Advances in Consumer Research, Volume 19

(Provo, UT: Association for Consumer Research, 1992)

Preface

Contributors to this volume presented their work at the 19th Annual Conference of the Association for Consumer Research, October 17-20, 1991, in Chicago, Illinois. Scholars submitted 177 competitive papers, of which 78 were accepted. Thirty-seven of the 57 special topics sessions proposed were accepted. All of the former, and many of the latter, are included in this volume. Over 550 consumers registered for the conference.

A scan of the conference program or the Index quickly reveals the diversity of methods and perspectives adopted by contemporary consumer researchers. Ours is an increasingly multidisciplinary and multinational enterprise. The Annual Conference gives us all a chance to pause and appreciate the mosaic we are collectively creating. We hope that this volume will catalyze both additional growth and interdisciplinary integration.

Congratulations and gratitude are accorded to all the authors who submitted their work to the peer review process, regardless of the outcome. It is their industry, enthusiasm and insight that advances the field.

Everyone submitting a paper benefitted from the characteristically kind and careful criticism the Association has come to expect from its legion of reviewers. Our thanks is given to the Program Committee who evaluated all special topics proposals, and to the reviewers who evaluated the competitive papers. Thanks also goes to those scholars who wrote to us to volunteer their services as reviewers. We are glad to have been able to publish such a quantity of high quality research in an increasingly competitive environment.

We are especially grateful to two groups of people that helped us negotiate the infrastructure of the conference world. Our local arrangements committee ensured that all hotel functions ran smoothly, and orchestrated a most enjoyable reception at the Museum of Contemporary Art. Our administrative staff processed an ocean of paperwork, coped with errant filing systems (and, often enough, filing cabinets themselves), helped us meet honest deadlines, ran on-site registration activities, and even shepherded registrants to sessions. Each of these groups helped the Cochairs recognize the managerial implications of consumer research in real time.

A number of individuals remain to be thanked. Sid Levy provided us with the challenge of harnessing the diversity of the ACR membership in the service of creative scholarship, modelled that challenge for us in his own professional style, and fanned our enthusiasm as the challenge escalated. Keith Hunt provided the wise counsel and good fellowship for which he is justly renowned. Carolyn Hunt greatly expedited the registration process for us. Paul Anderson, Bob Calder, Becky Holman, Mike Solomon, Alice Tybout and Melanie Wallendorf each served in their way as sounding board and reality check as we renegotiated conference traditions and conventions. Peter Bloch ably handled the conference announcements that appeared in the ACR newsletter. Jim Muncy transformed the authors' contributions from software to the volume you now hold in your hands. Finally, our colleagues at Northwestern afforded us a humorous glimpse of our own antics as we juggled our conference responsibilities with the more mundane aspects of departmental life.

We greatly enjoyed our collaboration on this project, and we hope you enjoy poring over and browsing through what has become one of the most reliable one-stop-shopping sources of introduction to our evolving discipline: *Advances in Consumer Research*.

Table of Contents

Preface	iii
Table of Contents	iv
Conference of Committee	xvi
Conference Program	xvii
Presidential Address	
Constructing Consumer Behavior: A Grand Template.....	1
Sidney J. Levy, Northwestern University	
ACR Fellow Awards	
On Debts Due:	
Presentation of ACR Fellow-In-Consumer-Behavior Awards.....	7
Jerome B. Kernan, George Mason University	
Fellows Award Speech	
Musings on Method in Consumer Research.....	9
Paul E. Green, University of Pennsylvania	
Some Observations of a Developing Field.....	12
Joseph W. Newman, University of Arizona	
Session 1.1	
Consumer Processing of Social Ideas Advertising: A Conceptual Model.....	15
Lalita A. Manrai, University of Delaware	
Meryl P. Gardner, University of Delaware	
Session 1.2	
Toward Articulating Theories, Triangulating Concepts, and Disambiguating Interpretations: The Role of Converging Operations in Consumer Memory and Judgment.....	23
Thomas K. Srull, University of Illinois at Urbana-Champaign	
Session 1.3	
Do Hispanics Constitute a Market Segment?.....	28
Geraldine Fennell, Consultant	
Joel Saegert, The University of Texas at San Antonio	
Francis Piron, The University of Alaska Anchorage	
Rosemary Jimenez, The University of Texas at San Antonio	
Cultural Value Orientations: A Comparison of Magazine Advertisements from the United States and Mexico.....	34
John A. McCarty, University of Illinois at Urbana-Champaign	
Patricia M. Hattwick, University of Illinois at Urbana-Champaign	
Session 1.4	
What It All Adds Up To: Culture and Alpha-Numeric Brand Names.....	39
Janeen Arnold Costa, University of Utah	
Teresa M. Pavia, University of Utah	
Meaning Construction in a Cultural Gallery: A Sociosemiotic Study of Consumption Experiences in a Museum.....	46
Jean Umiker-Sebeok, Indiana University-Bloomington	

Parallels Between Hypnotic Suggestion and Persuasive Marketing Communications: Insights for New Directions in Consumer Communications Research.....	56
Stephen J. Gould, Rutgers University	
Session 1.5	
Context Effects on Social Judgments: Implications for Measurement in Consumer Research	62
Geeta Menon, New York University Barbara Bickart, University of Florida	
Context Effects in Proxy Judgments	64
Barbara Bickart, University of Florida Geeta Menon, New York University Seymour Sudman, University of Illinois at Urbana-Champaign Johnny Blair, University of Maryland	
Assimilation and Contrast Effects in Attitude Measurement: An Inclusion/Exclusion Model.....	72
Norbert Schwarz, ZUMA Herbert Bless, University of Mannheim	
Session 1.6	
Rationality of the Culture of Goods	78
M. Sahlins, University of Chicago	
Session 1.7	
Person Perception Carry-Over Effects: An Exploratory Look at How Our Partners' Traits Influence The Evaluation Of Ourselves.....	81
Therese A. Louie, UCLA	
Effects of Involvement, Arousal, and Pleasure on the Recognition of Sponsorship Stimuli.....	85
M. Tuan Pham, University of Florida	
The Relationship Between Distractor Similarity and the Recognition of Print Advertisements	94
James W. Peltier, University of Wisconsin-Whitewater John A. Schibrowsky, University of Nevada-Las Vegas	
Session 2.2	
Ask Not What the Brand Can Evoke; Ask What Can Evoke the Brand?.....	101
Stephen J. S. Holden, University of Florida Richard J. Lutz, University of Florida	
Session 2.3	
A Revised Product Involvement Inventory: Improved Usability and Validity.....	108
Edward F. McQuarrie, Santa Clara University J. Michael Munson, Santa Clara University	
The Use of Multiple Methods to Explore Three-Way Person, Brand and Usage Context Interactions.....	116
Niraj Dawar, INSEAD S. Ratneshwar, University of Florida Alan G. Sawyer, University of Florida	
Chernoff Faces: A Useful Technique for Comparative Image Analysis and Representation.....	123
Linda L. Golden, University of Texas at Austin Mayur Sirdesai, University of Texas at Austin	
Session 2.4	
Cocaine As Innovation	
A Social-Symbolic Account.....	129
Elizabeth C. Hirschman, Rutgers University	

Further Findings on Self-Gifts: Products, Qualities, and Socioeconomic Correlates.....	140
David Glen Mick, University of Florida Michelle DeMoss, University of Florida	
Symbolic Communication Among Consumers in Self-Consumption and Gift Giving:	
A Semiotic Approach.....	147
Anil Pandya, Northeastern Illinois University, Chicago A. Venkatesh, University of California, Irvine	
Session 2.5	
Retrieval Inhibition and Related Adaptive Peculiarities of Human Memory.....	155
Robert A. Bjork, University of California, Los Angeles Marc Vanhuele, University of California, Los Angeles	
Consideration of Inhibition as a Mechanism in Decision Processes	161
Mary Frances Luce, Duke University	
Session 2.6	
Driving Passions: Vehicles and Consumer Culture	166
Michael R. Solomon, Rutgers University	
"Have You Kissed Your Professor Today?": Bumper Stickers and Consumer Self-Statements.....	169
Barbara B. Stern, Rutgers, The State University of New Jersey Michael R. Solomon, Rutgers, The State University of New Jersey	
Volkswagen as "Little Man" Extended Abstract.....	174
Bruce G. Vanden Bergh, Michigan State University	
Session 2.7	
Issues in Consumer Choice With Uncertain Product Outcomes.....	175
David E. Hansen, Virginia Polytechnic Institute and State University	
Decision Making Under Risk: Applications to Insurance Purchasing	177
James Shanteau, Kansas State University	
The Time and Outcome Valuation Model: Implications for Understanding Reactance and Risky Choices in Consumer Decision Making.....	182
John C. Mowen, Oklahoma State University	
Session 3.1	
Knowledge and Knowledge of Knowledge: What We Know, What We Think We Know, and Why The Difference Makes a Difference.....	190
Lawrence Feick, University of Pittsburgh C. Whan Park, University of Pittsburgh David L. Mothersbaugh, University of Pittsburgh	
Consumer Knowledge Assessment: How Product Experience and Knowledge of Brands, Attributes, and Features Affects What We Think We Know	193
C. Whan Park, University of Pittsburgh Lawrence Feick, University of Pittsburgh David L. Mothersbaugh, University of Pittsburgh	
Session 3.2	
Postmodernism, Consumer Culture and the Society of the Spectacle	199
Alladi Venkatesh, University of California, Irvine	

