE LOGIT CHOICE MODEL

STORE ATTRIBUTE	COEFFICIENTS FOR:			
	TOTAL SAMPLE	SUBSAMPLES WHO SAID EACH ATTRIBUTE WAS MOST IMPORTANT IN CHOOSING PREFERRED STORE		
		Low Price	Assortment/ Variety	Location

* Not significant at .05 level

** Read: For the total sample of 903 respondents, the highest logit coefficient occurred for the "location/convenience" variable at 1.48. The coefficient rises to 2.69 for the sub-sample that indicated location was the most important variable in choosing their preferred store.

a) New variables

If we assume that convenience to home is a necessary condition to move a chain into the consideration set, then it would seem reasonable to hypothesize that many consumers would shop most often at the chain that was the "easiest one to get to from home". Thus, we would expect to find that in the associative technique, a large proportion of consumers would report that the chain at which they shopped most often was also the chain that was easiest to get to. The first row of Table 2 confirms that hypothesis. The average percentage across the row (weighted by chain market size) is 71 percent and there is very little variance across the chains. Thus, in terms of the analytical procedure used by MDA, the mean

TABLE 2

SUMMARY: SHARE OF MENTIONS GOING TO EACH CHAIN AMONG THOSE WHO SHOP MOST OFTEN AT THAT SAME CHAIN

Store Characteristics	Store Shopped Most Often

scores on this dimension across the six shopper groups would show little variance and would not therefore, provide much discriminatory power. As a consequence, in spite of the fact that location is a critical determinant of store choice, the results of the MDA would be negative in terms of the classification objectives. Attributes which do exhibit a high variance across the columns include: i) lowest prices; ii) specialty baked goods; iii) best delicatessen; iv) cleanest stores, etc. In fact, these were the dimensions that were the most significant in the MDA analysis. In short, what MDA does is provide strong diagnostics on how the chains are perceived by their own customers to be different on the various attributes but not which attributes were the most critical in determining store choice.

The Logit analysis focusses directly on store choice. It is because the chains all score fairly high on easiest to get to from home among their own customers that the net difference scores are so high. Unchosen stores received very few mentions as rating best on location.

This basic difference in the research objectives of logit and MDA lead to very different results in terms of predictive power in classifying respondents as shoppers of their preferred outlet. Table 3 shows the MDA analysis generated only 55.4 percent correct predictions compared to 81.4 percent for the logit analysis. The improvement in pred-

ictive power of the logit over the MDA was 26/55 or about 47 percent.

More important, the logit classification was very close to the actual market share positions of the chains while the MDA results were off by more than 100 percent for some chains. Yet, MDA continues to be used extensively in marketing research for purposes of classifying consumers and predicting choice. In fairness to MDA, we should report that when MDA mis-predicted, it tended to misclassify respondents into the shopper set closest to the correct chain in the perceptual map (not shown). For example, the misclassified Kash N Karry shoppers were almost all classified as either U-Save shoppers or Pantry Pride shoppers.

Testing Homogeneity of Choice

The underlying assumption of logit analysis is that all consumers have a homogeneous and "representative" set of attributes by which they maximize their utility of store choice. To test this assumption in terms of the relative strength of the logit coefficients, we re-ran the logit analysis for the three sub-samples described earlier. For the sub-sample that indicated earlier in the questionnaire that "lowest prices" were the most important store attribute in choosing the store where they shopped most often, the size of the logit coefficient on "lowest

prices", rose dramatically, from 0.71 for the total sample, to 1.87 for this sub-sample. Simultaneously, the coefficient on assortment of food dropped precipitously to a non-significant level and the coefficient for location dropped by half. The conclusion about this segmentation analysis is transparent. Consumers who seek out primarily low prices are prepared to trade away both location and assortment for price. The results have major strategic significance for grocery retailing and suggest that both warehouse discount stores and limited assortment box stores in good locations have a bright future.

In the column labelled location in Table 1, the logit coefficient for location/convenience is so overpowering that a number of other coefficients, including the price coefficient, became non-significant. Consumers appear to be operating in a tradeoff mode between price and location. The significance of that tradeoff can be seen more clearly in Exhibit II. Across 14 major markets, in the U.S., Canada, The Netherlands, and the U.K., the authors have asked the same direct questions about attribute importance. At the same time, chains have been monitored in terms of their relative price positions by a large grocery basket of 120 items. Exhibit II reports on the proportion of respondents who said either low prices or location/convenience were the most important reasons for choosing their preferred grocery outlet. When price differentials across chains are small, upwards of 50-55 percent of consumers say they choose their preferred store on the basis of location/convenience. When price differentials rise, the consumer is sensitized to these differentials through advertising, shopping experiences (learning) and word-of-mouth behaviour. The higher the price differential, the larger is the consumer segment that trades away location for price.

Finally, note in Table 1 that the sub-sample labelled assortment/variety yielded the highest logit coefficient for the assortment/variety attribute, the highest coefficient for the "fast checkout" attribute and a moderately strong coefficient for location. This market segment could best be described by the concept of "one-stop shopping....for the hassled consumer". One can visualize a customer who says..."find me a convenient supermarket with everything I need and get me out fast". The super combo, best exemplified by Albertson's in Tampa/St. Petersburg, would seem to be ideally suited to serve this consumer segment.

Logit Coefficients Versus Attribute Importance By Direct Questioning

Table 4 reports on the results of our direct questions to respondents about the most and second most important

Source: Tigert (1980)

reasons for choosing their preferred grocery outlet. The four attributes receiving the most mentions, i.e., location, price, assortment and service, are identical to the four attributes with the highest logit coefficients in Table 1. Attributes such as best delicatessen and best specialty baked goods, that were most significant in the MDA analysis, do not even appear on the list in Table 4. More important, the relative size of the scores in the average column on the right hand side of Table 4 are closely paralleled by the relative size of the logit coefficients in Table 1. Location is clearly the dominant attribute in both tables with price, assortment and service fairly close in second, third and fourth positions.

The logit coefficients, therefore, provide strong support for the direct questioning technique in measuring attribute importance. They also provide support for the early work with gravity models which utilized only two outlet characteristics: i) location (distance from home) and ii) store size (a proxy for assortment). Both the gravity models and conditional logit attempt to incorporate information about all alternatives in the consideration set. MDA does not.

Conclusions

Logit analysis is a powerful tool for understanding consumer choice of food stores, particularly in diagnosing determinant attributes. While MDA is adequate for purposes of perceptual mapping and understanding weaknesses and strengths of alternative chains, its performance is weak in predicting choice and in validating determinant attributes.

A number of research steps should follow the results achieved here. First, there is a need to examine the improvement in results that could be achieved by measuring both attribute importance and store ratings through alternative scales such as semantic differentials or perhaps forced choice. Given the wealth of models now available that allow for differential evoked sets, further improvements could be made in alternative ways of defining evoked sets for individual respondents. Finally, logit analysis is only one of a variety of new models now available for analyzing consumer choice. More comparative analysis across competing models would be helpful in uncovering the most powerful alternatives.

RESEARCH INTO SHOPPING MALL CHOICE BEHAVIOR

Roy D. Howell, University of Illinois-Urbana
Jerry D. Rogers, Southwest Missouri State University

Abstract

This paper explores some of the issues relevant to research into shopping mall choice behavior, including the measurement of patronage, situational specificity, and the level of aggregation in parameter estimation. Results of an exploratory study addressing these issues are presented. The findings suggest that shopping situation should be specified, that multiple indicators of patronage should be employed, and that parameters in a model of mall-choice behavior should initially be estimated separately for each shopping area under study.

Introduction

Consumer researchers have in recent years begun to focus more of their theory-building and empirical research efforts in the area of consumer patronage behavior (Darden 1980). Most of the research in this area has dealt with the store choice decision (Granbois 1977), as is proper and to be expected. Few retail outlets, however, exist as isolated entities. The synergistic effects of multiple retail establishments located in proximity to one another, zoning ordinances which restrict locations in which retail businesses may operate, and the limited availability of "good" free-standing retail sites tend to encourage the clustering of retail trade into relatively compact areas. This clustering may be planned and formalized as a shopping center or shopping mall, may be unplanned, as in traditional downtown shopping areas, or may be formalized *ex post facto*, as in "revitalized" downtown malls. As such, the shopping area has become a legitimate object of research both in its own right and in its effect on the stores of which it is comprised.

As Bucklin (1967) has noted, the intra-urban shopping area, as a retail entity, lies somewhere between the individual store and the urban-entity itself on a scale of disaggregation. Research on shopping center preference and patronage has reflected this positioning, with theory and methodology being drawn from trading area theory, emphasizing the mass-distance relationship (Huff 1964), and from the store choice literature, which emphasizes store "image" and its components (Lindquist 1974-75). Stanley and Sewall (1977) demonstrate how these two approaches can be combined in store-choice research, as do Jain and Mahajan (1979). Recently, Nevin and Houston (1980) have applied a model containing both gravitational and image components to the area of shopping mall choice behavior.

Research into shopping center or shopping mall choice behavior cannot, however, be simply a straightforward extension of the trade area and store choice research streams. While some of the problems present in researching shopping mall preference and patronage are similar to those faced by the researcher investigating at the level of the retail store, others are unique. In particular, three issues confronting researchers investigating shopping mall choice behavior are addressed in this paper. The first of these issues concerns the choice and measurement of image components relative to shopping malls. The second concerns the measurement of patronage behavior. Third, the level of aggregation

appropriate for parameter estimation in models of mall choice behavior is discussed.

These issues are discussed in the context of a study conducted in a medium-size midwestern SMSA. Personal interviews were conducted with two-hundred sixty middle to upper class females chosen from a two-stage area sample. Fifty-one respondents had not patronized any of the three shopping areas in the city, or had otherwise unuseable questionnaires and were thus eliminated from further analysis. The respondents were asked to rate the adequacy of two enclosed shopping malls ("B" and "P") and the "revitalized" downtown area (D) on eighteen attributes (1=very unsatisfactory, 7=very satisfactory), as implied by the adequacy importance model (Mazis, Ahtola, and Klippel 1975). Also measured was the shoppers' distance from each of the three centers, and preference and patronage measures which are discussed below.

Both malls have approximately 270,000 sq. ft., with the downtown area relatively comparable in terms of number and types of stores. All have seven to nine stores carrying women's fashion items (the shopping situation specified in this research), and represent the only major shopping areas in or around the community.

Attribute Measurement

Nevin and Houston are essentially correct in stating that, "...little work has been done on the dimensions of shopping area image" (1980, p. 84). Most applications in mall-choice research have relied heavily on the store image/attitude dimensions described by Lindquist (1974-75). While little work has been done on those dimensions specific to mall choice, some agreement seems to be emerging in the literature on the store image dimensions applicable to the shopping mall.

Aggregating observations across shopping centers studied, Hauser and Koppelman (1979) found, using factor analysis, four dimensions from sixteen attributes, labeled variety, quality and satisfaction, value, and parking. Assessing the structure of sixteen attributes separately for each of the shopping centers in their study, Nevin and Houston (1980) found three dimensions (labeled assortment, facilities, and market posture) which are similar to the dimensions found by Hauser and Koppelman (1979). What is not clear, however, is the appropriateness of items drawn from the store image literature in mall choice research. Clearly, some store image items such as price/value, credit availability, and sales personnel are applicable to the mall choice process only to the degree that the center as an entity has been successful in establishing a cohesive and consistent overall image. Similarly, the mall has attributes which are not among those composing store image, such as special events/exhibits, recreational value, and commons-area atmosphere. Additionally, the contribution of the various store images to the image of the mall, and vice versa, is a question which begs further research.

Also not firmly established is whether the dimensionality of the image/attitude items employed is consistent across centers, or whether consumers' perceptual space differs for each center studied. Hauser and

Koppelman (1979) assume a "basic structure of perceptions" and perform a factor analysis across centers. Nevin and Houston (1980) perform separate factory analyses for each center and, using a test for factor congruency, indicate "a consistent factor structure for all five shopping areas.

In this study, confirmatory factor analysis (Joreskog 1971) was employed to assess both the hypothesized factor structure and the equality of factor structures for each of the centers. The hypothesized factor structure is presented in Table 1. When non-zero covariances are allowed between the factors (Ψ not diagonal), the structure in Table 1 provides an acceptable fit for each of the three centers (average $\chi^2 = 137$ with (171-51=120) d.f., $p < .14$) and for the pooled data. While the coefficients in A and specific variances are substantially similar for each group, the hypothesis that $\Sigma_1 = \Sigma_2 = \Sigma_3 = \Sigma$ (equal covariance matrices for each of the centers), based on the F-statistics derived from Box's M, must be rejected. While the hierarchical hypothesis testing procedures described by Joreskog (1971) for assessing the equality of factor structures of several groups is not strictly applicable in this situation (where we are dealing with one group measured on different sets of variables), we find that the hypothesis of invariant factor pattern cannot be rejected, while the hypothesis of equal specific variances is rejected at the .05 level.

It can be inferred from this that the five factor solution with a general factor pattern such as that in Table 1 is applicable to the attributes of each of the centers, but that the magnitude of the λ in Table 1, and thus the variance of the variables not accounted for by the common factors, differs for the three centers. This further implies that the variance-covariance matrices of the five factors are not equal for each of the three centers.

In order to provide comparability of the coefficients in tests of the overall model, unit weights were employed such that summated scales were formed for each dimension of each center. Table 2 contains the reliability analysis of these and other measures used in this study. The alpha coefficients reported are consistent with the findings of the confirmatory factor analysis in that the attribute structures for B and P (the two enclosed malls) are more similar to each other than either is to the structure of Downtown. The reliabilities reported here compare favorably with those reported by Nevin and Houston (1980).

Distance

The variety of different measures of proximity or distance have been applied in patronage research (Granbois 1977). While it is generally accepted that perceived as well as actual distance is important (Brunner and Mason 1968), many studies have relied on map distance. Others have used ratings of proximity (Gentry and Burns 1977-78) or drive time (Nevin and Houston 1980). In this study, the multiple indicator approach is employed in the measurement of distance in order to account for both perceptual variations and objective distances. One scale, labeled proximity, is composed of map distance measured in blocks and a subjective time estimate measured in minutes. The standardized item scale composed of these two measures exhibits acceptable reliability. To capture more fully the "convenience" aspect of the distance construct, respondents were asked to rate each of the centers with regard to its general availability, the degree of traffic congestion usually encountered in driving to the center, and the general degree of difficulty they encountered in making a shopping trip to the center. These items form the scale labeled accessibility.

Situational Specificity

In this study respondents were asked to rate the attributes of the centers and to report their patronage of each of the centers only in the context of shopping for women's fashion clothing items for themselves or members of their family. In this respect the study is different from most reported research in this area, wherein shopping situation has not been specified.

In store choice research, the stores included as competitors are often highly similar in the distribution of types of merchandise carried by the stores (e.g., department stores are usually analyzed vis à vis other department stores, supermarkets vis à vis other supermarkets, etc.). In such research, global measures of patronage such as number of visits over a given time period, average frequency of visit, last store visited, and other measures of this type are acceptable to the extent that the type of merchandise carried by the stores under consideration is similar. This is not an unacceptable assumption. The distribution of types of stores and thus merchandise line availability in shopping centers is subject to great variability, however, and this variability in merchandise distribution may substantially affect the number of dollars spent, frequency of visit, and other possible measures of patronage, as well as influencing the relationships between image/attitude variables, mass/distance variables, and patronage.

For example, one of the shopping areas in this study (B) is anchored by a large supermarket in addition to a national chain department store. Similarly, the presence of a large discount-drug store distinguishes center P. Observation tends to suggest that such diversity of store types among centers is the rule rather than the exception. In the case where the researcher does not specify the shopping situation, a center such as B, anchored by a supermarket, will show a higher average frequency of visit, etc., than will a center without a supermarket, with this difference quite independent of overall preference or image. Similarly, the relationship between distance and patronage is likely to be larger for a center with a large area devoted to convenience goods and frequently purchased merchandise.

This phenomenon may account for the findings of such studies as Gentry and Burns (1977-78), where proximity is found to out-perform image/attitude variables in explaining frequency of visits.

Specifically, as discussed in the brand choice area by Warsaw (1980), the probability that an individual shops at area j , $P(s_j)$, is in fact dependent on the probability that the individual encounters and shops under condition i , denoted $P(S_i)$. The probability of shopping at area j is thus

$$P(s_j) = \sum_i P(S_i)P(s_j|S_i) \quad (1)$$

Since $P(S_i)$ is not equal for all i (e.g., shopping for food is likely to occur more frequently than shopping for fashion clothing), nor for all individuals (e.g., some individuals shop for food more often than others), and $P(s_j|S_i)$ is not equal for all j given the distribution of merchandise available at the j centers in addition to perceptual factors, attempts to explain the frequency of individuals' shopping trips to j shopping areas, as in Nevin and Houston (1980) and Hauser and Koppelman (1979) are likely to meet with limited success.

By specifying a particular shopping situation, we are dealing with only one S_i . While individual differences in $P(S_i)$ remain, the analysis is not contaminated by merchandise distribution causes of variation in $P(s_j|S_i)$. It is suggested that, in research in this area, the researcher either (1) specify the shopping situation(s), or (2) include variables in the model which represent the number of stores (or square footage) devoted to various types of merchandise in each center.

Much of the research in both store and mall-choice behavior has utilized measures of affect, preference, or behavioral intentions as dependent variables. While this is useful, predicting and explaining behavior is a more rigorous and preferred task. The question is however, just what behavior or behaviors constitute patronage? A variety of measures have been utilized as operational measures of patronage (see Cranbois 1977). The most popular seems to be frequency of visit. Nevin and Houston (1980), for example, utilize shopping frequency measured on a six-point scale ranging from "less than once a year" to "once a week". Hauser and Koppelman (1980) utilize self reported frequency of visits, while Gentry and Burns (1977-78) also utilize frequency of use.

It seems that "patronage" implies more than simply frequently visiting a shopping center. Is the individual who shops frequently, but seldom buys, a "patron" to the same degree as one who not only shops frequently but also buys a large quantity of merchandise at the center? What about the individual who shops infrequently but makes large volume purchases? These considerations, along with the increased measurement reliability obtainable through the use of multiple measures, suggest the use of several indicators in the measurement of patronage.

As can be noted in Table 2, four measures of patronage were combined as a (standardized item) summated scale in this study, exhibiting reasonably good reliabilities. Purchases, frequency of visits, and dollars spent (all over the three months prior to the study) and number of weeks since last purchase were reported by respondents for each of the three centers under study. As there were no strong reasons, *a priori*, that any of the measures were more important than the others, equal weight was given to each. Alternatively, managerial or theoretical considerations may indicate unequal weighting, or the first principle component could be utilized. (Since the items are measured in different units and thus have unequal variances, each was standardized before summation).

Although neither the summated scale approach nor the weighting schemes mentioned above may be optimum in an empirical sense, the measurement of patronage is not an empirical question. In applied, managerially oriented research each of several measures of patronage may be utilized separately as a dependent variable, with the impact of image, distance and other variables estimated for each. For the development of theory in the area of patronage behavior, whether store or shopping mall patronage is concerned, a consistent operationalization of the patronage construct should be defined, and this operationalization should be theoretically richer and operationally more meaningful and reliable than simple frequency of visit.

Estimation

Yet another issue to be addressed in mall-choice research is the specification of and estimation of a model. Inherent in the model estimation issue are decisions concerning the form of the dependent variable(s), the level of aggregation at which the parameters are to be estimated, and the statistical method to be employed. Considerations concerning each of these areas and the approach employed in this study are discussed in turn below.

Dependent Variables

Patronage, however defined or measured, is the compelling choice as an ultimate dependent variable in either store

or mall centered research. However, as discussed earlier, individual differences exist in $P(S_i)$, the probability of encountering and shopping under various situations. The literature on shopping and prepurchase information search clearly documents one rather obvious conclusion: That some people do much more of it than others. Darden's patronage model (1980) suggests numerous factors which may influence the absolute amount of shopping engaged in by an individual. Demographic, life style, life cycle, and socioeconomic variables affect the amount of shopping the consumer will engage in by affecting the length and composition of the individual's "shopping list", or "need queue", and thus the probability and frequency of encountering various shopping situations. Similarly Darden (1980) and Howell (1979) have shown that individuals differ in their shopping specific life styles, or shopping orientations. Shopping orientations such as enjoyment of shopping, recreational shopping, and shopping proneness affect the predisposition to shop and thus the amount of shopping done by consumers encountering a given shopping situation.

The point of this discussion is to indicate that unless one has a very rich data set containing measures such as those described above, attempts to model patronage, as such, will generally be less than satisfactory. In the absence of variables which explore the amount of shopping done by the individual, it would seem that the appropriate ultimate dependent variable should be patronage share rather than any absolute measure of patronage.

Also, most applications in the mall patronage (and store patronage) literature measure either affect, preference intentions, or behavior, in addition to cognitive attitudinal (image) variables and external facilitators (distance). The somewhat lower ability of image measures to explain patronage when included with distance measures can be to some degree accounted for by the failure to model the linkage of these through preference, as is suggested in the behavioral and brand choice literature (see Reibstein 1978), although Nevin and Houston (1980) were actually more successful in explaining frequency of visit than in explaining affect or intentions.

Preference (Y_{ij}) is measured in this study on a 1-6 scale ranging from least preferred to most preferred.

Similarly, it is not clear whether distance/proximity, however measured, is related to behavior through preference or whether it is a facilitator which moderates the affect of preference on behavior. Hauser and Koppelman (1980) address this issue directly by holding availability/accessibility constant. Nevin and Houston's (1980) results seem to indicate that distance is relatively more powerful in explaining intentions and behavior than in explaining affect.

These considerations lead to the testing of a model of the general (simplified) form:

wherein perceptions of each center affect preference for that center, which in turn affects patronage share. Proximity and accessibility are hypothesized as affecting both preference and patronage share.

Model Specification

Given the concept of determinant attributes, and Luce's choice axiom, it does not necessarily follow that having

a high (low) perception of the adequacy of a center on a particular attribute will lead to higher (lower) preference or patronage share for that center, since all of the competing centers could be perceived as being adequate (inadequate) (Bearden 1977).

Thus the adequacy of each center relative to the perceived adequacy of the other competing centers should prove a better predictor of patronage share than absolute level of adequacy. Similarly absolute proximity or accessibility should not be as effective as relative proximity or accessibility in explaining preference or patronage share.

It follows directly from the above discussion that a preferred model in this situation would be a multiplicative competitive interaction model, which has been often employed in retailing research (Stanley and Sewall 1976; Jain and Mahajan 1979; Hansen and Weinberg 1979). To estimate the MCI model through least squares techniques, however requires, in this case, that each center have a non-zero patronage share for each individual. When this is not the case, either (1) individuals who have not patronized all three centers can be deleted, or as is more often the case, (2) individuals can be aggregated by area (Stanley and Sewall 1976; Jain and Mahajan 1979). The first solution may, in many cases, result in an unacceptable and potentially biasing loss of data (Jain and Mahajan 1979), while the second approach presupposes a homogeneity of perceptions within each area. In the absence of substantial empirical evidence to the contrary, this would seem to be a somewhat unrealistic assumption.

Level of Aggregation

Also, the MCI model assumes that the parameters which relate each of the predictors in the model to the dependent variable are the same for all objects (centers) in the market. It seems that this should be treated as an empirical question rather than as an assumption.

The MCI is not unique in its assumption of the applicability of pooling across stores or centers in the parameter estimation process. The use of discriminant function analysis has similar implications. Other techniques, such as least squares regression, can be estimated either across centers or for each center individually. Both approaches are evident in the literature, although the issue is seldom explicitly addressed (Hauser and Koppelman 1980; Nevin and Houston 1980).

An examination of the regression coefficients estimated separately for each center under consideration by Nevin and Houston (1980) seems to indicate that an assumption of equal coefficients would be unwarranted, although they do not test for this explicitly. In particular, the coefficients they obtain for the downtown area in their study seem to be substantially different from those they obtain for the four mall-type shopping centers.

If the parameters relating the predictors to preference and patronage share are (statistically) equal for each of the centers, aggregation is preferred, as the increase in the number of observations used to estimate each parameter will yield estimates with lower variance. However, inappropriate aggregation can lead to biased parameter of estimates. The approach taken in this study is to estimate at the lowest level of aggregation possible; those centers with equal coefficients can be subsequently pooled and reestimated.

Based on the above considerations, the model estimated in this research is

$$Y_{1j} = \sum_{k=1}^7 \beta_{jk1} X_{jk}^* + \epsilon_{1j} \quad (2)$$

$$Y_{2j}^* = Y_{1j} Y_{1j} + \beta_{j62} X_{j6}^* + \beta_{j72} X_{j7}^* + \epsilon_{2j} \quad (3)$$

where:

Y_{1j} - (n x 1) vector of preferences for center j

$$Y_{2j}^* = \frac{Y_{2j}}{3} = \text{n-length of patronage share for center j}$$

$$\sum_{j=1} Y_{2j}$$

$$X_{jk}^* = \frac{X_{jk}}{3} = \frac{X_{jk}}{\sum_{j=1} X_{jk}} = \text{relative perceptions of center j on variable k.}$$

Y_{1j} = influence of preference for center j on patronage share of center j.

As such, this model, though cross-sectional, bears some resemblance to the market share model proposed by Houston and Weiss (1974). As a recursive model, each equation can be estimated using ordinary least-squares methods. However, since equations (2) and (3) are estimated separately for each center (j), important information contained in each error term (ϵ_{1j} and ϵ_{2j}) can be brought to bear on the estimation process.

Consider the three estimates of equation (2) estimating preference for each of the three centers. To the extent that the model fails to account for an individual's preference for shopping center "B", it probably fails similarly to account for that individual's preference for centers "P" and "D" due to factors influencing that individual's preference not included in the model. Similarly, to the extent that the error term for an individual in one of the three preference equations is small, error terms for the other two equations are likely to be small, since the model has captured to a large extent the variables salient to that individual's preference function. Thus, positive covariance is expected between the j error vectors of equation (2).

Since the three error vectors of equation (3) represent mis-estimation of dependent variables whose sum is constrained equal to one, overestimation of patronage share for one center may lead to underestimation of patronage share in the other equations (although \hat{Y}_{2j}^* is not constrained to equal 1.0). As a result, negative covariance is expected among the three error vectors estimated through equation 2. In situations where there is non-zero covariance among the error terms and the variables in the equations are not all equal, the technique developed by Zellner, Seemingly Unrelated Regressions (SUR), can produce estimates with smaller variance than OLS estimates (Johnston 1972), and is thus employed in estimating equations (2) and (3).

Results

Table 3 contains the standardized coefficients corresponding to the parameters to be estimated in equations (2) and (3). Tests for the equality of regression coefficients for the three centers reject the hypothesis of equality at or below the .05 level (Johnston 1972); the estimation of an aggregate model would be inappropriate.

B						
P	.19					
D	-.27	.02				

Generally, the model performs acceptably. In particular, it can be noted that accessibility is a more important predictor of preference for the downtown center than for the other three centers. It can also be noted that proximity is a good predictor of neither preference nor patronage when included in a model including perception of accessibility. Also, accessibility generally affects both preference and patronage, indicating that it acts both as a component of preference and as a facilitator in addition to its affect on preference.

As expected, there is a negative covariance of errors across the three models of patronage share. Unexpectedly, however, the contemporaneous error covariance matrix, Σ , for the equations predicting preference contains both negative and positive elements. In particular, as the model overestimates an individual's preference for center B, it underestimates preference for center D (Downtown). Thus individuals in this sample who prefer "B" do not prefer Downtown, and vice versa, while the errors for "B" and "P" positively covary. This seems to indicate a "preference map" dimension with mall type centers at one extreme and downtown at the other, which is independent of the predictors included in this model.

Conclusions

It is anticipated that this paper has raised more questions than it has answered conclusively. This is intended however, because the issues of attribute and patronage measurement, situational specificity, and model specification and estimation must be specifically and empirically addressed if the investigation of mall-choice behavior is to prove fruitful.

Other issues remain which are not addressed in this paper. One such issue is the relationship between the retail store and the shopping area. Surely this relationship is reciprocal, with store image and preference affecting the image of and preference for the shopping area and center in which it is located, while the image,

location, and preference for a shopping area affects the stores located there. The "special store" variable included by Nevin and Houston (1980) is a step in this direction; more work in this area is required.

Similarly, the model tested in this paper presupposes a one-way relationship between perceptions, preference, and behavior. However perceptions and preference are measurable at a point in time, while behavior is measurable only over a given (past) time period in cross-sectional research. This, in addition to cognitive consistency theories, might indicate a reciprocal relationship between behavior and perceptions. Research is currently underway to test this hypothesis.

RETAIL SHOPPING AREA IMAGE: STRUCTURE AND CONGRUENCY
BETWEEN DOWNTOWN AREAS AND SHOPPING CENTERS

Michael J. Houston, University of Wisconsin-Madison
John R. Nevin, University of Wisconsin-Madison

Abstract

Consumer images of competitive retail outlets are important determinants of retail patronage decisions. The structure of image as it applies to retail shopping areas, i.e., downtown areas and shopping centers, is investigated in this paper. The underlying dimensions of shopping area image are identified and their congruency between downtown areas and shopping centers is tested. Their relative strength of association with overall evaluations of shopping areas is tested for downtown areas and shopping centers. Implications for downtown revitalization efforts are suggested.

Introduction

With the advent of major shopping centers as a type of retail institution another level of retail patronage decisions by consumers has emerged, i.e., choices between different shopping clusters or areas. Shopping clusters are represented by heterogeneous groupings of individual stores, i.e., shopping centers and downtown areas. In many communities the popularity of shopping centers has resulted in a decay of the downtown area as a major retail center. Downtown areas have been unable to effectively compete as shopping clusters with major shopping centers in these communities.

The deterioration of downtown areas has not gone without notice in many communities. Efforts to revitalize downtown areas as important retail trade centers have occurred in many cities and will continue in other cities. These efforts should be based in part on improving the capability of the downtown area to compete with shopping centers. Important input into such efforts would be an understanding of the factors that influence retail patronage decisions at the shopping area level and whether these factors operate in the same way for downtown areas as for shopping centers. With such knowledge merchant associations and municipal governments can develop appropriate marketing strategies for downtown areas.

Factors Influencing Retail Patronage Decisions

The bulk of research on retail patronage decisions has focused on choice behavior among individual stores. Two major lines of inquiry characterize this research. One approach involves the so-called gravitational model (Huff 1962) which views retail patronage as a function of store size and distance from the consumer. The gravitational model assumes stores are otherwise similar. Bucklin (1971) and Huff himself (Huff and Blue 1966) recognized that the gravitational model was inadequate if consumers perceived differences between stores on other dimensions.

The second line of inquiry, which recognizes store differences beyond size and distance, has focused on store image. Store image is the complex of a consumer's perceptions of a store on functional attributes (e.g., assortment of goods offered, price level, physical layout, etc.) and emotional attributes (e.g., perceived clientele, atmosphere, etc.). Research findings (e.g., Doyle and Fenwick 1974, Stanley and Sewall 1976) have shown that store image is significantly related to store choice.

Although to a much lesser extent than at the individual store level, both lines of inquiry have been extended to research on retail patronage decisions at the shopping area level. A few studies have confirmed the validity of size and/or distance as determinants of shopping center patronage (Brunner and Mason 1968, Bucklin 1967, Cox and Cooke 1970). Other studies (Bellenger, Robertson, and Greenberg 1977, Gentry and Burns 1977) have confirmed the importance of image-like variables in shopping center patronage. The focus in all of these studies was primarily on shopping center patronage decisions. They did not incorporate downtown areas into the design. A study that did incorporate both downtown areas and shopping centers (Bearden 1977) examined decisions at the individual store levels rather than at the shopping area level. It did confirm the importance of image in discriminating between patrons of a downtown department store and those of shopping center department stores.

Problem Definition

The research on retail patronage decisions at the shopping area level suggests that the gravity variables of size and distance and the affective variable of image can explain consumer shopping behavior with respect to downtown areas and shopping centers. This set of variables provides a framework then for determining the focus of efforts to revitalize downtown areas as major retail centers within communities. Given the nature of the gravity variables versus the image variable, it would seem that the latter offers the most practical focus for downtown revitalization efforts. Size and, especially, distance are minimally, if at all, controllable. Image, on the other hand, is largely a result of marketing efforts and the physical nature of a shopping area within given geographic boundaries. The proper manipulation of the image of downtown retail areas can enhance the competitiveness of these areas as major shopping areas. Therefore, the purposes of this paper are:

1. To investigate the nature of consumer images of shopping areas by determining the key underlying dimensions of image structure;
2. To determine if the structure employed by consumers to form shopping area image is consistent between downtown areas and shopping centers.

The second purpose is particularly important. If the structure of consumer image for downtown areas is unique then the basis for the development of image-oriented marketing strategies must differ from that of shopping centers. On the other hand, if they are similar, then downtown areas will have a common structure from which to develop image-based competitive strategies.

The possibility that downtown areas differ from shopping centers in terms of image structure would seem significant. Shopping centers are developed as integrated, self-contained shopping areas. They are typically managed by a single firm who is responsible for the promotion of an overall center. Downtown areas are much older. An evolutionary process characterizes the manner in which many of them have reached their present state.

They are a conglomeration rather than an integration of individual stores.

TABLE 1

Shopping Center Image Items

Methodology

To address the issues relating to consumer images of shopping areas a study was conducted in the Madison, Wisconsin SMSA which contains approximately 300,000 people. Five major intraurban shopping areas exist in the SMSA, four regional shopping centers and a downtown area.

Sampling

A probability sample of 2,000 households was chosen systematically from the telephone directory. Identical five-page self-administered questionnaires were mailed to sample households. A total of 827 questionnaires were returned for a response rate of 41.4%. While no direct assessment of nonresponse error was made, a comparison of the demographic profile of sample households to that of the total population suggested that older, lower-income households, a segment of the market not typically pursued by major shopping areas, were under-represented in the sample.

Development of an Image Measure

Retail shopping area image is a composite of beliefs held by a consumer on a number of dimensions. Several authors have investigated the dimensions used by consumers to form images at the retail level. For example, Lindquist (1974) in his summary of the store image literature, synthesized the frameworks of 19 studies into a set of nine categories that he called image/attitude attributes: merchandise; service; clientele; physical facilities; convenience; promotion; store atmosphere; institutional and post-transaction satisfaction. Bearden (1977) identified seven specific salient attributes of stores: price level; quality of merchandise; selection; atmosphere; location; parking facilities, and friendliness of sales people. Based on these studies and discussions with shopping center managers, a total of 16 items were generated to represent the domain of shopping area image.

The sixteen items were incorporated into a measure of consumer perceptions of each shopping area. Each item was measured on a 5-point modified semantic differential rating scale. The semantic differential format was used because it is easy to self-administer, assumes minimum verbal skills on the part of the respondents, is relatively reliable, and has been common in past research on image. See Table 1 for a listing of the 16 items and descriptions of the anchor points for each scale. Using this format respondents were asked to evaluate each of the five shopping areas with which they were familiar.

Data Analysis

In order to determine the underlying dimensions of the structure of shopping area image responses to the image measure were factor analyzed using principal components analysis and varimax rotation for each shopping area. In order to assess the stability of image structure across downtown areas and shopping centers a factor congruency test (Harman 1967, pp. 271-2) was performed for each pair of shopping areas. The result of a factor congruency test is a congruency coefficient which relates each factor of one factor matrix to each factor of another matrix. Congruency coefficients have properties similar to those of correlation coefficients. Corresponding factors are those with coefficients approaching one, while noncorresponding factors are indicated with small coefficients. Thus, stability across two factor matrices is indicated by a matrix of congruency coefficients with

<u>Item</u>	<u>Anchor Descriptors</u>
Quality of Stores	high-low
Variety of Stores	excellent-poor
Merchandise Quality	excellent-poor

Great Place to Spend a Few Hours	agree-disagree
A Conservative Center	agree-disagree

the diagonal values close to one and off-diagonal values that ideally approach zero.

Further insights into the nature of the image of downtown shopping centers were obtained by forming component scores of image based on the factor analysis results. Scores were computed by summing the values of items loading on the relevant factor. As a test of criterion-related validity and a basis for assessing the relative impact of each image component on global evaluations of shopping areas, these scores were regressed in stepwise fashion on a measure of general evaluative feeling (5-point scale ranging from "poor" to "excellent") for each shopping area. Also, comparisons of means for each image component yielded relative performance data for the five shopping areas.

Results

Structure of Image

For each shopping area factors were extracted until eigenvalues less than one were obtained. Factor matrices for each of the five areas are presented in Table 2. Three factors were consistently extracted for each shopping area. Explained variance ranged from 52.0% to 56.7% across the five areas. Factor loadings reveal that each factor contains a relatively unique set of items, allowing for relatively easy interpretation of the underlying dimensions of image structure.

Factor I consists primarily of six items--quality of stores, variety of stores, merchandise quality, product selection, special sales/promotions, and great place to spend a few hours. This factor appears to reflect an overall dimension associated with the perceived assortment of benefits offered to consumers by a shopping area. Factor II is indicated by parking facilities, availability of lunch/refreshments, comfort areas, easy to take children, and, to some extent, layout of area. This factor reflects a dimension related to the facilitative nature of a shopping area, i.e., the features it offers to ease the shopping effort. Factor III consists pre-

dominantly of four items--general price level, atmosphere store personnel, and conservative. This factor is less consistent across areas but appears to be associated with the market posture or positioning of the area as an integrated complex of stores.

Stability of Structure Across Areas

While visual examination of the factor matrices across the five shopping areas suggests a reasonable level of stability, more meaningful evidence is provided by the factor congruency test. The results of the congruency test for each pair of shopping areas is provided in Table 3.

The benefit-assortment factor and the facilitative factor are both highly congruent across the five shopping areas. All but one of the diagonal coefficients involving Factors I and II are above .80 and the majority are .90 or greater. Thus, it appears the first two dimensions of shopping area image are consistent between downtown and shopping centers.

Turning to Factor III--market posture/position--the stability between downtown and shopping centers disappears. Congruency coefficients for Factor III between downtown and each of the shopping centers are low, all of them being under .50. Furthermore, the congruency of Factor III between the four shopping centers, while not as strong

as for the first two factors, is relatively high. Thus market posture/position does seem to be a significant dimension of image structure in the perceptions of shopping centers but does not distinctly emerge in the case of the downtown area.

This finding is reinforced when the regression analyses of the impact of the three components of image on overall evaluations of each shopping area are considered. In all five cases the measures of the three components accounted for a significant ($p < .001$) amount of explained variance. R^2 values ranged from 45% to 50% with a mean of 47%. When the relative contributions of each component are considered, a distinct pattern emerges. For all five areas the assortment component entered the equation first and was most strongly associated with the general evaluation of the area. For the four shopping centers the market posture/position factor was second in impact, entering the equation second in all four cases. However, for the downtown area it was the weakest of the three components, entering the equation last and exhibiting the smallest standardized beta coefficient. Thus, the market posture/position component plays a more significant role in forming evaluations of shopping centers than downtown areas.

In Table 4 mean values for each of the image components and overall evaluations for each of the five areas are provided. It is evident that of the five areas the

	III	.35	.23	.48	.64	.54	.90	.62	.72	.90	.73	.69	.86

downtown area consistently performs at the worst level for the three components and in an overall sense. The greatest discrepancy occurs with respect to the facilitative component of image.

TABLE 4

Mean Values for Each Shopping Area

Variable	Downtown	Center A	Center B	Center C	Center D
Benefit Assortment	13.01	17.73	14.36	15.03	17.44
Facilitative Component	12.48	18.47	17.51	17.33	18.19
Market Posture/Position	10.93	11.75	12.00	12.01	11.49
Overall Evaluation	1.75	2.95	2.59	2.67	3.03

Implications

At first thought the implications of the above findings would be that the dimensions on which shopping area image is formed for a downtown area are different than those for shopping centers. Therefore, the marketing strategies for a downtown area would be based on a different structure. However, such a conclusion is probably

erroneous because of the nature and causes of image.

The structure of image, as indicated in the above findings, is based on measures of existing beliefs about the shopping areas. These beliefs have several sources. Beliefs from which the first two factors, benefit assortment and facilitative nature of the center, are formed result in part from behavioral or word-of-mouth experiences with a shopping area. Exposure to or information about the assortment of stores and products and the physical facilities of an area provide for the development of these underlying dimensions. The first two dimensions can be formed in the absence of promotional strategies by a shopping area, although promotion can certainly contribute to their development.

Such is not the case with the third factor. The positioning of a shopping area vis-a-vis other areas is largely the result of promotional efforts. The incongruency between downtown and each center and the congruency across all centers on this factor should not suggest that the positioning dimension is not relevant to downtown image. Rather it suggests that incomplete information from which to evaluate downtown on this dimension is available. Since such information derives largely from promotional efforts, it in turn suggests the absence of a promotional strategy for the downtown area as an integrated retail trade area. Therefore, the successful revitalization of downtown areas depends not only on the right stores carrying the right goods and physical renovations that facilitate shopping efforts but also on a promotional strategy that positions downtown

as an integrated shopping area. It appears that in the case of the community within which this study was conducted the downtown area has failed to do so.

Summary

A considerable amount of previous research suggests that image, as well as size and distance, is an important variable in explaining retail patronage decisions of consumers. Its role appears to be important at both the individual store level and the shopping area level. Its importance at the shopping area level suggests that image should be considered in efforts to revitalize downtown areas as major retail centers.

A study which examines the nature of consumer images of major shopping areas has been reported. Measures of consumer perceptions of a downtown area and four shopping centers on 16 image items were factor analyzed to reveal the underlying structure of consumer images of shopping areas. Three major dimensions emerged: the assortment of benefits offered by an area, the facilitative nature of an area, and the market posture assumed by an area.

Factor congruency tests were performed to determine the stability of image structure between downtown and shopping centers. Results suggested that the first two dimensions were quite stable across all five areas. The third dimension exhibited stability across the four centers but was not stable in comparisons between downtown and each center. Regression analyses of consumer perceptions of the three dimensions on global evaluations of the five areas provided further confirmation by showing that the third dimension was the weakest of the three for the downtown area but second strongest in its association with general feelings about each of the four shopping centers.

These results, while limited to one community, suggest that downtown areas may be deficient in promoting themselves as integrated shopping units. Successful revitalization of downtown areas depend upon promotional strategies that clearly position them within the retail environment. A failure to do so will hinder consumer abilities to form impressions of downtown areas on a major dimension of image, a key variable in explaining consumer retail patronage decisions. Therefore, downtown merchant associations and/or municipal governments, as unifying agents, should develop promotional efforts for the downtown area beyond those of individual stores.

DEVIANCE AND DISSATISFACTION: AN EXPLORATORY STUDY

Michael K. Mills, University of Southern California

Abstract

This paper reports the results of an exploratory study which tested the notion that the power of a retail store would directly influence both the level of consumer dissatisfaction and the incidence of deviant consumer acts occurring in that store. The results support the hypothesized relationships.

Introduction

The recent wave of consumerism and the available literature indicate that consumer dissatisfaction is quite widespread. Much of this dissatisfaction occurs at the retail level (cf. Valle and Wallendorf 1977, Miller 1976, Kraft 1977, Krishnan and Mills 1978, Bearden and Mason 1979), and may subsequently be directed at retail stores in the form of various "deviant consumer behaviors" occurring in the retail context (cf. Mills 1979 for a review of the deviant consumer behavior problem).

The research presented in this paper utilized the notions of power theory as these may apply to explaining the link between consumer dissatisfaction and the incidence of deviant consumer behavior in retail stores. The basic notion that was tested in this study was that the power of a retail store (as perceived by the customer) would directly influence both the level of consumer dissatisfaction with that store and the incidence of deviant consumer behavior occurring therein.

Evidence from previous empirical work would tend to support the contention that the power context (image) of a store influences the degree of customers' deviant acts. In several studies (Kraut 1976, Robin 1963) highly ranked reasons given for shoplifting included the fact that the person wanted to get back at the store, had political motives, or felt shoplifting was acceptable.

Power is implicated further by a second factor that shows that most shoplifting and other deviant consumer behavior is done by juveniles (Cohen and Stark 1974), the "weaklings" of adult society. Further, rebellion, alienation, and powerlessness are important reasons given by apprehended juveniles for their deviant behavior (Pedrini 1972, Thall 1973).

The effects of store image and attitudes held toward a store as they affect the level of consumer satisfaction have also been explored, though not with respect to either deviance or power preceptions (cf. Swan 1977), but the extrapolation is a fairly intuitive one.

Thus, based on the literature and a seemingly sensible theoretical extrapolation, this study was an attempt to answer the following hypotheses.

H₁: The greater the customer's perceptions of power differences between store and customer, the greater will be the incidence of deviant consumer behavior as a counterpower move by consumers.

H₂: The greater the consumer's perceptions of power differences between store and consumer, the lower will be the level of consumer satisfaction.

H₃: There will be a significant relationship between the

level of consumer satisfaction with regard to retail power contexts and to the incidences of deviant consumer acts occurring in those stores.

Methodology

A usable sample of 153 retail shoppers, gathered through mall and similar interventions, responded to a written survey instrument which featured seven scenarios of retail stores representing one or another type of retail outlet, randomly arranged, and which corresponded to retail power types as classified by the Bonoma (1976) power theory. (See Mills and Bonoma 1979 for pretests of the methodology.)

The Bonoma (1976) theory identifies three prototypical power systems that occur in everyday socio-cultural contexts, and which form a kind of "power continuum." The unilateral power system is characterized by a strong versus weak relationship among the interactive partners, by its focus on target compliance, and by the existence of conflict over scarce resources or mutually exclusive behavioral preferences. The mixed or bargaining power system falls between the unilateral and the group welfare (bilateral) power systems. Bargaining as an influence mode is used to determine outcomes, because force or rewards are not generally or effectively used between equals. The bilateral or group welfare system is characterized by a kind of social altruism as the determining mechanism of exchange.

Thus a "power continuum" ranging from high (unilateral) to low (group welfare) is formed by these three social systems, which seem to have their equivalents in retail settings--as operationalized in the scenarios. For example, the scenario for store A--a unilateral department store, read as follows:

Store A is a large, "prestige" department store in the downtown area. It occupies 200,000 square feet and nine floors of its own building. Store A aims its marketing efforts primarily at the upper-middle income ranges. Its pricing structure is rather high; it is "known" for its clothes and furniture. Significant sales and discounts are only infrequently offered. Store A has its own credit cards and maintains a strict credit policy. Parking is difficult; a parking rebate is offered to buying customers.

The scenario for store A, like all scenarios, was accompanied by a 5 x 7 inch black and white photograph of the store interior.

For each scenario, respondents were asked to anonymously self-report both the extent and types of their own deviant consumer behavior within these various retail power contexts, and were asked as well to report how likely they felt it was that relevant others would engage in these acts.¹ Respondents were also asked to indicate their

¹Several previous researchers have submitted convincing evidence for the use of the self-report methodology in deviance studies (cf. Hirschi 1972, p. 57-64, Short and Nye 1957, Wilkes 1978). Projective "third person techniques" (Tull and Hawkins 1976) have a long history of use in marketing studies (cf. Haire 1950, Hill 1968).

general level of satisfaction/dissatisfaction at the retail level for each of the store "power types" and completed a full demographic profile.

Measures of Interest and Operationalization

Measurement of the dependent variables of perceived store power and the incidence of deviance was essentially identical to that used in earlier pilot tests (Mills and Bonoma 1979). Each scenario was followed by a list of fifteen questions, broken up into three types. The store-power manipulation check section asked five questions about the perceived power of the store depicted in the scenario as viewed by the subject. Following from the power theory base, the five questions asked whether the store made too much money, whether the store was very powerful relative to the respondent, whether there was a lot of conflict between the store depicted in the scenario and the respondent, whether the respondent could influence what was stocked in this type of store, and if the respondent had been treated wrongly in that store, whether he or she could effectively communicate with someone about it. The coding scheme for the manipulation check was a Likert scale varying from one to five in the theoretically dictated direction, except for the questions pertaining to whether the subject could influence what was stocked in the store, or could communicate with someone if they were treated wrongly in the store context, which were reverse scored. The five manipulation check measures were added to get a summary index for each respondent on each scenario.

The remaining questions were concerned with the incidence of five deviant consumer acts, including destroying or damaging merchandise, fraudulent merchandise returns, shoplifting, vandalism, and fraudulent complaints. The questions were asked in two different ways. One set of questions asked whether the subject had engaged in these actions. The other set of questions asked how likely subjects thought it would be that "someone" would engage in the behaviors so described. Both sets of "deviance" questions used a five-point Likert scale which ranged from (1) very unlikely (never) to (5) very likely (always).

These "self" and "other" questions were included for an express purpose. It was felt that subjects' self-reporting of deviance would likely be understated. On the other hand, it was regarded as quite likely that subjects would endorse that a relevant other might engage in such behaviors. The "self" questions described above were combined to form a summary index variable which could range from five (all "never") to 25 (all "always"). The "someone" questions were also summed to form a composite variable varying from five (all "very unlikely") to 25 (all "very likely").

The measure of consumer satisfaction was the subject's responses to questions inquiring about the level of satisfaction from shopping at each of the store types, and was measured on a five point Likert scale ranging from five (always satisfied) to one (never satisfied) for each store.

Results

Frequency of Deviant Acts

Table 1 shows, for each of the five deviant acts investigated in the study, the average percentage of sample respondents who self-reported that they always, very often, sometimes, frequently, or never commit these acts. As is evident from Table 1, the relative percentages of individuals in each category are quite consistent across acts. Examination of the table shows further that the percentage of individuals who always or very often engage in these deviant acts is quite small, although it should

be noted that the average percentage figures shown here are quite consistent with previous sampling estimates of the percentages of individuals engaging in each activity.

Table 2 shows the percentage breakdowns for dissatisfied consumers. As is evident from Table 2, the average percentage of dissatisfied consumers who engage in each of the deviant acts is higher than that for the entire sample population.

Manipulation Check

Table 3 shows the results for the manipulation check (power variable). A repeated measures analysis of variance run, with Scheffe (1953) comparisons, was done on the data. As shown in Table 3, the manipulation check was

successful. The overall F-test computed on the summary of the five manipulation check questions yielded a highly significant value of 84.45, reliable at the .001 level. Individual Scheffe (1953) comparisons--made considering all store types, department stores only, and across different store types--were all significant at the .01 level. (The "Big Chicken" test, also successful at the .01 level, pitted two equally large but "power different" department stores against each other to test an alternative notion, suggested by a colleague that store "size" and not power was the important dimension.) Thus the manipulations were all significant in the direction predicted by the theory. That is, consumers' perceptions of unilateral, bargaining, and bilateral store scenarios was such that they represented a "power continuum" ranging from high (unilateral) to low (bilateral).

TABLE 3
Results on Manipulation

Planned Comparisons. F (6,912) = 84.45 (p<.0001)

- Overall:

Unilateral = Scenario $\overline{A + G}$	= 16.803	.01
Bargaining = $\overline{C + E}$	= 14.513	.01
Bilateral = $\overline{D + F}$	= 11.156	.01
- Within Department Stores only:

Unilateral = Scenario $\overline{A + G}$	= 16.803	.01
Bargaining = Scenario E	= 14.091	.01
Bilateral = Scenario F	= 11.477	.01
- Across Retailers:

Unilateral = Scenario $\overline{A + G}$	= 16.803	.01
Bargaining = Scenario C	= 14.934	.01
Bilateral = Scenario D	= 10.836	.01
- "Big Chicken" Theory:

Unilateral = Scenario $\overline{A + G}$	= 16.803	.01
Mixed Big = Scenario B	= 14.542	

Hypothesis One

Tables 4 and 5 show the results for the levels of deviance reported that formed the basis for testing Hypothesis One. To save space, only the "someone" (Table 4) results will be discussed here (the "self" results, while not as strong as the "someone" results, generally confirm the hypothesis in question). As shown in Table 4 the overall F-test yielded a highly significant value of 55.19, reliable at the .0001 level. Planned comparisons made for all stores considered, within department stores only, and across retail outlets were all significant in the direction predicted by the theory at the .01 level, with the exception of the across retailers-bargaining versus bilateral comparisons. The "Big Chicken" comparison, while in the direction predicted by the theory, was nonsignificant.

Thus, Hypothesis One was confirmed. The data showed that more powerful stores, as measured by the composite store power index, were felt likely to have a greater incidence of deviant consumer acts committed in them than less powerful stores. We turn now to the test of Hypothesis Two.

TABLE 4
"Someone" Results

Planned Comparisons. F (6,912) = 55.19 (p<.0001)

- Overall:

Unilateral = Scenario $\overline{A + G}$	= 16.709	.01
Bargaining = $\overline{C + E}$	= 13.751	.01
Bilateral = $\overline{D + F}$	= 11.362	.01
- Within Department Stores only:

Unilateral = Scenario $\overline{A + G}$	= 16.709	.01
Bargaining = Scenario E	= 15.261	.01
Bilateral = Scenario F	= 10.954	.01
- Across Retailers:

Unilateral = Scenario $\overline{A + G}$	= 16.709	.01
Bargaining = Scenario C	= 12.241	.01
Bilateral = Scenario D	= 11.771	ns
- "Big Chicken" Theory:

Unilateral = Scenario $\overline{A + G}$	= 16.709	ns
Mixed Big = Scenario B	= 16.130	

TABLE 5
"Self" Results

Planned Comparisons. F (6,912) = 11.82 (p<.0001)

- Overall:

Unilateral = Scenario $\overline{A + G}$	= 6.869	.05
Bargaining = $\overline{C + E}$	= 5.905	.01
Bilateral = $\overline{D + F}$	= 5.493	ns
- Within Department Stores only:

Unilateral = Scenario $\overline{A + G}$	= 6.751	ns
Bargaining = Scenario E	= 6.104	.01
Bilateral = Scenario F	= 5.457	ns
- Across Retailers:

Unilateral = Scenario $\overline{A + G}$	= 6.751	.01
Bargaining = Scenario C	= 5.705	.01
Bilateral = Scenario D	= 5.529	ns
- "Big Chicken" Theory:

Unilateral = Scenario $\overline{A + G}$	= 6.751	ns
Mixed Big = Scenario B	= 6.392	

Hypothesis Two

Table 6 shows the results for the test of Hypothesis Two. Once again a repeated measures analysis of variance was performed on the data, with the resulting overall F-test

yielding a highly significant value of 9.86, reliable at the .001 level. Planned comparisons performed on the means yielded somewhat mixed results, however.

TABLE 6
Results on Satisfaction

Planned Comparisons. $F(6,912) = 9.86$ ($p < .0001$)

1. Overall:		
Unilateral = Scenario $\overline{A + G}$ = 2.63	.05	
Bargaining = $\overline{C + E}$ = 2.379		ns
Bilateral = $\overline{D + F}$ = 2.562		ns
2. Within Department Stores only:		
Unilateral = Scenario $\overline{A + G}$ = 2.63	.05	
Bargaining = Scenario E = 2.882		.01
Bilateral = Scenario F = 3.47	.01	
3. Across Retailers:		
Unilateral = Scenario $\overline{A + G}$ = 2.63	.01	
Bargaining = Scenario C = 1.876		.01
Bilateral = Scenario D = 1.654		ns
4. "Big Chicken" Theory:		
Unilateral = Scenario $\overline{A + G}$ = 2.63	.01	
Mixed Big = Scenario B = 3.046		

As shown in Table 6, for the overall comparisons one significant relationship was noted, but it is a direction contrary to the hypothesized relationship. However, significant results were seen when consumers' mean levels of satisfaction were considered with respect to department stores only. Here, the direction of all comparisons was in harmony with the hypothesized relationship and was statistically significant as well. Across retailers, however, two significant, but directionally not predicted, results were seen. Finally, the "Big Chicken" test was significant at the .01 level in the direction predicted by the theory. Additionally, it is quite apparent that, across all store types, customers' mean levels of satisfaction with these stores was quite low.

Thus, the test of Hypothesis Two yielded somewhat mixed results. A possible explanation for these results may be rooted in the nature of the comparisons made, as well as in the nature of the store types themselves. That is, significant findings in the direction of the hypothesized relationships were noted in both the within department stores only and the "Big Chicken" tests. These comparisons were of similar types of retail outlets (i.e., department stores), rather than of differing types, and hence these comparisons may be more indicative of the phenomena under investigation. It remains for additional research to resolve this issue.

Hypothesis Three

Table 7 shows the results for the correlational analysis that was used as the statistical test of Hypothesis Three. As shown in Table 7, there is the expected negative relationship between the level of shopping satisfaction in each of the stores and the incidence of deviant acts committed in those stores. However, the size of the correlation coefficients is quite small, albeit statisti-

cally significant in three instances, and hence some caution is required in interpreting these results.

TABLE 7
Correlations Between Shopping Satisfaction
in Store and Deviance in Store

Store						
A	B	C	D	E	F	G
-.1441	-.2031	.0257	-.0719	-.1437	-.1259	-.0701
(.038)	(.006)	(.376)	(.189)	(.038)	(.061)	(.195)

Conclusion

This study was an attempt to examine the possible relationship between perceived power of a retail store, consumer dissatisfaction, and deviant consumer behavior in retail stores. The results seem to indicate that stores perceived as more powerful by the consumer have higher levels of deviant consumer behavior occurring in them and, at least in some instances, have lower reported levels of consumer satisfaction than less powerful stores. Further, it appears that there is a relationship between the level of consumer satisfaction with a store and the incidence of deviant consumer behavior committed against that store.

While some caution is necessary in interpreting these results given the exploratory nature of the study (and because of the small sizes of the correlation coefficients) the results are, nonetheless, interesting and point the way towards additional research in this area. This is particularly true with regard to further tests of the importance of power perceptions on consumer dissatisfaction. While some attempt has been made by Valle and Wallendorf (1977) and others to bring theory to the question of consumer dissatisfaction and complaining behavior, it appears likely that power theory may shed some new light in this area (as well as on the question of consumer deviance). It is the author's hope that this study will serve as an impetus to more research in these and related areas.

COMPREHENSIVE IDENTIFICATION OF CONSUMERS' MARKETPLACE
PROBLEMS AND WHAT THEY DO ABOUT THEM

F. Kelly Shuptrine, University of South Carolina
Gerhard Wenglorz, University of South Carolina

Abstract

A representative sample of households in a medium-sized southeastern city were surveyed by personal interviews concerning the last product of any type that the respondent could remember having any type of problem. In contrast to other studies reporting one-fourth to one-third of the respondents having a problem, this survey found 76.3% of the respondents experiencing some recent problem of any type and this percentage increased to 83% when those who said they didn't have any problems were asked a "how sure" question. Significant comparisons of those who had problems/no problems, made a complaint/no complaint, and were successful/unsuccessful complainers are also provided.

Introduction

Numerous studies about consumers and their complaints emerged with the rise of the "consumerism movement" during the last two decades. Such attention helped to result in such acts as the Consumer Credit Protection Act (1968), Poison Prevention Packaging Act (1970), and the Consumer Product Safety Act (1972). Consumer Protection Agencies, Consumer Affairs Offices, Consumer Organizations, and related consumer associations have evolved in this period.

However, our knowledge in the area of consumer problems in the marketplace and their resolution are fragmented. Some studies have dealt with consumer's attitudes and opinions toward the marketplace and others have recorded behavioral information.

Reviewing some recent studies, Barksdale and Darden (1972) note that younger, more liberal subjects were more critical of marketing practices and more impressed with the accomplishments of the consumer movement. In a summary of 912 women consumers (Hustad and Pessemier 1973), it was found that those who felt negative toward business tended to be younger women who are intellectually, socially, and economically upscale.

In their study of consumer dissatisfaction with household appliances Mason and Himes (1974) found 44% of this sample to have experienced dissatisfaction severe enough to register a complaint. The initial retailer was the most effective at satisfying the consumer's discontent resolving 55% of the problems with repair centers following behind at 16%. As many as 18% of the problems reported were still unresolved at the time of the study.

Using Lundstrom's (1976) Consumer Discontent Index, Lundstrom and Kerin (1976) attempted to identify psychological and demographic correlates of consumer discontent. They reported consumer discontent to be statistically related in a positive direction to alienation, especially the powerlessness and social isolation components, anomic, being male, age, income level and occupation level. Consumer discontent existed predominately in older males from the middle to upper middle class and not in the lower socio-economic groups.

A study on elderly reactions to unsatisfactory purchases indicates that propensity-to-complain declines with age (Zaltman, Srivastava, Deshpande 1978). Kraft (1978) in a

paper on characteristics of consumer complainers notes that more complaints are made on large-ticket items, by whites than blacks, and by younger than older respondents.

Fornell and Westbrook (1979) report that those who are more assertive and aggressive are more likely to exhibit complaining behavior. A comprehensive study (Shuptrine, Thomas, Sharma 1979) on the consumer complaint process involving durables found that of those who complained and reported successful resolution, no significant demographic differences between successful/unsuccessful complainers were found. A study by Day and Landon (1976) suggests a more comprehensive model of complaining behavior is needed and provided major input with a national study for the FTC on a large number of product categories cross-classified by specific consumer complaints or complaint categories.

Another group of studies has investigated who complains about the marketplace and the products and services they complain about. In these studies the dependent variable is behavioral, action or inaction, whereas in the first series of studies the dependent variable was an attitude. In another part of their study on a sample of female's dissatisfaction with appliances Mason and Himes (1973) found those who took action tended to be from larger households, had higher incomes, were primarily middle aged and tended to own their own home. Miller (1974) reports that the number of complaints or suggestions for improvements a customer expresses for a store tends to come from younger, more mobile and better educated women. Lielfield, *et al.*, (1975) found that Canadian consumers who had written complaint letters were middle aged, better educated, earned higher incomes, and had professional heads of household. According to Hair, *et al.*, (1976) chronic complainers have negative attitudes toward business and marketing practices. They attend church less frequently, belong to fewer organizations, younger, less educated and have lower incomes.¹

By including both an attitudinal and behavioral dimension in their study Warland, *et al.*, (1975) found that two types of dissatisfied consumers emerge--dissatisfied consumer activists (Upset-Action Group) and dissatisfied passive consumers (Upset-No Action Group). The Upset-Action both reads and participates in consumer and political activities. They are younger, have higher social status, income and education. The Upset-No Action Group have lower incomes, are less educated and do not engage in consumer and political actions. They exhibit low social involvement and are the most politically alienated. The authors feel that the Upset-No Action Group have potential to become an important force in the consumer movement if given leadership, direction and education. They are not a segment business can afford to ignore. Wall, Dickey, Talarzyk (1977) also found that complainers are more upscale in socio-economic status.

¹Many additional studies concerning consumer complaints are available from the four annual conferences on consumer satisfaction, dissatisfaction, and complaining behavior (Day and Hunt 1976-1979). Other research concerning complaining theories, models and correlates are available in previous ACR proceedings. Much of the research findings available are quite similar to the research reviewed in this paper.

On a more comprehensive study of consumer complaints (Andreasen, Best 1977), it was found that one in five purchases of products and services resulted in consumers' dissatisfaction with something other than price, less than half of these problems resulted in a consumer complaint, and about two out of three complainers ended up with a satisfactory resolution of their problem. A study by Shuptrine, Thomas, and Sharma (1979) reported earlier on durables found about 70% of those complaining receiving satisfaction.

In another study (Advertising Age, June 21, 1976) consumer organizations report that one-fourth of all households have some sort of marketplace problem and of these only one in three are actually reported. Where complaints are registered, however, the study finds about 56% of the consumers get satisfaction. Low-income consumers are least likely to complain, while the likelihood that the consumer will complain increases if it is an expensive item, if the problem is clear-cut rather than a matter of judgement, and if it is a big-tag credit transaction.

And finally, a study by the U.S. Office of Consumer Affairs reported in the Marketing News (February 22, 1980, p. 8) on a nationwide sample of 2500 households says:

Most private industries and government agencies are inept when it comes to handling consumer complaints and do an inadequate job of informing the public on how to file and follow through on their protests.

The study found that about one-third of the sample had one or more consumer problems in the last year and about 75% of all complaints were about the poor quality of products and services. Most complaints, consistent with previous research, were directed at the auto industry followed by appliances. A majority of the consumers said their first contact with reporting their complaint was with the retailer. About 75% of the consumers will complain if the value of the product is between \$6 and \$10; whereas, 95% will complain about a product costing \$500 to \$1000.

This brief review of the literature indicates that there are many inconsistencies when comparing studies. Some research only looks at those who complain (who are often different from those who don't), others examine attitudes and behavior of those with problems (though not much persistence is seen in determining whether people have had any type of problem), and others have examined briefly the consumer complaint process and comparisons of successful and unsuccessful complainers. However, when summarizing, inconsistent profiles develop; with some studies saying discontent and complaining are related to high income and education and others report they are related to low income and education and so on.

Because of the fragmented approaches that have been largely used so far, the intent of this study was to provide a more systematic approach to the area of consumer marketplace experiences. Specifically, the study is designed to:

- Probe strongly to identify any type of problem(s) consumers have had in the marketplace.
- See if they had a problem, whether they would attempt complaint resolution.
- Examine the process complainers would go through in attempting resolution.
- Compare profiles of successful and unsuccessful complainers.
- To obtain opinions of non-complainers as to why they didn't attempt resolution.

The results of the study will help to serve as one of the building blocks needed for a comprehensive theory of complaint behavior.

Method

A questionnaire was designed along similar lines as a previous questionnaire used in a consumer durable complaint study. It was pretested and revised twice on small samples (25) of households reflective of the population of interest. Major emphasis was placed on the first question as to whether the respondent had a recent problem (of any size) with products or marketplace activities. To really be confident, a later question for those who said no was a how sure are you question to see if the first question was supported.

A random sample of 275 households was selected from a cross-section of census tracts in a middle-sized south-eastern city. A criss-cross telephone directory was utilized to randomly select residential addresses (business addresses were not included). There were 224 usable questionnaires from the sample of 275 (81.5%) which were obtained from a personal interview with an adult household member at the chosen address.

Results

Overview

Summary responses of the total sample (224 respondents) on some questions and demographics are presented in the Appendix. The most common problems respondents had (consistent with prior research) were automotive related (25.7%) and appliances -- small (10.5%) and large (17.5%). The main types of problems consumers had were: product not functioning as claimed (25.4%), was poorly constructed (39.1%), some problem with the actual functioning of the product (33.7%) and problems with repairs/service (19.5%). The product was under warranty 37.7% of the time when problems arose and 32.9% of the products were never covered with warranties. The dollar value of the products that people had problems with ranged from less than \$5 (17.7%) to over \$500 (28%).

The demographic composition of the sample was widely dispersed by age, profession, education, and income. Twenty-one percent were single and 67.4% were married. There were 37.4% males and 62.2% females and 22.5% blacks and 77.5% whites. From prior research in this metropolitan area, the demographic profile was fairly representative of the entire population.

Complaint Resolution Efforts

Table 1 presents efforts by those who had a problem and complained. This effort could be classified as a first stage consumer complaint process. Most complaints were made to the retailer selling the product (82.3%) and was made by a personal visit (62.8%) or telephone call (38.9%). Most complaints were answered (86.7%) either immediately or within 1-7 days (28.1%). There were 68.4% of the complaints adjusted to the complainant's satisfaction--refund (11.4%), exchange (30%), and repaired with charge (48.6%). A summary of resolution for this first stage complaining was success for 61% of the complainers, complaint not answered for 13.6%, and complaint was answered but not resolved for 25.4%.

Consumers That Have Problems

Several previous studies cited have stated that 1/4 to 1/3 of the sampled populations had a problem. This questionnaire was set up to really check these earlier findings and thus a major emphasis was put on seeing how many of our

sample have had any type of problem in the recent past. There were 171 out of 224 or 76.3% who stated they had a problem of some type. With a follow-up question, another 15 or an additional 6.7% admitted to some problem. So, in total, our study identified 83% of the respondents having experienced a recent problem (of any magnitude) in the marketplace.

A comparison was made of those who had problems and those who didn't by respondent's demographic characteristics. The significant findings are presented in Table 2. Younger respondents were more likely to express having problems than older ones. The self-employed (93%), white (88%) and blue collar (91%), students (100%), and housewives (98%) were more likely to have problems than the retired (71%) and the unemployed (50%). The higher one's educational background, the more likely they were to have had problems (college graduates 93%); whereas those with less education were less likely to have problems. Whites (85%) were significantly more likely to have problems than Blacks (70%).

Consumers That Complain

Comparisons were made between those who have a problem and complain and those who don't on product characteristics and respondent demographics. The significant findings are presented in Table 3. According to product group, clothes and miscellaneous items (small ticket items) were less likely to be complained about, 44% and 50% respectively. Automotive related (82%), furnishings (83%), and house related problems (83%) were product groups most likely to have a complaint made. In line with other studies, the more expensive the product the more likely one was to make a complaint. By profession, the self-employed (77%), white collar employees (77%), and housewives (77%) were more likely to complain. Blue collar workers (37%) and the retired (53%) were much less likely to make a complaint.

Successful Complainers

Significant comparisons between successful and unsuccessful complainers are presented in Table 4. Only two factors were found to be significantly related-profession and educational level of the respondent. The self-employed (80%) and the retired (78%) were more likely to be successful. Blue collar workers were least likely to achieve resolution

χ^2 calculated = 15.3, significant at less than the .02 level.

(only 14%). Those with some college (68%) and college graduates (76%) were most likely to be successful. Those with some high school training and high school graduates were less successful, 50% and 50% respectively.

Followup on Noncomplainers

An additional question was asked of those who had a problem but didn't complain (see Table 5). About 86% of the non-complainers gave reasons for not complaining of: too much trouble (21%), price too low, not worth the time (30%), won't do any good (26%), and waste of time (9%). All of these seem to indicate a feeling of separation from the seller and the buyer's feelings that they will not get any satisfaction if they complain. When we contrast this view with the results in Table 1 where 61% of the complainers got satisfaction on their first complaint, we feel that the consumer may be giving up too quickly. The business firms may be much more responsive than what many people perceive them to be.

Discussion

A representative sample of households in a medium-sized southeastern city was contacted and answered a detailed questionnaire concerning any problems they have had in the marketplace and what they did or did not do about them.

³Percentage greater than 100% due to multiple responses.

The study was systematic in that comparisons were made of those who had problems/no problems, complainers/noncomplainers, and successful complainers/unsuccessful. The complaint process was also examined for those who made a complaint.

Though one cannot generalize these findings to the entire U. S. population, the results are representative of the southeastern area from which they were taken and provide useful points of comparison with other related studies. It is unique in that it is much more comprehensive in that it doesn't examine only those people who complain, or those who are successful complainers, or those with problems, but includes all of these groups.

A major result of this study was the identification of such a large number of people who have had problems in the marketplace. Previous research (Warland, et al. 1975, Advertising Age 1976, Andreasen, Best 1977, Marketing News 1980) have noted between 20 to 35% of their samples with some consumer problem within the last year or less. Our

survey found 76.3% of our respondents experiencing some recent problem of any type and this increased to 83% when those who said they didn't have any problems were asked a "how sure" question. These included very large items such as houses and automobiles down to small items such as cottage cheese, records and bread. Now it is debatable as to whether all studies are comparable, especially when some look only at certain marketplace problems, or ask if you were good and mad, and so on, but it appears to us that there are many more problems than most studies lead us to believe. (For corrective or educational actions, reports that are broken down into more detailed problem/service categories such as Andreasen and Best (1977) would likely be more useful for private or public change agents).

The nationwide study done for the U. S. Office of Consumer Affairs (Marketing News, February 22, 1980) only found about one-third of those questioned to have had one or more consumer problems within the last year. We feel that our sample is definitely not that much different from the U. S. populace. In fact, it is in a rather conservative, pro-business area and one would expect even fewer consumer problems with goods and services.