Fragmentations in the Postmodern.....	203
A. Fuat Firat, Arizona State University West	
What Are You Doing After the Orgy? or Does the Consumer Really Behave ("Well")?.....	207
Ahmet Suerdem, University of California, Irvine; Mimar Sinan University, Turkey	
Session 3.3	
Examining the Descriptive Value of "Ritual" in Consumer Behavior: A View From the Field.....	213
Douglas B. Holt, Northwestern University	
Halloween As A Consumption Experience.....	219
Stacey Levinson, Rutgers University	
Stacey Mack, Rutgers University	
Dan Reinhardt, Rutgers University	
Helen Suarez, Rutgers University	
Grace Yeh, Rutgers University	
Session 3.4	
An Exploration of Materialism and Consumption-Related Affect.....	229
Marsha L. Richins, University of Massachusetts, Amherst	
Kim K. R. McKeage, University of Massachusetts, Amherst	
Debbie Najjar, University of Massachusetts, Amherst	
An Investigation of the Attribute Basis of Emotion and Related Affects in Consumption: Suggestions for a Stage-Specific Satisfaction Framework.....	237
Richard L. Oliver, Vanderbilt University	
Interpreting Perceiver Reactions to Emotional Stimuli.....	245
Jeremy D. R. Pincus, University of Connecticut	
Session 3.5	
Incorporating Consideration Sets Into Models of Brand Choice.....	251
Prakash Nedungadi, University of Toronto	
Vinay Kanetkar, University of Toronto	
An Empirical Investigation of Consideration Set Formation.....	253
John S. Hulland, University of Western Ontario	
Session 3.6	
Categorization Research and Brand Extensions.....	255
Laurette Dubé, Université de Montréal	
Bernd H. Schmitt, Columbia University	
Sheri Bridges, Wake Forest University	
Cognitive Associations and Product Category Comparisons: The Role of Knowledge Structure and Context.....	260
Deborah J. MacInnis, University of Arizona	
Kent Nakamoto, University of Arizona	
Gayathri Mani, University of Arizona	
Session 3.7	
Thoughts on the Importance of Psycholinguistics to the Understanding of Effective Advertising Communication.....	268
Larry Percy, Lintas:USA	
The Relation Between Syntactic Complexity and Advertising Persuasiveness.....	270
Tina M. Lowrey, University of Illinois, Urbana-Champaign	

Using Syntax to Direct Processing Resources.....	275
Slimen Saliba, Andrews University	
Session 4.1	
Comment on Factors Affecting Evaluations.....	276
Richard F. Yalch, University of Washington	
The Impact of Measurement Context on the Relationship Between Attitude Toward the Ad and Brand Attitude for Familiar Brands.....	279
Karen A. Machleit, University of Cincinnati Arti Sahni, University of Cincinnati	
The Effects of Missing Information on Consumer Product Evaluations.....	284
Deepak Sirdeshmukh, Ohio State University H. Rao Unnava, Ohio State University	
An Investigation of Self-Referencing's Influence on Affective Evaluations.....	290
Jean B. Romeo, Boston College Kathleen Debevec, University of Massachusetts	
Session 4.2	
Postmodernism, Consumer Culture and the Society of the Spectacle.....	See Session 3.2
Alladi Venkatesh, University of California, Irvine	
Session 4.3	
What You See Is Not Necessarily What You Get: The Effects of Pictures and Words on Consumers' Inferences.....	296
Ruth Ann Smith, Virginia Polytechnic Institute and State University	
Session 4.4	
Consumer Stereotyping: The Cognitive Bases of the Social Symbolism of Products.....	299
Eva M. Hyatt, Appalachian State University	
A Model of the Scripting of Consumer Lovemaps: The Consumer Sexual Behavior Sequence.....	304
Stephen J. Gould, Rutgers, The State University of New Jersey	
The Effects of Product Symbolism on Consumer Self-Concept.....	311
Newell D. Wright, Virginia Polytechnic Institute and State University C. B. Claiborne, James Madison University M. Joseph Sirgy, Virginia Polytechnic Institute and State University	
Session 4.6	
New Perspectives in Attitude Research.....	319
Youjae Yi, University of Michigan Ken Gray, University of Michigan	
Attitude Functions in Advertising Effectiveness: The Interactive Role of Product Type and Personality Type.....	323
Sharon Shavitt, University of Illinois Tina M. Lowrey, University of Illinois	
Session 4.7	
Nine Consumption Lifestyles.....	329
Susan Fournier, University of Florida David Antes, University of Massachusetts Glenn Beaumier, Westinghouse Savannah River Company	

Consumption Choice Within the Black Extended Family Network	338
Judy Cohen, Rider College	
Carol Kaufman, Rutgers University	
Psychographic Variation Across United States Geographic Regions.....	346
Lynn R. Kahle, University of Oregon	
Ruiming Liu, University of Oregon	
Harry Watkins, University of Oregon	
Session 5.3	
Effects of Source Likability on Attitude Change Through Message Repetition.....	353
Jean-Charles Chebat, University of Quebec at Montreal	
Michel Laroche, Concordia University	
Daisy Baddoura, University of Quebec at Montreal	
Pierre Filiatrault, University of Quebec at Montreal	
The Effects of Message Valence on Inferential Processes.....	359
Lydia J. Price, INSEAD	
Attention, Memory, Attitude, and Conation: A Test of the Advertising Hierarchy.....	366
Esther Thorson, University of Wisconsin-Madison	
Annie Chi, University of Wisconsin-Madison	
Clark Leavitt, Ohio State University	
Session 5.4	
Nostalgia: An Exploratory Study of Themes and Emotions in the Nostalgic Experience	380
Susan L. Holak, Rutgers University	
William J. Havlena, Rutgers University	
Nostalgia in Advertising Text: Romancing the Past	
Abstract.....	388
Barbara B. Stern, Rutgers, The State University of New Jersey	
Nostalgia: A Neuropsychiatric Understanding.....	390
Alan R. Hirsch, Smell & Taste Treatment and Research Foundation, LTD.	
Session 5.5	
The Role of Consumption and Disposition During Classic Rites of Passage:	
The Journey of Birth, Initiation, and Death.....	396
Julie L. Ozanne, Virginia Polytechnic Institute and State University	
Consumption and the Crisis of Teen Pregnancy: A Critical Theory Approach.....	404
Newell D. Wright, Virginia Polytechnic Institute and State University	
Jon Shapiro, Virginia Polytechnic Institute, and State University	
Session 5.6	
Consumer Inference.....	407
John Kim, Oakland University	
Frank R. Kardes, University of Cincinnati	
Session 6.2	
Mundane Everyday Consumption and the Self: A Conceptual Orientation and Prospects	
for Consumer Research.....	411
Robert E. Kleine III, Arizona State University	
Susan Schultz-Kleine, Arizona State University	
Jerome B. Kernan, George Mason University	

Self Examination	
Preference Spaces, Interpretive Inferences, and Consumption Systems.....	416
Jerome B. Kernan, George Mason University	
Patterns, Personalities, and Complex Relationships in the Effects of Self on Mundane	
Everyday Consumption: These are 495 of My Most and Least Favorite Things	417
Morris B. Holbrook, Columbia University	
Mundane Addiction: The Cinematic Depiction of Cocaine Consumption.....	424
Elizabeth C. Hirschman, Rutgers University	
Session 6.3	
Ethnicity and Consumer Product Evaluation: A Cross-Cultural Comparison of Korean	
Immigrants and Americans	429
Wei-Na Lee, University of Texas at Austin	
Koog-Hyang Ro Um, Florida State University	
The Cultural and Political Economy of the Indian Two-Wheeler.....	437
Bruce de Pyssler, University of Texas-Austin	
The Ethnicity and Consumption Relationship.....	443
Johanna Zmud, University of Southern California	
Carlos Arce, NuStats, Inc.	
Session 6.4	
"All the World's a Stage": Drama and Consumer Research	
Introduction.....	450
Barbara B. Stern, Rutgers University	
"What's in a Name?": Aristotelian Criticism and Drama Research	
Abstract.....	452
Barbara B. Stern, Rutgers University	
The Service Experience as Theater.....	455
Stephen J. Grove, Clemson University	
Raymond P. Fisk, University of Central Florida	
Sincerity, Sham and Satisfaction in Marketplace Performance	462
John Deighton, University of Chicago	
Session 6.6	
Feminist Theory and Marketing Thought: Toward A New Approach for Consumer Research.....	464
Mary Ellen Zuckerman, SUNY Geneseo	
Mary Carsky, Barney School of Business	
Are the Models Compatible for Empirical Comparison? An Illustration with an Intentions	
Model, an Expectations Model, and Traditional Conjoint Analysis	472
Rajan Natarajan, Auburn University	
Paul R. Warshaw, California Polytechnic State University	
Session 7.1	
Ho, Ho, Woe: Christmas Shopping for "Difficult" People.....	482
Cele Otnes, University of Illinois	
Young Chan Kim, University of Illinois	
Tina M. Lowrey, University of Illinois	