In examining the complaint resolution process, it was noted that most complaints were directed to the retailer, communicated by personal visit or phone, responded to immediately or within less than 7 days, was answered, and when adjusted to the customer's satisfaction, was with a refund, exchange, or repaired with charges. Most notable was the fact that 61% of those making an attempt to resolve a problem obtained satisfaction. We did not follow-up to see if those who were rebuffed on their first attempt persisted and obtained satisfaction. So, the final group receiving satisfaction is undoubtedly greater than 61%.

The following statements are descriptive of comparisons of those who had problems/no problems, made a complaint/no complaint, and were successful/unsuccessful complainers.

Problems/No Problems

- Those with problems tend to be younger while older respondents have fewer problems.
- The retired and unemployed tend to report fewer problems than other professions.
- College graduates are much more likely to report consumer problems than high school graduates.
- Whites report a greater number of problems than blacks.

Complaint/No Complaint

- Those with automotive related, house related, and house furnishings problems are more likely to complain. Those with clothing problems and small miscellaneous problems are much less likely to complain.
- The more expensive the item in question, the more likely one is to complain.
- The self-employed, white collar workers, and housewives are more likely to be complainers. Blue collar workers and the retired are more likely to be non-complainers.

Successful/Unsuccessful Complainers

- The self-employed and retired are more likely to report satisfaction. Blue collar workers are more likely to be unsuccessful.
- Those with some college and college graduates

are more likely to be successful. Those with some high school and high school graduates tend to be more unsuccessful.

These findings are similar to other studies and are more systematic in that all of these issues are examined in the same study. They do point out areas where substantive educational efforts could be beneficial in improving the consumer's welfare.

And finally, of those who had a problem but did not complain, we note from Table 5 that about 86% of the reasons given for not complaining relate to their perceptions that it was too much trouble, price too low, not worth the time, won't do any good, and waste of time. Now, it very well may not be in the consumer's most economic use of time and travel to worry about a small ticket item. But, for other items that these people feel they won't get any satisfaction on, it appears from this study and other reported studies that they would likely experience a 60-70% chance of satisfaction if they would attempt to resolve their problem.

In conclusion, there appears that a serious review is needed of the existing attitude among many businesses that a relatively small number of complaints received is a measure of general consumer satisfaction. Our findings show that a very large number of problems are encountered in the marketplace by consumers with many unwilling to make a complaint about their problems. Obviously, one way of improving the situation is to better educate consumers and have them become more responsible. Profiles developed in this and previous studies will be useful inputs for designing educational programs. Another way is to use government or consumer organizations as intervenors. A better way might be for business firms to recognize the extended product concept which implies satisfaction after purchase. So, instead of leaving the burden of the complaint process entirely with the consumer the business firm needs to enter the picture and provide adequate mechanisms for communicating and resolving problems.

AN INTEGRATED VIEW OF THE STORE CHOICE/PATRONAGE PROCESS

Donald Granbois, Indiana University

Abstract

Three papers, each touching on one or more aspects of store choice/patronage behavior, are reviewed here with the goal of relating each to a simple phase model. Contributions, methodological issues and ideas for future research growing out of this review are presented.

Introduction

Beyond their common concern with consumers' retail patronage behavior, the three papers presented vary considerably in method, the underlying bodies of theory and research drawn on, and the degree of innovativeness the authors have shown in conceptualizing the behaviors studied. Each paper reports an investigation of one or more phases of a sequence of mental processes and overt behaviors consumers exhibit in their store choice/patronage behavior. Beyond the usual compliments, criticisms and suggestions triggered by the individual papers under review which are expected in a discussion paper, each paper's relation to a simple phase model of store choice/patronage will be shown. Suggestions for the authors' future research growing out of this attempt at integration will be made.

The Store Choice/Patronage Process

Elements in the store choice/patronage process can be categorized as four linked phases, including:

Image Formation → Patronage →
Post-patronage Evaluation → Further Behavior

Image formation includes those mental processes whereby information and experience are processed and evaluated resulting in predispositions which generally guide patronage. Patronage refers both to customers' actual shopping trip behavior -- number and sequence of store visits -- and their in-store behavior, as goods are acquired, interactions with sales personnel and other customers are entered into, etc. Post-patronage evaluation has been thought of both as a comparison of actual and expected behavior and as an attribution process through which consumers attempt to assess the causes of the outcomes of their patronage behavior. Further behavior includes remedy-seeking among unhappy consumers, word-of-mouth (both positive and negative) reflecting the outcome of the post-patronage evaluation process, and even punitive behavior directed at retailers.

Retail Shopping Area Image

Consumers probably have at least rudimentary knowledge about available stores and shopping clusters prior to most store visits, although the extent and character of this knowledge is seldom if ever the subject of research. As in the literature on brand and product choice, there has been a tendency for researchers to assume that an evaluation process based on two or more attributes underlies an overall affective orientation towards individual stores. Houston and Nevin, like earlier researchers, refer to the output of this evaluation process as the store's "image," the "complex of a consumer's perceptions of a store on attributes." It seems possible, however, that an affective orientation towards a store sufficient to trigger a store visit can develop with little or no cognitive evaluation,

a position consistent with a considerable body of evidence in both psychology (Zajonc 1980) and consumer behavior (Olshavsky and Granbois 1979). Respondents' seeming ability to assign ratings to listed alternatives in terms of criteria specified on a questionnaire does not support the conclusion that we carry such neatly-structured images around in our brains! There is ample precedent for Houston and Nevin's assumption, however, although studies asking if and how such images are formed would be quite interesting in the context of retail shopping clusters.

Houston and Nevin's research on Madison shopping clusters assumed a multi-attribute structure comprised of 16 dimensions underlies shoppers' images of the five clusters studied. Respondents provided up to 80 judgments (depending upon their familiarity with the clusters). The 16 cluster attributes were represented by short, very abstract phrases of 2 or 3 words. Again, there is much precedent for this approach, but one wonders what meanings respondents associate with such terse statements.

To the extent that consumers do not have complete knowledge about stores or shopping clusters, "images" may best be thought of as expectations or predictions. As such, these may be biased by information processing errors and deficiencies such as the incorrect application of "surrogate indicators." There is, in fact, already evidence in the literature that such biases do indeed occur in judgments about individual stores' price levels and locations (Brown 1969, Thompson 1963, Olshavsky, MacKay and Sentell 1975).

Finally, the 16 shopping cluster dimensions were taken from the store image literature, with some modifications apparently based on the judgment of the researchers after consulting with shopping center managers. Surprisingly, two attributes of great potential importance -- location (distance and/or driving time from home or other trip origin) and depth of assortment -- were excluded (assortment depth may be captured somewhat by the dimension "Product Selection," although other meanings may well have been interpreted by respondents). Gravitational studies cited by the authors have found these two variables to effectively predict aggregate movement of fashion goods shoppers even when measured with crude proxy variables such as map distance and shopping goods stores' square footage.

Houston and Nevin's factor analysis findings provide what seems to me to be rather indirect evidence of an unsurprising conclusion; that is, downtown Madison as a shopping cluster is perceived differently from the four planned shopping centers in the area. The nature of these differences is only hinted at in Table 4, where downtown is shown somewhat lower in respondents' evaluations than all four shopping centers.

Since even summary measures of the Madison shoppers patronage behavior are not reported, it is not possible to assess the predictive validity of the study's results, so we are not able to evaluate the importance, or the nature of the less favorable evaluation given downtown. For all we know, Madison patrons could be shopping downtown despite lower evaluations on the study's 16 attributes. The paper's conclusion, then, about the need for repositioning downtown through promotion seems premature, since it is by no means clear that the image dimensions studied are

salient ones, driving actual patronage behavior. Beyond this, mere knowledge that downtown is rated lower on "General Price Level," "Friendly Atmosphere," "Helpful Store Personnel" and "Conservative" seems insufficient guidance for creating an effective promotional campaign to stimulate patronage. Indeed, price and personnel policy changes might well prove to be more appropriate responses by downtown merchants.

Consumers' Marketplace Problems

Shuptrine and Wenglorz, in another city, report a study fitting our store choice/patronage model somewhat less directly. Like many earlier studies, their findings reveal some consumers having some problems seeking remedy from sellers, which overwhelmingly were the retailers selling the product (82.3% of all complaints). This behavior, an important type of "Further Behavior" identified in our phase model, was found to be considerably more prevalent than in earlier studies, perhaps because questions were purposely included to probe and encourage reports of problems. The study's primary contribution is its conclusion that consumer problems may be more widespread than has been shown in earlier research, thus focusing even greater concern on the retailer as an important factor in remedying consumer dissatisfaction. Beyond this, the study is totally descriptive in character, its many cross-classifications revealing product and consumer-type variations in both problem incidence and tendency to complain quite similar to many earlier studies.

While the research serves to heighten our concern for the level of consumer problems reported (even though over 2/3 were reportedly adjusted satisfactorily) it provides no insights into the evaluation process whereby the consumer concludes a problem exists. Post-patronage evaluation processes are hardly touched on in consumer research, yet this seems to be a necessary next step if we are to begin to understand and explain the phenomenon of consumer dissatisfaction and subsequent behaviors. Such understanding and explanation need to precede serious recommendations for policy action. For example, possible consumer education efforts are difficult to conceive of without far greater understanding of consumer expectations formation; how product experience is interpreted and evaluated; and the nature of the attribution process as consumers attempt to decide whether they themselves, the manufacturer, the retailer, or some of the party should be blamed for less-than-satisfactory experience.

Deviance and Dissatisfaction

Mills' research fits our phase model too in that the five deviant behaviors studied occur either during the shopping process itself (part of the Patronage phase) or as part of Further Behavior. Since respondents predicted both their own and others' likely behavior in response to "scenarios" comprised of store descriptions and photographs, the perceptions evoked as the settings in which the deviant behaviors of interest were to be imagined by respondents seem to correspond to the concept of store image as it is normally defined. An interesting theoretical twist distinguishes the study in that the retail unit's power relative to that of customers is added as a significant dimension of retail image. Self-reported and projected deviant behavior was hypothesized to vary with the three power "types" represented by the various scenarios, as was consumer satisfaction.

Relating the perceptions evoked by Mills' scenarios to the concept of store image focuses attention on the interesting issue of how consumers form impressions of retail power. Apparently the image elements included in the written scenarios and photographs were successful in evoking the "proper" perception of power among respondents; from the written sample scenario presented, these elements seemed

to include building size and type, market segment served, price policy, credit policy, and parking. Since we are shown just one scenario and don't know the nature of the process used in developing the written and photographic stimuli, we can only speculate about why the scenarios contained the elements that they did. Given the results of the study, which tended to confirm the importance of perceived power as an influence on self-reported and projected deviant behavior, the issue raised here has much practical significance. Other things equal, manipulating those elements perceived as indicators of retail power or changing consumers' beliefs about the relationships which exist between store attributes or policies and store power could conceivably both increase consumer satisfaction and reduce deviant behavior directed at stores.

Some Methodological Concerns

The surveys by Shuptrine and Wenglorz and by Houston and Nevin both utilized good-sized samples selected randomly from city populations, a method still not common in academic research. The cost and effort in such relatively ambitious surveys is substantial, placing a burden on the researchers to be sure the research question not only requires but is worthy of such a costly setting. Judging by the conclusions and recommendations offered by these two papers, neither study seems highly cost efficient, but it is possible that additional findings not reported here were obtained in each case.

Shuptrine and Wenglorz's research largely replicated the research question already investigated in a number of earlier studies. The justification appeared to be their desire to provide a more valid estimate of the true incidence of consumer problems growing out of their realization that earlier research may have understated the importance of consumer dissatisfaction. Assuming this objective to be the purpose of the research, one questions their estimate of the incidence of various consumer problems, since each respondent apparently reported on a single problem. An alternative method would have identified product categories first, then established the incidence of recent purchases in each, followed by probing questions getting at types and frequencies of problem experiences.

Houston and Nevin appeared to miss an opportunity to get at true differences in consumers' perceptions of downtown versus shopping center attributes by imposing the same set of image dimensions on responses for both kinds of shopping cluster. Unless questions not reported here covered both familiarity and actual patronage of the shopping clusters investigated, some very important validating data were excluded from the study.

While factor analysis simplifies interpretation by reducing large numbers of variables into a much smaller number of dimensions, the nature of the question pursued here seems to call for more rather than less detailed analysis. Each of the 16 initial image dimensions represents a somewhat complex set of variables (how many aspects of "atmosphere" characterize downtown Madison?) each worthy of investigation if workable proposals for stimulating increased downtown patronage are to be derived. At the least, examination of the profiles of each shopping cluster on all 16 attributes should be made.

Mills' study recruited a group of shoppers in malls and elsewhere with no apparent attempt to sample a defined population. Details about the scenarios used and their method of development are not known. In Mills' design, hypothesis testing was based on totally hypothetical situations presented on the basis of quite artificial stimuli. There are real questions of external validity in this

approach. As a preliminary (and perhaps not very expensive) test, the study is of value. Judgments of Mills' results, though, should probably await verification in research relying less on artificial scenarios. (Admittedly, given the sensitive nature of the issues investigated, more realistic designs don't come easily to mind). Since the behaviors in question are deviant acts, the validity problem is still more serious. It would be useful to know if actual levels of deviant acts by consumers experienced by retail outlets in each of the three power types vary as would be predicted by Mills' hypothesis. Measures of satisfaction with actual stores, classified similarly into the three types, would provide a stronger test of the hypothesis relating satisfaction to perceived power.

Future Research

The linkage between consumers' perceptions of shopping clusters' attributes and actual patronage behavior has seldom been investigated, and Houston and Nevin's study represents an important start in what should be a fruitful stream of research. More detailed study of perceptions and misperceptions of shopping cluster characteristics (including location/convenience factors!) seems called for, followed by validating studies in which relationships between shoppers' evaluations of shopping clusters are compared with their actual patronage behavior.

The next step in Shuptrine and Wenglorz's dissatisfaction and complaining behavior research might well follow up their finding that probing questions appear to stimulate recall of dissatisfying experiences. Perhaps different levels of probing questions could be devised and the level of incidence of dissatisfaction indicated by each level could be experimentally determined. Further evidence that dissatisfaction is in part an artifact of the persistence of the interviewer would certainly force some reinterpretation of earlier research, and provide further incentive for researchers in this increasingly-popular area to devise more comprehensive (and perhaps less overt) measures of dissatisfaction. A second direction worthy of much additional effort is the exploration of evaluation processes giving rise to varying levels of satisfaction and dissatisfaction.

Deviant consumer behavior is clearly important to study but the sensitivity of the issues involved serve to magnify our usual problems in devising valid self-report measures. Nonetheless, Mills' hypotheses are of sufficient interest to warrant his continued efforts on the topic. More thorough exploration of the retail firm's attributes underlying consumers' perceptions of the firm's power type might give insights into aspects of store design, advertising media and copy, salespersons' behaviors and other controllable dimensions of the retail "mix" that could be manipulated to influence consumers' perceptions.

PRODUCT AND BRAND USER STEREOTYPES AMONG SOCIAL CLASSES

J. Michael Munson, University of Santa Clara
W. Austin Spivey, University of Santa Clara

Abstract

This research investigated the relation of social class to product and brand-user stereotyping. The data base included over 200 females evaluating 48 brands in 8 product categories. As hypothesized, significant differences between upper, middle and lower social classes were observed for both product and brand-user stereotypes.

Introduction

Marketers have given considerable attention to social class and opinion leadership. Both constructs are felt to play an important part in decisions about market segmentation and the selection of mass media aimed to reach specific target markets. Interestingly, a review of the marketing and communications research highlights the fact that these constructs have been studied independently. There is little, if any, explicit recognition of theoretic linkage. In addition, a review implies that the perceived usefulness of the constructs may vary depending upon specific product class, situation, and target market. Indeed, some seem to feel that one construct is "better" than the other.

Some researchers decry the difficulties associated with operationalizing opinion leadership. Rogers (1972) as well as King and Summers (1970) bemoan the problems in identifying and using opinion leaders directly. Robertson (1970) comments on the difficulty in simulating opinion leadership via testimonials, slice-of-life vignettes, and man-on-the-street recommendations. Loudon and Della Britta (1979) point out how hard it is to stimulate leaders to talk about a product and exert personal influence. There are conflicting findings about whether the influence of opinion leaders tends to be product specific (e.g., Robertson and Myers 1969; Silk 1966) or generalizable to overlapping product categories (e.g., King and Summers 1970).

Other researchers question the usefulness of social class. The "dated" nature of much social class research--most of the studies are 15 to 20 years old--leads some to question the relationship between social class and today's consumption patterns. Some believe that social classes are disappearing or becoming more homogeneous. Bieda and Kassarian (1969) suggest that differences in product preferences among social classes may have disappeared because of common exposure to mass media. Their suggestion implicitly argues that mass media has had a leveling influence on the values and life style aspirations of all individuals. If this is true, the stereotypes of specific brand or product users should be relatively homogeneous across social strata.

In light of the weaknesses associated with both social class and opinion leadership, it seems incorrect to view either construct as better than the other. Rather, it would seem advertisers should concentrate more effort on "integrating" the potential inherent in each. It may well be that many of the effects of opinion leadership are contingent upon social class considerations. Indeed, Klapper (1970) views mass media communications as operating through mediating factors--group membership, interpersonal contacts, selective exposure and defense mechanisms--so that it typically is a contributing agent but not the sole cause of audience reactions.

The desire to integrate the potential inherent in the two

constructs provided the impetus for this research. Two key questions are addressed based upon Bieda and Kassarian's (1969) suggestion that differences in product perception among social classes have disappeared:

- (i) do perceptions of brand and product user stereotypes differ across social classes?
- (ii) if so, for what types of product classes?

The Study

If social class is to become a resurgent key to implementing opinion leadership, advertisers must answer a key question: to what extent do differential stereotypes exist across social classes at both the micro brand level and the macro level of product category. If common exposure to the mass media has acted as a leveling influence across all individuals, as Bieda and Kassarian suggest (1969), then differences in product perception among social classes may have disappeared.

Given that prior marketing research on social class has focused on one of three areas--shopping, media and product class usage behavior (as opposed to brand usage)--little is known about how perceptions of specific brands may differ across social class. Moreover, much of the previous research is based on samples of university students which limits the generalizability of results.

Study Hypotheses

The need to fill in these gaps dictated that two working hypotheses be formulated to guide the study. Stated in alternative form, they are:

- H1: Stereotypes of people who own or prefer a specific brand will differ across social classes.
- H2: Stereotypes of people who own or prefer a specific category of product will differ across social classes.

Two corollaries (C1 and C2) were formulated from the working hypotheses. The first related to the magnitude of any observed differences among social classes:

- C1: Any differences in stereotypes will be largest between lower and upper social classes.

The second corollary related to observed differences for a product category:

- C2: Differences in user stereotypes will exist only for value-expressive product categories.

Specific support for H1, H2 and C1 comes from many sources. Warner (1960) suggested that the further apart two people are in class level, the further apart will be their usage and understanding of a product. Martineau (1957) noted social class helps to define the hierarchy of things on which people wish to spend money. The further apart two people are in social class, the greater the difference will be in perceived likelihood of purchase. Levy (1966) states "...As one looks at the social class ladder, the further he goes down it, the more difference he sees in life styles and values, and thus, the difference in

consumption patterns becomes greater..."

C2 is based upon research by Locander and Spivey (1978). They discussed the basic differences between utilitarian and value-expressive products. Value-expressive products help an individual to give positive expression to their values and self concept. For these types of products, the key concern is the stereotype of the person who owns or prefers the product. On the other hand, for utilitarian products, user stereotyping is relatively unimportant compared to specific product attributes. Another point is noteworthy. Value-expression and utilitarianism are not opposite ends of a continuum; rather, they are independent dimensions (Spivey 1977). Therefore, a product quite possibly can be considered utilitarian and still provide an opportunity for self-expression. Generally, however, one would expect to observe few differences across social classes regarding the perceptions of utilitarian product users.

Method

Sample Design

In order to test the hypotheses and the corollaries, 203 women were interviewed in their homes. They were chosen by using a stratified, multi-stage probability sample with quotas. Approximately equal sample sizes were obtained for each social class: 64, upper; 87, middle; and 52 lower.

The women were chosen from a city frequently used for test marketing. The sampling universe was the total number of city households. Initial stratification was done on the basis of income. Census tracts were used as the primary sampling units; each tract was designated as representative of either upper, middle, or lower social class. Interviewers were sent to random starting points and instructed to proceed in a clockwise direction around each block until a quota of six interviews per block had been completed. Block quotas were filled subject to two restrictions: (1) at least one and preferably two of each six respondents were employed; (2) no women under 18 years or no more than two women 65 years old or older be included so as to make the characteristics of the sample as similar as possible to the general population. Some call-backs were required to fulfill the quota within each block.

Product Typology

Across the entire sample of 203, a wide range of product categories and brand names were incorporated into the survey. Two primary criteria were used to select the products which were included in the study. First, the products had to represent categories which could be designated as convenience, shopping and specialty goods. Second, the products had to reflect a wide range with respect to their ability to communicate symbolically. Twelve judges familiar with these criteria were used to categorize 23 product categories. Of the 23, a smaller subset of 8 product categories which reflected the highest levels of inter-judge agreement were selected for inclusion in the final survey.

Two product categories high on the value-expressive dimension (VED) were selected: automobiles and magazines. Three categories moderately high on VED were chosen: washing machines, vacuum cleaners and gasoline. Three product classes low on VED were selected: brassieres, deodorants, and laundry detergents. Available research supports these categorizations. For example, Lessig and Park (1978) found automobiles to have the highest score, 3.65, on the value-expressive dimension among the 20 products studied; magazines ranked eight with a score of 3.08; laundry detergent ranked 17 with a score of only 2.42. Present re-

search also suggests that for at least 6 of the 8 product categories, wives may be the dominant spouse in any decision processes involving their purchase (e.g., Fabian 1965, Davis and Riguax 1974). Within each product category six brands were selected for possible evaluation on the basis of greatest familiarity among a demographically representative pilot sample. Hence, the hypotheses were tested over a comprehensive product typology which included 8 product categories comprised of 48 individual brands.

Operational Definitions

Brand or product user stereotypes were obtained by having each respondent evaluate how she viewed "a person who owns or prefers" a particular brand over 16 semantic differential scales. These scales (e.g., successful-unsuccessful, informed-uninformed, etc.) have been shown in previous research to be well suited to assessing product and brand user stereotypes for various product categories (e.g., Ross 1971; Munson 1973; Munson and Spivey 1979). The scales represent major dimensions of how the individual views either himself and/or others and "...represent clear examples of self-concept definition" (Bills, et.al. 1951). These scale items have demonstrated adequate test-retest reliability over a three week interval, with reliability coefficients (r) ranging from $r = .72$ ($p < .01$) to $r = .68$ ($p < .01$). Additionally, Ross (1967) has undertaken specific converging operations in demonstrating the construct validity of the measure while others (Munson 1973 and Ross 1967) have established their freedom from social-desirability effects. Social class was determined for each respondent by using the Socioeconomic Index for Occupations (Duncan 1961). This index provides social class values for each of the detailed occupational classifications of the census based on a combination of occupational prestige ratings, educational status, income level, and age distribution.

Analytical Technique

The two hypotheses and the corollaries were tested by using one-way, univariate analysis of variance (ANOVA) coupled with a form of the chi-square statistic. For each ANOVA calculated the response variable was the sum of an individual's responses to all 16 semantic differential scales which indexed her stereotype of a specific brand user. Social class was the "treatment" effect of interest. H1, about differences in perceptions for specific brands, was tested within the ANOVA framework by using the standard F-ratio computed for each brand (Hicks 1973). To test H2, the probability of differences in perception at the macro level of product category, a chi-square statistic was computed based upon the ANOVA results associated with each brand within a product category (Winer 1962). The appropriate chi-square statistics were computed based upon contrasts calculated at the micro level of brand. The reader interested in a detail explanation of the relationship between ANOVA and the chi-square statistic used to test H2 should see Appendix 1 where the latter statistic for testing the difference in product category perceptions between lower and upper class is derived.

C1, about differences among social classes regarding perceptions of both brand and product class, was tested by using the principle of orthogonal contrasts (Hicks 1973). A linear and a quadratic contrast were considered simultaneously: the linear contrast considered the difference in mean perception between upper and lower social classes; the quadratic contrast considered the difference in mean perception between the middle class and the average of the upper and lower classes. C2, about differences among social classes existing only for perceptions about value-expressive products, was tested by noting the pattern of results. No specific test statistic was necessary since the hypothesis could be rejected simply by contradiction (Daniel and Terrell 1979).

Results

A summary of the ANOVA and chi-square results is presented for all product classes and brands in Table 1. Note that only the linear contrasts and chi-square are shown; quadratic contrasts are omitted in the interest of clarity. In addition, note that the results are ordered: highly value-expressive products are mentioned first; more utilitarian products are mentioned last.

Value-expressive Brands and Products

Significant differences in brand-user stereotypes were found between upper and lower social classes for 9 of the brands tested (Table 1): Chrysler, Ford, Buick, Standard, Texaco, General Electric, Vogue, Ladies Home Journal and Playboy. These significant differences in brand user stereotypes were most pronounced between lower and upper class--as indicated by the significant linear F-ratios. In only one product category, washing machines, were significant quadratic effects observed. A significant difference in perception for Sears Kenmore washer was found between middle class compared to both lower and upper class. This indicates that the perceptions of lower and upper classes sometimes merge for this brand. Similar results were observed regarding differences among social classes about product categories. As shown by the chi-square statistics derived from the linear F-ratios, three of the eight categories--automobiles, gasolines, and magazines--were perceived differently by the lower social class compared to the upper class. In addition, middle class perceptions were different than the other classes with respect to washing machines as indicated by a quadratic contrast.

Utilitarian Brands and Products

Results for the utilitarian product categories--brassieres, deodorants, and laundry detergents--show relatively few significant differences in stereotypes at either the brand level or macro product category level. Only Right Guard and Salvo were perceived differently.

Conclusions About the Hypotheses

Generally, H1, H2, and C1 were supported; C2 was not supported.

The results for the individual product categories clearly support previous research. The findings for magazines are consistent with Warner and Lunt's (1941) earlier Yankee-City research, while those for automobiles are consistent with Coleman (1960), Peters (1970), and Akers (1970). Peters (1970), for example, found occupational class income (defined as a combination of family income and occupation) to be differentially related to automobile buying behavior for foreign economy, intermediate-sized, and compact cars.

Findings were as expected for automobiles and magazines because other research has shown that among women, these two product classes are perceived as more conspicuous and important than many others (Cohen and Barban 1970). Both may be perceived as having considerable potential to facilitate symbolic communication. The results for gasoline may, in part, be attributed to a type of complimentary relation they have with automobiles. These two products may represent logically associated categories within the consumer's cognitive structure. The findings were not quite as expected for washing machines. Given the similarity of this product to refrigerators, differences between social classes were expected based upon the results of Lessig and Park (1978). But the differences were expected between upper and lower social classes and not between middle class and both extremes.

Implications

Social Classes Have Different Perceptions

Overall, these results refute the contention of Bieda and Kassarjian (1969) that differences in social class have disappeared because of common exposure to mass media. True, as indicated by these results, there is unanimity of perception, but only for some products. Further, it is clear that differences in brand perception across social class are related to the generic product's ability to communicate symbolically. The highly value-expressive product categories had many brands with significant differences in user stereotypes while the utilitarian categories had few. Moreover, for highly value-expressive products, the product categories themselves were perceived as different by upper and lower social class.

The pattern of significant differences in user stereotype across social classes observed for value-expressive but not for utilitarian products has implications for researchers studying opinion leadership. To better understand the processes by which opinion leaders exert their influence, greater knowledge about their social class is essential. The results of this study imply that marketing efforts which attempt to employ either social class or opinion leadership in isolation will be less effective than efforts which consider both simultaneously. Focusing exclusively on one is an inadequate representation of a theoretic system in which both are interrelated. This is true for two reasons. First, the construct "opinion leadership" only assumes meaning within the context of some relevant social system in which the opinion leader is implicated. From a pragmatic viewpoint of identifying market segments and selecting media to reach target segments, social class is the most easily identifiable "social system" construct within which an opinion leader can operate. Second, where instances of opinion leadership occur, it would seem that complex social system and communication effects can intervene between both the opinion leaders' reception of the message from the mass media and his relaying of the message to others.

Appendix 1

Table 1A shows the derivation of the chi-square statistic derived from the linear contrasts associated with the various brands (makes) of automobiles. Brands within the product category can be regarded as a series of k experiments designed to test the same hypothesis (e.g., H2). The probabilities of the observed outcomes with respect to the common hypothesis tested can be designated P(1), P(2),... P(k). If the experimenter desires to make an overall probability statement, the following statistic may be used (Winer 1962):

$$\chi^2 = 2 \sum u_i \text{ where } u_i = -\ln P(i) \quad (1)$$

Under the hypothesis that the observed probabilities are a random sample from a population of probabilities having a mean of .50, the chi-square statistic in equation (1) has a sampling distribution which is approximated by the chi-square distribution having 2k degrees of freedom.

For example, the chi-square based on linear contrasts for automobiles in Table 1A may be determined as follows. The probabilities of obtaining the linear F ratio or one more extreme is given in the column headed Probability. The natural log of the probability with the sign changed is given in the next column. The numerical value of the chi-square statistic is equal to twice the sum of the negative natural log of each probability. The number of experiments (k) or brands equals six; the degrees of freedom is 2(k). An arbitrary alpha level of .05 was selected against which to test the null hypothesis. Hence, the probability of obtaining a chi-square statistic of 28.30 or larger is less than .005 when (chi-square .995 = 28.30) the mean

EXTENSIONS OF THE BASIC SOCIAL CLASS
MODEL EMPLOYED IN CONSUMER RESEARCH

Terence A. Shimp, University of South Carolina
J. Thomas Yokum, University of South Carolina

Abstract

Social class research in consumer behavior has a long history, but the contributions have indeed been minimal. This is partly because the model that has dominated thinking and research is both inconsistent with major trends in American society and incompatible with the socialization perspective that represents a major orientation in studying consumer behavior. This paper proposes extensions to the standard procedure for operationalizing social class and presents data that support the rationale for these extensions.

Introduction

An historical examination of a scientific discipline entails an exhaustive review of that discipline's literature. Analysis of contemporary journal articles and conference proceedings provides insight into those scientific units (i.e., theories, concepts, and methods) that are the subject of current interest, while a review of textbooks over a period of years reveals those enduring scientific units that have transcended the discipline's occasional excursions into faddish areas.

Such an analysis of the consumer behavior literature would likely lead to a major conclusion that many of the cherished theories and concepts which have remained virtually intact for years in textbooks have done so in the absence of any significant advances in insight or explanatory ability. The social class concept is a notable example. Consumer behavior texts invariably include a chapter on social stratification, and the material coverage is, as invariably, highly similar. This literature presumably reflects current knowledge and thinking, yet the scientific value and practical usefulness of social class for understanding and predicting consumption phenomena is dubious.

This paper presents a critical analysis of the manner in which social class has been treated in consumer behavior and offers suggestions for improvement. These suggestions are predicated on the belief that the conceptual model of social class prevalent in consumer behavior is both inconsistent with major trends in American society and incompatible with the socialization perspective that represents a dominant orientation in studying consumer behavior.

Social Class in Consumer Behavior

Consumer behavior interest in social class has waxed and waned over the past two decades. Martineau's (1958) seminal article provided the momentum for other solid works which appeared in the 1960s. Most notable were the writings of Coleman (1960), Carman (1965), and Levy (1966). Where Levy demonstrated that significant differences do exist among social classes with regard to various general behaviors, Coleman cautioned that the social class concept has been misunderstood and over-simplified. Carman, though critical of the overly simplistic manner in which researchers had applied the social class concept, presented a strong case supporting its potential usefulness.

The reflection and conceptualization personified by these works was followed by a period of empirical activity. Rich and Jain (1968) examined the relationship between social class and shopping behavior and concluded that social class has dubious usefulness in understanding this behavior.

Their skeptical perspective was countered by Wasson (1969), who argued, with a modicum of supportive evidence, that social class is superior to income as a predictor of consumer behavior. The social class vs. income debate was initiated, and a series of studies appeared (Hisrich and Peters 1974; Mathews and Slocum 1969; Myers, Stanton, and Haug 1971; Myers and Mount 1973; Slocum and Mathews 1970).

Empirical activity has been sporadic since then, exceptions are the store patronage research by Foxall (1975) and Prasad (1975) and Jain's (1975) novel application of conjoint analysis for delineating individuals' implicit social class concepts.

Interest in social class has not vanished, however. This is reflected in Nicosia and Mayer's (1976) writing on the sociology of consumption and in the provocative piece by Zaltman and Wallendorf (1977). These latter writers argue convincingly that a sociological perspective is needed to supplement the prevailing psychological orientation if a comprehensive understanding of consumer behavior is to be achieved. Their sentiments are echoed by Sheth (1977) who claims that demographic and SES variables, including social class, should not be discarded prematurely; instead, more sophisticated measurement and application are needed. Carman (1978) arrives at a similar conclusion while asserting that social class research has ignored his earlier criticisms (Carman 1965).

Critical Analysis

A variety of reasons account for why social class has provided minimal explanation of consumption phenomena. In fact, there are nearly as many reasons as there are empirical studies (cf. Dominquez and Page 1978; Zaltman and Wallendorf 1979). This critical analysis will provide a useful framework for suggesting improvements in the application of social class to consumer behavior. First, however, it will be useful to examine the exact nature of social class and also explore the reason why social class should provide a useful explanation of consumption phenomena.

The Nature of Social Class

A fundamental difficulty in working with the social class concept is arriving at a clear understanding of its meaning. From a strict sociological perspective, social class is just one dimension of a more general social stratification construct. Class is a power-based concept, including both economic and political elements. But stratification also includes a prestige dimension, or what sociologists term "status."

Carman (1965) has argued that a third dimension, cultural class, is one of primary relevance to consumer behavior. Cultural classes are self-perpetuating sub-cultures which differ with respect to the value placed on education, solidarity of the family, religious involvement, media exposure, recreational activities, etc. Cultural class can be operationalized with real variables (e.g., values, attitudes, behaviors) or with such proxy variables as occupation and education (Carman 1965).

Viewed from the perspective that a particular social class is a group of individuals who share a common culture and manifest similar life styles, the concept of social class

should be useful for understanding and predicting various consumption phenomena: Since human behavior is determined in large part by the particular elements of culture which are learned and transmitted from generation-to-generation, different social classes should exhibit differences in values, motives, and other precursors to consumption behavior.

Why has it "Failed?"

Applications of social class in consumer behavior have not been extensive. The only sustained research has involved the social class vs. income controversy, and this research cannot be regarded as definitive since non-equivalent tests were employed, including different products, diverse data collection procedures, and different operationalizations of social class. The failure of social class rests more on the prevailing orientation that has guided the research.

The basic research approach has been to: administer a standard social class index (e.g., Warner's or Hollingshead's); use the household head's (typically husband's) score as the basis for determining the family's social class; and to statistically test whether different social classes differ with regard to product-, store-, or brand-choice behavior.

Three major assumptions are implicit in this "basic model." First, it is assumed that social class is capable, by itself, of explaining choice behavior, oftentimes without regard to whether or not the consumption behavior in question is subject to cultural influence. A second assumption is the tacit belief that a husband's social class by itself is the sole determinant of a household's class position. An additional assumption is that current consumption behavior can be explained by present social class, without regard to one's class standing during that period of primary socialization influence. These assumptions are now discussed in detail as the "choice behavior," "husband-only," and "present social class" fallacies.

The Choice Behavior Fallacy. The only substantive conclusion that can be drawn from empirical applications of social class is that neither social class nor income is an adequate explanan of consumer choice behavior. It is simplistic to expect a single variable to account for behavior that is caused by multiple determinants. Kassarian (1971) has made this point cogently in his review of personality research, and it is equally applicable here.

A second aspect of the choice behavior fallacy stems from the fact that although social class is an indicator of life style, different products can be used to fulfill the same life style, and the same product can be consumed by different people, in different ways, for different reasons (cf., Kernan 1977). It is thus unreasonable to expect social class to explain and predict choice behavior. Its proper role should probably be to account for the values and motives that underlie this behavior rather than attempting to explain the behavior per se, especially when that behavior may not be subject to cultural influence (e.g., brand choice in a low-unit-value product category).

The Husband-Only Fallacy. Measurement of social class based exclusively on the class position of the household head, who is typically the husband in conventional American families, assumes that the husband's social class is the sole determinant of a household's class standing. In years past this assumption may have been tenable (in paternalistic societies the assumption still holds), but in contemporary America it is not. Indeed, nearly a third of all U.S. households include a wife who is working outside the home at least part-time (Pralle 1980). In addition to augmenting the family's purchasing power, this employment status, together with educational achievements, must have some effect on the family's class standing.

The social class categorization of households based exclusively on the husband's class indicators would be less un-

acceptable if there were a high degree of similarity (homogamy) in husbands' and wives' backgrounds and educations. Research performed by Blau and Duncan (1967) indeed reflects this. "For men 45 to 54 years of age, the correlation between husband's and wife's education is .580, and for men 55 to 64 years old it is no less than .632" (p. 190). These correlations, though apparently invalidating the above argument, actually suggest two reasons why a husband-only measure of social class is inadequate: (1) although husbands and wives share common backgrounds and educations in the majority of families-of-procreation, a large number of pairings are not homogamous; (2) assuming the lower correlation for the younger age cohort reflects a trend (Blau and Duncan did not suggest this), then American families are becoming even less homogamous.

The Present Social Class Fallacy. Operationalizing social class based on the husband's present class position assumes implicitly that every household that is classified into the same social class will exhibit the same consumption behavior because they share this one commonality. The assumption would not be so limiting if American society were free of vertical mobility, but this is not the case. The father-son correlation for occupational status is of the order of .4 (Blau and Duncan 1967). Evidently, a very considerable amount of status modification does occur.

The consumer socialization literature (Moschis and Churchill 1978; Ward 1974; Ward, Wackman, and Wartella 1977) affords an explanation of why this extensive status modification invalidates the assumption that current choice behavior is determined by one's present social class position alone. Basic consumption skills are acquired through a lifetime of information receipt and value inculcation. One's present values, beliefs, and attitudes are partially attributed to recent acculturation but, in addition, are in large part the result of the childhood enculturation process.

Since behavior is partly a function of deep-seated values, beliefs, etc., it follows that consumption behavior is largely determined by past social position in addition to present position. In short, people arrive at the same class position in different ways; just because they occupy the same class position at a particular point in time (the time at which a cross-sectional study is performed) is no reason why their consumption behavior should be the same.

This point takes on added significance when the nature of vertical mobility is examined. The greatest mobility occurs among the "sons" of skilled and semi-skilled workers, i.e., children from upper-lower and lower-middle class families are moving both up and down the class hierarchy. Since the mass market for most businesses (and researchers also) consists of the upper-lower, lower-middle, and upper-middle classes, the respondents in a social class study are the ones who are most likely to occupy a particular social class position that is different from the one in which they received their initial consumption socialization.

Extended Operationalizations of Social Class

Revision and extension of the basic model that has dominated social class research in consumer behavior is long overdue. Previous extension efforts have achieved some success. Coleman's (1960) consumer privilege concept and Peter's (1970) relative occupational class income concept have both enhanced the ability of social class to predict select consumption phenomena. Neither extension goes far enough, however,

A number of extensions are possible. However, the present effort is not intended to provide an exhaustive treatment. The aim, instead, is merely to illustrate two extended concepts and to suggest the consumption conditions when each may augment the explanatory ability of the standard operationalization of social class. The logic of discovery

rather than that of justification provides the philosophy of science rationale for these efforts (Hunt 1976).

A Husband-and-Wife Combined Measure of Social Class

The identification of a household's social class based exclusively on the husband's occupation, education, or other social class indicators has been criticized as a fundamental weakness of social class research in consumer behavior (Zaltman and Wallendorf 1979). Sociologists (e.g., DeJong et al. 1971) have also called for a re-examination of the use of husband-only indicators as the sole determinants of a family's social position. However, how husband's and wife's individual social class indicators should be combined to form an overall family social class score is an open issue.

One method would be to simply average husband's and wife's separate social classes (Haug 1973). This method, though computationally convenient, would be wrong conceptually. The United States is a "leveling-up" society: the marriage of an individual from an upper social class with one from a lower class would not produce a middle-class couple. An alternative would be to assign the higher social class of the husband or wife to the family as a whole (Haug 1973; Haug and Sussman 1971). Conceptual problems also plague this approach. In fact, it would yield results different from the husband-only approach only in those situations where a wife's social class exceeds her husband's.

Both methods ignore the joint influence of husband and wife in consumption-oriented decision making. They would structure a process wherein all consumption decisions would be predicted using the same set of spouse weightings. What is needed is a weighting scheme that assigns weights based on each spouse's relative influence in a specific decision process.

We propose a procedure that places weights on husbands' and wives' social classes proportionate to their relative influence in the consumption situation at issue. The procedure is based on two premises. First, it is assumed that much consumption behavior involves joint decision making. The foundation for this premise is solid (e.g., Davis 1976). A second premise is that the particular social class concept and corresponding operationalization used in consumer research should be situation-specific. To make an analogy, just as a single measure of IQ is inadequate across all cultures, a single social class measure is inadequate across all consumption situations.

For example, if the objective is to predict differences in product use for a product which involves a husband-dominant decision and whose use is not related to deep-seated enculturated values (say the purchase of a lawnmower), then the standard, husband-only concept may serve quite well. If, however, the objective is to account for the frequency of family vacation behavior, which is known to involve joint decision making (Davis and Rigaux 1974) and which likely is influenced greatly by childhood experience, then it is doubtful that the standard concept will account for much variance in vacation frequency.

Implementation of the proposed husband-and-wife-combined measure of social class necessitates two types of measurements. One would entail measurement of the relative influence of husband and wife in the consumption activity at issue; the other measure would involve indicators of husband's and wife's social class. Each is examined separately, and then we turn to the issue of indexing them into an overall family social class score.

Measurement of relative influence of husband and wife would require precise specification of the consumption situation, since the roles of husbands and wives are variable by decision process stage. Once this is done, it becomes a

relatively simple matter of assigning influence to each partner. A common procedure would be to have husband and wife rate themselves on rating scales ranging from "husband decided" to "wife decided" (Davis 1976). Another method would be to have respondents divide a number of points between husband and wife, using a constant sum scale, to indicate each partner's influence (Haley and Overholser 1975).

The separate social classes of husbands and wives could be measured using traditional indices: Warner's Index of Status Characteristics, Hollingshead's Index of Social Position, and Carman's Index of Cultural Classes. Although the validity of these has been challenged in terms of both the choice and weighting of indicators (Dominguez and Page 1978; Haug 1977; Haug and Sussman 1971; Jackson and Curtis 1968), we will assume for simplification sake that the indices are valid so that we can turn to the more fundamental concern of the paper.

The procedure for combining the separate social classes of husbands and wives is illustrated below. The discussion assumes that separate measures of social class have been obtained for both husband and wife, using for illustration Hollingshead's two-factor index. This procedure places each respondent into one of seven occupational and educational categories. The occupational score is weighted by seven, the educational score by four, and the indexed score is then assigned to one of five social classes (cf., Hawkins, Coney, and Best 1980). Using this procedure, the derived family social class would be a weighted sum of each spouse's social class:

$$F_{SC} = \sum_{i=1}^2 w_i SC_i \quad (1)$$

where F_{SC} is the family's overall social class; w_i is the weight for each spouse, derived from the measure of relative role for the decision process at issue; and SC_i is each spouse's social class, ranging from class 1 (the highest) to class 5 (the lowest), following Hollingshead's convention.

A simple numerical example will illustrate the procedure. Consider a decision making situation that varies from household-to-household in terms of relative influence of husband and wife. Assume for illustration that the decision involves the choice of vacation site. Data for four hypothetical families are presented.

	Decision Process Weight: Wife	Wife's SC	Decision Process Weight: Husband	Husband's SC	Family SC
Family 1	0.8	3	0.2	2	2.8 (2)*
Family 2	0.0	3	1.0	2	2.0 (2)
Family 3	0.3	2	0.7	3	2.7 (3)
Family 4	1.0	2	0.0	3	2.0 (3)

*Values in parentheses represent each family's social class based on the husband-only procedure

These illustrations show how social class assignment for a family is weighted in the direction of the spouse who has a greater decision influence. Where the husband-only measure would have categorized Family 1 as class 2, the husband-and-wife-combined measure yields an indexed score that is closer to the wife's class position, since she plays the dominant role in the particular decision. The combined procedure has the opposite effect for Family 3, where the weighting emphasizes the husband's dominant influence. The illustration for Family 4 reflects a situation where the family would be assigned to the wife's social class, because she has sole influence for this particular decision.

Family 2 reflects the only case where the husband-only index provides an equivalent result to our combined procedure. This occurs because the husband is the sole decision maker. Such a situation is the only occasion where it is theoretically appropriate and empirically prudent to designate a family's social class based exclusively on the husband's class position.

A Conjoint, Past-and-Present Measure of Social Class

The focus now turns to the issue of devising a social class index that extends beyond a family-of-procreation's present social class by incorporating the social classes of the families-of-orientation in which husband and wife received their early consumption socialization. In other words, what we are proposing is a social class index which combines "past" and "present" social classes. The considerable amount of intergenerational mobility or status modification provides the theoretical justification for such an index. It is unrealistic to expect to explain a household's current consumption behavior when this behavior in many instances is due to habits, choice rules, and other choice-determining factors that were acquired when family members occupied different (typically lower) class positions during childhood.

The rationale for combining past and present social classes is conceptually sound, but procedures for accomplishing this are not so obvious. For present purposes, we will simply conceptualize what the determining factors might be. Again, the premise is invoked that the amount of weight or influence that is assigned to the to-be-indexed components, past and present social classes, must vary by consumption situation, since there is also variability in the determinants of the particular behavior that the social class measure is attempting to explain. Vacationing behavior illustrates this point. While the decision to take a summer vacation may, for a particular family, be influenced greatly by what husband and wife were accustomed to doing as children, the decision concerning the particular vacation destination may be entirely independent of their past customs or experiences.

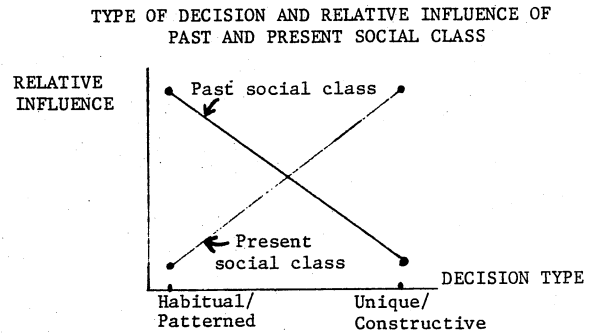

In a more general sense, we propose that the relative roles of past and present social position are a function of how "unique" the particular decision is. Where many decisions are highly habitual and based on past patterns (e.g., consumption decision relating to child-rearing practices), other decisions are unique and require the construction or creation of choice procedures (e.g., the choice of whether to try an innovative birth control method).

This logic is similar to Bettman and Zin's (1977) distinction between stored rules and constructive mechanisms, where the latter is likely employed when a choice is made for the first time or when a changed situation is encountered. We hypothesize that the more unique or constructive the decision, the less the role of past social class as a determinant of current consumption activity. In such a situation, the indexing procedure should assign less weight to past social class. The proposition is portrayed in the Figure.

The empirical upshot is the need for a procedure to identify the relative influence of past and present social classes in context of the consumption decision at issue. Though obviously not a simple task, it would be possible to devise a series of questions to get at the extent to which a family-of-procreation's decision is based on a constructive mechanism, or, instead, results from stored rules acquired during husband's and wife's respective families-of-orientation.

We close this section by suggesting that the empirical difficulties are not as insurmountable as might appear. This is predicated on our view that social class should in the first place be employed as an explanan only in those situations where the consumption activity is truly influenced by cultural class antecedents (Carman 1965). Provided that research is restricted to such situations, then adults in families-of-procreation should be capable of providing reasonably accurate responses concerning the types of behavior performed by their parents during the period of initial consumption socialization in their families-of-orientation.

FIGURE 1

Data Supporting the Need for Extended Conceptualizations of Social Class

Implicit in the foregoing arguments are two crucial assumptions. One is that husbands' and wives' social classes are indeed inconsistent in a relatively large number of households: If the amount of discrepancy were minimal, the combination of their separate classes would be moot, since the husband-only method would capture all the relevant information. A second assumption is that intergenerational mobility is sufficiently extensive to warrant the effort to devise a procedure for combining past and present classes.

A study was performed to test these assumptions. A statewide sample of approximately 800 South Carolina households received a questionnaire in 1979; measures of social class were included among many other questions. The initial mailing and a follow-up generated an 80% response rate. Respondents were somewhat upscale, mostly white, and predominantly from urban locales.

They were asked to describe as specifically as possible the occupation and education of: the husband, the wife, the husband's father, and wife's father. They were instructed to identify their fathers' occupations and highest educational achievement at that period when they (respondents) were "growing up," i.e., "when you were in elementary school." The intent was to capture fathers' social classes at the time of respondents primary consumption socialization.

Hollingshead's two-factor index was used to assign each household's responses to four possible social classes associated with husband, husband's father, wife, and wife's father. Incomplete data were extensive due to such reasons as inability or unwillingness of respondents to designate their father's occupation or education; respondents were retired or had student status, and thus no current occupation could be assigned, a spouse was not employed outside the home; respondent was unmarried; etc.

One person coded all the questionnaires on two separate occasions, with a minimum separation of one month between recoding the same questionnaire. The agreement was substantial. When coding differences could not be reconciled, the questionnaire was removed from further analysis.

Congruity of Husbands' and Wives' Social Classes

The relationship between husbands' and wives' social classes is presented in Table 1. These data represent only those households where both husband and wife were employed outside the home. A total of 311 cases, or almost exactly one half of the total responses, provided this data.

The main diagonal in Table 1 reflects instances of status congruency--a total of 46.9% of the 311 cases. Entries above the diagonal indicate instances where the husband's

TABLE 1

CONGRUENCY BETWEEN HUSBANDS' AND WIVES' SOCIAL CLASSES

Husband's social class	Wife's social class given husband's class					Totals
	1	2	3	4	5	
1 ^a	0	5	6	0	0	11
2	0	38	75	0	0	113
3	0	24	94	5	0	123
4	0	13	34	14	0	61
5	0	0	2	1	0	3
Totals	0	80	211	20	0	311

^aIn the Hollingshead two-factor procedure, lower numbers represent higher social classes.

social class exceeds his wife's. There were 29.3% such cases. Though not surprising, it is noteworthy that the higher the husband's social class, the greater the probability that the wife's class was lower than his, with the obverse holding as well.

The most revealing result concerns the prevalence of cases where the wife's social class exceeds her husband's. There were a total of 23.8% entries, or nearly one-fourth of all cases, below the diagonal. Considering the upscale sample involved in this analysis, it is likely that much greater frequency of wife's-class-greater-than-husband's would be found in a more representative sample. The implication is clear: The traditional, husband-only measure of social class probably under-represents the true social class and purchasing power of a large percentage of families.

Intergenerational Mobility

Table 2 presents data indicating the relationship between the social class of husbands and wives in families-of-procreation with their respective father's social class. There were a total of 457 cases where data were available on husband's and husband's-father's social classes, and a total of 325 cases of wife's and wife's-father's social classes.

Entries on the main diagonal reflect the absence of intergenerational mobility, i.e., children in families-of-procreation possess the same social class as their fathers. The proportion of such cases is essentially equivalent for husbands and wives, 26.3% for the former and 24.9% for the latter. In other words, approximately three-fourths of all families-of-procreation have experienced status modification.

Upward mobility is indicated in the entries below the diagonal, which reflect fathers' social classes as lower than children's. In fact, 65.2% of all the husbands experienced upward mobility, while a slightly larger 67.1% of the wives experienced this mobility.

Entries above the diagonal reveal relatively few instances of downward mobility; there were only 8.5% cases of this nature for husbands, and 8% such cases for wives. These data are harmonious with previous results (e.g., Blau and Duncan 1967) indicating the extensive upward mobility in American society.

Discussion

These data have obvious limitations; foremost, perhaps, is the non-representative sample. However, the data are presented for illustration purposes only, and are not intended as definitive. Limitations aside, the data clearly manifest extensive intergenerational mobility as well as

significant discrepancies between the social classes of husbands and wives in those households where both partners have employment outside the home.

The upshot is that the traditional approach to social class research in consumer behavior is conceptually and empirically flawed. Measuring only the husband's social class and then attempting to predict choice behavior based on this information alone assumes that the husband's class is the sole indicator of a family's class standing. This assumption is untenable in view of the fact that women from approximately one-third of all households are in the work force, and many possess indicators of higher class than their husbands'. We have proposed a method which takes into consideration the social class of both husband and wife, and combines the two by weighting each by the degree of influence each partner has in the particular decision process that is subject of inquiry.

It is also unreasonable to assume that current behavior is solely a function of a household's present class standing. A present-only operationalization disregards past socialization influence. The empirical problem resulting from this is that a sample of households assigned to the same social class by a present-only measure may be quite heterogeneous with regard to values, motives, and other real determinants of consumption behavior.

It is one thing to recommend the indexing of past-and-present social classes into an overall conjoint scale. Doing so is another matter. We have conceptualized a general procedure for determining the relative weights of past and present classes, but specific procedures await future research.

The procedure for combining the separate social classes of husbands and wives is feasible, however; it is merely a matter of doing the research to ascertain whether a combined husband-and-wife index provides superior predictions to the simple, husband-only procedure that has dominated past research.

AN ANALYSIS OF ALCOHOL ADVERTISING USING
FRENCH AND RAVEN'S THEORY OF SOCIAL INFLUENCE¹

Scott B. MacKenzie, University of California at Los Angeles,²
Judy L. Zaichkowsky, University of California at Los Angeles

Abstract

Previous research on the content of advertising has found limited use of information based appeals and has asserted that advertising is typically non-informative in nature. The present study investigated this assertion using a theoretical classification system based on French and Raven's Theory of Social Influence to classify alcohol advertisements. Results of the study showed that within the product category studied, information based appeals were used far more frequently than previously thought. In particular, wine ads were found to concentrate primarily on informational and expert based appeals, while liquor and beer ads concentrated more on referent, reward and coercive appeals.

Introduction

Perhaps one of the most often asked questions in advertising research is "What does advertising do?" Economists have contended that the value of advertising is in the information it provides the consumer. However, it is not clear exactly how much information is actually conveyed in most advertisements. Similarly, in recent years, public policy makers have expressed their concern with how advertisements influence the consumers' choice of products and if advertisements supply consumers with enough information to make "informed choices". In response to these concerns research into the information content of advertising has been carried out by various researchers (Resnik and Stern 1977, Marquez 1977, Shimp 1979 and Pollay et al 1980). Results of these studies show only limited support for the contention that advertising provides information to consumers upon which they can then make informed choices. But if advertisements are not making information based appeals then what types of appeals are being made? It is the purpose of this study to examine the content of advertising using a theoretical framework that will provide insight not only into the information content of advertising but also into the types of non-informational appeals being used.

Review of the Literature

Research dealing with content analysis of television advertising (Resnik and Stern 1977 and Pollay et al 1980) has indicated that only about 50% of all advertising supplies some information cues to the consumer. Resnik and Stern (1977) analyzed the content of 378 videotaped television ads randomly drawn from those aired on the major networks during April 1975, while Pollay et al (1980), using exactly the same methodology analyzed the content of 884 television ads from 1971, 1973 and 1977.

These studies were very generous with their definition of informational cues and looked for these cues along fourteen and twenty dimensions respectively. All specific claims were accepted as valid and classified as information. Assertions in the ad copy were coded so that ads could be

classified as providing information on any or all dimensions, (rather than coding just the dominant theme or 'copy premise'). For example, an informational cue of convenience would be an assertion by the ad that the product is easy to use and/or easier than some alternative. Some of the other cues classified were price, safety, availability, taste, guarantees, etc.. The Resnik and Stern (1977) findings indicated only about 1% of the ads contained three or more informational cues, some 16% provided two cues, and slightly more than half (50.8%) provided no informational cues at all. The Pollay et al (1980) findings also concluded that the advertising studied presented little in the way of informational cues to the consumer. One of the problems with studying the content of advertising in this way is that no information is gained about the types of non-informational appeals being made. If in approximately half of the ads studied no informational cues were given, then what are the advertisers saying in their commercials?

A study by Marquez (1977)³ using print advertisements attempted to address this issue. Using a variety of nationally distributed magazines, he classified 600 advertisements on the dimensions of persuasion, information and intimidation. An advertisement was classified as basic persuasion if it did not contain specific facts about the product and if the claims made could not be verified. Basic information is the converse of basic persuasion and was defined as the specific, relevant and verifiable facts about an advertised product. Intimidation was defined in this study as an act of creating a desire for the product through the use of fear appeals.

Marquez reported that 43.3% of advertisements were basic persuasion, 22.8% of the advertisements were basic information, 22.4% of the ads were high persuasion/low information, 10.2% were high information/low persuasion ads and that 1.2% were primarily intimidation based. Persuasive appeals were thus used twice as often as information based appeals. In addition, he found that the different types of appeals were used more frequently for some product categories than others. Wine and liquor advertisements contained more persuasive appeals than any other product category, while institutional advertising relied heavily on information based appeals.

Marquez's study was a step in the right direction in that he attempted to classify, albeit broadly, both the informational and non-informational types of appeals being made in the advertisements. However, his operational definitions completely lacked any theoretical basis. The definition of persuasion was derived from the dictionary as "an act of causing (someone) to do or believe something, especially by reasoning, urging, etc.; convince". Similarly the definition of information was also based on the dictionary definition of the word, "something told or facts learned; news or knowledge". These definitions are not mutually exclusive. The "reasoning" mentioned in the definition of persuasion could possibly be expected to include "facts, news or knowledge".

What is needed is a classification system that is more soundly based on theory. It is the purpose of this study

¹The authors would like to thank Carol Scott and Jim Bettman for their comments on an earlier draft of this paper.

²Scott MacKenzie and Judy Zaichkowsky are doctoral students, Department of Marketing, Graduate School of Management, UCLA.

³This study made no mention of who exactly judged the ads or of any reliability measure usually associated with content analysis.

to propose such a classification system and use it to investigate the types of appeals being made in advertising. The theoretical framework proposed is French and Raven's theory of social influence, and the advertisements classified will be printed alcoholic beverage ads. This medium and product category were chosen in order to make the ads in this study as similar as possible to those used by Marquez, so that any differences in the results obtained could be attributed to the different classification systems used.

Marquez found wine and liquor ads during 1973-1976 to be highly persuasive in nature and very low in basic information. The present study samples print alcohol advertising from the same time period. Ideally in order to make this study comparable to the previous studies a random sample of all types of ads should have been used. However, since this research is somewhat exploratory in nature, it was deemed sufficient to select one category of advertisements previously judged as non-informational and compare the results using a classification system that is conceptually more precise.

French and Raven's Theory of Social Influence

French and Raven (1959) define influence as a change in a person's cognition, attitude, or behavior, which has its origin in another person or group. Their theory is appropriate for the study of advertising because advertising can really be defined as an attempt on the part of one person or group (the sponsoring firm) to influence the purchase behavior of another person or group (the consumer).

In extending the theory, Raven (1965) identified two types of influence; socially dependent and socially independent influence. Independent influence depends entirely on the "content of the communication" between the influencing agent and the actor, whereas dependent influence depends not only on "what is said" but on "who said it". Raven (1965) theorized that independent influence is the result of a basic change in cognitive elements having its basis in information communicated by the influencing agent. Here the content of the communication is of primary importance, not the nature of the influencing agent.

Five different types of dependent influence were identified: reward,⁴ coercive, expert, referent and legitimate. Reward power stems from the ability of the influencing agent to mediate rewards for the influencee; coercive power results from the ability of the agent to mediate punishment. (It should be noted that rewards can either be physical or symbolic). Expert power (or influence) stems from the attribution of superior knowledge or ability to the influencing agent. The influencing agent then functions as a guide for the other person indicating the path which will most likely lead him to his goals. It is necessary both for the person to think that the influencing agent knows the truth, and for the person to trust that the influencing agent is telling the truth, for expert influence to occur. Referent power results from the person's identification with the influencing agent and his desire to maintain similarity with him. By identification they mean a feeling of oneness between the influencing agent and the person or a desire for such an identity. Legitimate power stems from internalized values in the person which dictate that the influencing agent has a legitimate right to influence them. In other words, the person feels obligated to accept this influence. In all cases the concept of legitimacy involves some sort of code or standard accepted by the individual, by virtue of which the external agent

4

Following Raven (1965), the terms power and influence are used somewhat interchangeably. Raven defines power as potential influence and influence as kinetic power.

can assert his power. (Only a brief description is possible here, see French and Raven 1959 for more details).

In this study a group of judges were asked to determine the extent to which each of the above mentioned types of appeals were presented in a set of advertisements. The judges responded on seven point scales ranging from "definitely not implied" to "definitely implied". The influence bases were operationalized as follows:⁵

1) Information: The ad explains why this is a good product, citing available evidence such as quality of ingredients, caloric content, price, taste, etc.. An example of an informational appeal would be,

"Lite beer has one third less calories than your regular beer."

2) Expert: The ad implies that someone who is an expert, who knows about such products, thinks this product is the best and recommends it. For example, having a wine master stating that, in his opinion, a certain product is the best, would be an expert appeal.

3) Referent: The ad implies that other people, whom you admire or want to identify with, use the product. The following is an example of a referent appeal for Ambrosia Liqueur,

"Are you an Ambrosiac? Have you ever seen the sun rise? Did you ever swim in the nude? Do you enjoy walking on autumn leaves? Have you ever seen the same movie three times?"

4) Reward: The ad implies that if you use the product you will experience some positive consequences from others; i.e., social approval, acceptance, sexual success. The following appeal implies some increase in social approval or sexual success if the product is used,

"Gene Robins recently introduced his girlfriend to Ballantine's Scotch. She, in turn, introduced five friends to Ballantine's. Now Gene Robins has six girl friends. Moral: It pays to be loyal."

5) Coercive: The ad implies that if you do not use this product you will suffer some negative consequences from others; i.e., loss of social approval or prestige, rejection. The following appeal implies some loss of social prestige if the proper wine is not selected,

"Will your chilled wine get a chilly reception? Will the white be wrong? The Chablis shabby?"

These operationalizations of information, expert and referent power are directly derived from French and Raven's definitions. However, the definitions of reward and coercive power used in this study were not exactly the same as French and Raven's. The definitions of reward and coercive had to be broadened to include rewards and punishments mediated by third parties because there obviously was no direct contact between the sponsors of the advertisements and their target audiences. Appeals of this type are really a mixture of information and reward/coercion. The ad gives the person information, but the information is not about the product or its benefits, but concerns what other people will do if the product is used. Therefore, in this study a reward or coercion based appeal is one that gives information concerning what other people (who presumably have direct contact with the target audience) will do if the person does or does not do as the advertisement says.

Legitimate based appeals were excluded from the analysis

⁵The authors would like to thank Bert Raven for his help in operationalizing these concepts.

because it is difficult to imagine any truly "legitimate" advertising themes for alcoholic beverages. Such an appeal would have to persuade you to buy the product because you feel you 'ought' to buy it. Even if such appeals have been used on occasion in the past it is felt that their occurrence would be so rare that their exclusion would not significantly effect the analysis.

Methodology

The Sample

The sample of beer, wine and liquor ads chosen for the study was drawn from a large group of nationally distributed magazines. This medium is representative of alcohol advertising because all liquor and most wine advertising appears in print media. While much of the advertising for beer appears on television, industry experts and advertising agency executives indicated that the same themes and campaigns were used on television and in print advertising. Thus, even though most beer advertising does not appear in print, the print ads are still representative of beer advertising in general.

For each of the eight years between 1971 and 1978, fifteen ads were selected; five liquor ads, five wine ads and five beer ads. One ad for each beverage was randomly selected from each of the five magazines carrying the most advertising pages for the product categories during the year. These five top magazines accounted for 30% to 55% of the total alcoholic beverage advertising pages appearing during the year.

Using the sampling procedure described above, 120 ads were selected. A 35mm color slide was made of each ad. The ads were then randomly assigned to one of the three coding sessions.

Subjects

The judges were introductory psychology students who participated as a part of a course requirement. Ninety coders participated, 30 in each coding session. However, not all of the judges completed the task, thus reducing the number of coders in each session to approximately 24.

Procedure

At the beginning of each coding session the experimenter carefully explained the various power bases to the judges giving them numerous examples, and then answering any questions that arose. All of the judges indicated that they fully understood each of the types of appeals they were to rate. The judges were instructed to consider only the advertisements they were currently viewing when making their judgements and to ignore any images or concepts they had developed from prior experience. (Obviously in some instances it is impossible to ignore past experiences, however in this situation, given the relatively straight-forward judgment task, it seemed reasonable to assume this was possible).

Each slide was projected onto a screen and rated by a group of approximately 24 judges. The judges were asked to: 1) Rate the extent to which each of the five social influence appeals was used in each advertisement and 2) Indicate which of the five appeals they thought was the main point of the ad.

Results and Discussion

The purpose of this exploratory study was to examine the types of appeals made in alcohol advertisements and to assess the usefulness of French and Raven's Theory of Social Influence in classifying them. Consequently, the analyses focused on determining: 1) the extent to which each of the theoretical bases of social influence was used

in the ads studied, and 2) how reliable the appeals could be classified.

The extent to which each of the five types of appeals was present in a given ad was determined by calculating the mean rating for each type of appeal averaging across all judges who rated the ad. For a given product (i.e. beer, wine or liquor), the strength of each type of appeal was assessed by averaging the ratings across all judges and all the ads in that category. The product class mean ratings for each type of appeal were the result of averaging across all judges and all ads. Table 1 contains the mean ratings for each type of appeal for the three products and over all products.

TABLE 1

MEAN RATINGS OF ADVERTISING CONTENT

	<u>REFERENT</u>	<u>INFO</u>	<u>COERCIVE</u>	<u>EXPERT</u>	<u>REWARD</u>
Liquor	3.09	3.49	2.14	2.19	3.83
Wine	2.38	4.57	1.84	3.20	3.20
Beer	2.83	3.23	1.91	2.09	3.74
All Ads	2.75	3.78	1.95	2.51	3.58

The strength of each type of appeal or the extent to which each type of appeal was present is indicated by the magnitude of the mean ratings. From the bottom line of Table 1 it can be seen that information had the highest mean rating (3.78) followed by reward (3.58), referent (2.75), expert (2.51), and coercive (1.95). These means are significantly different at the .001 level, thus indicating that, overall, information based appeals are the strongest type of appeal made in alcohol advertising.

Table 2, which contains the percentage of ads in which each type of appeal was judged to be the main point, also supports this ordering of effects. Thirty-nine percent of the ads were judged to have information based appeals as their main point. Again, reward, referent, expert, and coercive, followed in precisely the same order.

TABLE 2

PERCENT OF ADVERTISING HAVING EACH TYPE OF APPEAL AS THE MAIN POINT

	<u>REFERENT</u>	<u>INFO</u>	<u>COERCIVE</u>	<u>EXPERT</u>	<u>REWARD</u>	<u>TOTAL</u>
Liquor	22%	34%	5%	7%	32%	100%
Wine	10%	51%	4%	17%	17%	100%
Beer	20%	32%	4%	6%	38%	100%
Total	17%	39%	4%	10%	29%	100%

The strength of the information based appeals observed in this study are in direct opposition to Marquez's findings. Both studies sampled ads from virtually the same product category published during the same years. (Marquez sampled wine and liquor ads published between 1973 and 1976, this study sampled wine, liquor and beer ads published between 1971 and 1978). Yet Marquez observed that the ratio of 'persuasive' to 'informational' ads in this product category was 37 to 1. In this study, if all the source dependent appeals (reward, coercion, expert, and referent) are combined into a 'persuasive' category similar to Marquez's, the ratio of persuasive appeals to information based appeals is only 1.5 to 1 (see Table 2). A difference of this mag-

nitude indicates how sensitive the results are to the type of classification system chosen. The choice of the classification system thus becomes an extremely important decision, one that should be as soundly based on existing theory as possible.

The above discussion has been concerned with the overall nature of alcohol advertising as a product class. In looking at the results for beer, wine, and liquor separately, some interesting differences in advertising strategy become apparent. A multivariate analysis of variance, using the judges ratings of referent, information, coercive, expert and reward appeals as the dependent measures and the type of product (beer, wine or liquor) as the grouping variable, was performed to investigate the possibility that the ads for the three types of products reflected different advertising strategies. An overall F of 52.1, which was significant at the .001 level, was obtained. Group level differences across the three product types were tested for by summing each judge's ratings on the five types of appeals and then using this summed variable as the dependent measure in a univariate analysis of variance where product type was again the grouping variable ($F = 22.15, p < .001$). It was also important to determine whether there was an interaction between the type of product advertised and the kind of appeal being used. To test this the following four quantities were computed for each judge on every ad: referent minus information; information minus coercion; coercion minus expert; and expert minus reward. These quantities then became the dependent measures in a multivariate analysis of variance designed to test for product-appeal interactions. An F of 57.27 ($p < .001$) was obtained thus indicating that the profiles for the three types of products are not parallel. In sum, as shown in Figure 1, the three types of alcoholic beverages use significantly different advertising strategies.

FIGURE 1

ADVERTISING STRATEGIES BY PRODUCT TYPE

From the figure it appears that liquor and beer ads are basically the same but that they differ in content from the wine ads. This is in fact the case for referent, information, expert and reward mean ratings. The wine mean ratings for these variables are all significantly different ($p < .001$) from either the liquor or beer means, while the liquor and beer means never differ significantly. (The fact that the coercion mean ratings did not follow this pattern

is not too disturbing since coercion was the weakest of the five types of appeals and was the main point of only 4% of the ads studied).

Furthermore, it can be seen that wine ads use significantly ($p < .001$) stronger information and expert based appeals, while liquor and beer ads use significantly stronger referent, reward and coercive appeals. (Table 2 confirms this pattern of results). It appears that liquor and beer are sold primarily on the basis of "social" appeals, while wine is sold on the basis of "rational" appeals. Referent, reward and coercive appeals are all based on the social consequences of using or not using the product. Information and expert based appeals are in a sense more rational because the decision to purchase the product is based on either information about the product or on expert testimony concerning the product. We might say the person purchases the product because they believe it is better than the competition, rather than because they are concerned with what other people will do or think.

As is typically the case in content analyses, the reliability of the judges ratings was assessed by determining the percentage of times their judgments agreed. In order to do this it was necessary to transform the judges ratings, which were continuous in our study, into dichotomous variables. This was done by recoding the judges ratings so that a rating of 1, 2, or 3, was scored as a zero on the new variable and a 4, 5, 6, or 7 was scored as a one. The newly created variable crudely represents the absence (0) or presence (1) of a given type of appeal. The percentage of agreement between the judges was then calculated for each appeal on each ad. These percentages were then averaged across the appropriate groups of ads to produce the percentage agreements shown in Table 3.

TABLE 3

PERCENT AGREEMENT BETWEEN JUDGES

	REFERENT	INFO	COERCIVE	EXPERT	REWARD	AVERAGE
Liquor	75%	75%	81%	80%	70%	76%
Wine	80%	78%	90%	72%	66%	77%
Beer	75%	79%	86%	82%	67%	78%
Average	77%	77%	86%	78%	68%	77%

Across all types of ads and all types of appeals the judges agreed an average of 77% of the time (93% of the ads had greater than 70% inter-judge agreement). In order to determine how sensitive these percentages were to the way in which the judge's ratings were recoded, an alternate recoding was tried, (1, 2 versus 3, 4, 5, 6, 7). The overall percentage of agreement was 75%. On the basis of these figures in Table 3, we can therefore conclude that the judges' ratings of the types of appeals used in the ads were quite reliable.