Thanks But No Thanks: Rejection, Possession and Disposition of the Failed Gift (Abstract).....	488
Margaret Rucker, University of California, Davis Tamara Balch, University of California, Davis Fiona Higham, University of California, Davis Kimberly Schenter, University of California, Davis	
Session 7.2	
Special Session Summary	
Consumer Behavior Research and its Implications for Product/nutritional Information Programs.....	489
Siva K. Balasubramanian, Session Co-chair Catherine Cole, Session Co-chair Nadine M. Castellano, University of Iowa	
Session 7.3	
Influence of Problem Recognition on Search and Other Decision Process Variables:	
A Framework for Analysis.....	491
Girish Punj, University of Connecticut Narasimhan Srinivasan, University of Connecticut	
Effect of Locus of Control on Information Search Behavior.....	498
Narasimhan Srinivasan, University of Connecticut Surinder Tikoo, University of Connecticut	
Mapping the Relationship Between Preattentive Processing and Attitudes.....	505
Stewart Shapiro, University of Arizona Deborah J. MacInnis, University of Arizona	
Session 7.4	
Till Death Do We Part: Family Dissolution, Transition, and Consumer Behavior.....	514
Ritha Fellerman, University of Massachusetts Kathleen Debevec, University of Massachusetts	
Measuring Conflict in Household Decision Behavior: Read My Lips and Read My Mind.....	522
William J. Qualls, Massachusetts Institute of Technology Francoise Jaffe, University of Michigan	
Consumer Socialization Associated with Relocation to a New Community: A Framework and Pilot Study.....	532
Cathy Goodwin, University of Manitoba	
Session 7.5	
Recovering From Drug Addiction: A Phenomenological Account.....	541
Elizabeth C. Hirschman, Rutgers University	
Helping the Homeless: A Radical Consumer Behavior-Oriented Solution	550
Ronald Paul Hill, Villanova University	
Marketplace Estrangement and Consumer Theft	554
Anthony D. Cox, Indiana University Dena Cox, Indiana University	
Consumer Behavior in Coping Strategies for Divorce.....	555
James H. McAlexander, Oregon State University John W. Schouten, University of Portland Scott D. Roberts, Old Dominion University	

The Cigarette Advertising Controversy: Assumptions About Consumers, Regulation, and Scientific Debate.....	557
John E. Calfee, Boston University	
Debra Jones Ringold, University of Baltimore	
Session 7.6	
Role of Affect and Need for Interaction in On-Site Service Encounters.....	563
Pratibha A. Dabholkar University of Tennessee	
The Role of Post-Experience Comparison Standards in the Evaluation of Unfamiliar Services.....	570
Ann L. McGill, Northwestern University	
Dawn Iacobucci, Northwestern University	
Determinants of Word-Of-Mouth Communications During Product Consumption.....	579
Paula Fitzgerald Bone, West Virginia University	
Session 8.1	
Buying More than We Can Use: Factors Influencing Forecasts of Consumption Quantity.....	584
Mary Frances Luce, Duke University	
When Are Higher Social Class Consumers More and Less Brand Loyal Than Lower Social Class Consumers?: The Role of Mediating Variables.....	589
Rajesh Kanwar, San Diego State University	
Notis Pagiavlas, San Diego State University	
Session 8.2	
Playing with Pictures: Postmodernism, Poststructuralism, and Advertising Visuals.....	596
Linda M. Scott, University of Colorado, Boulder	
Remembrance of Things Past: Music, Autobiographical Memory, and Emotion.....	613
Hans Baumgartner, Pennsylvania State University	
A Framework Providing Direction for Research on Communications Effects of Mental Imagery-Evoking Advertising Strategies.....	621
Laurie A. Babin, University of Southern Mississippi	
Alvin C. Burns, Louisiana State University	
Abhijit Biswas, Louisiana State University	
Session 8.4	
Examining Alternative Operational Measures of Internal Reference Prices.....	629
William O. Bearden, University of South Carolina	
Ajit Kaicker, University of South Carolina	
Melinda Smith de Borrero, University of South Carolina	
Joel E. Urbany, University of South Carolina	
Session 8.5	
Transcendent Benefits of High-Risk Sports.....	636
Richard L. Celsi, California State University, Long Beach	
Session 8.6	
Discussant's Comments on Competitive Papers Presented Session 8.6 - Services.....	642
Michael A. Belch, San Diego State University	
Incorporating Consumer Judgments into Aggregate Choice Models.....	644
W. Steven Perkins, Pennsylvania State University	

Validating Realtime Response Measures.....	649
Thomas C. Boyd, University of North Carolina, Chapel Hill	
G. David Hughes, University of North Carolina, Chapel Hill	
Deriving Attribute Utilities from Consideration Sets: An Alternative to Self-Explicated Utilities.....	657
David B. Klenosky, DePaul University	
W. Steven Perkins, Pennsylvania State University	
Session 9.1	
New Perspectives for Self-Research	664
Beth Ann Walker, Arizona State University	
Session 9.2	
Consumer and Employee Roles in Service Encounters.....	666
Michael Guiry, University of Florida	
Organizational Characteristics and Employee Excuse Making: Passing the Buck for Failed Service Encounters.....	673
Donna J. Hill, Bradley University	
Robert Baer, Bradley University	
Rustan Kosenko, Bradley University	
Health Promotion Services Consumption: Involvement and Program Choice.....	679
Nora J. Rifon, Michigan State University	
Brian E. Mavis, Michigan State University	
Elizabeth Tucker, Michigan State University	
Bertram E. Stöffelmayr, Michigan State University	
Session 9.3	
A Factor Analytic Investigation of Belk's Structure of the Materialism Construct	688
Seth R. Ellis, University of San Diego	
Applying Conjoint Analysis to Social Advertisements.....	696
Moshe Engelberg, Stanford University	
Rosalind M. Pierson, Stanford University	
Hiroshi Kashio, Stanford University	
Confirmatory Factor Analysis of a Country-Of-Origin Scale: Initial Results	706
R. Mohan Pisharodi, Oakland University	
Ravi Parameswaran, Oakland University	
Session 9.4	
Listen to the Music: Its Impact on Affect, Perceived Time Passage, and Applause	715
Brian Wansink, Dartmouth College	
The Use Of Rap Music In Children's Advertising	719
M. Elizabeth Blair, Ohio University	
Mark N. Hatala, Ohio University	
The Experience of Time as a Function of Musical Loudness and Gender of Listener.....	725
James J. Kellaris, University of Cincinnati	
Moses B. Altsech, Pennsylvania State University	
Consumer Esthetics Outside the Lab: Preliminary Report on a Musical Field Study.....	730
James J. Kellaris, University of Cincinnati	
Session 9.5	
To Choose or Not to Choose: This Is The Question	735
Ravi Dhar, University of California, Berkeley	

Session 9.6

- Good Guys Don't Wear Polyester: Consumption Ideology in a Detective Series.....739
Cathy Goodwin, University of Manitoba
- The Marlboro Man as a Twentieth Century David: A Philosophical Inquiry into the Aristotelian
Aesthetic of Advertising.....746
Barry Vacker, University of Texas
- Consumers and Movies: Information Sources for Experiential Products756
Elizabeth Cooper-Martin, Georgetown University

Session 10.1

- Involvement and Advertisement Size Effects on Information Processing762
Jin K. Han, Columbia University
- Clarifying the Simple Assumption of the Information Load Paradigm.....770
Robert S. Owen, Ohio State University
- The Influence of Level of Involvement on the Feature Matching Process in Consumer
Preference Judgments.....777
Alan Strathman, University of Missouri-Columbia
David S. Boninger, University of California-Los Angeles
Sara M. Baker, Ohio State University

Session 10.2

- A Spreading Activation Model of Consumers' Asymmetric Similarity Judgment782
Ehsan Ulhaque, University of Texas at Arlington
Kenneth D. Bahn, University of Texas at Arlington
- Schemata in Consumer Research: A Connectionist Approach.....787
Tom J. Brown, University of Wisconsin-Madison
- Priming and Implicit Memory: A Review and a Synthesis Relevant for Consumer Behavior795
Abhijit Sanyal, University of Massachusetts at Amherst

Session 10.3

- Goal-Related Consumption and Extension Advertising: The Impact on Memory and Consumption806
Brian Wansink, Dartmouth College
Michael L. Ray, Stanford University