Summary and Conclusions

One of the most interesting findings of this exploratory study was the extent to which the advertisements were classified as having informational based appeals. This finding is in contradiction to Marquez's (1977) study and could be due to two points; 1) the fact that the present study only looked at alcohol advertisements, so there was no room for comparison across product categories, and 2) the different classification schemes used in the two studies had a significant impact on the conclusions reached. It could be the case that the use of French and Raven's framework results in a higher percentage of the appeals being classified as informational, but that this increase occurs for all product

categories, thus leaving the relative amount of information unchanged.

Perhaps the main contribution of this paper is the theoretical framework proposed to study and classify the advertisements. French and Raven's Theory of Social Influence not only allows one to distinguish between informational appeals and non-informational appeals but also distinguishes between the various types of non-informational appeals. This information would be very helpful in assessing the value of advertising from both an economic and public policy point of view. For example, public policy makers might become less concerned with controlling advertising for product categories that concentrate on 'rational' appeals and perhaps more concerned with product categories that rely on ads using 'social' or 'emotional' appeals.

Although the present study used print media, the classification scheme also seems adaptable to television advertising. The next step in developing the application and suitability of the French and Raven framework, would be to classify a cross section of print advertisements to see if the results are comparable. It would also be interesting to reclassify the Resnik and Stern (1977) or the Pollay et al (1980) television advertisements to determine what kinds of appeals are being made in that 50% non-informational category.

THE INFLUENCE OF GEOGRAPHIC SUBCULTURES IN THE UNITED STATES

Del I. Hawkins, University of Oregon
 Don Roupe, University of Oregon
 Kenneth A. Coney, Arizona State University

Abstract

Geographic subcultures can be an important variable for detecting differences in consumptive and nonconsumptive behaviors. Physical region and urban-rural-suburban categories provide the basis for specifically identifying regional subcultures, while the nature of geographical influence is defined as being physical or psychological. There appears to be reason to believe that geographic subcultures are fairly stable and that significant behavioral differences of interest to marketers do exist. An explanatory model of geographic subcultural influence is presented, as well as a format for analyzing that influence in the development of marketing strategy.

Introduction

Are there differences in consumption behaviors between individuals that can be predicted or explained by their membership in differing geographic subcultures? If so, what is the nature of the differences? Are these differences likely to increase, decrease, or remain stable during the 1980's? These important questions have largely been ignored in the marketing literature. (For an exception, see Revzan 1978). Yet, as this paper will demonstrate, geographic subcultures exert strong influences on the consumption patterns of their members. These influences have important implications for both marketing practice and the development of marketing theory.

The purpose of this paper is: (1) to describe the nature of geographic subcultures; (2) to point out some of the consumption and nonconsumption behaviors influenced by geographic subcultures; and (3) to present a process for developing marketing strategies based on geographic subcultures.

Nature of Geographic Subcultures

A subculture has been defined as a segment of a culture which shares distinguishing patterns of behavior (Robertson 1970). It is important to remember that subculture members are also members of the dominant culture. Thus, subculture members generally have many behaviors in common with members of the broader culture. However, for a group to constitute a subculture, its members must also share certain behavior patterns that are not shared by most members of the dominant culture. When these unique behaviors affect the consumption process, they become of interest to marketers.

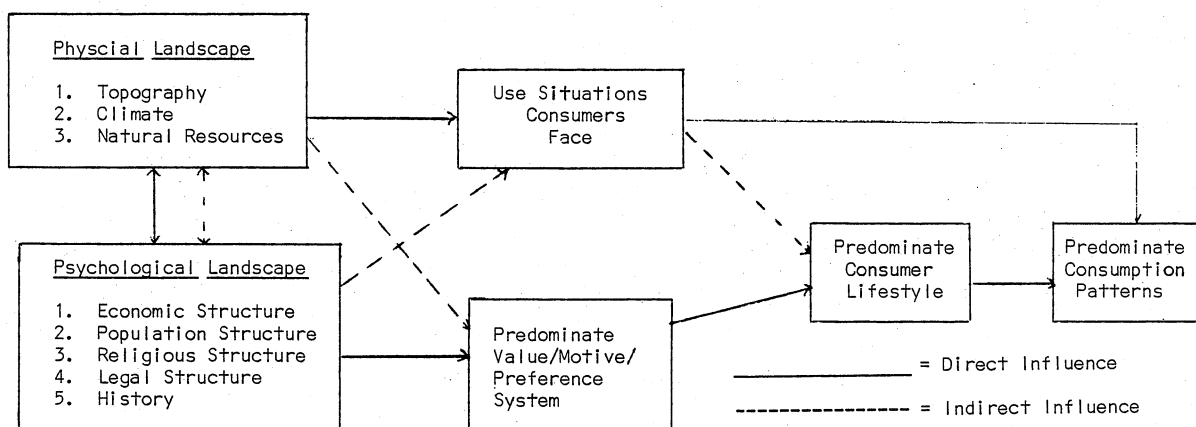

Based on the above definition of a general subculture, a geographic subculture can be defined as a part of the country whose residents share patterns of behavior that are distinct from those of the remainder of the country. There are two fundamental schemes for isolating and defining geographic subcultures: region of the country categories and urban-suburban-rural categories. These schemes may be used either singularly or in combination. Secondary data sources such as the Census Bureau, Target Group Index, and others generally provide underlying data using one or both of these schemes. The factors producing and maintaining the unique behavior patterns associated with a subculture are of the same type for either classification system.

A Model of Geographic Subculture Influences

Figure 1 presents a model of the factors that compose a geographic subculture and the relationship of those factors to the consumption process. The first and most obvious factor is physically bound and influence consumer

FIGURE 1

MODEL OF GEOGRAPHIC SUBCULTURE INFLUENCE ON CONSUMPTION

use situations, and hence predominate consumption patterns, directly. For example, individuals living in very cold climates face particular consumption use situations because of the climate. Warm clothing, antifreeze, insulation and so forth are examples of product purchases caused by physical features of a geographic subculture. A change in physical features (eg. moving to a warm climate) will generally change the use situations consumers face and hence the predominate consumption patterns related to those situations. Physical geographical factors also can affect the predominate value/motive/preference system that is the basis of consumer lifestyle. This influence is more indirect, however.

The second type of influence proposed in the model is psychologically bound. These influences affect relatively permanent characteristics of the individual and have a more enduring nature. Should an individual leave a physical geographical region, the attitudes and behaviors formed as a result of psychological bounds are likely to be carried along. Likewise, an individual moving into a new geographic location will not generally adopt the geographically bound attitudes and behaviors at once, but will have to undergo a period of acculturation before adopting some or all of the new psychologically bound behaviors. Psychological influences directly affect a geographical area's predominate value/motive/preference system and hence the predominate consumption lifestyle of the region. This lifestyle in turn is directly related to consumption patterns since a major reason for many purchase decisions is the desire to maintain or enhance a desired lifestyle.

A brief examination of the major elements of the model will clarify further the nature of geographic influence.

Physical Landscape

The physical landscape is composed of the area's topography, climate, and resources. The topography and climate have a major direct influence on geographically bound behaviors. In combination with the area's resources, they also have a direct influence on the human landscape. That is, the physical landscape determined, in part, the type of people who settled in the region and how those individuals evolved over time. Likewise, the individuals who settled in the area affected the natural resources through either development or depletion activities. The physical environment also affects the value/motive/preference system. For example, relatively "hostile" climates are likely to produce groups that value survival-related skills and activities.

Human Landscape

The human landscape is composed of the economic, population, religious, historic, and legal structures of the area. Obviously, these are not independent variables. Furthermore, each variable may exert direct influences on the value/motive/preference system or the consumption process independent of the geographic region. For example, the Mormon religion influences its followers independently of the area of the country that they are in. However, it becomes a factor in a geographic subculture when it influences the predominate value/motive/preference system of the area, or when it directly influences the behaviors of most members of the region even if they are not Mormons.

Predominate Value/Motive/Preference System

As an area develops a human history, it also develops a value/motive/preference system that is shared in varying degrees by most of the members of the area. New members of the area tend to acquire this value/motive/preference system over time (acculturation). A value can be defined as a widely held belief that affirms what is desirable and has some impact on activities (Nicosia and Mayer 1976). For example, the West Coast and the Northeast regions of the

United States differ rather sharply on the tradition-change value. Learned motives, such as the need for achievement, also vary across geographic regions (McClelland 1961). Preference refers to acquired tastes in such areas as food and architecture which obviously vary from region to region.

Predominate Lifestyle Preferences

Lifestyle refers to how an individual or family chooses to live. It is how one uses discretionary time, the things one owns, how one uses those things, and the meanings those things have to the individuals involved. One hears of suburban lifestyles, informal lifestyles, traditional lifestyles, and so forth. Lifestyles are heavily based on the individual's value/motive/preference system. Therefore, geographic areas often have a generalized lifestyle that is desired by a majority of the members of the area.

Stability of Geographic Subcultures

Given the high rate of geographic mobility, the popularity of national mass media, increased urbanization, increased industrialization, increased travel, and the increased standardization of the education system, it has been suggested that geographic subcultures have or will soon cease to function (see Berger 1960; Mayo 1964; Glenn and Alston 1967; and McKinnery and Bourque 1971). This is sometimes referred to as the massification theory.

However, it appears more likely that, while geographic subcultures, like the broader culture, are changing, they do not appear to be losing their distinctive characteristics (Glenn 1967; Glenn and Simmons 1967; and Peterson and Demaggio 1975). A number of reasons appear to account for this.

Geographic mobility generally involves moves within the same geographic region. Furthermore, individuals often move to a region because they admire the perceived values or lifestyle of that region. Thus, many of those moving into a region already accept many of the region's cultural values. Finally, those moving into a region generally come from a variety of other regions and thus are relatively heterogeneous. The easiest pattern of behavior is to conform to the norms of the existing group. This in time generally leads to acceptance of the regional norms.

Mass media cut through regional areas. However, viewing patterns differ between regions and numerous regional media exist. Furthermore, given the nature of most mass media content, it is more likely to reinforce widely shared cultural values than it is to challenge the unique values associated with individual regional subcultures. In addition, when Glenn and Simmons (1967) examined the effect of mass communication upon different geographic regions, they concluded that it may actually increase the variation between regions because of the differing effect it had in different localities. Similar analyses can explain the limited "massification" impact of increased industrialization, travel, and standardization in the education system.

Research Traditions on Geographical Subcultures

Historians, sociologists, anthropologists and geographers have all tried to conceptually and operationally define and apply the notion of geographical subcultures to their own respective areas of interest. Sociologists, however, are primarily responsible for the evolution of research on geographic subcultures. The founding father of sociology's geographic perspective, Howard W. Odum, characterized a geographical region as having: (1) spacial limits and bounds, (2) flexibility in those bounds, (3) structural and functional aspects that denominate a region, (4) people

"culturally conditioned" through time and spacial relationships (Odum 1942; Odum and Moore 1938). Hertzler (1944) took a social psychologists' perspective towards the notion of geographic regionalism. Hertzler stressed that the underlying concept of a region was its natural landscape. The topography, climate and natural resources determines the specific lifestyle or "social life" of the group. This, in turn, fashions the "cultural landscape" of the group. This landscape includes the economic structure, the composition of the population, the historical social processes of the area and the combination of cultures each successive population increment has contributed to the geographic region. From these variables the regional culture is developed and this makes representatives of that region easily identifiable. Interactions between individuals rest upon this regional base and, in turn, behavior and personality patterns result through the regional "conditioning".

Anthropologists have primarily relied upon a "community analysis" approach. That is, anthropologists have focused their attention upon specific communities and made inferences about the area's culture. When anthropologists analyze a community, they become familiar with the "cultural context" that extends beyond its historical and current social characteristics (Park 1972). Arensberg (1954,1955) utilized this community study approach in an attempt to develop a classification scheme and typology of American culture and geographic subcultures. Arensberg felt that communities which are properly sampled do reflect their culture and to some degree, the cultural qualities of the surrounding area. He then suggested that anthropologists could develop a model that compared communities and effectively delineated regions. This model would examine five variables (individual, space, time, function, and structure and process) and the relationships they had with one another inside a community setting. Gillin (1955) built upon Arensberg's theory and actually formulated a regional descriptive structure. Community cultural data was utilized by Gillin to develop a "list of values" dominant in the American national culture as well as various regional cultures.

As can be seen from the above discussion, a number of research traditions exist with respect to geographic subcultures. While these traditions can provide both data and methodological guides to the marketing researcher, it is likely that a product category specific approach will be required by marketers. This means that marketing researchers should avoid the mistake of "blind" borrowing from other research traditions (an error that has hampered several areas of consumer research, such as personality).

Geographic Subcultural Influences on Consumption and Nonconsumption Behaviors

A popular method used to analyze the significance of geographic subcultures is to analyze regional diversities in respect to a "common social indicator." Homicide and violence (Wolfgang and Ferracuti 1967), educational performance (Ferriss 1969; Sheldon and Moore 1968), infant mortality, fertility (Ram 1976), prejudice (Middleton 1976), authoritarianism (Williams 1966), poverty (Miller 1971), and urbanization (Grasmick 1974; Fisher 1975) are some of the primary social indicators used to understand geographical diversity.

Williams (1966) asserts that there seems to be an association between an individual's level of authoritarianism and prejudice and the geographic setting he/she originates from or lives in. In respect to urbanization, Fisher's article (1975) supports the belief that the increased concentration of population will: (1) produce increased subcultural diversity, (2) strengthen existing diversity patterns, and (3) excite the level of diffusion of subcultural diversity.

Geographic subcultures can also influence any of the steps in the consumption process. It is rather easy to find examples of variations in behavior between regions in the consumption process. For example, more antifreeze is sold in Maine than in Florida. This is due primarily to a variation in problem recognition caused by geographically bound influences (climate). The proportion of beverages sold in returnable bottles is substantially higher in Oregon than in California. This variation in disposition behavior is caused by psychologically bound influences reflected in Oregon state law.

Table 1 illustrates variations in the consumption and preparation of coffee across four broad regions of the United States. As can be seen, there are dramatic differences. Similar differences can be found for other product categories, other types of geographic areas, and other aspects of the consumption process. For example, ratings of television show types showed "adventure" shows to have the lowest ratings of six show types in the Northeast and the West Central regions and the highest rating in the South (A.C. Nielsen).

Table 1
Regional Variation in the Consumption and Preparation of Coffee

	East	Midwest	South	West
Percent consuming (on a winter day)				
Coffee	63%	60%	58%	55%
Tea	32	19	32	20
Soft Drink	47	49	57	39
Milk	44	51	50	59
Fruit Juice	51	41	40	47
How coffee is consumed at home--				
Black	15	39	30	48
Sweeteners only	6	10	14	14
Sweeteners and creaming agents	53	27	38	24
Creaming agents only	26	24	18	14

Even based on the limited evidence presented in Table 1, it is clear that marketing practitioners should consider geographic subcultures as a potentially useful variable when developing marketing strategies. The next section of this paper presents a simplified framework for systematically analyzing the potential influence of a geographic subculture.

A Format for Developing Marketing Strategies
Based on Geographic Subcultures

Figure 2 presents a useful format for analyzing potential geographic influences and determining whether or not those differences will vary, both in nature of and intensity of, between and within geographic regions. The intent of the format presented is not to provide marketing managers with a "formula" that will identify geographic influences automatically. Rather, the format provides a systematic procedure for looking at the decision making process of a specific target market for a specific product across differing geographic regions and boundaries. This systematic consideration of possible geographical influence is an attempt to provide marketing managers with a way to become aware of geographical influence and the ability to pinpoint where in the decision making process the influence occurs. This should then make the development of appropriate marketing strategy more complete and effective.

The geographic influences and differences in the influences by region can best be translated into marketing strategy if looked at from a consumer decision process focus. In other words, the consumer should be looked at from a problem solving/information processing point of view and strategies developed that relate to one or more relevant parts of the decision making process. The decision process utilized in Figure 2 is broken down into problem recognition, information search, evaluation and selection, outlet selection and implementation, product use, product disposition, and satisfaction evaluation.

It may be helpful in understanding the format to use a hypothetical example of the geographic influences on the purchase and use decision of home freezers. Rural subcultures experience a larger degree of problem recognition related

to home freezers than do urban and suburban residences. Furthermore, this problem recognition is of a different nature. Perhaps the primary problem recognition factor in urban and suburban areas is for the convenience offered by a freezer while rural residents recognize the economic benefits of freezing home grown foods. Information search is shown to be less in rural areas due to the limited number of retail outlets (geographically bound) as well as being different due to differing media habits (psychologically bound). Outlet selection is different for rural residents because of a greater reliance on home shopping (mail-order). The disposition of a used freezer is more difficult in an urban areas because of a generally lesser amount of storage space. It also would seem natural to expect that there would be a great deal of variation between regions, even when looking at the rural category, e.g. the Northwest versus the deep South.

Given an analysis such as the one presented, a marketing manager would be alerted to the fact that a standardized distribution or advertising campaign for home freezers across the United States may not be as effective as a geographically based one. Additionally, when one examines the lifestyle characteristics of specific geographical areas, segmentation strategies may become apparent.

Conclusions

In this paper, we tried to illustrate the usefulness if not the necessity of considering the potential influence of geographic subcultures in the development of marketing strategies. In addition, we presented a structured framework to aid in analyzing the influence of geographic subcultures. It is our position that using a single marketing mix throughout the United States without considering poten-

U = urban S = suburban R = rural

tial geographic variations makes no more sense than applying the marketing mix in a variety of countries without first examining the cultural variations among those countries.

While less obvious, geographic subcultures may also influence the development of consumer behavior theory. For example, the responsiveness to various persuasive techniques (authority figures, fear appeals, and so forth) may vary across geographic regions because of differing values. Studies conducted in only one geographic region may produce results that are specific to that region. Likewise, national studies that are aggregated for analysis may hide the fact that the variable being examined has differing impacts across geographic regions.

It is hoped that this paper will alert both marketing practitioners and academicians to the potential advantages of recognizing the strong geographic influences within this culture.

CONSUMERISM IN DEVELOPING COUNTRIES - THE BRAZILIAN EXPERIENCE

John Stanton, Temple University
Rajan Chandran, Temple University
Jeffrey Lowenhar, Temple University

Abstract

Consumerism in developing countries has not been analyzed and discussed in current literature. In part this has been due to the lack of an appropriate methodological framework. This paper adopts a model developed by Kotler to the analysis of consumerism in developing countries. Consumerism in Brazil is explored as a case example. Guidelines for policy are suggested.

Consumerism in Developing Countries The Brazilian Experience

Introduction

Consumerism in the United States has received much attention in recent business literature. Most of the articles dealing with the topic have been descriptive, commenting on its importance and implications, and/or prescriptive, outlining alternative activities and policies for consumers, governments, and firms. However very little attention has been paid to consumerism abroad, especially among developed and developing countries where consumerism is in its infancy or early growth stage. In these countries, protest over consumer issues has advanced from basic causes such as lack of food, clothing and shelter; to more sophisticated issues like consumer information reforms, consumer education, and consumer protection. Since a large part of American trade is with these developed and developing countries, government policy makers, consumer behavior researchers and the business community must be aware of and concerned about the growth of consumerism in these countries and its economic and social ramifications. For example, promotions used by the baby food subsidiaries of Nestles and Bristol Myers have been attacked in many developing countries (Sethi 1978). These firms have been held responsible by its critics for the unintended deaths of infants, which resulted from the misuse of their products. There has also been an increasing incidence of government intervention and control of all aspects of business life abroad. It is essential that American business firms strategically intervene when confronted with the growth of consumerism in developing and developed countries, rather than take a benign stance. Governmental policymakers can also learn from studying consumerism abroad by noting the methods used by other governments in tackling this issue. For example, Gazda (1977) has noted that the Canadian Government has influenced the growth of consumerism by timely and active responses. Despite its importance, international consumerism has not been systematically discussed in current literature. In part, this has been due to the lack of a methodological framework for examining and comparing consumerism in developing and developed countries.

In this paper the authors will attempt to (1) discuss the global use and interpretation of the term "consumerism" by examining some current consumer literature (2) analyze consumerism in Brazil using a theoretical framework developed by Kotler, (3) highlight the social and economic implications and (4) suggest guidelines for consumer policy. The article focuses on Brazil because: (1) it is a developing country faced with problems which are typical of those encountered in developing countries; (2) it contributes significantly to the overall Latin American economy by virtue of being the biggest country in Latin America and (3) the authors have been able to gather first

hand information during recent visits.

Some Current Definitions

A determination of whether historical and current consumer movements can be adequately characterized by universal definitions requires an analysis of current definitions and examples.

Buskirk and Rothe (1970) in a oft quoted definition of consumerism characterize it as:

"The organized efforts of consumers (whatever the economic system they live under) seeking redress, restitution and remedy for dissatisfactions they have accumulated in the acquisition of a standard of living." (emphasis ours)

Hermann (1970) on the other hand explains consumerism as:

"A conglomeration of separate groups, each with its own particular concerns, which sometimes form temporary alliances on particular issues."

Kotler (1972) defines consumerism as:

"A social movement (under any system) where buyers seek to augment their rights and powers in relation to sellers." (emphasis ours)

The common feature of these definitions is the organized efforts of consumers, or identifiable consumer groups in any system to right perceived and/or actual wrongs. (Coppet 1974) The wrongs may have been committed by businesses in countries where the free enterprise system exists, or by government in countries where the government plays an active role in the economic system. Kotler's definition is broadest in that he interprets consumerism as a social movement where a group of people coalesce to accomplish a shared goal. Kotler's model provides a framework for examining and comparing consumerism in different countries. Kotler explains the social factors contributing to consumerism as a social movement. First, there must be present (1) Structural Conduciveness: an environment conducive to consumerism - an educated group of people, growth of income, certain problematic issues that require collective behavior. These factors induce greater expectations, which when unfulfilled produce (2) structural strains in the existing socioeconomic system. These structural strains contribute to the (3) generalized belief that business has not been responsive to society's expectations of performance. This general belief is then ignited by external factors that act as a catalyst or a (4) precipitating factor. Professional consumer spokespersons, politicians and the media (5) mobilize for action to solve the identified problems. Businesses usually act, but if their actions are perceived as inadequate, some form of legislation or (6) social controls result.

Hendon (1975) documents the fact that, historically, some manifestations of consumer discontentments have been recorded as social movements. Consumers have organized and sought redress at various times under different political systems. He cites the Grain riots (1775), Revellion riots (1789), and Grocery riots (1792-93) in France as examples of organized protests based on consumer issues. In Eng-

land the Grain riots (1736), Price control movement riots (1776), Garden riots (1780), Church and King riots (1790-92) and Rebecca riots (1839-42) also were based on consumer issues. In Poland the recent food riots were the result of consumers seeking redress for some basic dissatisfactions. In the United States the Boston Tea Party (1760) the Whiskey rebellion (1790), collective consumer movements of the 1900's and 1930's, and the more recent meat price agitations were likewise based on consumer dissatisfactions. Hendon notes that until a nation is economically mature, consumer issues usually revolve over basic issues like food, clothing and shelter and tend to be violent. As the country develops, problems of consumption outweigh problems of production, consumer issues become more sophisticated and less violent. In the economically mature countries, consumer issues focus upon auto safety, nutritional labelling, advertising to children, wool products labelling, boat safety, Consumer Credit Protection and the like.

Gaedeke and Udo Aka (1974) queried diplomatic representatives of 58 nations on consumer concerns in their respective countries and seemed to confirm Hendon's theories. They found that the degree and focus of consumer concerns and consumer protection programs depended upon the level of industrial development of the country. As countries develop, consumer concerns and the need for protection assume increased meaning and importance and become vital elements in business and government policy.

In summary, it is safe to conclude that the above definitions of consumerism are typical and generally accepted. The consumer movement has always existed in some form throughout history in many areas of the world under a spectrum of political systems. The United States is not, and has not been, a leader in worldwide consumerism. Consumerism is a social movement dependent upon national economic conditions. Its progression in different countries can be analyzed using the Kotlerian framework. The economic maturity of a country dictates the sophistication of the topics involved, the violence of the movement, and future.

Brazil and Consumerism

Having discussed and explained consumerism, for the purposes of the article we will attempt to assess the status of consumerism in Brazil. First, a very short introduction to the country will be provided which highlights the importance of studying consumerism in Brazil.

Brazil has an estimated population of 120 million people; it is the most populous country in Latin America and has the seventh largest population in the world. The approximate annual growth rate of the population is 2.8%. Half the population is located in urban areas; approximately 35% reside in Brazil's eight largest cities. The 1979 GNP was approximately \$200 billion.

Geographically a large country, Brazil has extremely rich mineral resources, particularly iron ore, manganese and semi precious gems. In addition, a new kind of bauxite was recently discovered in the Amazon region. Brazil's industry is quite strong, with exports of \$10.1 billion in coffee, \$2.2 billion in iron ore, and \$1 billion in soybeans. With the aid of severe restrictions on imports, Brazil has generally maintained a fairly good balance of payments. Recently oil imports have posed a problem, but they are likely to be reduced by up to 20% when a new alcohol program is operationalized. This will hopefully result in a more favorable balance of payments position.

Foreign investment represents a small but important part of Brazil's capital base. Although the United States makes a significant portion (4.5 billion) of the approximately \$10 billion of foreign investments, other countries

such as Japan and Germany are increasing their capital commitments.

The world's financial institutions expect the continued growth and development of Brazil. Brazil is currently Latin America's largest borrower from international financial institutions, with \$50 billion in commitments to commercial banks and other institutions such as the World Bank and International Monetary Fund. (Business Week 1978)

After examining its economic status, one can conclude that Brazil is one of the most important emerging countries. In addition, recent social changes make the study of consumerism in Brazil more attractive. Military control has been reduced and there is a movement towards a more democratic society. Secondly, improvements in education, and better dissemination of information through the mass media indicate that factors conducive to consumerism evolving into a broad social movement are present.

Application of the Model to Brazil

Using the framework developed by Kotler we can analyze consumerism in Brazil in greater detail. (See Figure 1)

1. Structural Conduciveness

Brazil has four structurally conducive characteristics that permit or create the potential for a consumer movement: a) advances in income and education; b) growth of technology; c) exploitation of the environment and d) disparities between the quality of local and exported products.

(a) Income and Educational Advances

Brazil, like other developing countries, has experienced a steady increase in per capita income each year, although the average income is still far below that of developed countries. One estimate of the per capita income of residents of the areas surrounding Rio de Janeiro is \$556 per month (Pesquisa de comercio 1974), an estimate for similar areas of Sao Paulo is \$350 per month. (Cunningham, Moore, Cunningham 1974) The average number of automobiles per family is estimated to be .72, although the average for families with at least one car is 1.32. (Pesquisa de Comercio 1974) A 1974 study of Brazil indicated that 41.3% of the population of Sao Paulo could be classified as middle class. (Pesquisa de Comercio 1974) Consumers visit shops frequently and spend considerable time shopping for food, clothing and appliances. The fact that should be stressed is the prominence of middle income consumers who now have the opportunity to buy goods and services. Furthermore, this growing middle class has higher levels of education. In Rio and San Paulo a majority of the residents have had at least secondary school education. This is particularly important since an educated middle class plays an important role in advancing consumerism due to its higher expectations. (Diamond, Ward and Farber 1976) When these expectations are not met, frustration usually results, setting the stage for consumerism.

(b) Growth of Marketing Technology

The sudden growth of imported technology, both in marketing and manufacturing, plays an important role in creating social contradictions and strains. The problem of marketing technology, especially unwholesome marketing technology, is exemplified by the exposure of the Brazilian consumer to subtle marketing campaigns that could cause confusion for more sophisticated consumers. For example, consider pricing tactics in Brazil. Various pricing alternatives are offered to consumers in advertisements in Sunday newspapers in several large Brazilian cities. The main alternatives are: 1. the monthly payment price often stated without specifying the actual number of required payments. 2. the full price if payment is made at time of purchase (called a vista). 3. both the a vista price and the monthly payment price (both with and without the number of payments).

This type of pricing makes it virtually impossible to shop comparatively. Yet for many product categories, Brazilian shoppers use the newspaper as the primary source of information. When information was available to compare the monthly price of a product with the a vista price, the time payment method was extremely costly, even after considering the effect of inflation. Confusing marketing strategies, shoddy products dominate the market system. Games, prizes, discounts, and other gimmicks cause additional mis-information to be communicated to the Brazilian consumer.

(c) Exploitation of Environment

The progressive exploitation of the environment is a factor that has special significance in Brazil. Many Brazilian cities are situated in areas of magnificent natural beauty, but the development of business and urban housing has been accomplished with utter disregard for the ecological balance. Copacabana in Rio de Janeiro is a classic example of this situation.

Pollution is yet another problem. Many of the largest Brazilian cities have pollution levels that are far worse than those that resulted in consumer and governmental action in comparable American cities. In a recent public opinion poll of the 11 million inhabitants of the Greater Sao Paulo area, residents indicated that their major concern was air pollution. (Brazil Herald 1977) Brazilians are proud of their cities and their beaches, and the decay of both has aroused many residents.

(d) Quality of Local versus Exported Products

A factor unique to developing countries contributes to social contradictions: the quality difference between products produced for local consumption and those produced for export. In Brazil the finest coffee and leather is exported and not available for local consumption. One Brazilian automobile (PUMA) has 50 safety options that are available only on the exported model. (Ribeiro 1974) In essence, export products are of higher quality and have better features than those produced for domestic consumption. These inconsistencies and limitations become a major impetus for change.

In summarizing this section, one can conclude that the presence of an educated population, a prominent new middle class demanding quality goods and services, and the increasing exploitation of the environment, form the basic elements for consumerism and that the potential for consumer action exists.

2. Structural Strains

The existence of the above elements lead to social contradictions resulting in conflicting attitudes and deteriorating relations between consumers, businesses and government. These conflicting attitudes and relations in turn produce structural strains among parts of the socioeconomic system causing frustration and discontentment.

Economic discontentment is very real in Brazil and other developing countries. Inflation, cited as a structural strain in the United States is a major economic problem in Brazil. Average monthly inflation is estimated to be about 6% unadjusted or about 78% in 1979. Consumers are aware that their salaries do not rise at the same rapid rate. There is pressure on consumers to spend all their income, because attempts at saving are futile due to inflation.

Political discontentment is a major problem in Brazil. Unlike other developing countries, Brazil has a stable government, but it is a military government. There is much discussion about returning the government to a true democracy, and some steps have been taken in that direction this past year. However, the interaction between the military and the population appears to be a special strain,

although the military is not without internal discontentment. The labor movement has claimed the right to strike and the middle class is increasingly discontented with the country's economic institutions and unresponsive bureaucracies.

The first two antecedent conditions for the growth of consumerism structural conduciveness and strains are evident in Brazil. If these were all that were needed for consumerism, one would expect that Brazil would soon have a very active and vocal consumer movement. Yet a consumer movement has not appeared. The last four conditions appear to be acting as restraining influences. Of course, the question of the degree of development required before the conditions can coalesce is subjective. Recent social changes and the authors' personal experience this past year suggest that the other components of the change model are emerging in importance.

3. Generalized Belief

The existence of stress leads to the proliferation of certain consumer beliefs. As a social movement consumerism cannot develop unless there is a generalized belief about problems in the marketplace. This generalized belief, however, is not well developed in Brazil. ANDEC (Associacao Nacional de Defesa do Consumidor) is trying to create this awareness and generalized belief, however it has a limited budget and staff. Several legislators have an interest in the consumer's cause, but they lack clout. Nina Ribeiro, Deputato Federal, addressed the congress on the plight of the Brazilian Consumer as early as 1971. He has a regular TV show on consumer problems in Rio. Ualo Neto, a former biology teacher is now head of the environmental protection division in the Ministry of Interior, and is active in environmental protection.

In general, it appears these efforts have made only a slight impression on Brazilian consumers. There are two major reasons for this problem. First, the press in Brazil is not absolutely free. It does little to communicate consumer beliefs. Second, there is a predominance of fatalism among Brazilians as with the members of most underdeveloped countries. (Neilson and Stanton 1972) Although Brazil is now emerging from its underdeveloped economic state, its culture, attitudes, values and other social characteristics are slower to change. Social-psychological changes take longer than economic changes and require that consumers perceive their attempts at change will be ultimately successful. If consumer confidence does not exist, a generalized belief about problems and solutions will not develop.

The consumer movement is less likely to flourish without generalized consumer beliefs. Consumerism needs sustained consumer or general population support. In Brazil although these conditions are presently not readily apparent, a basic structure is developing that would make the maturing of the remaining conditions faster than would be expected. Inflation and other economic pressures are growing, it is likely that consumerism will soon become familiar to Brazilians. Some of the impetus, of course, will hinge on the future actions of the Brazilian government.

4. Precipitating Factors

The existence of a common belief is a necessary condition for a social movement to evolve. However, a catalyst is needed to precipitate the movement. Catalysts or precipitating factors are usually specific events or major problems that spark the growth of the social movement, in this case, consumerism.

Precipitating factors can develop quickly and without warning. For example, in the United States Ralph Nader was a lawyer and unknown freelance writer in 1964; one year later he was the author of the well-known book Unsafe at any Speed and ignited the consumer movement. (McCarry 1973) A Brazilian could just as quickly come to the fore-

front of consumerism in Brazil. A major roadblock to any precipitating factor emerging is the National Security Laws of Brazil. When liberally interpreted, it prohibits all actions perceived as contrary to the interests of the government. If the government does not create an environment that is conducive to consumerism, its genesis will be slow, and probably violent.

This condition should not be viewed too pessimistically, however. For example, the existence of similar laws in Poland did not hinder consumers from rioting over high food prices. Further sharp rises in prices or any other problem in the Brazilian economic environment may become the spark necessary to precipitate a consumer movement. Another catalyst might be the natural environment. With increasing urbanization, groups are forming to address environmental issues. Although one may question whether "all" sides believe this issue is important, progress on raising the level of the population's awareness of this issue is evident.

5. Mobilization for Action

The success of a consumer movement ultimately depends upon how effectively it is organized and managed. This can be accomplished either by a single dynamic individual or groups of individuals. Working links are usually established with people in universities and other professions to acquire technical expertise and credibility. Politicians, prestige seekers and other groups coalesce and the movement is born.

In Brazil, although still small, special purpose consumer groups are beginning to form. A group in Sao Paulo organized a Walk-a-thon to focus attention on pollution within the city. Residents in Rio made an overnight trip (in a caravan of forty cars and buses) to the neighboring state of Espirito Santo to protest government attempts to convert a world-famous biological reserve into a commercial palm plantation. Other residents in Rio have blocked construction of high rise apartments around one of the city's most beautiful parks. Residents of Sao Paulo also battled the city over plans to build a paper factory at the headwaters of what is said to be the state's last unpolluted river. Although these are at most rudimentary beginnings, they indicate the genesis of a structure that could support rapid growth if encouraged. A few politicians are now campaigning on consumer issues, as consumer awareness develops, more and more politicians will use this strategy. Consumerism is a non-political social issue that lends itself well to the "bandwagon" effect and will in all likelihood draw followers in the times ahead.

Another element for mobilization is the mass media. In Brazil (as in other developing countries), there is censorship of the media. Although censorship is usually not directed at issues like consumerism, it can often be capricious, thereby restraining the media from controversial issues in general. Lack of wide media coverage has to a certain extent stifled the organization of a consumer movement in Brazil, but with the return of certain freedoms under the new government there could be better mobilization for action.

6. Social Control

The progression of the consumer movement in a country will ultimately depend upon the reaction of business and government leaders. Counterveiling forces must be considered in assessing the progress and course of consumer movements. If business or government leaders fail to respond appropriately, consumer activists are encouraged. In the United States, legislators and the business community mostly ignored the early signs of growing consumerism. This response created greater frustration and resulted in an even more organized and concerted consumer effort.

It is too early to determine how the Brazilian domestic and multinational business community will respond to the activities of consumerists. The government appears to be trying to participate in the process, but like all bureaucratic bodies it moves slowly. Still, increasing budgets, new departments, and so forth indicate that the government is not ignoring the potential consumer movement. It is also possible that the domestic business community may learn from the mistakes of developed countries and react more quickly to protests and complaints, although this appears improbable. Multinational corporations in Brazil could play a more active role in determining future consumer needs and rights rather than reject proposals for change. They can listen to "reasonable" proposals and act jointly with the government as influential change agents, and thus negate the need for overly stringent legislation. Certain industries, like the Brazilian advertising industry, are developing codes and procedures that are attempting to provide consumer protection from fraudulent and misleading advertising. This is an initiative taken by the industry because it feels it has professional expertise that policy makers lack.

Summary and Implications

When the previously discussed conditions were present in the United States in the 1960's, the consumer movement advanced to where it was recognized and accepted as a part of the American society. In developing countries like Brazil, consumerism appears to be in an infant stage. But, as can be seen in this article, many of the antecedent conditions that gave rise to the American movement are present in Brazil. The emergence of a generalized belief and certain precipitating factors could activate the dormant movement. It only took approximately 15 years for consumerism to become a household expression in America. The United States, however, was at a much higher level of economic development than Brazil at the time.

It is difficult to predict when or how quickly the movement will flourish in Brazil or other developing countries. A great deal depends upon the government's role in the process. The significance of the government's position has both positive and negative potential implications. The government of developing countries have traditionally played active roles in stimulating public sectors of the economies to grow faster than would be expected in free market situations. It appears that Brazil's government will continue to play a major role in the country's economic development. For example, Brazil's Minister of Finance, Henrique Simonsen has said he prefers a hybrid economic system to minimize the imperfections of both free markets and planned economies. He believes that it is not a question of finding out which works better under ideal conditions but which makes the fewer mistakes under normal conditions. (Simonsen 1977) The government in Brazil has not played an active role so far.

Likewise, until the government realizes that consumerism is an expected and important adjunct to economic development, it will not encourage the business sector to support the consumer movement or introduce the legislation to force compliance. For that reason, it will be important for the newly formed consumer groups to demonstrate to government officials that in the long run the effect of the consumer movement is to provide better, safer and more efficient products and thus stimulate economic growth rather than hinder it.

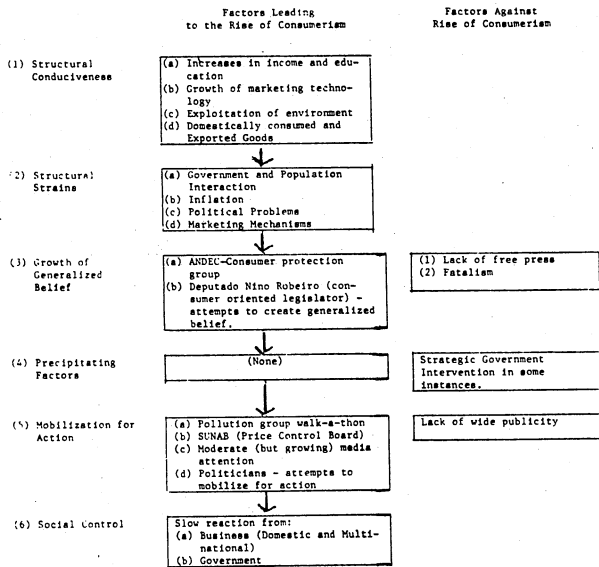

Two situations illustrate this point. Used car dealers are required by law to disclose all defects and potential problems to the buyer. The effect of this law was lower car prices, since in general prices were higher when defects could be "forgotten." It was estimated that the savings to the consumers of one state was \$40 million in one year. These savings are now available to the consu-

mers to either save, which encourages investment, or spend. (Anderson and Whitten 1977)

In Brazil new legislation, although still unclear, is being considered to force retailers to give both the a vista price and the monthly price with the number of payments. The impact on consumers might be to encourage comparative shopping. Monthly payments might still be selected due to lack of funds or credit availability but the purchase decision will be based on accurate and comprehensible information. Consumers who select the a vista price will have additional monies to spend on other items rather than on interest.

Consumerism is inevitable in developing countries, as conditions conducive to its development emerge. The direction of consumerism in Brazil is yet to be determined and its leadership is still unclear. The multinational community can and should engage in a more positive role with the governments of developing countries in future consumer issues. Rather than maintaining a passive or reactive stance, the multinational firms can utilize their experiences in developed countries to shape consumer programs in developing nations that reflect their interests. This should not be thought of as an attempt to subvert the consumer movement, only to suggest that the mutual interests of both groups may be more closely attained if they share a joint role in establishing policy.

TESTING THE STABILITY OF MARKET
SEGMENTATION ANALYSIS¹

Tony Schellinck, Dalhousie University²
Ian Fenwick, Northeastern University²

Abstract

The validity of segments formed by search procedures is of major concern to marketers. Currently split-half analysis is the most recommended method, but this requires large samples. This paper presents an alternative validation method which does not require large samples. The procedure is illustrated using a segmentation by AID analysis.

Introduction

Market segmentation is well entrenched as an integral part of marketing theory, but market segmentation analysis still faces many problems. As Wind (1978) points out: The validity of segmentation research is by far the most crucial question facing management. Do the segments discovered in a segmentation study exist in the population? Is the estimated segment size accurate? And how accurate are the estimated segment responses to the firm's marketing actions?

These questions are particularly important when the researcher uses a clustering based segmentation method. Powerful search techniques scan the data and will almost certainly identify a structure. The authors have yet to find a real data set that did not yield distinct, interpretable clusters from at least one clustering algorithm. Unfortunately the identification of such "segments" in the data is no guarantee of their existence on the ground. The susceptibility of search procedures to sampling error is well known (Doyle and Fenwick 1975) and there is a real danger that the segmentations produced may be highly unstable. Typically, consumer researchers have few a priori hypotheses about their segments and consequently can rationalize almost any segmentation, spurious or not.

Validating segment structures is recognized as a particularly difficult task (Anderberg 1973; Frank and Massey 1975; Hartigan 1975; Sherman and Sheth 1975). Replication is the most frequently recommended validation method, usually in the form of a split-half or hold-out analysis (Frank and Massey 1975; Mehrotra and Wells 1978). These methods analyze one half of the data and use the other half to test the analysis' predictions. In the case of segmentations, groupings derived from one half of the sample may be compared with those derived from the other.

Split-half analysis has two major problems. First, for a viable split-half test, half the data set has to be sufficient for the analysis technique being used. Consequently the researcher has to collect a sample twice the normal size. In practical terms this often translates into either no attempt at validation or else two analyses both based on inadequate samples.

Second, split-half testing will identify discrepancies between the analyses applied to the different halves, but will offer no clue as to which is the better representation of reality. If the split-halves fail to agree in some respect (e.g. factor structures differ; segmentations change; or predictive power is low) it is usually impossible to tell whether the differences are due to idiosyncracies of the particular split used or genuine indications of an unstable analysis. If the sample had been split in a different way, different variations in the analyses might have been observed and different results labelled unstable. Indeed researcher's reaction to split-half disagreement is varied. While most applications simply drop all parts of the analysis that are not identical in both split-halves, some actually retain all results that are of importance in either split-half (Roberts and Wortzel 1979).

It would be of much greater practical use to have a validation method that was based on more than two sample variations. This could test stability and offer a majority opinion of what the true structure was like. The method presented, here called "N + 1 Sample Analysis", allows just such an estimation of stability without requiring additional data collection.

N + 1 Sample Analysis

N + 1 Sample Analysis is based on the jackknife procedure (Tukey 1958). The jackknife requires that the available sample be split, at random, into N equal-size subsets. The analysis to be jackknifed is carried out on the whole sample, and then repeated omitting each subset of the sample in turn. Each of these analyses on the sample with a subset omitted yields estimates \hat{p}_i , $i=1, N$. The jackknifed estimator, $J(\hat{p})$, is a weighted difference between the mean of these estimates and the results for the whole sample analysis:

$$J(\hat{p}) = N \hat{p}_{\text{all}} - (n-1) \bar{\hat{p}}, \quad (1)$$

where \hat{p}_{all} is the estimate derived from the whole sample analysis and $\bar{\hat{p}}$ the mean of the \hat{p}_i values.

Jackknifing will often reduce bias and enables significance tests to be performed (for a further discussion of the jackknife and its use in marketing, see Fenwick 1979).

As it stands the jackknife procedure cannot be applied to testing segment stability. It is designed for a parametric rather than grouping methods. However the principle of N + 1 separate analyses - one on the whole sample and N on samples with a subset omitted - is distinctly relevant. The N analyses of samples with a subset omitted can be used to validate the grouping formed in the whole sample analysis. In the example presented here N + 1 Sample Analysis is used to validate a segmentation produced using AID.

AID Analysis as a Segmentation Method

AID (Automatic Interaction Detection) developed by Morgan and Sonquist (1963) is frequently used as a segmentation

¹Part of this research was supported by a grant from the Dalhousie School of Business Administration and the assistance of Marie Kalbfleisch.

²Tony Schellinck is Assistant Professor of Marketing at Dalhousie University; Ian Fenwick is Visiting Associate Professor of Marketing at Northeastern University.

method (Assael and Roscoe 1976; Sheth and Roscoe 1972; Gensch 1978; Assael 1970). AID employs a sequential dichotomization technique to partition the sample into progressively smaller groups so as to maximize between group differences. This analysis forms a tree diagram the end groups of which are used to define market segments.

AID is notoriously unstable. Its developers cautioned against its use on samples smaller than 1000 and validation was strongly recommended. Validation has in fact rarely been attempted, and where it has AID has not held up well (Doyle and Fenwick 1975). Nonetheless AID is very appealing as a segmentation tool. It offers the capability to handle ratio, interval, ordinal or nominal data. It produces an analysis that is easily explained to management and therefore has a good chance of implementation.

N + 1 Sample Analysis allows AID to be validated without using a large sample. Moreover the method enables individual segments to be assessed, so stable groupings may be retained and unstable ones discarded. Similarly, outliers, sample members that do not fit within the segmentation, may be identified and either discarded or perhaps set aside for more detailed analysis.

An Application

The example presented concerns a segmentation analysis of data collected from telephone interviews with 200 households. Using normal methods this sample size would probably prevent any split-half validation and certainly prohibit the use of AID. Yet samples of this size are by no means unusual, particularly when the interview is detailed and the incidence of qualified respondents low. The

dependent variable measures the adoption of a service. The predictors used here are 20 general AIO items, found in pretesting to be related to the service in question.

The N + 1 Sample Analysis involves three stages. First, AID is applied to the whole sample. Using the "standard" stopping criteria (split eligibility of .01, split reducibility .01, minimum group size for splitting 40) in our case produced eight splits, forming 9 end-groups (segments). The AID tree from this analysis appears in Figure 1.

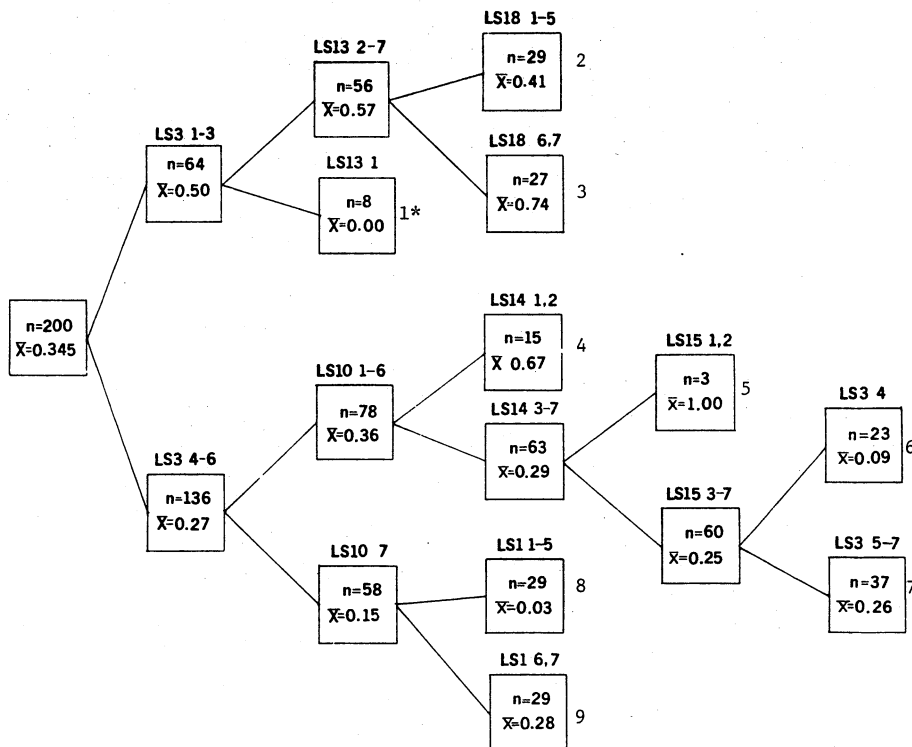

Second, the sample is split, at random, into equal-sized subsets and the AID analysis repeated, omitting each subset in turn. Although using identical stopping criteria these analyses are likely to produce rather dissimilar results. In the example presented here, 10 subsets of 20 cases each were formed, and so 10 further AID analyses were performed, each analysis omitting 20 cases. Both the configurations of the AID trees and the predictors entering the analyses varied considerably over the different runs.

The AID analysis appears to be affected by small sample variations. However, changes in the shape of the tree and changes in the predictors used are not by themselves evidence of unstable segments. If there is multicollinearity it is quite possible for the membership of the end-groups (segments) to remain unchanged although the variables defining them alter. So different AID trees could in fact be grouping together the same individuals. If we are to test the stability of segments we must look at segments, not the variables defining them.

The final stage of the N + 1 Sample Analysis is to compare

FIGURE 1

AID SEGMENTATION ANALYSIS ON WHOLE SAMPLE

*Original segment identification number.

the segment found in the whole sample analysis with those obtained from each of the runs with a data subset omitted. Before any meaningful segment comparison can be made it is necessary to align the segments - i.e., make sure we are comparing the most similar groups. Accordingly, for our example, the 9 segments derived in each of the runs with a data subset omitted were arbitrarily lettered. Ten tables can now be formed comparing each of the subset omitted analyses with the whole sample analysis. An example of one of these tables is shown in Table 1.

be the only members in a particular subset analysis segment. And the number of outliers, individual cases that are not well modelled by the segmentation.

Table 2 presents shared membership percentages for this set of data. Segment 1 is perfectly stable, 100% of its members are always classified together. Segment 2 is close to perfect stability with an average shared membership of over 90%. Segments 6 and 7 are rather unstable: on average they retain only slightly more than half of their

9	-	-	-	-	-	-	26 96.3% 100%	1 3.7% 100%	-	2	29

*Read as 6 of the cases classified as being in segment 4 in the whole sample analysis were placed in segment D of the first subset omitted analysis. These 6 cases represent 46.2% of segment 4 from the whole sample analysis and 42.9% of segment D of the first subset omitted analysis column. All percentages have been adjusted to exclude omitted cases.

For each of the segments formed in the whole sample analysis this table shows how that segment's membership was distributed over the segments formed in the first subset omitted analysis. For example, all the members placed in segment 1 in the whole sample analysis were in segment A of this particular subset omitted analysis. The members of segment 4 were considerably more dispersed: 46% turned up in segment D, 15% in segment E and 39% in segment E. The columns of the table are now re-ordered so as to maximize the diagonal elements, and the columns numbered. This procedure is repeated for each of the ten tables. This ensures that segments with the same number are indeed the most similar, i.e., that we are comparing like with like.

It is now possible to evaluate the segmentation. Three measures can be calculated. Shared membership, or common core, this estimates the proportion of a segment that would still be placed together were the analysis repeated. That is, if the original segment is stable then members should consistently show up in a common segment in each of the repeated analyses. Distinctiveness, an indication of the size of the shared membership relative to the segment as a whole, Members of the original segment should

original members.

Shared membership is not the only criterion however. In particular shared membership could be high as a result of comparing a small whole sample analysis segment with a large subset omitted analysis segment. We also require that the segment be distinctive or unique, i.e., the shared membership should be a major part of the whole segment. Table 3 shows the percentage of shared membership in each segment.

Notice segment 1 is unique. No other cases are ever included with those from segment 1. Segment 3 is rather less distinct. For example, in the 7th analysis, although shared membership was 92% (Table 2), this membership made up only 55% of the total segment. Segments 4,6,7, and 9 are particularly indistinct with a large proportion of their members drifting in and out.

Finally, it is possible that low shared membership may be the result of outliers. A few cases in the whole sample analysis segment may fail to be consistently segmented and so cloud the performance of the segment as a whole. Table 4 presents a frequency distribution for each segment

showing the number of times each case remains within the common core. Thus, for segment 1 all members are consistently segmented in every run in which they appear (notice the maximum number of subset omitted analyses for any case is 9, in one run it is in the subset excluded). In contrast segment 7 has not a single case that is consistently segmented in every run, and 5 cases only appear in this segment twice. However there are no bimodal distributions: segments with poor cases lack good cases as well. So outliers do not appear to be biasing the percentages in tables 2 and 3. If some segments had displayed a concentration of outliers these could have been excluded and Tables 2 and 3 re-computed.

Conclusions

The N + 1 Sample Analysis described has enabled the stability of a segmentation to be assessed, despite small sample size. Overall, 2 segments were found to have unacceptably low shared membership and 2 more to be insufficiently distinct. For the purposes of this analysis a segment was considered unstable if it failed to retain, on average, 60% of its original members or if the membership retained made up less than 60% of the whole segment. Clearly these cut-off proportions will vary with the purpose of the analysis. Exploratory research may well

TABLE 4 -

*Read as 8 members of segment 1 classified together in all 9 analyses in which they appeared.

accept segmentations considerably below those used here; high investment decisions will probably wish to impose more stringent requirements.

At the end of an $N + 1$ Sample Analysis the researcher has a clear idea of the segments in the data and of their likely stability. An informed decision can be made on which segments to exploit, which to reject and which require further investigation. Although the example presented here uses the AID algorithm the method is suitable for any segmenting search procedure.

Of course nothing can make up for any unrepresentativeness in the sample. Like the jackknife itself, $N + 1$ Sample Analysis merely makes more intensive use of the available data; the relevance of its results depends on the sample. Similarly, unstable segments show that the sample used is too varied to support that segmentation, not that a larger or more representative sample would not ensure stability. $N + 1$ Sample Analysis is intended to bolster confidence in segmentation results, not replace large sample analysis. Despite all these reservations this method does offer unique advantages to researchers forced to use small samples, and provides at least a first step towards full-scale validation.

VIVE LES DIFFERENCES

Roger M. Heeler, York University, Canada

Abstract

The three papers in this session are so different that there are no appropriate overview remarks. Each will be considered independently, vive les differences.

Geographic Subcultures - Hawkins et al

Basic marketing texts indicate many variables by which a market may be segmented. Geography is commonly one of these variables and one that according to the authors receives insufficient attention. The authors provide an interesting and succinct review of geographic differences as viewed by various disciplines, and illustrate the differences in consumption patterns that may occur with beverage consumption data. Strangely, the only reference to international marketing where geographic differences are the foundation of the field, is in a one sentence aside at the very end of the article.

In missing the international literature, the authors have missed one of the most compelling practical reasons for geographic segmentation, that is differential reachability. Segmentation requires both heterogeneity of consumers between groups (which the authors discuss) and an ability to reach these groups differentially with the marketing armoury. Geographic units are much easier to target for differential price, product, distribution, advertising etc. devices than units formed on many other segmenting variables, for example AIO measures. Practical marketers make full use of these possibilities.

There is an element of ambiguity in the authors' concept of geographic subcultures. Most of the paper is concerned with specific territorially contiguous areas such as "the West". These groupings are those most easily reached by differential targetting. The authors final example concerns "urban" versus "rural" USA. These two groups occur nationally, like "old" and "young" and are correspondingly more difficult to target.

Another concept missed through ignoring the international marketing literature is the exportability of many items simply because they are foreign. For example, "New York Bars" are popular outside of New York in part because of their foreignness elsewhere. Specialities from one area provide big opportunities elsewhere - look at Colonel Sanders!

The pre-publication version of this paper was missing half its references. If the published version is too, a supplementary listing should be provided to the audience.

Reviewers of this paper noted that (a) the lifestyle differences between regions should be examined per se (b) to what extent are differences a function of other variables such as population age in California (c) what is the importance of geography relative to other variables (d) how distinct are the regions.

Exporting Consumerism - Stanton et al

Consumerism having become big business in the USA, it is not surprising that academic entrepreneurs have turned to the task of examining its exportability. The Stanton et al paper examines the prospects for consumerism in Brazil which they regard as a paradigm for developing countries. For structural analysis they use Kotler's (1972) framework of the conditions likely to facilitate or limit the emergence of consumerism.

It is apparent that consumerism is still a difficult subject to define. In its widest sense, Kotler's (1972) definition

"A social movement (under any system) where buyers seek to augment their rights and powers in relation to sellers" could embrace everything from Marie Antoinette's advice on cake, and the subsequent spate of head chopping, government change, and rewriting of European history that emerged, to the benign concerns of middle american burghers over the display of unit prices. Where should the balance be struck? The authors do not seem sure, and perhaps avoid the issue by considering only the concerns of the minority of Brazilians who are both relatively wealthy and live in cities. The political and economic miseries of the majority are ignored, just as American winter visitors to Montego Bay can keep the horrors of Kingston from their vision. In this authors opinion the emphasis is probably appropriate for discussion of consumerism. As practiced, consumerism is a second level luxury for the very rich of the world, who are well beyond worrying about where the next meal is coming from. It is social concern with the gloves on.

This genteel limitation of consumerism makes the authors contribution relatively valid. Brazil is not a representative third world country. Most are much poorer and do not have the steady economic expansion of Brazil though many others also have a totalitarian regime of some type or another. But in major cities in many of these countries, a middle class for whom consumerism is a possibility exists. The authors should be projecting to this mini universe of Spartas around the world rather than to developing countries in general.

The analysis itself lacks the immediacy that might be added to the paper if it had been written by a Brazilian. But a useful array of secondary sources are used to indicate some of the pre-conditions and impediments to consumerism amongst the urban middle class. A couple of specific consumerism actions are quoted, but unfortunately the pervasiveness of consumerism actions is not well delineated. Towards the end the authors acknowledge that the government controls all and the press is restricted, so that consumerism might actually have a difficult time flourishing in Brazil. Perhaps they should have added an important prior corollary to Kotler's list of consumerism conditions. One must have a society that possesses and values liberal expression of competing viewpoints, and appropriate media to carry these expressions before the genteel force of consumerism can flourish. If this condition does not exist, the steady flow of consumerism may be replaced by the occasional eruptions of revolution.

Segment Stability - Schellinck and Fenwick

This paper uses Tukey's (1958) hold out procedure to test for the stability of segments found by an AID fishing trip. Although Tukey's technique has been well known to a generation of social scientists, it is less used than it deserves, so a current example is of value to consumer behaviour researchers.

The word "validity" is in many ways too strong a word to use in association with the techniques. Validity carries overtones of full testing of the proper meaning of a pre-hypothesized concept or measure (see Campbell and Fiske

(1959) or any social science research methods text). The jackknife is more of a reliability test, especially useful for showing the stability of fishing trip analysis. The authors show how this may be made to work for AID segments and acknowledge the degree of judgmental art that remains even after the science.

The analysis does not allow a small sample to stand in for a large one as the authors seem to imply. For example, the authors make much of one sub-segment that is found to be 100% stable through the hold out procedures. This segment consists of six cases drawn from a sample of 200. This sample has a confidence interval, considering random sampling error alone, of 1 case to 11 cases. If this segment is to be used for actual management purposes, clearly a more precise population proportion estimate is needed, which can only come from a larger sample.

Reviewers remarks included (a) an important topic for users of survey research (b) lots of guesswork still left in the analysis.

MOTHERS' ATTITUDES AND PERCEPTIONS OF CHILDREN'S INFLUENCE
AND THEIR EFFECT ON FAMILY CONSUMPTION¹

Mary Lou Roberts, Boston University
Lawrence H. Wortzel, Boston University
Robert L. Berkeley, Boston University

Abstract

A model is proposed in which a range of mothers' attitudes affect the amount of influence they perceive their children to have and the amount of influence, in turn, affects the amount of family consumption. Findings indicate that at least three attitudinal dimensions -- economic, health-related and liberal versus conservative -- affect the degree to which mothers report children are influential. Degree of influence had a significant effect on the amount of family usage of a set of products, all of which are appropriate for consumption by a single individual. Areas in which further research is needed are discussed, as are managerial implications.

The role of children as influencers in family purchasing decisions is an accepted part of the conventional wisdom of marketing. Empirical documentation of this role, however, is scant. Most studies have focused on only one product (Berey and Pollay 1968, Caron and Ward 1975, Frideres 1973), a small set of products (Jenkins 1978, Mehrota and Torges 1976; Moschis and Moore 1979; Popper 1979, Szybillo, Sosanie and Tenebein 1979; Sybillo and Soxanie 1976, Ward, Popper and Wackman 1970) or a single consumption decision (Nelson 1978), although at least one study did investigate a relatively large array of products (Ward and Wackman 1972).

The paucity of studies is not surprising in view of the difficulties of collecting valid and reliable data on family decision processes and consumption behavior (Davis 1977). The well-documented problems in collecting data on husband-wife influence processes are exacerbated when one tries to collect data on the input of children, especially young ones, to the process (Robertson and Feldman 1975, Rossiter 1978, Szybillo, Sosanie, and Tenebein 1979, Ward 1978). Hence, the important question of the effect of children's influence on the type and magnitude of family consumption remains empirically unanswered.

The existence of a data base from a large representative sample makes it possible to approach this question in an exploratory vein. In so doing, we are suggesting a simple model in which parental attitudes, in this case the mother's, will affect the amount of influence she perceives her children to have, and that this perception will, in turn, affect the amount of that product category consumed by the family.

In one of the earliest studies in this field Berey and Pollay (1968) identified the attitude child-centeredness as important in determining whether or not the mother yielded to the child's influence attempts. Ward and Wackman (1972) later found that the age of the child was a determinant of the frequency of parental yielding. The importance of the age variable is obvious, but other parental attitudes might prove to be of equal or greater value in explaining the success, or lack thereof, of children's influence attempts. General attitudes toward family financial matters, media and society all seem to be possible

determinants of parental yielding. Specific attitudes toward food prices and nutrition would seem to have special relevance to yielding to requests for food products. The importance mothers place on consuming, or not consuming, certain types of food and on nutrition in general should affect their willingness to yield to children's requests. In terms of both the effect of attitudes on influence and of influence on consumption, it is necessary to control for the age of the child.

Looking at our basic model from the mother's viewpoint is appropriate for several reasons. The mother is clearly a primary socialization agent during the early years of a child's life, though it is equally clear that peer groups become increasingly important as the child grows older. Peer groups may achieve dominant influence during adolescence (Moschis and Moore 1979). Early in the child's life, the mother purchases most of the products consumed by the child. As they become older children obtain more discretionary spending power and adolescents may actually purchase many, if not most, of the products they consume singly. However, the preponderance of evidence indicates that, throughout the family life cycle, the mother is the chief purchasing agent for products consumed jointly by various members of the family. The provision of food, especially, is an important part of mothering throughout the family cycle. If however, other family members, in this case children, do act as influencers, their influence may affect both the type and amounts of products actually consumed by the family.

Looking at the model from the mother's viewpoint suffers from the limitations of monomethod data collected from a single family member (Szybillo, Sosanie, and Tenebein 1979). However, these data have the advantages of robustness and a degree of replication which provides a useful reliability check.

Sample and Methodology

The data were obtained from the 1979 Needham, Harper and Steers Life Style Study, which uses the Market Facts mail panel. Needham, Harper and Steers describe the data base as follows:

"The Market Facts' mail panel is balanced for geographic region, age, income, and degree of urbanization. The very poor, the very rich, the transient, and minority populations are not well represented in the panel. Needham, Harper and Steers place a further restriction on the sample by requiring all individuals to be married. This latter restriction, coupled with the general characteristics of the Market Fact's mail panel, tends to confine the representativeness of the Life Style sample to stable, middle class households... (it) has proven to be an effective barometer of middle America."

The research questions to be answered using these data are:

1. Do mother's attitudes toward a variety of family-related and social issues influence their perceptions of the amount of influence their children have on their brand choices in selected product categories?
2. Does the amount of influence children have affect the amount of family consumption in that particular product

¹The authors wish to thank Needham, Harper & Steers Advertising, Inc. for providing access to its 1979 Life Style Study data which were used in this project.

category?

Data for mother's attitudes (Table 1) was obtained from the AIO Section of the questionnaire. Since the influence questions dealt primarily with food products, although they also included some items of children's clothing, we considered it desirable to include specific attitudes towards food (Concern for Nutrition), food prices, and money matters in general (Price Conscious, Family Financial Matters), and homemaking (Involved Homemaker). We also included more general measures of attitudes, social attitudes toward media (Concerned About Sex and Violence) and toward society. Some of the social attitudes seem to be focused inwardly on personal and family concerns (Traditional, Family Togetherness, Concerned About Our Society), while others suggest a reaching out for new ideas and experiences (Cosmopolitan, Venturesome).

The attitude scales were constructed by judgmentally selecting from the approximately 200 available AIO items, measured on a six-point agree-disagree scale, a set of items which appeared to tap the attitude of interest. Each set of items was then subjected to reliability analysis. Unreliable items were removed until examination of the item-total correlations and matrix indicated that no further improvement in alpha was possible. Cronbach's alpha is presented twice for each scale, once for all women in the sample (n=1601) and again for the subsample who had children or grandchildren aged 0-19 (n=1150). All remaining data deals with the subsample only.

Children's influence on brand choice for 35 products was measured on a four point 'Almost All the Time' to 'Never' scale. Because of the lack of precision in this measure, the responses were factor analyzed (Table 2). After

TABLE 1
MOTHERS' ATTITUDES SCALES²

Scales	Reliability (Cronbach's alpha)	
	All Women (n=1601)	Only Women Reporting Children's Influence (n=1150)
<u>Concerned About Sex and Violence</u>		
There is too much violence on prime time television.		
There is too much emphasis on sex today.		
There is too much sex on prime time television.		
TV commercials place too much emphasis on sex.	.73	.73
<u>Concerned About Nutrition</u> (12 items)		
I am more concerned about nutrition than most of my friends are.		
I try to eat natural foods most of the time.		
All food advertising should reveal the calories in the product.	.78	.78
<u>Price Conscious</u>		
I never know how much to tip.		
I always check prices even on small items.		
I'm eating out less often because of rising restaurant prices.		
I like to save and redeem savings stamps.		
I shop a lot for specials.	.49	.51
<u>Family Financial Matters</u>		
Our family is too heavily in debt today.		
Investing in the stock market is too risky for most families.		
My greatest achievements are still ahead of me.		
I use credit cards because I can pay the bill off slowly.		
Five years from now our family income will probably be a lot higher than it is now.	.68	.69
<u>Involved Homemaker</u> (11 items)		
When I see a full ashtray or wastebasket, I want it emptied immediately.		
I am a homebody.		
The kind of dirt you can't see is worse than the kind of dirt you can see.	.66	.68
<u>Cosmopolitan</u>		
I am interested in the cultures of other countries.		
I like to visit places that are totally different from my home.		
I would like to take a trip around the world.		
I would like to spend a year in London or Paris	.64	.65

varimax rotation, four factors were obtained which explained over 47% of the variance, a quartimax rotation was also carried out to see if all loadings could be forced onto one factor. Quartimax rotation also produced four factors, all having high correlations with the original four (unrotated) factors. Results of the varimax rotations were therefore used in the analyses.

The four influence factors, which bear strong resemblance to those in an analysis of earlier Needham, Harper and Steers data (Mehrota and Torges 1976), were called Children's/Pet Foods, Gum, Clothing/Cereal/Cookies, and Sweets and Snacks. The analysis consists of cross-tabulations of the attitude scale scores against the influence factors followed by crosstabulations of the influence factors against reported family use, measured on a six-point 'Less than once a Month' to 'More than once a Day' scale, of all available products in the influence factors. Limiting our analysis to a relatively few scales and factors tends to preclude finding a few significant relationships by chance alone.

Results

In analyzing the data we used cross-tabulations rather than correlations because the influence categories and the use frequency categories do not, strictly speaking, constitute scales in which categories are equidistant. The predictor variables, which are the mean scores from each attitude scale, have been collapsed into three categories representing high, medium and low levels of agreement with the attitudes making up the scale. The criterion variables represent, respectively, four influence categories and three usage frequency categories.

The analysis resulted in the production of forty-four three by four tables representing attitude/influence relationships. Space limitations make it impossible to present all of these data; therefore we will present only the probability of significance ($p \leq$) Chi-Square statistic for each table. (A complete set of tables is available from the authors on request). The analysis was conducted using as the research population all mothers and grandmothers who reported children's influence.

The Relationship Between Attitudes and Perceived Influence of Children

Table 3 shows the Chi-Square relationship between all of the attitude scales and each of the four product categories. All of the statistically significant relationships are linear. The pattern of results, while reasonable, is not always easily explainable.

High concern over Family Financial Matters predicted low levels of child influence for all product factors except Gum, yet Price Consciousness predicted low influence levels only for Children's/Pet Foods. Thus, one dimension which determines the extent of children's influence is economic, but it appears that general economic status is of more importance than specific price consciousness. Concerned about Nutrition predicted children's influence in three of the four categories. The fact that it did not predict for chewing gum may simply reflect mother's recognition that gum neither adds to nor subtracts from the child's nutritional well-being and is therefore of little consequence.

Some of the social-attitude-related scales also demonstrated significant predictive power. Although Traditional Orientation predicted a low degree of influence for Clothing/Cereal/Cookies and Children's/Pet Foods, high Venturesomeness predicted higher degrees of influence for Children's/Pet Foods, Gum and Clothing/Cereal/Cookies. A higher degree of Concern about Our Society and Family Togetherness (conservative dimensions) predicted significantly lower degrees of influence for all four product categories. It is not unreasonable to characterize these scales as constituting a rough measure of a liberal versus a conservative orientation toward child rearing and thus to conclude that a conservative orientation is indicative of a smaller role for the child in purchase decision-making.

Thus, there are at least three dimensions which affect the extent to which children are described by these mothers as having influenced purchase decisions for four groups of products. One dimension is economic, the second is health-related (nutrition) and the third is a liberal versus a conservative orientation. We shall next explore, by looking at the relationships between influence factors and product use, whether this influence results in greater purchases of the products by the family.

Controlling for Children's Ages

A further analysis was performed, controlling for the presence or absence of children in four age categories. The categories used were 0-2, 3-7, 8-12 and 13-19 years of age, the first two of which approximate the stages of cognitive development. In the majority of cases where the two-way crosstabs were significant, a consistent pattern emerged in the three-way tables.

This is an example in which Concerned About Nutrition attitude scale is crosstabbed by the Children's/Pet Food influence factor and controlled by the presence and absence of children in the four age categories (only the significance level of the Chi-Square is shown). The presence

TABLE 3

SUMMARY OF RELATIONSHIPS BETWEEN MOTHER'S ATTITUDE SCALES AND CHILDREN'S INFLUENCE FACTORS

Significance Level of Chi-Square Statistic ($p \leq$)

Age Categories	p ≤	Age Categories	p ≤
0 - 2	.000/.59	8 - 12	.37/.0001
3 - 7	.47/.0001	13 - 19	.01/.001

of children aged 0-2 is highly significant; the direction of the relationship is that the more concerned mother is about nutrition the less she allows her children to influence her, which makes good intuitive sense. However, it is the absence of children in the other three categories that shows significance, not their presence. In these tables the relationships also follow the direction seen in the two-way crosstabs in which more concern led to less influence. It is difficult to explain how the absence of children would have this effect, and for this reason the complete set of controlled crosstabs is not presented for either attitudes/Children's influence or influence/family product usage in which the same pattern also tended to emerge.