Session 10.4

- Some Measurement Issues in Consumer Research813
Ved Prakash, Morgan State University
- The Development of a Measure to Assess Viewers' Judgments of the Creativity of an Advertisement:
A Preliminary Study817
Gabriele S. Haberland, University of Wisconsin-Madison
Peter A. Dacin, University of Wisconsin-Madison
- A Multiphase Thought Elicitation Coding Scheme for Cognitive Response Analysis.....826
Paul L. Sauer, Canisius College
Peter R. Dickson, Ohio State University
Kenneth R. Lord, University at Buffalo (SUNY)
- Scales to Measure Social Power in a Consumer Context.....835
Jonathan E. Brill, Temple University

Session 10.5

Insider versus Outsider: Reflections of a Feminist Consumer.....843
Julia M. Bristol, University of Houston

**Reflections of a Black Middle-Class Consumer: Caught Between Two Worlds or Getting
the Best of Both?.....850**
Jerome D. Williams, Pennsylvania State University

Self-Fashioning Oneself Cross-Culturally: Consumption as the Determined and the Determining.....857
Stephen J. Gould, Rutgers, The State University of New Jersey
Robert N. Stinerock, Fairleigh Dickinson University

Session 10.6

**Implications of the Symbolic Interactionist Perspective for the Study of
Environmentally-Responsible Consumption.....861**
Ed Petkus, Jr., University of Tennessee

**Consumer Assessments of Responsibility for Product-Related Injuries: The Impact of Regulations,
Warnings, and Promotional Policies.....870**
Mitch Griffin, Bradley University
Barry J. Babin, University of Southern Mississippi
William R. Darden, Louisiana State University

Extended Warranties: A Behavioral Perspective.....879
Glenn B. Voss, Texas A&M University
Irfan Ahmed, Texas A&M University

Subject Index.....887

Author Index (Conference Sessions).....889

Author Index (Volume XIX).....891

George Zinkham

Conference Program
CHICAGO, MARRIOTT HOTEL
OCTOBER 17-20, 1991

THURSDAY, OCTOBER 17

REGISTRATION
4:00 - 8:00 P.M.

ACR EXECUTIVE BOARD MEETING
10:00 A.M. - 5:15 P.M.

EARLY BIRD COCKTAIL PARTY
6:00 - 8:00 P.M.

FRIDAY, OCTOBER 18

REGISTRATION
8:30 A.M. - 3:00 P.M.

SESSION 1
8:30 am - 10:00 am

1.1 Special Session: Consumer Behavior Related to Social Ideas Advertising

Co-Chairs

Lalita A. Manrai, University of Delaware
Meryl P. Gardner, University of Delaware

Discussant

Morris Holbrook, Columbia University

Consumer Processing of Social Ideas Advertising: A Conceptual Model

Lalita A. Manrai, University of Delaware
Meryl P. Gardner, University of Delaware

Sociological Perspectives on Social Issue Advertising

Gerald Zaltman, Harvard University

Public Service Announcement Campaigns vs. Paid Advertising Campaigns: Differences in Development and Evaluation

John P. Murry, University of Wisconsin - Madison
John L. Lastovicka, University of Kansas

A Field Test of Influence Strategies for Sustaining Blood Donation: Emotional Arousal versus Self-Concept Enhancement

Chris T. Allen, University of Cincinnati
Robert J. Kent, Drexel University
Terri F. Barr, University of Cincinnati

1.2 Special Session: Cognitive Organization of Product Information: Theory and Method

Co-Chairs & Discussants

Jong-Won Park, University of British Columbia
Robert Wyer, University of Illinois at Urbana-Champaign

Organization of Product Information in Memory: Some Exploratory Findings

Jong-Won Park, University of British Columbia

Robert Wyer, University of Illinois at Urbana-Champaign

Representation of Product Information in Memory: Some Experimental Evidence

Manoj Hastak, American University

Finding Choice Alternatives in Memory: The Effects of Cognitive Organization on Brand Name Recall

Wes Hutchinson, University of Florida

Murali Mantrala, University of Florida

Kalyan Raman, University of Florida

Methodological Issues in the Study of Memory Organization

Thomas K. Srull, University of Illinois at Urbana-Champaign

1.3 Special Session: Hispanic Consumer Research

Chair & Discussant

Laurel Anderson, Arizona State University - West

Do Hispanics Constitute a Market?

Geraldine Fennell, Consultant

Joel Saegert, The University of Texas at San Antonio

Francis Piron, University of Alaska, Anchorage

Rosemary Jimenez, The University of Texas at San Antonio

Cultural Value Orientations: A Comparison of Advertisements from the United States and Mexico

John A. McCarty, University of Illinois at Urbana-Champaign

Patricia M. Hattwick, University of Illinois at Urbana-Champaign

Border Crossings: An Ethnographic Exploration of Mexican Consumer Acculturation

Lisa N. Penaloza, California State University, San Bernardino

What Hispanic Folkstories Tell Us About Hispanic Health Patterns

Laurel A. Anderson, Arizona State University - West

1.4 Competitive Papers: Symbolism and Meaning

Chair

Paul Speck, University of Tennessee

Discussant

Rita Denny, Holen North America

What It All Adds Up To: Culture and Alpha-Numeric Brand Names

Janeen A. Costa and Teresa Pavia, University of Utah

Meaning Construction in a Cultural Gallery: A Sociosemiotic Study of Consumption Experiences in a Museum

Jean Umiker-Sebeok, RCLSS/Indiana University

Parallels Between Hypnotic Suggestion and Persuasive Marketing Communications: Insights for New Directions in Consumer Communications Research

Stephen J. Gould, Rutgers University

1.5 Special Session: Context Effects on Social Judgments: Implications for Measurement in Consumer Research

Chairs

Barbara Bickart, University of Florida

Geeta Menon, New York University

Discussants

Gerald Salancik, Carnegie Mellon University
Jack Feldman, Georgia Institute of Technology

The Role of Judgment Type and Cognitive Effort in Context Effects

Leonard L. Martin, University of Georgia
Thomas F. Harlow, University of Georgia

Context Effects in Proxy Judgments

Barbara Bickart, University of Florida
Geeta Menon, New York University
Seymour Sudman, University of Illinois at Urbana-Champaign
Johnny Blair, University of Maryland

Effects of Question Order on Correlates of Stated Voting Intentions: The Moderating Roles of Involvement and Prior Commitment

Carolyn J. Simmons, University of Illinois at Urbana-Champaign
John G. Lynch, Jr., University of Florida
Barbara Bickart, University of Florida

Context Effects in Attitude Measurement: An Inclusion/Exclusion Model of Assimilation and Contrast Effects

Norbert Schwarz, Zentrum für Umfragen, Methoden und Analysen (ZUMA), Mannheim, W. Germany
Herbert Bless, University of Mannheim

1.6 Special Session: You Eat What You Are: Food Symbolism in the U.S.A.

Chair

John F. Sherry, Jr. Northwestern University

Discussant

Grant McCracken, Royal Ontario Museum

Gender Symbolism in Food

Deborah D. Heisley, University of California - Los Angeles

Eating Prepared Food: In and Out

Sidney J. Levy, Northwestern University

Rationality and the Culture of Goods

Marshall Sahlins, University of Chicago

1.7 Competitive Papers: Attentional Processes

Chair

Durairaj Maheswaran, New York University

Discussant

Marilyn Jones, University of Houston - Clear Lake

Person Perception Carry-Over Effects: How Our Partners' Traits Influence the Evaluation of Ourselves

Therese A. Louie, University of California - Los Angeles

Effects of Involvement, Arousal, and Pleasure on the Recognition of Sponsorship Stimuli

Michel Tuan Pham, University of Florida

The Relationship Between Distractor Similarity and the Recognition of Print Advertisements

James W. Peltier, University of Wisconsin - Whitewater
John A. Schibrowsky, University of Nevada - Las Vegas

SESSION 2
10:20 am - 11:50 pm

2.1 Special Session: Repetition, Memory, and Low-Involvement Learning

Chair

Scott A. Hawkins, University of Chicago

Discussant

J. Paul Peter, University of Wisconsin, Madison

Repetition, Low-Involvement Processing, and Belief

Scott A. Hawkins, University of Chicago

Stephen J. Hoch, University of Chicago

The Development of Choice Heuristics Over Time: An Examination of The Learning Process

Wayne D. Hoyer, The University of Texas at Austin

Steven P. Brown, University of Georgia

Examining The Relationship Between Ad Repetition and Product Evaluations

Prashant Malaviya, Northwestern University

Joan Meyers-Levy, University of Chicago

Ad Format and Memory Structure: Measures and Methods of Building Brand Awareness

Paul M. Herr, Indiana University

Russell H. Fazio, Indiana University

Martha C. Powell, Indiana University

2.2 Special Session: Accessibility and Choice

Chair

Andrew A. Mitchell, University of Toronto

Discussant

Thomas K. Srull, University of Illinois, Urbana-Champaign

Ask Not What the Brand Can Evoke; Ask What Can Evoke the Brand?

Stephen J.S. Holden, University of Florida

Richard J. Lutz, University of Florida

The Role of Category Structure in Brand Recall During Choice

Prakash Nedungadi, University of Toronto

Amitava Chattopadhyay, McGill University

The Effect of Memory Organization on the Judgment and Choice of Consumer Products

Karen Finlay, University of Toronto

Andrew A. Mitchell, University of Toronto

Attitudes as Hypotheses: An Accessibility - Diagnosticity Perspective

John Kim, Oakland University

Frank R. Kardes, University of Cincinnati

Paul M. Herr, University of Colorado

2.3 Competitive Papers: Developing Valid Measures

Chair

Chris Puto, University of Arizona

Discussant

Merrie Brucks, University of Arizona

A Revised Product Involvement Inventory: Improved Usability and Validity

Edward McQuarrie, Santa Clara University

J. Michael Munson, Santa Clara University

The Use of Multiple Methods to Explore Three-way Person, Brand and Usage Context Interactions

Niraj Dawar, INSEAD

S. Ratneshwar, University of Florida

Alan G. Sawyer, University of Florida

'Chernoff Faces': A Useful Technique for Comparative Image Analysis and Representation

Linda Golden, University of Texas - Austin

Mayur Sirdesai, University of Texas-Austin

2.4 Competitive Papers: Self-Indulgence in Consumer Behavior

Chair

Mary Ann McGrath, Loyola University - Chicago

Discussant

Dominique Bouchet, Odense University

Cocaine as Innovation

Elizabeth C. Hirschman, Rutgers University

Further Findings on Self-Gifts: Products, Qualities and Socioeconomic Correlates

David Mick, University of Florida

Michelle DeMoss, University of Florida

Symbolic Communication Among Consumers in Self-Consumption and Gift Giving: A Semiotic Approach

Anil M. Pandya, Northeastern Illinois University

A. Venkatesh, University of California - Irvine

2.5 Special Session: On Becoming Inhibited: A Different Metaphor for Consumer Cognitive Processing

Co-Chairs

Wanda T. Wallace, Duke University

James R. Bettman, Duke University

Discussant

Jay Russo, Cornell University

An Inhibition-Based Theory of Attention

Lynn Hasher, Duke University

Retrieval Inhibition and Related Adaptive Peculiarities of Human Memory

Robert Bjork, University of California - Los Angeles

Mark Vanhuele, University of California - Los Angeles

Consideration of Inhibition as a Mechanism in Decision Processes

Mary Frances Luce, Duke University

2.6 Special Session: Driving Passions: Vehicles and Consumer Culture

Chair

Michael R. Solomon, Rutgers University

'Have You Kissed Your Professor Today?' Bumper Stickers and Consumer Self-Statements

Barbara B. Stern, Rutgers University

Michael R. Solomon, Rutgers University

Volkswagen as 'Little Man'

Bruce G. Vanden Bergh, Michigan State University

Hog Heaven: The Structure, Ethos, and Market Impact of a Consumption Subculture

John W. Schouten, University of Portland

James H. McAlexander, Oregon State University

The All-American Unobtrusive Measure... Or, You Are What You Drive, Even If You're Not From California

Douglas Banik, D'Arcy Masius Benton & Bowles

2.7 Special Session: New Theoretical Perspectives on Consumer Decision Making Under Uncertainty

Chair

David E. Hansen, Virginia Polytechnic Institute and State University

Robert J. Meyer, University of Pennsylvania

Discussant

Eric Johnson, University of Pennsylvania

Decision Making Under Risk

James Shanteau, Kansas State University

The Integration of Uncertain Gains and Losses in Multiattribute Decision Making

Robert J. Meyer, University of Pennsylvania

A Consumer's Model of Choice Under Uncertainty

David E. Hansen, Virginia Polytechnic Institute and State University

Towards a Unification of Time Dependent Valuation Processes: Implications for Consumer Decision Making Under Uncertainty

John C. Mowen, Oklahoma State University

FRIDAY, OCTOBER 18

LUNCH

12:00 pm - 2:00 pm

Business Meeting:

H. Keith Hunt, Brigham Young University

Ferber Award:

Presented by: Kent Monroe, University of Illinois

Presented to:

Jonathan Frenzen, University of Arizona

Prakash Nedungadi, University of Toronto

Presidential Address:

Sidney J. Levy, Northwestern University

SESSION 3

2:15 pm - 3:45 pm

3.1 Special Session: Knowledge and Knowledge of Knowledge: What We Know, What We Think We Know, and Why the Difference Makes a Difference

Chairs

Lawrence F. Feick, University of Pittsburgh

C. W. Park, University of Pittsburgh

Discussant

Meryl P. Gardner, University of Delaware

Exploring the Relationship Among Self-Reported Knowledge, Objective Knowledge, Product Usage and Consumer Decision-Making

Catherine Cole, University of Iowa
Gary Gaeth, University of Iowa
Goutam Chakraborty, Oklahoma State University
Irwin Levin, University of Iowa

What Consumers 'Really' Know and What They Think They Know: Investigations Into the Determinants of Confidence and Performance

Susan Broniarczyk, University of Texas - Austin
J. Wesley Hutchinson, University of Florida
Joseph W. Alba, University of Florida

Determinants of the Overconfidence Effect in Marketing Predictions

Jayashree Mahajan, University of Arizona

Consumer Knowledge Assessment: How Product Experience and Knowledge of Brands, Attributes and Features Affects What We Think We Know

C. Whan Park, University of Pittsburgh
Lawrence F. Feick, University of Pittsburgh
David L. Mothersbaugh, University of Pittsburgh

3.2 Special Session: Postmodernism, Consumer Culture and the Society of the Spectacle

Chair

Alladi Venkatesh, University of California - Irvine

Introduction

Alladi Venkatesh, University of California - Irvine

Postmodernism and Consumer Culture: A Synthesis

Mike Featherstone, Teesside Polytechnic

The Soul Of The Commodity: Benjamin's Model Of The Consumer

Alex Gelley, University of California - Irvine

Fragmentation In Postmodern Culture

A. Fuat Firat, Arizona State University - West

What Are You Doing After The Orgy?

Suerdem Ahmet, Momer Sinan University

3.3 Competitive Papers: Ritual in Consumer Behavior

Chair

Annamma Joy, Concordia

Discussant

Dennis Rook, University of Southern California

Examining the Descriptive Value of 'Ritual' in Consumer Behavior: A View from the Field

Douglas B. Holt, Northwestern University

The Consumption of Insignificant Rituals: A Look at Debutante Balls

Jennifer Edson Escalas, Duke University

Halloween as Consumption Experience

Stacey Levinson, Rutgers University
Stacey Mack, Rutgers University
Daniel Reinhardt, Rutgers University
Helen Suarez, Rutgers University
Grace Yeh, Rutgers University

3.4 Competitive Papers: Affect and Emotion

Chair

Nancy Artz, University of Southern Maine

Discussant

Rajiv Batra, University of Michigan

An Exploration of Materialism and Consumption-Related Affect

Marsha L. Richins, University of Massachusetts/Amherst
Kim K. R. McKeage, University of Massachusetts/Amherst
Debbie Najjar, University of Massachusetts/Amherst

An Investigation of the Attribute Basis of Emotion and Related Affects in Consumption: Suggestions for a Stage-Specific Satisfaction Framework

Richard L. Oliver, Vanderbilt University

Interpreting Perceiver Reactions to Emotional Stimuli

Jeremy D. Pincus, University of Connecticut

3.5 Special Session: Consideration Sets and Brand Choice: Combining Quantitative and Behavioral Approaches

Chair

Prakash Nedungadi, University of Toronto

Co-Discussants

Allan D. Shocker, University of Minnesota
Wesley J. Hutchinson, University of Florida

Incorporating Consideration Sets Into Models of Brand Choice

Prakash Nedungadi, University of Toronto
Vinay Kanetkar, University of Toronto

An Empirical Investigation of Consideration Set Formation

John S. Hulland, University of Western Ontario

Using Consideration Set Information To Improve Choice Model Specification

Jordan Louviere, University of Utah
Bill Moore, University of Utah

Advertising Effects on Consideration Set Size

Anusree Mitra, American University
John G. Lynch, University of Florida

3.6 Special Session: Categorization Research and Brand Extensions

Chair

Laurette Dube, Université de Montreal
Bernd Schmitt, Columbia University
Sheri Bridges, Wake Forest University

Co-Discussants

Joan Meyers-Levy, University of Chicago
Kevin Keller, Stanford University

Recent Theoretical Developments in Categorization Research

Lawrence Barsalou, University of Chicago

...And Their Relevance to Brand Extensions

Bernd Schmitt, Columbia University
Laurette Dube, Université de Montreal

Dominance and Typicality in Brand Extension
Peter Farquhar, Carnegie-Mellon University
Paul M. Herr, University of Colorado, Boulder

Contextual Variations in Product/Category
Deborah MacInnis, University of Arizona
Kent Nakamoto, University of Arizona

A Scheme Unification Model of Brand Extensions...
Sheri Bridges, Wake Forest University

...Applied to the Reciprocal Relationship Between Brand and Extension.
Sandra Milberg, Georgetown University
C. Whan Park, University of Pittsburgh