A further attempt was made to control for children's age by creating subsamples of families with children in specific age groups. However, only one group of families (those with children in the 0-2 age range) emerged as a separable subsample; all other families had children whose ages spanned two or more of the categories, even when age categories were re-defined as preschool (0-5), young (6-12) and teens (13-19).

Another controlling variable which separated families according to the age category into which the greatest number of children fell, or by the age of the oldest child(ren) when there were equal numbers of children in more than one category, was also used. This variable provided no further explanation of the variance in the data, and was discarded. Having children in other than the primary category appeared to create confounding effects.

The Relationships Between Children's Influence and Family Product Usage

Table 4 shows the Chi-Square relationships between influence factors and product usage. In this analysis, we will be comparing the extent to which mothers say their children influence purchases of each product factor with frequency of use of each of the available products within these factors.

This table shows that the relevant influence factor affected the household's usage of a substantial number of the products studied. In each case where there was a significant effect it was positive; a higher degree of influence was accompanied by a higher rate of product usage by the family. The common denominator among all the products, with the exception of canned dog food, is that they can easily be consumed alone by one of the family members. It is reasonable, therefore, that influence should predict household demand.

A comparison of the results in this table with those in Table 3, which presented the relationship between attitudes and influence, suggests that it may be important not only to identify whether children are influential but whether their influence is directed primarily at generic product category demand or toward brand level demand.

Implications for Research and for Marketing Action

Our findings should be considered as tentative and exploratory. In this paper we have only begun to explore data available even in the data set we used. Next analytical steps should aim towards developing multidimensional classifications of attitudes, perception of children's influence and consequential purchase behavior. Two techniques that might be employed in this analysis are multivariate analysis of variance (MANOVA) and cluster analysis. Both these techniques should contribute to our understanding of the relationship. A Manova analysis would use the set of attitude factors as predictors and the individual products within product influence factors as criterion variables. A cluster analysis would use all three sets of variables, attitude scales, influence factors and use frequencies to develop behavioral market segments.

Future research should also concentrate on obtaining data which indicates the influence each child has on the family's decision making process. In developing and testing models of influence, attention ought to be paid not only to the age of the children, but to the spacing between children. It may well be that children grouped closely together exert more influence, due not only to greater numbers but to allied interests, than those with more years between. It may also be that differences, attitudinal as well as cognitive, in individual children affect the degree

TABLE 4

to which they attempt and are able to exert influence.

The implications of our findings for marketing management are obvious. Evidently, children affect generic demand in some product categories as well as affecting brand choice. Therefore, it should be worthwhile to estimate the potential market size that can result from children's demand and to direct advertising to them.

Evidently, certain children also affect brand level demand in some product categories. Our findings suggest possible marketing strategies based on these findings. For example, children seem to be more influential when their mothers have a liberal orientation, and less influential when their mothers are conservative. One might then advertise primarily to children in the liberal Northeast and advertise the same brand primarily to mothers in the Midwest. Or, one could limit advertising to mothers to conservative-oriented vehicles. In either instance the advertisements should take into account product-specific parental attitudes and emphasize how the products contribute to children's well-being.

Conclusion

This analysis carries the work on children as influencers and consumers one important step further by expanding the scope of previous research on the effect of parental attitudes on children's influence and by demonstrating that children's influence does affect the frequency, and presumably therefore the magnitude, of household consumption of certain products. Although the difficulties inherent in extending this stream of research are great, the conceptual and practical insight to be gained from it will certainly justify the effort.

FOUR SITUATIONS AND THEIR PERCEIVED EFFECTS ON
HUSBAND AND WIFE PURCHASE DECISION MAKING

Alvin C. Burns, Louisiana State University
Stephen P. DeVere, Louisiana State University

Abstract

This study investigates the effects of four purchase decision making settings - at home alone, at the store alone, at home with a salesman present, and at the store with a salesman present - on husbands' and wives' perceptions of three dependent variables: relative influence, discussion times, and resolution modes given disagreement. An equivalent groups design was used with five subdecisions for each of four products. Physical surroundings and social circumstances were found to affect estimated discussion times and disagreement resolutions, but no effects were evident for perceived shared influence.

Introduction

Recent findings in the area of husband and wife purchase decision making influence have begun to reveal the complexity of the topic. It is common knowledge that influence distributions vary across products, across decisions within products, across phases in the decision making process, across families, and across spouses (Davis, 1976). Although context has been largely ignored in husband and wife purchase decision making studies, there is reason to believe that variance will also be found across situations in which the interaction takes place. In terms of individual purchase decision making, ample support for this contention comes from the arguments by Belk (1975) and Russell and Mehrabian (1976).

The husband and wife decision process would seem to be especially rich with regard to the opportunity for differences between situations inasmuch as the process necessarily occurs through interpersonal communication channels, most of which are overt. That is, spouses must communicate to each other their thoughts, opinions, and preferences. Furthermore, they interact to reach decisions. This requisite for joint decision making brings the process out into an observable realm. In fact, Burns and Granbois (1979) contend that analysis of tape recordings of husband and wives undertaking decisions is comparable to the protocol analysis approach applied to individuals and will greatly help in the understanding of collective purchase decision making.

One can envision situations in which the communication between spouses might be affected by the context. Obviously, individuals will differ in their sensitivities for situational factors, but when there exists the possibility of scrutiny of the conversation by a third party or parties, and the prospect of social evaluation of roles, it is conceivable that situation will influence the purchase decision making process. Consequently, this study may be regarded as an initial attempt to ascertain the effects of four different purchase contexts on three dimensions of the husband and wife purchase decision making process.

Conceptual Framework and Hypotheses

Much of the background for this study is described in a working paper by the authors (1979). This particular paper represents an initial empirical study investigating selected aspects of the comprehensive model proposed in the first paper. The model delineates attributes comprising each of the five "blocks" represented in the general schema:

FIGURE 1

The study focuses on two situational dimensions in which husband and wife purchase decisions can occur: the physical surroundings and the social circumstances. Taken as a 2x2 paradigm, the four situations of interest are: (1) at home alone; (2) in the store alone; (3) at home with a salesperson present; or (4) in the store with a salesperson present. Each of these circumstances implies different degrees of potential scrutiny by commercial agents. Similarly, the store atmosphere implies a less familiar context than does the home situation. Couched somewhat differently, one could contend that the greater the potential for social and commercial scrutiny and pressure, the more pressure for normative compliance, while the opposite would be the case in situations where influence interaction takes place in the privacy of one's home. Consequently, it seems appropriate to hypothesize differences in interaction results from situation to situation.

Three dependent variables are addressed in this study, all drawn from the "Results" block. Perceived distribution of purchase influence has been investigated as the primary dependent variable in most family purchase decision making studies (Davis 1976, Burns and Granbois 1979). The second dependent variable is the estimated time of discussion for various purchase decisions. This variable has not received attention, except in observation studies or analysis of spouses' discussions such as those reported by Kenkel (1957). The temporal dimension appears to be a logical impact point for situational influences. The third dependent variable, "disagreement outcomes," is analogous to the "recognized authority" variable studied and reported by Burns and Granbois (1977) wherein spouses indicated whose choice would be the final decision in the event of a disagreement on the resolution of a purchase decision. Again, the nature of disagreement outcomes is logically linked to discussion context. While other dependent variables are described in the model, these three were selected as representative and as ones most likely to be affected by the independent variables.

The study's hypotheses are stipulated below.

Hypothesis 1

Differences will be evident in all three dependent variables across the two situational dimensions.

Hypothesis 2

The "At Home Alone" situation will be associated with: (a) more equal sharing of influence; (b) longer purchase decision discussions; and (c) more joint resolution of disagreements than will the "At the Store with Salesman Present" situation.

The expectations of the behaviors of the dependent variables under the other two situations are not clear at this point. Consequently, only the two extremes are addressed

in this study.

Other hypotheses were also generated for the study as a result of knowledge about the husband and wife purchase decision making process. In general, the following hypotheses require support as corroboratory evidence that the current study is consistent with other studies.

Hypothesis 3

Husbands' and wives' perceptions of purchase decision influence will differ.

Hypothesis 4

Differences will be evident in purchase decision influence across products.

Hypothesis 5

Differences will be evident in purchase decision influence across product subdecisions.

Method

The Four Situations

Brief scenarios were constructed for each of the four situations, and all four descriptions are included in the Appendix. In each, the spouses were instructed to maintain a mental image of the context while responding to the questionnaire. In addition, the beginning of each dependent variable section in the questionnaire reminded respondents of the purchase situation they were to retain. Admittedly, these scenarios are weak stimuli, but the authors believe that significant findings in such a case are compelling.

Products and Decisions Studied

Four products were chosen which could "fit" into any and all of the situations. Additionally, certain constraints on the product choice were imposed by the nature of the sample of married couples (see below). The four products included were: (1) vacuum cleaner; (2) life insurance; (3) encyclopedia set; and (4) pots and pans. For each product, five subdecisions were distinguished: (1) verify the need to buy one; (2) what price to pay; (3) how to pay for it; (4) what brand to buy; and (5) what model or type to buy. These five subdecisions or close variations have been studied by others (Burns and Granbois 1979).

Dependent Variables

Relative purchase influence was operationalized as a specification out of 100 percentage points (constant sum scale) as to the amount of influence the husband and wife, respectively, would have for each of the five subdecisions for each of the four products. Jenkins (1978) has shown this approach to be somewhat more reliable than others, while Szybillo, Sosanie, and Tenenbein (1979) have shown the equivalence of a constant sum scale to 5-point scales. Discussion time was operationalized as an estimate of how long the couple would talk about each of the subdecisions for each product. Finally, disagreement outcomes were indicated by a specification of how the decision would be resolved assuming some disagreement did arise. Spouses could indicate "husband" or "wife," signifying that that person's choice would be selected, or "together," indicating that the disagreement would require a joint discussion and determination of the outcome. Test-retest correlations were determined to assess reliability. Forty-two respondents (21 husbands and 21 wives) were telephoned within two weeks of the survey and requestioned on representative items from each variable. The correlations were .88 and .77 for the influence and time estimates, respectively.

Also, 79% gave perfectly consistent responses to the disagreement outcomes item retested. Two respondents could not recall the situation presented; all others recalled it correctly (95%).

Research Design and Sample

Questionnaire length and contamination effects precluded asking each respondent to go through all four situations; consequently, a split-plot design with repeated measures on products and decisions was adopted. The sample was drawn from married students living in married student housing on the LSU campus. Only American students were used in the sample, and spouses received identical questionnaires. A field worker introduced the study to respondents and left the questionnaires with the couple. Questionnaires were color-coded; moreover, spouses were requested to sign a statement certifying that they had not compared answers and made any changes as a result. Sample selection was based on the desire to minimize variability between groups and convenience. The final sample size for the study was 148 couples with the following group sizes: At Home Alone, 38 couples; Alone in the Store, 37 couples; At Home with a Salesman, 39 couples; and In the Store with a Salesman Present, 34 couples.

Findings

Equivalence Tests

Equivalence tests verified the equality of the four groups. Several demographic variables were subjected to analysis of variance, and no statistically significant differences were determined. The demographic variables and their means were: Husband's Age (24.7 years); Wife's Age (23.2 years); Years Married (2.7 years); Number of Children (.6 children); Husband's College Education (4.6 years), Wife's College Education (3.4 years); Husband's Workweek (22.2 hours); and Wife's Workweek (27.8 hours).

Purchase Influence

The investigation of the distribution of purchase influence began with the mean percentage allocations for husbands and wives assigned by husbands and assigned by wives which are presented for inspection in Table 1. This information served as the data for an analysis of variance determination of the hypothesized differences. For this analysis, only the estimate of the husband's influence was used due to the constant sum interdependent nature of the scale. Because of the confounding efforts of the repeated measures, multiple error terms are required. The couple was used as the basic unit of analysis. The results of this analysis, and salient means are reported in Tables 2 and 3, respectively. The corroboratory hypotheses for products and decisions were supported; however, the hypothesis of differences in spouses' perceptions was not. Main effects for situations are not evident, but significant interaction effects were found, however, between physical situation and product as well as decision. At best, therefore, situation can be viewed as a moderator variable for the main effects of these two variable already known to influence perceived purchase decision making influence distributions.

Estimated Discussion Times

The analysis of the estimated time of discussion for each subdecision assumed a similar tact. The means for the husbands and wives groups are reported by situation in Table 4. Tables 5 and 6 contain analysis of variance results and relevant means, respectively. In this instance significant differences were found for the main effects of all independent variables (physical situation, social situation, spouse, product and decision); while interaction effects were determined for isolated cases.

* Husband Influence is reported; Wife Influence is (100% - Husband Influence)

Further presentation of the means is in Table 7 which compares the husbands group to the wives group. Duncan multiple range tests revealed that in relative terms, the estimates are consistent across spouses, yet differences persist in absolute levels with wives always specifying more estimated time than did husbands. Product and sub-decision effects differences are in evidence with the Pots and Pans decisions expected by both spouses to take the least time and life insurance decisions expected to take the most time. Need verification is expected to take the longest time by both spouses, while the resolution of how to pay is anticipated to be shortest in duration. The "At Home Alone" situation is perceived to be the one in which the discussion times would be the longest while the "At the Store With a Salesman Present" discussions are estimated to take about half as long, on the average. The second hypothesis is therefore supported.

Disagreement Outcomes

The final set of analyses concerned the recognized authority variable. Preliminary investigation began with husbands and wives groups distributions for each situation treatment. The distributions are too cumbersome for display here. Analysis of differences was performed with the use of a generalized least squares linear model approach developed by Grizzle, Starmer, and Koch (1969). The method partitions multinomial responses to test for main and interaction effects. The three corroboratory hypotheses were supported, and social situation main effects were evident but no support was found for physical situation effects. Significant interaction also emerged. Table 9 compares the two situations of interest for the second hypothesis. Only the percent of husbands and wives stipulating "joint" resolution is reported. The hypothesis is not supported. In fact, the reverse of the predicted result seems evident: more joint resolution is believed to occur in the store with salesman present than at home alone.

Discussion

The findings of this exploratory investigation of situational influences on husband and wife purchase decision making have revealed that spouses are sensitive to context. In particular, both husbands and wives believe that discussions held at home alone will last longer than when they were held in the store with a salesman present. Also, the character of resolution of disagreements is affected by social circumstances. More joint resolution of disagreements is believed to occur in the store and salesman situation. Specification of the amount of shared influence purchase, however, appears independent of the physical or social surroundings in which it is envisioned to occur.

Precisely why this pattern has been found is a matter of speculation, and the external validity of the experiment may be criticized. Conceivably, these couples require a stronger stimulus than the one presented. Counterarguments to this contention are elicited in the significant findings for estimated times and disagreement outcomes, both of which followed the influence assessments section of the questionnaire. A more logical explanation, it seems, emerges from the sample's characteristics. Well-educated, young, newly married couples with few children and in an obviously income-constrained period of their marriages probably engage in high degrees of perceived equal decision making regardless of physical or social circumstances.

What model or type	28%	15%	20%	23%

* Only the percent of "joint" specifications is reported.

This study of situational influences has served to demonstrate the multidimensionality of the husband and wife purchase decision making process. Clearly these and other dimensions deserve more research consideration with sensitivity for context.

Appendix

Descriptions of the Four Situations

At Home Alone

For each of the following purchase decisions, please assume that you and your spouse are discussing them at home alone. That is, there are no other people in the room during your discussion. By "alone" we mean there would be no children, friends, neighbors or relatives present. It is a discussion between you and your spouse concerning various aspects of the purchase listed below.

Alone at the Store

For each of the following purchase decisions, please assume that you and your spouse are discussing them while standing in a store. Other customers are in the store, some of whom are walking by and some of whom are shopping for items at various places in the store. You are not being helped by a salesperson. Even though sales people are within view, no salesperson is helping you at present, and no salesperson is about to approach you. If you have children, they are not with you in the store, and there are no friends, neighbors, relatives with you either.

At Home with Salesman Present

For each of the following purchase decisions, please assume that you and your spouse are discussing them at home with a salesman present. That is, the salesperson for that product has come to your home and made a sales presentation to you. You are now discussing the various aspects of the purchase of that particular product. Assume that no children, if you have children, are present. Also no friends, neighbors, or relatives are with you in this room -- only you, your spouse, and the salesperson are present.

In the Store with Salesman Present

For each of the following purchase decisions, please assume that you and your spouse are in a store discussing them after a sales presentation has been made to you. That is, there are people walking through the store and shopping for various items at various places in the store, and you are discussing the various aspects of this purchase with the salesman standing beside you and listening to your conversation. If you have any children, they are not present with you at this time, and there are no friends, neighbors, or relatives with you at the time. The salesperson will be present throughout the conversation.

THE ELDERLY CONSUMER: PAST, PRESENT, AND FUTURE

H. Lee Meadow, Virginia Polytechnic Institute and State University
Stephen C. Cosmas, Virginia Polytechnic Institute and State University
Andy Plotkin, Bridgewater State College

Abstract

This paper reviews literature relating to research on the elderly consumer. Relevant empirical findings and propositions are examined to provide a base for future theoretical development. Specifically, the findings and propositions are discussed in a manner conducive for continuing research on this increasingly important population segment. Finally, future directions are indicated to guide consumer researchers in theory development.

Introduction

In the last twenty years, a number of primary and secondary research studies have attempted to describe the elderly consumer. However, it has only been of late, due to increasing size and buying power, that the elderly consumer segment has become critically important. Given this development, it would seem judicious that an examination should be undertaken of what is currently known about the elderly consumers to aid in future consumer research efforts.

The purpose of this paper is to examine the findings of past elderly consumer research in order to provide for an overview of the nature and scope of the elderly segment. Toward this end, relevant findings will be presented to the exclusion of detailed methodological and theoretical criticisms. These findings should establish a foundation for future marketing and consumer research effort.

Literature Review

The Elderly Consumer: The Call for Attention

In the 1960's, U.S. demographers began to chart a growing population trend. The upcoming decades would be characterized by a senior citizen market, defined as those 65+, which would begin to grow at a faster pace than ever before experienced. Because of increasing life spans due to preventive medicine, the aging of the baby boom cohorts, the control of some death causing illnesses, and the increased quality of environmental living conditions, the elderly were predicted to become a major force in terms of size in the U.S. marketplace (Business Week 1960).

This recognition of the growing elderly population led to a number of calls for research to estimate the size and character of the elderly segment. Concurrently, calls were made for marketer reaction to create products and services that would meet the "special" needs of what was then perceived to be a unique \$40 billion market segment (Gidlow 1961, Goeldner and Munn 1964, Morse 1964). However, all did not agree that the elderly segment was important and/or unique enough for generating research and development. Reinecke (1964) concluded from his investigation that there was no unique elderly market, elderly consumption patterns were not homogeneous, and the elderly could not be discerned from other population groupings.

For whatever reasons, a period of three years passed in which interest in the elderly consumer waned. In 1967, Samli provided some empirical evidence that the elderly were indeed a unique demographic market segment. In addition, Goldstein (1968) used Bureau of Labor Statistics

(BLS) data from 1950 to 1960 to independently confirm the contention that the aged market indeed had unique consumption patterns in terms of goods purchased (a finding that he had earlier reported in the Journal of Gerontology, 1965).

Still, few if any attempts were made by researchers and practitioners either to indicate methods for marketing or attempting to market to the elderly (Forbes 1979, Nation's Business 1971). The lack of interest in this market appeared to be based on intuitive judgments of marketing practitioners that the aging (estimated now to be a \$60-\$200 billion market) did not possess unique wants or needs or even want to be reminded that they were growing old (Business Week 1971, Media Decisions 1973, U.S. Department of Commerce 1973). However, this position did not entirely eliminate the academic interest in the elderly consumer. Generally, two to four consumer behavior studies have appeared annually to the present time addressing the aged market.

To gain marketing reaction, Block (1974) and Waddell (1975) demonstrated that the elderly were deserving of special attention as a result of a higher level of victimization suffered relative to other population segments. Due to fixed income, inflation, lack of social interaction, and psychological insecurity among other factors, the elderly, it was asserted, are particularly susceptible to fraudulent practices. It was felt that a concerted marketing institution effort might ameliorate these factors and significantly benefit this disadvantaged group.

Louden (1976) also raised the issue of whether it was economically justifiable to ignore the aged market. Demographically, he argued, that not only did they constitute a major purchasing power, but that the elderly would increase this power in the future through rapid population growth (expected by the year 2000 to grow to 20% of population).

Most recently the banner has again been raised by business observers calling for a marshalling of effort to reach the elderly consumer (Business Week 1979). The findings indicate that reaching the "olderster" or "maturity" market (defined as 45+) could pay off (and has for a number of firms as illustrated by the examples reported). It was shown that: (1) the 45+ market accounts for 39.2 million households or 53.9% of all households, (2) the 45+ segment has an average income of \$13,388 (\$16,619 for the 45-64 year old and \$8,063 for the 65+ person), (3) the 45+ segment has 52.4% of all spendable income available, and (4) the 45+ segment accounts for 59.9% of all discretionary income.

To conclude, marketers and consumer behaviorists have begun to show interest in the aged market. However, even with the many calls for research that have been generated throughout the past 20 years, and in spite of the subsequent research efforts focusing on this group, it would appear that not enough is known about this population segment in terms of description, prediction, and explanation of behavioral phenomenon to fully develop conceptualized decision-making frameworks.

A Review of General Behavioral and Decision-Making Findings

Samli and Palubinskas (1972) conducted exploratory research in a west coast SMSA senior citizen center to explore two aspects of consumer behavior: consumption patterns and buying behavior activity. The research generated a number of initial findings among which were: (1) food accounts for a substantial proportion of the elderly's incomes, (2) the elderly are generally limited to weekend shopping periods because of restricted transportation sources, and competing activities such as hobbies, civic functions, and community activities, and (3) the elderly are heavy users of mass communication sources for consumer information.

Mason and Smith (1974) conducted a survey in an elderly public housing complex of a major SMSA. This was done in order to develop: (1) a shopping behavior profile of the low income senior citizen, (2) to determine the basic sources the elderly utilized in obtaining consumer information, (3) and to outline the travelling behavior of the elderly in making major purchases. Their findings suggested that the senior citizen: (1) relies slightly on in-home shopping services, (2) utilizes both newspapers and previous experiences as prime sources of information, and (3) shops as part of a life style, not just for particular purchases.

Reinecke (1975)--the author of the 1964 study which purported that a distinct elderly segment did not exist--examined retailing outlets in order to see the compatibility between the institutions and the needs of the senior citizen. He found that the buying needs and location of the elderly made the current array of supermarkets and shopping centers non-usable in meeting elderly consumption needs and thus, were not part of their system of buying.

Concurrently, using the younger consumer as a comparative group, Bernhardt and Kinnear (1975) conducted a random sample survey of senior citizens in a southeastern SMSA in order to develop a consumer profile of the senior consumer. This profile included such consumer phenomena as shopping behavior, credit card usage, media habits, and leisure time activities. Their findings indicated that the senior citizens were: (1) less likely to use discount stores and more likely to use traditional department stores than their younger counterparts; (2) much less likely to have credit cards than the younger group; (3) more likely to read newspapers than those under 35 but less likely than the group 35-64 years old; (4) much less likely to listen to FM radio rather than AM than the younger group; (5) much more likely to watch more daytime TV than younger groups; and (6) less likely to engage in reading, attend sporting events, go to movies, go out to eat, or attend religious services than those younger.

During that same period, Tongren (1975) conducted a study of the income and credit usage of the elderly by analyzing census data and using a random sample of elderly from the middle Atlantic states. He concluded that income of the elderly has doubled in the previous decade and that this trend will continue in the future due to: (1) higher investment income and returns on working assets than those of previous elderly generations and (2) continued expansion of private pensions in terms of dollar size and people covered. The first finding that the elderly possess more purchasing power than past elderly due to increased returns on assets and investments was confirmed in a study of retirement associations in Houston, where the following analysis resulted:

To look at the 65-and-over group as low income shoppers can be misleading in two ways. First, it means over-looking the possibility that a senior citizen with a \$500-per-month income may

be ready for a round-the-world trip. Assuming that income breaks down to \$180 for Social Security, \$320 from investments, the \$320 may be a 5 percent return on about \$77,000 (Gelb 1978, p. 45).

Tongren (1975) also found that 80% of the elderly used some form of consumer credit for periods less than 30 days. This finding appears contrary to Bernhardt and Kinnear (1975), until one examines Tongren's data carefully and observes that it implies that as age increases, the use of credit diminishes.

Martin (1976) conducted research on a convenience sample from southwest Missouri in order to examine behavior differences exhibited in varying age groups of fashion buyers. Using life cycle as his grouping classification system, he concluded from his analysis that the following major differences exist among generations: (1) the elderly emphasize alternative choices less than other generational groups, (2) the elderly have less formed predispositions prior to the shopping than other generational groupings, and (3) the elderly rely more heavily on newspaper and salespersons for marketing information than other generational groupings.

Towle and Martin (1976) began to question, as did Reinecke (1964), the assumption that the elderly age segment was homogeneous. However, unlike Reinecke (1964), their own assumption was that the elderly could be categorized into various segments, each different than younger age groupings. Using psychographic and buying study data (and demographic data which did not work) from a national panel, a cluster analysis was performed. They concluded that not only were the elderly different from their younger counterparts, but the following sub-segments were found:

- (1) Saver/Planner (buys unknown brands)
 - a. Psychographic description--frank, self-assured and confident
 - b. Possessed 25.1% of the elderly market
- (2) Brand Loyalist (Does not buy for approval of friends)
 - a. Psychographic description--brave and not stubborn
 - b. Possessed 8.4% of the elderly market
- (3) Information Seeker (persuasible)
 - a. Psychographic description--kind and sincere
 - b. Possessed 10.1% of the elderly market
- (4) Economy Shopper (not brand loyal).
 - a. Psychographic description--not brave, not demanding, not egotistical, and bland personality
 - b. Possessed 10.6% of the elderly market
- (5) Laggard (not persuasive)
 - a. Psychographic description--liberal, unreserved, and cold to others
 - b. Possessed 11.2% of the elderly market
- (6) Conspicuous Consumer (change brands and see approval from friends)
 - a. Psychographic description--dominant, egotistical, and stubborn
 - b. Possessed 34.6% of the elderly market

Mason and Beardon (1978) conducted research on a random sample of elderly in a southeastern SMSA to develop a profile of shopping behavior of elderly consumers. Their findings suggested: (1) that like other age groups, the elderly shop for a variety of reasons other than buying, e.g., exercise, leisure, and recreation, and (2) that they tend to use friends, personal experience, price comparisons, and mass media as information sources in making marketing decisions.

Finally, Deshpande and Krishnan (1979) using the coping skill conceptual frame of Botwinick (1973) examined how the elderly perceived their marketplace interactions. They investigated several decision rule strategies, via factor analysis, of a national panel of elderly consumers and then ran a discriminant analysis between consumers who claimed to have good versus bad marketplace experiences. They found that the order of prediction factors of decision rule strategies associated with bad shopping experiences (from most to least) was: flexible shopping rules, conservative shopping rules, brand conscious rules, sales pressure avoidance rules, and information avoidance rules. As they state:

The flexible shopping rules have to do with ignoring budgeted limits, going beyond shopping list items, and disregarding detailed information on contracts. This may open up elderly buyers to make unwise or hazardous purchases that they later regret. Contrast this with the Brand Conscious or Sales Pressure Avoidant Decision rules which imply more methodical and painstaking prepurchase activity. These rule sets seem intuitively to lead to better buying as evidence by less post purchase dissatisfaction. (p. 586)

In summary, the behavioral and decision-making findings generally show the elderly to have the following overall characteristics: (1) they tend to be somewhat limited in mobility; (2) they use large quantities of marketer generated information; (3) they engage in shopping for more than just buying reasons; (4) they have a similar pattern of leisure to younger age groups, just lower in quantity; (5) they have more sources of incomes than ever before because of pre-retirement investments; (6) they use long-term credit less as age progresses; (7) they are not just one homogeneous segment but many smaller segments, each differing from their younger counterparts; and (8) they depend on a wide array of shopping rules that result in varying amount of coping skill levels in dealing with marketing institutions.

The Aged Market: A Review of Information Processing Findings

Consumer information processing research has been the basis for developing several overall consumer buying models (e.g., Engel et al., 1978, Bettman 1979). The study of consumer information processing generally includes the following variables: nature of consumer's search activities, amount of information seeking by consumers, factors that influence the search process, type of information sought, sources of information, evaluating alternative factors influencing the amount of evaluation, and the results of the evaluation (Loudon and Della Bitta 1979, pp. 459-481).

Schiffman (1971; 1972; 1973) in studying the elderly consumers in a senior citizen community asked the following: (1) what was the impact that internal (research experiences) and external (marketing communications) sources of information had on new trial (product purchases) behavior, (2) what is the relationship between new trial and perceived risk, and (3) what is the relationship between product-related social interaction variables and general social interaction variables? His findings indicated that: (1) both internal and external sources of information affect the elderly's consumer decision-making, (2) the higher the perceived risk, the less likely the product trial, (3) there is a high significant relationship between new product related social interaction and general social interaction, and (4) socially active elderly are more innovative than social isolates.

Phillips and Sternthal (1977) provided the first major synthesis of related behavioral literature dealing with

age differences in information processing with the accent on the elderly consumer. Their focus was twofold: (1) to examine the differential sensitivity to processing information between the young and the old and (2) to determine when, in terms of age, these differentials are likely to occur. To address these issues, research on patterns of information exposure, learning, and influencibility were reviewed.

First, with regard to information exposure, Phillips and Sternthal (1977) in reviewing Frederick (1973), Graney and Graney (1974), and Schramm (1969) were able to conclude that the elderly have greater exposure and reliance on mass media for information relative to younger age groupings. Further, contrary to popular opinion, the elderly show similar patterns to their younger counterparts in information exposure and reliance on the extended family.

Second, with regard to learning, Phillips and Sternthal (1977) in reviewing Arenberg (1967), Botwinick (1973), Rabbitt (1965), Birren (1974), and Schonfield (1974) among others, concluded that age decrements can indeed exist in levels of learning, continuous attention, and information processing speed. These decrements tended to be especially apparent when the information presented is not self-paced and when distractions are present. When one goes outside the Phillips and Sternthal review and examines problem-solving contexts, there is confirmation of the existence of age related decrements especially with increases in problem-solving complexity (Young 1966, Arenberg 1968, Wetherneck 1966).

Finally, with regard to influencibility, Phillips and Sternthal (1977) in reviewing Whittaker and Meade (1967) and Klein (1972) among others, concluded that the empirical evidence was inconsistent as to differences in influencibility relative to younger age groupings. In most cases, influencibility was at least situation specific and could be present due to such factors as social isolation or self-perception of incompetence.

As a conclusion to their review, Phillips and Sternthal state that age related factors significantly affect the way individuals conduct information processing activities. However, they caution their readers that:

These differences do not necessarily occur at age 65; rather, they are related to the social, psychological and physical changes that accompany aging (p. 453).

Phillips and Sternthal's (1977) work on information processing provides a paradigm for explaining the consumer behavior of the aged by systematically relating a variety of studies from studies from various disciplines. Methodologically known as intersubjective certifiability (Popper 1968), Phillips and Sternthal's work is a crucial phase in developing a comprehensive consumer behavior theory for the elderly.

During the same year of the Phillips and Sternthal review, French and Crask (1977) conducted research on the relationship of persuasibility and media appeals using a random sample of elderly from a major SMSA. Using hypotheses developed from Phillips and Sternthal (1977) conceptualizations and Layton's (1975) documented findings of diminished sensory capabilities associated with age, French and Crask found the following results: (1) the elderly perceive no differences in source credibility of advertisements carried by different media, (2) advertising in general has a significant impact on senior citizen buying behavior, and (3) the young-old are more influenced by advertising than old-old--using the Neugarten (1974) elderly classification scheme.

Beardon and Mason (forthcoming) studied a random sample of elderly consumers from a southeastern SMSA and compared their findings to a national sample of grocery shoppers in order to examine "the familiarity with and use of grocery shopping aids and other consumer oriented information" provided by marketers. Additionally, product unavailability and complaint experiences were also examined. Their research was based on the Krosk and Srivastava (1977) findings that indicated there was lessened sensitivity to unfairness and less tendency to be assertive about complaining among elderly in comparison to other groups. Beardon and Mason found that: (1) differences between elderly and a national sample of representative grocery shoppers existed, in that the elderly use and are less familiar with consumer information made available in the grocery outlet and (2) that dissatisfaction with food was higher for the national sample than the elderly sample due to decreased sensitivity of the older shoppers to negative shopping occurrences.

A similar study was conducted by Lawther (1978) using national panel data, which examined social integration of the elderly and the relationship this variable had with unfairness awareness, complaint actions, and information usage. Previous research had shown that social integration affects brand preferences of consumers in general and that social integration affected the behavior of the elderly in particular (Stafford 1966, Larsen 1978). Utilizing the paradigm of social integration which is composed of social values, social roles and informed group membership, she explored the impact social integration had on elderly consumer behavior (Rosow 1974). Some of her findings indicated that: the greater the degree of social integration. The greater the awareness of unfair marketing practices (e.g., bait and switch tactics) and the greater the likelihood of complaining about a buying experience that was less than satisfying, the more likely is the use of marketer dominated sources of information, as opposed to consumer dominated sources.

In summary, the information processing research has been useful in developing an initial descriptive understanding of the elderly's consumer behavior. From the reviewed studies, the following relationships were found to be most significant: (1) social interaction/integration is highly correlated to consumer decision processes and the utilization of marketing related sources, (2) age differences do indeed exist between young and old in information processing abilities, and (3) age related insensitivity to marketing unfairness and less assertive behavior in the fact of such practices, appear to put the elderly at a comparative disadvantage relative to younger age groups.

Future Directions

Researchers in the past twenty years have made significant inroads toward an understanding of the elderly consumer. Information about behavioral patterns that heretofore went unrecognized have now begun to come together into an overall generally accepted picture of the aged segment. Advancement from this point on rests upon subjecting the empirically found relationships to causal analyses based on sound theoretical foundations. If the elderly are to completely be understood and behavioral explanations offered, researchers must pursue the root causes for the observed behavioral phenomenon. Once such research is conducted it will be legitimate to assert that not only are the elderly deserving of attention, but the foundation will have been laid for developing normative decision actions.

To provide specific direction for future research effort directed at the elderly consumer, the following issues must be addressed. One, the issue of definition is paramount for consistent and coordinated empirical work.

The labels of elderly, aged, and senior citizen all imply constructs that need precise definition for continuous research in future years. In essence what is required is a precise set of bounds delimiting the character of this population segment.

Two, a priori cause and effect relationships need to be conceptualized for elderly consumer behavior. A sound theoretical basis for all researched relationships must be established for empirically verifying root causes. For example, an important arena for future research is the area of whether or not age is the driving force or just an intervening variable spuriously related to behavior that masks cohort and/or period effects. Answers to cause and effect issues such as the age related effects could begin to provide enough answers to correctly develop necessary decision actions by public and private sectors on behalf of the elderly in meeting their specific needs.

Three, research effort should be directed at providing inputs into policy decisions geared toward meeting the needs of the elderly consumer. In a time of contracting resources and financial restraint decision makers may be forced into 'either/or' decisions at the expense of the elderly consumer. Its an issue such as this that makes it imperative for consumer researchers to generate findings that will have policy impact.

Four, there is the question of elderly consumer quality of life. In recent years policy makers, who have tried to satisfy the needs and enhance the well-being of the elderly consumer, have encountered difficulty in measuring the outcomes of their decisions. In order to overcome this difficult, a coherent conceptual framework needs to be developed that can describe, predict, and explain the system of variables, relationships, and processes that produce a given level of well-being, or quality of life. Such research could be extremely important in providing for the consumer needs of the elderly.