Asymmetrical Influence Between Brand and Extension...
David Boush, University of Oregon

...and the Negative Impact of Extensions on the Brand
Barbara Loken, University of Minnesota
Deborah Roedder John, University of Minnesota

3.7 Special Session: Uses of Psycholinguistic Theory in Advertising Research

Chair

Tina M. Lowrey, University of Illinois

Co-Discussants

Esther Thorson, University of Wisconsin - Madison
Larry Percy, Lintas:USA

The Relationship Between Psycholinguistic Structure and Advertising Effectiveness
Tina M. Lowrey, University of Illinois

Understanding the Circumstances Under Which People Make Misleading Inferences
Trudy Kehret-Ward, University of California - Berkeley

Using Syntax to Direct Processing Resources
Slimen Saliba, Andrews University

FRIDAY, OCTOBER 18

SESSION 4

4:00 pm - 5:30 pm

4.1 Competitive Papers: Factors Affecting Evaluation

Chair

C.S. Craig, New York University

Discussant

Richard Yalch, University of Washington

The Impact of Measurement Context on the Relationship Between Attitude Toward the Ad and Brand Attitude for Familiar Brands

Karen A. Machleit, University of Cincinnati
Arti Sahni, University of Cincinnati

The Effects of Missing Information on Consumer Product Evaluations

Deepak Sirdeshmukh, Ohio State University
H. Rao Unnava, Ohio State University

An Investigation of Self-Referencing's Influence on Affective Evaluations
Jean B. Romeo, Boston College
Kathleen Debevec, University of Massachusetts

4.2 Special Session: Postmodernism, Consumer Culture and the Society of the Spectacle

Chair
Alladi Venkatesh, University of California - Irvine

Discussant
John F. Sherry, Jr., Northwestern University

Modernist & Postmodernist Overtones in the Photographic Representation of the Consumer Culture
Sally Stein, Yale University

Understanding Social Context Through Photography
Gerald Zaltman, Harvard University

Postmodernism & the European Scene
Dominique Bouchet, Odense University

The Postmodern Consumer Environment: A Case Study
Alladi Venkatesh, University of California - Irvine

4.3 Special Session: Is a Picture Really Worth a Thousand Words? The Effects of Visually and Verbally Presented Information in Advertising

Co-Chairs
Laura A. Peracchio, University of Wisconsin - Milwaukee
Joan Meyers-Levy, University of Chicago

Discussant
Morris B. Holbrook, Columbia University

Interactive Advertising: Using Picture Copy Combinations to Enhance Memory for Advertisements
Susan E. Heckler, University of Arizona
Terry L. Childers, University of Minnesota

What You See Is Not Necessarily What You Get: The Effects of Pictures and Words on Consumers' Inferences
Ruth Ann Smith, Virginia Polytechnic Institute and State University

The Impact of Complete Versus Partial Visuals on Children's Learning
M. Carole Macklin, University of Cincinnati

Are All Pictures Created Equal?: How Pictures Can Influence Consumer Interpretation of Verbal Information
Joan Meyers-Levy, University of Chicago
Laura A. Peracchio, University of Wisconsin - Milwaukee

4.4 Competitive Papers: Symbolic Consumer Behavior

Chair
Thomas O'Guinn, University of Illinois, Urbana-Champaign

Discussant
Rebecca Holman, D'Arcy Masius Benton & Bowles

Consumer Stereotyping: The Cognitive Bases of the Social Symbolism of Products
Eva M. Hyatt, Appalachian State University

A Model of the Scripting of Consumer Lovemaps: The Sexual Behavior Sequence
Stephen J. Gould, Rutgers University

The Effects of Product Symbolism on Consumer Self-Concept
Newell D. Wright, Virginia Polytechnic Institute and State University
C.B. Claiborne, James Madison University
M. Joseph Sirgy, Virginia Polytechnic Institute and State University

4.5 Special Session: Behavioral Theories of Marketing Strategy

Chair & Discussant
Rashi Glazer, University of California - Berkeley

Strategic Inimitability: Preemptive Positioning Through Meaningful and Meaningless Differentiation
Gregory Carpenter, Northwestern University
Rashi Glazer, University of California - Berkeley
Kent Nakamoto, University of Arizona

Consumer Consideration Set and the Pioneering Advantage
Gurumurthy Kalyanaram, University of Texas - Dallas
Frank Kardes, University of Cincinnati
Ronald Dornoff, University of Cincinnati

The Strategic Use of Phantoms
Peter Farquhar, Carnegie Mellon University
Anthony Pratkanis, University of California - Santa Cruz

On the Managerial Relevance of a Theory of Market Behavior
Allan Shocker, University of Minnesota
S. Ratneshwar, University of Florida
Rajendra Srivastava, University of Texas - Austin

4.6 Special Session: New Perspectives in Attitude Research

Chair
Youjae Yi, University of Michigan

Discussant
Bernd H. Schmitt, Columbia University

Enactment Processes in the Theory of Reasoned Action
Richard P. Bagozzi, University of Michigan

The Eye is Better than an Aye
Chris Janiszewski, University of Florida

Attitude Functions in Advertising Effectiveness: The Interactive Role of Product Type and Personality Type
Sharon Shavitt, University of Illinois
Tina M. Lowrey, University of Illinois

The Effect of Attribute Diagnosticity on Attitudes
Kenneth Gray, University of Michigan
Youjae Yi, University of Michigan

4.7 Competitive Papers: Lifestyle Analysis

Chair
Marty Horn, DDB Needham Worldwide

Discussant
Sharon Beatty, University of Alabama

Nine Consumption Lifestyles
Susan Fournier, University of Florida
David Antes, University of Massachusetts
Glenn Beaumier, Westinghouse Savannah River Company

Consumption Choice within the Black Extended Family Network

Judy Cohen, Rider College
Carol Kaufman, Rutgers University

Values and Psychographic Variation across United States Geographic Regions

Lynn R. Kahle, University of Oregon
Ruiming Liu, University of Oregon
Harry Watkins, University of Oregon

4.8 Special Session: Ferber Award Presentations

Chair & Discussant

Kent Monroe, University of Illinois

Purchasing Behavior in Embedded Markets

Jonathan K. Frenzen, University of Arizona

Recall and Consumer Consideration Sets: Influencing Choice Without Altering Brand Evaluations

Prakash Nedungadi, University of Toronto

FRIDAY, OCTOBER 18

Cocktail Party

6:00 pm

Museum of Contemporary Art

SATURDAY, OCTOBER 19

SESSION 5

8:30 am - 10:00 am

5.1 Special Session: Personality and Psychoanalytic Theory: Current Theoretical and Empirical Research

Chair

Paul J. Albanese, Kent State University

Discussants

Stephen J. Gould, Rutgers University
William D. Wells, DDB Needham Worldwide, Chicago

Durable Fantasies: A Case of Judy and Her Refrigerator Wonderland

Dennis W. Rook, University of Southern California
Morris B. Holbrook, Columbia University

Psychological Undercurrents of Materialism

Jonathan E. Schroeder, University of Rhode Island

Adapting the California Q Sort to Psychoanalytic Object Relations: A Pilot Project to Operationalize the Personality Organization for Empirical Research

Paul J. Albanese, Kent State University

5.2 Meet the Editors

International Journal of Research in Marketing, Piet Vanden Abeele, Catholic University, Leuven
Journal of Consumer Research, Kent Monroe, University of Illinois
Journal of Consumer Psychology, Thomas Srull, University of Illinois
Journal of Marketing Research, Barton Weitz, University of Florida
Marketing Letters, Harold Kassarjian, UCLA & Robert Meyer, University of Pennsylvania

5.3 Competitive Papers: Factors Influencing Consumers' Responses

Chair

Christian Pinson, INSEAD

Discussant

Jill Klein, Northwestern University

Effects of Source Likability on Attitude Change through Message Repetition

Jean-Charles Chebat, University of Quebec at Montreal

Michel Laroche, Concordia University

Pierre Filiatrault, University of Quebec at Montreal

Daisy Baddoura, University of Quebec at Montreal

The Effects of Message Valence on Inferential Processes

Lydia J. Price, INSEAD

Attention, Memory, Attitude, and Conation: A Test of the Advertising Hierarchy

Esther Thorson, University of Wisconsin

Annie Chi, University of Wisconsin

Clark Leavitt, Ohio State University

5.4 Special Session: Back to the Future,...Forward to the Past: Manifestations and Characteristics of Nostalgic Experience

Co-Chairs

Susan L. Holak, Rutgers University

William J. Havlena, Rutgers University

Discussant

Fred Davis, University of California - San Diego

Nostalgia: An Exploratory Study of Themes and Emotions in the Nostalgic Experience

Susan L. Holak, Rutgers University

William J. Havlena, Rutgers University

Nostalgia and Holidays: Ritual Forms of Celebrating the Past

Melanie Wallendorf, University of Arizona

Eric J. Arnould, California State University - Long Beach

Nostalgia in Advertising Text: Romancing the Past

Barbara Stern, Rutgers University

Nostalgia: A Neuropsychiatric Understanding

Alan R. Hirsch, M.D., F.A.C.P., Smell & Taste Treatment and Research Foundation, Ltd., Chicago, IL

5.5 Special Session: The Role of Consumption and Disposition During Classic Rites of Passage: The Journey of Birth, Initiation, and Death

Chair

Julie L. Ozanne, Virginia Polytechnic Institute and State University

Discussant

John W. Schouten, University of Portland

Consumption and the Rite of Passage into Parenthood

Newell D. Wright, Virginia Polytechnic Institute and State University
Jon Shapiro, Virginia Polytechnic Institute and State University

Material Concerns While Coming of Age in the Mormon Faith: Spiritual Work in a Secular World

Julie L. Ozanne, Virginia Polytechnic Institute and State University

Transition in Turmoil: When Becoming an Adult Involves Criminal Behavior

Ron Paul Hill, Villanova University

Rituals of Adversity and Re-membering: The Role of Possessions for Persons and Community Living With AIDS

Mara B. Adelman, Northwestern University

5.6 Special Session: Consumer Inference

Co-Chairs

John Kim, Oakland University
Frank R. Kardes, University of Cincinnati

Discussant

Douglas M. Stayman, Cornell University

Determinants of the Persuasiveness of Open-Ended Versus Closed-Ended Advertisements

Alan G. Sawyer, University of Florida

Consumer Inference Making and Indirect Effects of Advertising

Youjae Yi, University of Michigan

Contingent Inference Making

Carolyn J. Simmons, University of Illinois
John G. Lynch, Jr., University of Florida

Consumer Expertise and the Perceived Diagnosticity of Inferences

Frank R. Kardes, University of Cincinnati
John Kim, Oakland University
Jeen-Su Lim, University of Toledo

5.7 Special Session: Advertising Effects on Brand Equity: A Variety of Perspectives on Brand-based Memory Networks

Co-Chairs

Susan E. Heckler, University of Arizona
Kevin L. Keller, Stanford University

Discussant

Michael J. Houston, University of Minnesota

The Interaction of Brand Name and Brand Positioning Strategies on Advertising Effectiveness Over Time

Susan E. Heckler, University of Arizona
Kevin L. Keller, Stanford University

Ad-Induced Affect and Brand Equity: An Exploratory Study

Marian Chapman Moore, Duke University
Julie Edell, Duke University

The Impact of Extension Advertising on Brand Equity

Brian Wansink, Dartmouth College

SESSION 6
10:30 am - 12:00 pm

6.1 Special Session: Consumer Research in Services Marketing

Chair & Discussant

Dawn Iacobucci, Northwestern University

A Service Users Typology

Terri Swartz, Arizona State University

Nancy Stephens, Arizona State University

Classifying Service Encounters Based on Affective Dimensions: A Preliminary Approach

Cathy Goodwin, University of Manitoba

Can You Control Your Consultant?

Jill A. Grace, University of Southern California

Gender Differences in Preferences for Services Attributes

Dawn Iacobucci, Northwestern University

6.2 Special Session: Mundane Everyday Consumption and the Self

Co-Chairs

Susan Schultz-Kleine, Arizona State University

Robert E. Kleine III, Arizona State University

Discussant

Jerome B. Kernan, George Mason University

Mundane Everyday Consumption and The Self: A Brief Introduction

Susan Schultz-Kleine, Arizona State University

Robert E. Kleine III, Arizona State University

These Are 125 of My Favorite and Least Favorite Things: How Nostalgia Matters, Even for Young'n's

Morris B. Holbrook, Columbia University

Consumptions Systems Revisited

Sidney J. Levy, Northwestern University

Mundane Addiction: The Cinematic Depiction of Cocaine Consumption

Elizabeth C. Hirschman, Rutgers University

6.3 Competitive Papers: Multicultural Consumer Behavior

Chair

Rohit Deshpande, Dartmouth College, Tuck School of Business

Discussant

Douglas Stayman, Cornell University

Ethnicity and Consumer Product Evaluation: A Cross-Cultural Comparison of Korean Immigrants and Americans

Wei-Na Lee, University of Texas - Austin

Koog-Hyang Ro Um, University of Texas - Austin

The Cultural and Political Economy of the Indian 2-Wheeler

Bruce de Pysler, University of Texas - Austin

The Ethnicity and Consumption Relationship
Johanna P. Zmud, University of Southern California
Carlos H. Arce, Nu Stats, Inc.

6.4 Special Session: All the World's a Stage: Drama and Consumer Research

Chair
Barbara B. Stern, Rutgers University

Discussant
William D. Wells, DDB Needham Worldwide

What's in a Name?' Aristotelian Criticism and Drama Research
Barbara B. Stern, Rutgers University

The Service Encounter as Theater
Stephen J. Grove, Clemson University
Raymond P. Fisk, University of Central Florida

Sincerity, Sham and Satisfaction in Marketplace Performance
John Deighton, University of Chicago

Empathy and Vicarious Performances of Meaning During Exposure to Commercial Dramas
Gregory W. Boller, Memphis State University
Jerry C. Olson, Pennsylvania State University

6.5 Special Session: Sociological Issues in Consumer Research

Chair & Discussant
Paul F. Anderson, Pennsylvania State University

Naturalistic Exploration of Exchange Processes
Trevor Pinch, Cornell University

The Hidden Injuries of Social Class: Implications for Consumer Research
Paul F. Anderson, Pennsylvania State University

Working Class Views and Blues: A Qualitative Examination
Brent Johnson, Pennsylvania State University

6.6 Competitive Papers: Philosophical Overviews

Co-Chairs & Discussants
Paul Speck, University of Tennessee
Craig J. Thompson, University of Wisconsin - Madison

Feminist Theory and Marketing Thought: Toward a New Approach for Consumer Research
Mary Ellen Zuckerman, State University of New York - Geneseo
Mary Carsky, Barney School of Business

Are the Models Compatible for Empirical Comparison?
Rajan Nataraajan, Auburn University
Paul R. Warshaw, California Polytechnic State University

A Method to Analyze the Structure of the Consumer Research Discipline
Phillip Emerson, University of Technology, Sydney
Ken Miller, University of Technology, Sydney

6.7 ACR Program Committee 1992

Leigh McAlister
Michael Rothschild

SATURDAY, OCTOBER 19

Lunch
12:00 pm - 2:00 pm

JCR Award. Presented by: Kent Monroe, University of Illinois

ACR Fellow Award. Presented by: Jerome Kernan, George Mason University, to:
Joseph Newman, University of Arizona
Paul Green, University of Pennsylvania

SATURDAY, OCTOBER 19

SESSION 7
2:00 pm - 3:30 pm

7.1 Special Session: More Tales from the 'Dark Side': Expanding the Study of Negativity in Gift Exchange

Chair

Cele Otnes, University of Illinois

Discussant

David Glen Mick, The University of Florida

Ho, Ho, Woe: Christmas Shopping For Difficult People

Cele Otnes, University of Illinois
Young Chan Kim, University of Illinois
Tina M. Lowrey, University of Illinois

'Many Unhappy Returns:' Disposition of the Gift

Mary Ann McGrath, Loyola University
John F. Sherry, Jr., Northwestern University
Sidney J. Levy, Northwestern University

Thanks But No Thanks: Rejection, Possession and Disposition of the Failed Gift

Margaret Rucker, The University of California - Davis
Tamara Balch, The University of California - Davis
Fiona Higham, The University of California - Davis
Kimberly Schenter, The University of California - Davis

7.2 Special Session: Consumer Behavior Research and Its Implication for Product/Nutritional Information Programs

Co-Chairs & Discussants

Catherine A. Cole, University of Iowa
Siva K. Balasubramanian, University of Iowa

Characteristics of Successful Product Information Programs

Jay Russo, Cornell University
France Leclerc, Massachusetts Institute of Technology

Individual Differences in Consumers' Willingness To Use Nutritional Information

Catherine A. Cole, University of Iowa
Siva K. Balasubramanian, University of Iowa

The Effects of a Public Nutrition Information Program on Consumer Behavior: The Case Informing the Public About the Risks of Dietary Fat

Daniel S. Putler, Purdue University
Elizabeth Frazao, Economic Research Service, USDA, Washington D.C.

Nutrition Knowledge Levels About Dietary Fats and Cholesterol: 1983-88
Alan S. Levy, Food & Drugs Administration, Washington D.C.
Marilyn Stephenson, Food & Drugs Administration, Washington D.C.