Finally, before research is begun, a caution should be noted. Though the preponderance of empirical evidence supports the contention that the elderly, though not totally homogenous, are significantly different from other population segments, the reader should be aware that this is not a universally held position. It has been suggested by some gerontologists that society is "moving in the direction of what might be called an age-irrelevant society; and it can be argued that age, like race or sex, is diminishing in importance as a regulator of behavior (Neugarten and Hagestad 1976, p. 52). Still, even in light of this cogent argument, it is these authors' conclusion that the differences indicated in the consumer research examined warrant the contention that the elderly comprise a recognizable if not totally homogeneous market segment. This is sufficient reason for continuing the effort by consumer researchers to seek an understanding of the behavioral phenomena surrounding this increasingly important population segment.

DIFFERENT INFLUENCES ON CONSUMER DECISION MAKING

E. H. Bonfield, Temple University

Abstract

Three papers dealing with diverse aspects of consumer behavior are discussed. While a few methodological problems are apparent, the more global concerns of lack of control/comparison groups, uncontrolled anchoring, and labeling in consumer research are addressed.

Introduction

The three papers presented for this discussion are diverse in subject matter. Each makes a contribution, and each leads to further questions for research. Two of the papers, those by Roberts, Wortzel, and Berkeley and by Burns and DeVere deal directly with family decision making. They contain primary research data. Meadow, Cosmas, and Plotkin present a literature review suggesting consumers described as elderly are different from other consumers.

If all three papers dealt with family consumer decision making, they would fit into the general model of intra-family influence Burns and DeVere briefly describe at the beginning of their paper. Burns and DeVere have explored two situational dimensions, while Roberts, Wortzel, and Berkely could be categorized as exploring a mothers-children relational dimension. While Meadow, Cosmas, and Plotkin correctly do not place their research in the family decision process domain, the individuals in the group they study are frequently actors in family decision making.

The discussion of each paper which follows contains little concern for the shortcomings found with the specific research projects. The exploratory nature of all three studies leads instead to a concern for suggestions for improving future research based on the present experiences.

Mothers' Perceptions

The Roberts, *et al* research is a positive case of "massaging data." The data from a current, large-sample, commercial study was apparently made available to the authors for additional analysis. This is enlightened behavior on the part of Needham, Harper, and Steers, and is to be commended.

Additional analysis of data gathered for other purposes is rarely as suited for testing additional hypotheses as studies designed for that specific purpose. That situation exists for the present research. Therefore, as the authors point out, their analysis is exploratory, and any findings must be taken as tentative.

"Attitudes"

Because of the exploratory nature of the study, the sets of scales labeled "attitude" are useful as indicators of such constructs as "concern about nutrition" and "cosmopolitaness." It should be clear, however, there is no basis, other than anecdotal, that these scales are valid measures of any attitude. Furthermore, the reliability measures of the "attitudinal" constructs suggest consistency in the way people mark scales expected to measure the construct. If there is only face validity of a construct, however, the analyst must question the reasons for these high interscale correlations. For example, are "concern about sex" (typical among ACR members) and "concern about violence" the same thing? Do they co-vary because of the admitted "middle America" bias of the sample, because all

respondents were women, because they were women with children,...? Is it possible the scales are marked the same, but the depth of concern--the involvement--is different? Some of these alternative hypotheses might be explored within the context of the present data set, while others would have to be tested with new research.

Labeling

After using factor analysis on the scales measuring perception of children's influence on brand choice, the author's labeled each factor despite the fact that only one, "gum," readily lends itself to such a label. Labeling can be a dangerous task in factor analysis, as well as in other areas, because it can be misleading. Are cheese and pasta children's foods? Are cold cereal and restaurants sweets or snacks?

A further problem stems from the sample used in factor analysis. If the authors used listwise deletion of cases as an option in factor analysis, only those respondents indicating use of all 35 products by marking the perceived influence scales could be included in the factor analysis. Considering pets alone, it is questionable whether a large proportion of the households owned, and therefore probably bought, both dog and cat food. The scales used forced respondents who did not use a product into a "least frequency" category. While there is legitimacy in utilizing this type of scale, inclusion of nonusers with users clouds interpretation.

Controlling for Children's Ages

Controlling for children's ages is difficult as the authors amply demonstrate. The problem is easily handled in one-child (and zero-child) households. Where more than one child is present, for any one product category, the mother might anchor on one child or somehow cognitively average her perception of the influence of her children on brand choice. An answer for this problem would be to instruct the mother to anchor on a specific child whenever more than one child is present. A randomization process for child selection could easily be developed to assure representativeness of the total sample, as well as adequate sample size for each major category of family composition.

Situation Dimension Effects

Burns and DeVere have developed a "general model of intra-family influence" which was used to guide their selection of the study presented here. They utilized written scenarios as stimuli differentiating four treatment levels. While it can be argued the written scenarios would not be realistic to the couples in each experimental group, their approach is a viable compromise to more expensive and more difficult to physically control alternatives. A useful alternative the researchers might have considered as a manipulation check would have been to add a control situation. This addition would have added some 40 additional couples to the total sample, but, given the sampling frame and data collection methods, the increased time and dollar cost would have been small. No scenario would have been provided the control group.

There is no quarrel with the data analysis as given. The use of figures, particularly when interaction effects are

involved, would make the results both easier for the researchers to interpret and for readers to follow.

Overstated Agreement

The use of means for husbands and wives are likely to increase the apparent level of agreement on the dependent variables. Since data on both spouses in the household is available, it is possible to compare responses on a household-by-household basis. Davis and Rigaux (1974) and Bonfield (1978) have found considerably greater disagreement when spouses' responses are compared on nominal scales similar to the disagreement outcome variable used by Burns and DeVere. The constant sum and discussion time estimates would show even greater disagreement unless some reasonable nominal scale were superimposed. A "scientific" approach might be to utilize standard deviation estimates to create nominal boundaries. An *ad hoc* approach of trying 10 to 20 percent differences in constant sum estimates and five-minute differences in discussion times might be even more useful.

Uncontrolled Anchoring

A problem which appears common to most, if not all, family decision process research can be labelled, "uncontrolled anchoring." That is, there is a lack of specificity as to what stimulus arrays respondents are reacting. For example, Burns and DeVere nicely imply a temporal anchor in their four scenarios. The respondents probably predicted what they thought would happen. In other research, however, it is impossible to determine whether respondents are predicting or reporting perceptions of what has happened in the past. If the latter is the anchor desired by the researcher, respondents should be asked to think about their last purchase occasion for the product.

Controlled anchoring means specifically describing products. Life insurance can be purchased on husbands' lives, wives' lives, children's lives, and in the case of mortgage insurance, jointly on both husbands' and wives' lives. A decision to buy a set of pots and pans is different from buying a replacement pot or pan or an additional pot or pan. Encyclopedias might be bought for household use or for children's use.

Finally, decisions should be more specifically described. While need verification is a relatively clear construct among family decision making researchers, "the need to buy one" may imply need recognition to respondents. "What model or type" may well mean different things to different respondents. Controlled anchoring might lead to the specification, for example, of "whether to buy term or whole life insurance," and "what size pot or pan," on future questionnaires. The model/type question might simply be deleted as inappropriate for encyclopedias.

An important aspect of having a model to guide research is the provision of a framework for exploring questions of differential anchoring. The questions addressed above suggest further exploration in the situational block of the Burns and DeVere model.

"What Do You Mean, 'I'm Elderly'?"

Meadow, Cosmas, and Plotkin provide a good literature review on an age category segment of the United States population. Their review is a useful addition to the consumer research literature in that it brings to this group a set of annotated sources in a single place. They add evaluation which cannot be found elsewhere. Two observations about the research and literature reviewed seem appropriate.

Labeling People "Elderly"

A label is a convenient, short-hand code used to indicate a group. When researchers label, the intent is to be able to generalize about whatever has been labeled. An important problem associated with labeling is the potential for labeling to lead to stereotyping. Stereotyping is the process of ascribing an attribute possessed by some members of a group to all members of that group.

Clearly, those people who have been labeled "elderly" are chronologically older than other age groupings of people. Some, even many or most, of the people who have been labeled "elderly" use dentures, are retired, and use less long-term credit. Labeling people "elderly" in the stereotyping sense, may lead to restricted granting of long-term credit--which, in turn, would make the group's limited use of long-term credit a self-fulfilling prophecy.

Some labeling of sub-segments among older age groups may result in mis-labeling. For example, Towle and Martin (1976) labeled a single psychographic sub-segment "Information Seeker" and "persuasive" apparently because the psychographic description of them was "kind" and "sincere." Whether one goes backward or forward in the logical process, no one label follows from any of the others.

Perhaps the most negative result of labeling is that some members of the group, in accepting the label, end up with lowered self images and reduced self esteem. For example, some individuals may decide they cannot exercise as much or continue in a job they enjoy and are capable of handling well simply because they have had a birthday.

Control/Comparison Groups

Consumer research, in general, has been characterized by nonuse of control groups. This generalization characterizes the research of those who have studied those in our population who are over 40, 45, or 65 depending on the study. Unless there is an appropriate comparison group, any characterization of a specific group as different is unsupported.

Conclusion

It was not the purpose of this paper to evaluate three exploratory studies. The discussion of each paper has led to general statements about problems with uncontrolled anchoring and labeling in consumer research, as well as a need for control or comparison groups in this research. The specific discussions suggested ways of combatting these problems.

KNOWLEDGE STRUCTURES, PRODUCTION SYSTEMS AND DECISION STRATEGIES

Merrie Brucks, Carnegie-Mellon University
Andrew Mitchell, Carnegie-Mellon University

Abstract

We suggest that in examining consumer decision making, more effort should be directed at understanding why consumers use a particular processing strategy instead of simply describing the resulting process. In addition, we suggest that more effort should be directed at understanding consumer decision making in "real world" situations. A conceptual model is presented which identifies the critical elements that affect the selection of a particular decision process. These elements include the task environment, problem perception, general goals and values, knowledge structures and production systems. Finally, knowledge structures and production systems are discussed in greater detail.

Introduction

Over the last five or six years, considerable research has been directed at understanding the dynamics of consumer decision making. Most of this research has used a process tracing methodology, a brand/attribute information format and a choice task (e.g., Bettman and Zins 1977, Payne 1976, Green, Mitchell and Staelin 1978). Under this research paradigm, subjects are asked to select a particular brand from a set of brands that differ along a prescribed number of attributes where this information is generally presented in either a verbal (e.g., "very good on decay prevention") or a numerical form (e.g., "gets 35 miles per gallon"). To record the order in which subjects examine the information, protocols (e.g., Payne 1976), eye movements (e.g., Russo and Rosen 1976), or information monitoring techniques (e.g., Bettman and Kakkar 1977) are generally used.

This research began, in retrospect somewhat naively, with the belief that consumers use one of the many hypothesized information integration rules (e.g., linear compensatory) when making choices between brands and that the use of a process tracing methodology would reveal which decision rule an individual used. In addition, it was generally assumed that the use of a particular decision rule would be relatively stable either within subjects over choice tasks or between subjects within choice tasks. It was soon realized, however, that a process tracing methodology reveals information search strategies -- not information integration processes. Although a relationship probably exists between search strategies and information integration processes, the relationship will not be perfect since subjects are able to store some information about the brands in long term memory.

Even though information integration processes cannot be directly inferred from search strategies, the results of the studies in this area seem to indicate that consumers do not use one of the hypothesized information integration rules (Mitchell 1978, Bettman and Park 1980). Although processing patterns can be identified (e.g., attribute vs. brand processing), these patterns tend to change frequently. These changing patterns have led Bettman to suggest that decision making under these conditions is frequently a constructive or a bottom up process (Bettman and Zins 1978). This means that the subjects are changing their processing strategy as they gather data during the task. The resulting processing strategies are, therefore, to a certain extent, data driven.

This research also indicates that consumers are very flexible in how they process information. Seemingly subtle changes in the information or its format can result in very different processing patterns (e.g., Bettman and Kakkar 1977). Finally, given a particular information set, there is considerable heterogeneity in how individuals process the information (e.g., Bettman and Jacoby 1976). In other words, each consumer seems to have his or her own idiosyncratic way of processing the information.

These results raise a number of interesting and inter-related problems concerning future research directions in this area. For instance, if individuals do not use one of the information integration rules, how do we define their processing strategies? If each individual has his or her own idiosyncratic way of processing information, how can we find generalizable principles that explain their behavior?

In this paper, we would like to present a preliminary discussion of these problems and a conceptual model that may prove useful in resolving them. The discussion and model represent our current thinking on these problems and we fully expect both to change as our research in the area evolves.

Research Goals and Problems

Although there are a number of possible goals for research on consumer decision making, we would like to suggest that the general goal for this research should be the prediction of how a given individual will make a decision in a particular situation and an understanding of why he or she used a particular processing strategy. We would also like to suggest that the general domain of phenomena studied in this area should be expanded beyond the information board paradigm. Since the task used in this paradigm appears to represent only a small percentage of the actual decision making tasks confronted by consumers, we believe that more effort should be directed at studying decision making in more "real world" environments.

In general, we believe that two important shifts need to occur in order to accomplish these goals. First, more emphasis needs to be directed at identifying the elements of the task and the individual that cause the between subject and task differences that we observe. This will require the development of a typology of task characteristics and procedures for measuring the individual level variables that affect the selection of a particular decision strategy. Second, more emphasis needs to be directed at understanding the cognitive activities (e.g., planning) that surround consumer decision making. In the past, we have been primarily concerned with describing how individuals processed or searched for information instead of investigating why they used a particular processing strategy. Both of these shifts require the integration of theories from cognitive psychology into conceptual models that provide an understanding of consumer decision making. We believe these shifts in emphasis will result in a better understanding of consumer decision making and may result in better models for predicting choice.

There are a number of problems, however, that need to be resolved before these goals can be accomplished. The first concerns the level of analysis. Process tracing procedures

produce a series of dense observations preceding final choice. Bettman and Park (1980), for instance, have decomposed protocols taken in a choice task using the information board paradigm into a typology of 70 different phrases and found that their subjects used an average of 35 phrases in making a choice. The fundamental problem, then, is how to develop measures of decision strategies that are causally related to elements of the task and the individual. One type of measure might be obtained by aggregating the processes measures. Alternatively, measures of general problem solving strategies such as "mean-ends analysis" and "operator subgoaling" (Newell, 1980) or "divide and conquer" and "define and successively refine" (Aho, Hopcraft and Ullman 1974) might be used.

In the same vein, there are many different conceptual dimensions of the variables that are thought to influence decision strategies. A number of studies, for instance, indicate that knowledge about a particular domain will affect how individuals process information (e.g., Edell and Mitchell 1978, Marks and Olson 1981) and their search strategies (e.g., Bettman and Park 1980, Johnson and Russo 1981). There are, however, many possible conceptual dimensions that one might use to identify differences in a domain of knowledge between two individuals. In addition, there are many possible conceptual dimensions that might be used to differentiate between two different tasks. In summary, the first problem involves the question of how to develop a typology of decision strategies and obtain measures of the task and individual so that causal relationships between the two may be identified.

The second, and related problem, concerns the indication that many decision processes are constructive or bottom up processes. How can we hope to predict how an individual will make a decision when he or she doesn't know how the decision will be made when he or she begins the task? This problem, of course, is related to the first. If, for instance, we use the proper level of aggregation for the dependent variable, we may be able to predict which decision strategy an individual will use in a given task based on specific elements of the task and the individual. This, of course, would be essentially a static analysis of a dynamic process. Alternatively, as discussed later in this paper, we may be able to develop procedures for understanding and predicting a constructive process.

This suggests that there are at least two different approaches for achieving the goals outlined earlier. The first involves the development of a typology of decision strategies which describes the process the individual used in making a decision. The second involves the prediction of the evolving dynamic process when it is constructive. At this point its difficult to assess which approach will prove more useful. Consequently, it would appear that fruitful research may proceed at both levels.

Finally, we would like to note that the consumer choice situation is essentially an ill-structured problem. Simon (1978) suggests that these problems differ from well-structured problems in three important ways. First, the criterion for determining if the goal has been achieved is poorly defined. Second, the problem instructions do not contain all the information required to solve the problem. Finally, the set of possible alternative moves at each stage of problem solving is not well defined. These differences, of course, increase the difficulty of understanding consumer decision making. Since there is no well defined goal to the problem, for instance, we need to understand how consumers decide when they have enough information about the alternatives to make a choice.

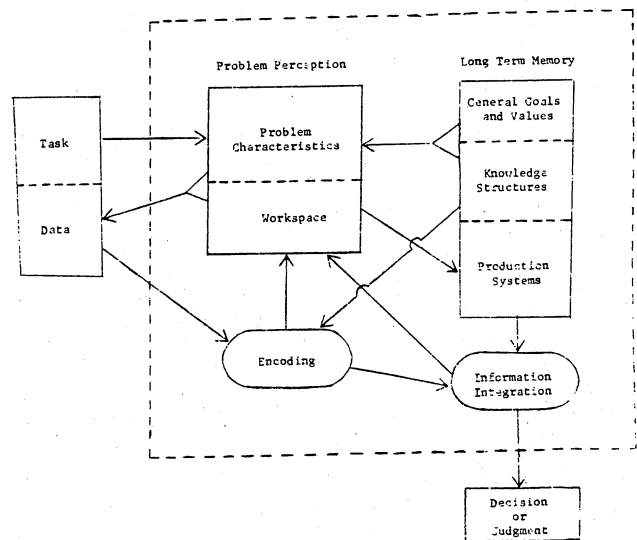

In the next section we present a simple conceptual model which we believe will be useful for studying decision strategies using either a static or a dynamic approach.

This model is heavily influenced by previous research examining problem solving in well-structured domains (e.g., Greeno 1978, Simon 1978). The critical individual level variables of this model are briefly discussed and then examples of how the model may be used to understand decision processes in both information board situations and more "real world" situations are outlined.

Conceptual Model

A conceptual model of the elements affecting the decision making process is presented in Figure 1. This model is a relatively simple one since little research has been directed at understanding the cognitive processes involved in decision making in ill-structured task environments (Simon 1978). We expect, however, that as research progresses in this area we will have a better understanding of these elements and cognitive processes.

FIGURE 1
CONCEPTUAL MODEL

Within this model, there are three different sets of critical elements that affect the decision making process. The elements of the first set exist in long term memory, are unique to each individual and affect all decision making processes. These are structural variables which include general goals or values, knowledge structures and production systems. The second set define the particular task and third are process variables which evolve during the decision process. These include, problem perception, information integration, and if the task involves the acquisition of external information, encoding processes. These specific elements will now be discussed in greater detail and then, two examples will be used to illustrate the model.

Elements of the Model

General Values and Goals. An individual's general values and goals are behavioral end states that the individual wants to achieve. These may include states such as professional success, wealth, and attractive physical appearance. These general values or goals will affect an individual's general approach to a purchase decision and the attributes that are used in evaluating the alternative brands. For instance, in purchasing clothes, an

individual who is concerned with having an attractive physical appearance will probably be concerned with the style of the clothes while someone who does not highly value this general goal may be primarily concerned with price.

Knowledge Structures and Production Systems. The remaining two elements of the first set are knowledge structures and production systems. These two elements represent the distinction that is frequently made between declarative knowledge and procedural knowledge (e.g., Anderson 1980). Declarative knowledge is our knowledge about concepts, objects or events. It is generally believed that this information is organized into packets of information or schemata (e.g., Rumelhart and Ortony 1977, Schank 1980). We may, for instance, have an organized set of information about fuel efficient automobiles, in general, and the Volkswagon Rabbit, in particular. We may also have stored organized information about events, such as visiting an automobile dealer to look for a new car, which are called scripts (Schank and Abelson 1977).

Production systems are representations of cognitive skills such as typing letters or solving geometry problems. The basic element of a production system is a condition-action statement. This statement allows the system to take a particular action when a particular condition is recognized. The particular condition may be an external stimulus such as a green traffic light or an internal state such as the lack of knowledge about a particular automobile. Similarly, the action may be a particular behavior such as stepping on the gas pedal of an automobile or a mental act such as adding two numbers together.

Problem Perception. Problem perception is the individual's internal representation of the problem. Considerable research on problem solving indicates that this internal representation will affect the strategy that an individual uses to solve the problem (e.g., Newell and Simon 1972, Greeno 1978, Einhorn and Hogarth 1981). Tversky and Kahneman (1981) and Simon and Hayes (1976) have shown that individuals may use different strategies for solving the same problem when the problem is presented differently (i.e., problem isomorphism).

A number of researchers have used different terms for this general notion. These include problem space (Newell and Simon 1972), decision frame (Tversky and Kahneman 1981), and problem frame (Wright and Rip 1980). We have selected a different term because we believe that our conceptualization differs from the definitions applied to these other terms. We currently view problem perception as containing two factors. The first are the general characteristics of the problem. These characteristics may include, for instance, the amount of time before a decision is required, the specific goals and subgoals for the problem, and the possible consequences of making a poor decision. The second factor, which we call the workspace, is the current state of the system with respect to the decision process. The current state of the system might contain, for instance, the number of automobile dealers visited and the amount of knowledge about the various alternative brands stored in long term memory.

This conceptualization differs from the definition of a decision frame as "the decision maker's conception of the acts, outcomes and contingencies associated with a particular choice" (Tversky and Kahneman 1981), or problem frames which Wright and Rip (1980) view as the information integration rules used to integrate information in making a decision. We find the former to be somewhat limiting in terms of the problems we wish to consider and we view the latter as a production system. Our notion of problem perception is probably closest to the concept of a problem space which was developed from the study of well-structured problems (Newell and Simon

1972). This concept contains two basic factors (a) a conceptual understanding of the problem consisting of the initial state, the goal state and the path constraints and (b) the different possible states of the space and the operators (Newell 1980). However, since our model is developed for ill-structured as opposed to well-structured problems, elements such as path constraints and operators may not be critical elements of problem perception. Finally, it should be noted that the cognitive limitations of humans imply that the cognitive elements of problem perception must necessarily be few in number (five to seven), unless some of this information is transferred to long term memory.

Encoding and Information Integration Processes. Encoding processes represent the transformation of external data into an internal symbolic code. These processes are influenced by knowledge structures and include both inferences and evaluative processing (i.e., counterarguing). For instance, an individual may infer that a particular automobile gets good gas mileage even though this information was not available to that individual. The information integration process involves the integration of encoded information from either external sources or from memory to form an evaluation or to make a choice.

Decision Making Examples

We will now discuss the conceptual model with respect to two different decision tasks. The first involves the standard information board task, while the second involves a more "real world" task. This latter example uses the task and model proposed by Hayes-Roth and Hayes-Roth (1979).

In the standard information board task, the subject is presented with an array of brands that vary along a number of different attributes. The information presented to the subject in the task (e.g., the product class and the brand names) and the relevant knowledge the individual has stored in long term memory (e.g., knowledge about the product category) result in a cognitive representation of the problem (i.e., problem perception). This cognitive representation for evaluating the alternative products may include the critical attributes that need to be considered. We have found, for instance, differences in how individuals process nutritional information when this information is associated with different foods (Brucks, Mitchell and Staelin 1980). This cognitive representation of the problem then triggers a particular set of productions that are used to start processing the information. In other words, the perception of the problem represents the condition portion of a production and the actual processing of information (e.g., encoding and information integration) represents the action portion. These productions may be at the level of the typology of phrases developed by Bettman and Park (1980) or they may be combinations of these phrases.

After a particular production has been executed the workspace is updated. This updated workspace, along with the subject's original understanding of the problem, then triggers a new production which then processes more of the information. These cycles continue until a choice is made.

What is critical, then, within this framework is understanding how an individual cognitively represents the problem and how the individual updates this representation at different points in time during the decision making process.

In more "real world" situations, the system becomes somewhat more complex; however, the structure remains the same. As mentioned previously, we use the task and the model proposed by Hayes-Roth and Hayes-Roth (1979) to

demonstrate this. The task involved having subjects develop a plan for completing a number of errands in an afternoon. The subjects were given the errands (e.g., meet a friend for lunch, pick up medicine for dog at the vet) and a map of a city with all the critical locations marked (e.g., veterinarian). The problem was designed so that it was very difficult to complete all the errands in a single afternoon.

The model developed for understanding the cognitive processes that the individual uses in developing the plan contains two basic elements: a number of different "specialists" and a "blackboard". The "specialists" are essentially production systems and their decisions are recorded on the "blackboard". The "blackboard" performs the function of recording the current state of the system with regard to the planning process. It is, therefore, similar to our notion of the workspace in problem perception. These different states trigger "specialists" which make decisions with regard to the planning process which, in turn, change the state of the system. For instance, knowledge that the individual is at a certain location in the town at a particular point in the planning process may cause a particular "specialist" to then select the errand that is closest to the current location. The process continues until a plan is formulated.

This, of course, is a simplified description of the model. In the actual model, the "blackboard" consists of five different planes called the plan, plan-abstraction, knowledge-base, executive and meta-plan. These five planes also contained different levels. An artificial intelligence program was developed based on this model, which provided a good representation of different subjects' planning processes.

This description is provided to indicate how our model might be used to understand actual "real world" decision processes. An obvious extension would be to understand how the formulated plan would change if it were actually implemented. An individual, for instance, might use more time completing a particular errand than expected (e.g., long time waiting for the vet) and then would have to revise the plan. The model, however, can also be used to describe the cognitive activity involved in revising the plan. With some adjustments this model might also be used to examine the strategy or plan that an individual uses in purchasing an automobile or a refrigerator. We are currently examining how the Hayes-Roth and Hayes-Roth model might be revised to study this task.

In summary, we are suggesting that in studying consumer decision making, more effort should be directed at understanding the cognitive activities surrounding the decision process. In other words, we should be more concerned with understanding why a consumer used a particular strategy instead of simply recording the actual process. We have presented a relatively simple conceptual model that might be used to provide a better understanding of these processes. In this model, the critical elements are problem perception, generalized goals or values, knowledge structures and production systems. In the next two sections we examine the latter two elements in greater depth.

Knowledge Structures

Knowledge structures contain our generalized knowledge about the external environment. Models of this generalized knowledge are generally conceptualized as network models, where the nodes of the network represent concepts and the links between nodes represent the relationship between concepts (e.g., Anderson 1976). As discussed in the previous section, it is currently believed that human knowledge is organized into packets of information called

schemata (Rumelhart and Ortony 1977). Individuals, for instance, may have a schema for fuel efficient automobiles that contains their generalized knowledge about these objects. Consequently, when we are presented with information about a fuel efficient automobile we activate this schema to process, encode, evaluate, and interpret the information. Ortony (1980) has recently suggested a dual layered theory of memory. The first layer contains our organized knowledge about specific concepts (e.g., schemata), while the second layer contains the relationships between schemata. Both of these layers are conceptualized as networks.

It is generally believed that our generalized knowledge will affect how we make decisions (e.g., Mitchell 1978, Olson 1978, Bettman 1979). Only recently, however, have researchers begun to actually examine how knowledge affects decision making (Bettman and Park 1980, Johnson and Russo 1981). Most of these studies, however, use only a single measure of an individual's knowledge of a particular domain. Frequently, this measure is based on the subjects' previous purchase behavior with respect to the product. Bettman and Park, 1980, for instance, use a subject's self reported experience with the product class as a measure of knowledge. Given the complexity of possible knowledge within a domain, multiple measures of knowledge should provide a better understanding of any related cognitive processes than a single measure. Objective measures of knowledge structures would also appear to be better than measures of previous behavior with respect to the product or self report measures. A teenager, for instance, who has never owned an automobile, may be more knowledgeable about different aspects of automobiles than an adult who has owned three automobiles.

Since there are many different possible conceptual dimensions of knowledge structures, we must identify which dimensions will provide the best explanatory power to explain the phenomena of interest. Kanwar, Olson and Sims (1981) have moved in this direction recently by proposing three different measures of cognitive structure -- dimensionality, abstraction and articulation. These measures are obtained through the use of free elicitation (Olson and Muderrisoglu 1979) and a modification of the repertory grid (Kelly 1955). The first measure, dimensionality, is the number of concepts activated by elicitation procedures within a particular content domain. The second, abstraction, refers to the level of abstractiveness that the related concepts within a domain are encoded. The third measure, articulation, is the number of levels that the individual uses to discriminate between objects within the domain.

The measures proposed by Kanwar, Olson and Sims (1981) are structural measures of an individual's knowledge within a particular domain. They essentially measure how information is organized within a domain. Alternative measures might be based on the content of knowledge within a particular domain. Although structural measures and content measures may be related, there may be important differences between these two types of measures. Kanwar, Olson and Sims (1981), for instance, found that a single measure of the content of knowledge within a particular domain (i.e., nutrition) was orthogonal to their structural measures.

Currently, we believe that content measures of a domain may provide a better explanation of the resulting cognitive processes within that domain than structural measures. In other words, we believe that what you know is more important than how much you know about a particular domain. It seems clear, however, that multiple measures are required to determine the extent of an individual's knowledge within a domain.

Some work on developing typologies of the content of knowledge within a domain has been done by educational psychologists (e.g., Bloom et al. 1956). We have recently developed a similar typology for classifying the knowledge that a consumer may have about a particular product category or purchase decision. The different types of knowledge within this typology are: (1) terminology (2) specific facts (3) relationships (4) criteria for evaluation and (5) procedural information.

Terminology refers to knowledge of terms used within a particular domain. These might include knowledge of the meaning of U.S. RDA percentages within the nutritional domain or the meaning of electronic fuel injection within the automotive domain. Specific facts are knowledge about objects within the domain. Examples of these are "apples do not contain much vitamin C" in the nutritional domain and "a Datsun B-210 gets 35 miles per gallon" in the automotive domain.

Causal relationships are knowledge about how different attributes of the objects within a domain affect the object's performance. Within the nutritional domain, for example, knowledge that if you don't get enough vitamin C you will get scurvy or within the automotive domain, knowledge that small four cylinder automobiles get good gas mileage are examples of this type of knowledge. The criteria for evaluation measure refers to knowledge that is used in evaluating objects within the domain. Examples of this measure might involve "cutoff" values for the different attributes. In the nutritional domain, a criteria for evaluation might be the knowledge that any fruit that has over 20% of the U.S. RDA of Vitamin A is "good" on that dimension or any small four cylinder automobile that gets over 40 miles per gallon is "good" on that dimension.

The final measure is procedures. This is knowledge concerning how the individual should behave with respect to objects within a domain. For instance, knowledge that you should have a green vegetable every day or that you should change the oil in your car every 5,000 miles are examples of procedures for the nutritional and the automotive domains, respectively.

In summary, an individual's knowledge about a particular domain will have a critical effect on how he or she processes related information. In order to understand the relationship between knowledge and processing activities, we need to develop procedures for measuring the different conceptual dimensions of knowledge.

Production Systems

As mentioned previously, production systems are a representation of procedural knowledge or cognitive skill. Production systems have been used to represent cognitive skills in memory scanning (Newell 1973), language comprehension (Anderson, Kline and Lewis 1977) and solving geometry problems (Neves and Anderson 1981).

The basic element of a production system is a condition-action statement. If an individual recognizes a particular condition (e.g., a green traffic light), he or she executes a particular action (e.g., walk across the intersection). A production system contains four basic elements (Rychener and Newell 1978): (1) a production memory, (2) a working memory (3) a recognize-act cycle and (4) conflict resolution principles. The production memory contains the condition-act statements while working memory contains information about the present state of the system. This is the knowledge that triggers the condition element of the condition-act statements. Consequently, working memory is similar to our notion of the workspace in problem perception. Conflict resolution principles are evoked whenever the current state of the

system may trigger more than one condition-act statement. Finally, the recognize-act cycle executes a particular condition-act statement which, in turn, changes the state of the system. In general, network models have been used to represent procedural information in memory (e.g., Anderson 1976, Norman, et. al. 1975, Rumelhart and Ortony 1977).

FIGURE 2
RELATIONSHIP BETWEEN THE TIME REQUIRED TO COMPLETE THE TASK AND THE NUMBER OF TIMES ITS BEEN REPEATED

Learning obviously occurs within production systems. In many tasks, a power law type relationship has been found between the number of times a particular task has been executed and the amount of time that it takes to complete the task (Figure 2). These tasks include perceptual motor skills, perception, motor behavior, elementary decisions and problem solving (Newell and Rosenbloom 1981). In a pretest of an experiment, we found the same relationship between the number of times an individual evaluated different brands based on the same prescribed attributes and the amount of time that it takes him or her to make the evaluation.

Anderson (1980) has suggested that three basic stages occur in learning a cognitive skill. The first is a cognitive stage where the individual learns the steps that one must go through in performing the task. For example, in learning to drive a standard shift automobile, the individual learns that to shift gears the clutch must first be depressed, then the shift lever is moved from one position to the other, and finally the clutch must be released. At this stage, the information is stored in declarative form. The second stage is the associative stage. Here, the individual uses the declarative knowledge to execute the different steps required to perform the task. This causes a production system for the different steps to be formed. At this point in the learning process individuals generally need to devote all of their cognitive resources (e.g., attention) to executing the task. As they execute the task a large number of times, less and less attention is required. Finally, at the third stage, the autonomous stage, individuals can execute the task with little or no conscious attention -- the task has become automatic. A number of studies have examined automatic processes in both perception and reading (e.g., La Berge and Samuels 1974, Schneider and Shiffrin 1977) and research is currently being directed at understanding the factors affecting the development of automatic processes (Shiffrin and Dumais 1981).

Although the stages identified by Anderson (1980) provide insights into the learning of a cognitive skill, they do not provide an explanation of why the amount of time to execute a task seems to follow a power law. Two explanations for this phenomena have been presented. The first, by Newell and Rosenbloom (1981) uses a chunking hypotheses. Under this hypotheses, individuals learn to react to a pattern of stimuli in the environment instead of individual stimuli. For instance, in a task where an individual must give a particular response to a particular

sequence of lights, the individual may at first process the status of each light sequentially or serially. With practice, however, the individual may react to the entire sequence of lights. Evidence for this explanation comes from research examining novice and expert chess players. This research, for instance, indicates that expert chess players react to the general pattern of the pieces on the chess board (Chase and Simon 1973). Newell and Rosenbloom (1981) have shown mathematically that this form of chunking will result in power law type relationship between the time required to execute the task and the number of times the task has been repeated.

A second explanation comes from Neves and Anderson (1981). They hypothesize two mechanisms that may yield the power law type relationship. The first is proceduralization which occurs at the early stages in learning a cognitive skill. With this mechanism, declarative information that is required in executing a production is integrated into the production system. This, of course, reduces the need to retrieve the required information in executing the production which, in turn, reduces the amount of time required to execute the task. The second mechanism is composition which may occur at both early and late stages of learning. This mechanism combines two or more productions into a single production. Consequently, instead of a single condition activating a production, multiple conditions activate the production. This is similar, then, to the chunking notion of Newell and Rosenbloom (1981). Neves and Anderson (1981) have used simulations to demonstrate that these two mechanisms can result in the power law type relationship between the number of times a task is executed and the time required to complete the task.

It seems clear that understanding an individual's procedural knowledge is critical in understanding consumer decision making. To date, however, little research has been directed at understanding the development of the cognitive skills involved in consumer decision making or the measurement of these skills. We suspect that more research will be directed in this area in the near future.

Conclusion

In this paper we have suggested that the goal of future research on consumer decision making should center on predicting what decision strategy an individual will use in a particular situation. In addition, we have suggested that more research should be directed at understanding consumer decision making in "real world" situations. The achievement of these goals require the identification of the critical elements of the situation and the individual which cause the selection of a particular decision strategy. Once these elements have been identified and measured, they may be used to predict either global measures of the decision strategy or the evolution of the actual decision strategy when it is a constructive process. The former is essentially a static analysis while the latter provides an understanding of the dynamics of decision making.

These approaches require more emphasis on why a particular decision strategy was selected as opposed to simply a description of the resulting strategy. They also require a better understanding of the cognitive activity involved in decision making.

Whichever approach is used, and we believe that both will prove fruitful, effort must be directed at identifying and measuring the critical elements of the task and the individual that will affect the selection of a particular decision strategy. In this paper, we represent a simple conceptual model that identifies these elements. They include the task environment, problem perception, general

goals or values, knowledge structures and production systems. If we want to predict the selection of a particular decision strategy, future research effort will need to be directed at obtaining a better conceptualization of these elements and procedures for measuring the critical dimensions of these elements.