Insights from Multiple Methods Regarding Food Consumption
Melanie Wallendorf, University of Arizona

7.3 Competitive Papers: Information Processing

Chair
Terry Shimp, University of South Carolina

Discussant
Dipanker Chakravarti, University of Arizona

Influence of Problem Recognition on Search and Other Decision Process Variables: A Framework for Analysis
Girish Punj, University of Connecticut
Narasimhan Srinivasan, University of Connecticut

Effect of Locus of Control on Information Search Behavior
Narasimhan Srinivasan, University of Connecticut
Surinder Tikoo, University of Connecticut

Mapping the Relationship Between Preattentive Processing and Attitudes
Stewart Shapiro, University of Arizona
Deborah J. MacInnis, University of Arizona

7.4 Competitive Papers: Family and Household Dynamics

Chair
Susan Spiggle, University of Connecticut

Discussant
Janeen Arnold Costa, University of Utah

Till Death Do We Part: Family Dissolution, Transition, and Consumer Behavior
Ritha Fellerman, University of Massachusetts
Kathleen Debevec, University of Massachusetts

Measuring Conflict in Household Decision Behavior: Read My Lips and Read My Mind
William J. Qualls, Massachusetts Institute of Technology
Francoise Jaffe, University of Michigan

Consumer Socialization Associated with Relocation to a New Community: A Framework and Pilot Study
Cathy Goodwin, University of Manitoba
Murphy Sewall, University of Connecticut

7.5 Special Session: Applying Consumer Research to Social Issues

Chair & Discussant
Elizabeth Hirschman, Rutgers University
Ron P. Hill, Villanova University

Recovering From Drug Addiction: A Phenomenological Account
Elizabeth C. Hirschman, Rutgers University

Helping the Homeless: A Radical Consumer Behavior-Oriented Solution
Ronald Paul Hill, Villanova University

Compulsive Buying and the Mass Media: An Examination of Social Responsibility and Irresponsibility
Ronald J. Faber, University of Minnesota
Thomas C. O'Guinn, University of Illinois

Marketplace Estrangement and Consumer Theft

Anthony Cox, Indiana University

Dena Cox, Indiana University

PRESIDENTIAL ADDRESS
Constructing Consumer Behavior: A Grand Template
Sidney J. Levy, Northwestern University

This is one of the most exciting times in my life. Some of you may not have realized when I was elected that you were getting the oldest president ACR has ever had. After thirty years at Northwestern University, I have just become a professor emeritus. For younger presidents of ACR, election was a fine achievement along the way; for me, it is a kind of culmination or peak of a long career. I submitted my first professional article to the *Journal of Educational Psychology* in 1946; and I recently received an acceptance for the December 1991 issue of the *Journal of Consumer Research*.

It was hard to decide what to talk about today. The good thing was, I had two years to think about it since I was elected. The bad thing was, I had to think about it for two years. Being a thorough-going obsessive academic, I've had many a sleepless night ruminating about what to say. By now, I may actually have forgotten most of my best ideas.

Presidential talks have many possibilities. They are often concerned with urging us toward excellence or creativity. They recall our glorious history, and the giants on whose shoulders we stand. They appraise the state of the art, explaining how new methods and new subjects are changing our realms of inquiry. They may look to the future, telling where we are going or where we should be going; Morris Holbrook (1990) recently told us that we should be more lyrical and last year Elizabeth Hirschman (1991) asked that we be more concerned with contemporary problems such as crime, prostitution, and addiction. When I finally settled to it, I decided that when all was said and done, the only thing I could do was to be myself and to talk about my current preoccupations. What they amount to is a summary of how I think about the study of consumer behavior, in keeping with the integrative thrust in Erik Erikson's (1982) description of the elderly stage of life. I keep thinking about the multiple ways we have of explaining the Consumer Event.

When I started to study consumer behavior in 1948, I had certain main interests as a graduate student in an interdisciplinary program. My work for a degree with the Committee on Human Development at the University of Chicago, made possible by the G.I. Bill, stimulated an enduring concern with the stages of the life cycle. I was absorbed in personality study, especially as expressed in psychoanalytic theories, and as investigated through the use of projective techniques. I also was thoroughly indoctrinated in the importance of stratification as a fact of social life.

These topics intrigued me. I was a setup for the bold probing of depth psychology because I had always been a shy, introspective boy who read a lot, searching intently to learn about the mysteries of life, especially those related to sex and violence. At the time, I hardly even thought to expect explanations of these mysteries--it was enough to gain an increasingly vivid awareness of the enigmas of human history, the

amazing complications of life as conveyed in school, in books, on the radio, and especially in the movies. For a suppressed and repressed boy growing up in a proper household and working class neighborhood, the fear of violence could be mastered somewhat by vicarious experience. There was also the possibility that in these media I might run into some exciting information or depiction of sex, to find out what people really did in private--that is, of course, other people who were beyond the hairy-handed Pee-Wee Herman stage, who were more grown-up, more experienced, and more daring than I was. I remember being so irked and frustrated that the best parts of *The Decameron* of Boccaccio were in Latin. The newspapers recently reported a survey of the frequency with which men think about sex: an average of six times an hour. I'll probably use more times than my share during this talk, as I always remember the quotation in a study of sex, contraception, and family planning by Lee Rainwater, from a subject who said, "Before I was married I was scared of sex. I thought it was a crime to do something like that. [Afterwards], I found out that...let's put it this way, if God made anything better he kept it to himself." (1960, 97).

Depth psychology theories also please me because no matter how challenged or modified by their neo forms, they offer a sense of revelation, of taking us toward a layered understanding of the human psyche, with vigorous positions on what human nature is like, and how behavior arises from the ways our bodies and emerging personalities interact with our families and caretakers. Depth psychology recognizes issues that should be important in the study of consumer behavior: history, complexity, multi-causation, the symbolic and the evaluative character of experience. The role of motivation becomes salient; we are energetic, impulsive, surging creatures, so we cannot blame everything on external stimuli. And the power of perceived good and evil that we invest in all objects and actions plays its part. If we do not bring such richness to the study of consumer behavior, our constructs are simple, our variables are superficial, and results often just summarize observations or fit our intuition and mere common sense. Then we do not need much expertise. My colleague, Dipak Jain, tells me that in India dream interpreters say that happy dreams are bad omens and unhappy dreams are good portents. I realized that such contradictory complexity is wise and necessary; if only because were it not so, we would take the dreams at face value and would not then need the dream interpreters. In any event, we need subtlety because consumers commonly cannot adequately explain their own behavior, even if Scott Armstrong (1991) provides some evidence that they can predict it better than we can.

The study of social stratification is a way of becoming alert to the inevitability of hierarchy in human affairs. The uneven acquisition and distribution of resources, the different socio-economic levels in

society, make for outstanding variations in consumer behavior, pointing to the dynamic forces of aspiration and competition. As a Depression child, a poor boy in a family that was for a time on relief (as we called welfare then), I learned vividly the realities of some people having more and others having less. W. L. Lloyd Warner (1949) later taught me that every person occupies a social place that reflects how the community perceives the value of the individual's family status and participation. Circularly, that perception governs how much each of us gets in deference and money, and is also based on how that income is translated into symbols of status belonging and expression. A recent survey by NORC showed how the prestige of 740 occupations was ranked by a sample of adults: surgeons, astronauts, lawyers, and college professors were ranked highly, whereas panhandlers and fortune tellers were at the bottom. Such knowledge fed my striving to be socially mobile and to associate with professors--although I confess fortune tellers are still among my best friends, and someone wrote a letter to the editor pointing out that St. Francis of Assisi was a panhandler.

I am reminding us of these rudiments of psychology and sociology as a basis for my vision of our common enterprise in carrying out consumer research. I see us all working together in our various ways, seeking to construct and fill out a grand template of what consumer behavior is about. Following in the august steps of the Mendeléff periodic table that laid out a pattern of what was known and might be known of the world's chemical elements, of the various visualizations of the atom and the universe, and of the current efforts to map the human genome, I picture in my mind a large configuration that represents an ideal goal of the knowledge toward which we work. This configuration draws upon the many disciplines that contribute to the study of consumers, it respects the numerous methods that are used, and encourages the contention of concepts that compete to provide explanations. Thus, this grand consumer research template is integrative and dynamic, organized and full of life.

The grand template stretches over the whole society and its structure, and by extension to other societies, so that we study across cultures to discern their commonalities and differences. Examining consumers in the large social groups that are geographically and culturally dispersed around the world superimposes the template over the globe. It has to address consuming at the level of the great millions of people wishing to be fed, clothed, and housed in basic, ongoing ways. This realm of problems connects us to a commodities-oriented and economics-oriented world in which consumers are at the tender, and often not so tender, mercies of governments, non-profit organizations, and the multi-national corporations that provide or do not provide life's fundamentals of a viable housing stock, sustenance, and some fabric for dresses, shirts, and trousers, to say nothing of essential needs for health, education, and participation in the arts.

We may hope that some day those subsisting hungrily will be elevated to situations in which

models of consumer brand choice suited to a prosperous environment will become more relevant to them, also; although at even the most basic levels of consumption, one finds subtleties of preference and choice being exercised. The latitudes, longitudes, and isobars of international consumption bring forth issues of cultural diffusion, images of countries of origin, and how consumers will and will not retain their local identities in the face of globalization, the European Community, and the seductive and homogenizing effects of Coca-Cola, McDonalds, Levis, and Disney parks. There is the need to reconcile and make sense of the admixtures of the old and the new. I recall seeing a timeless looking woman trudging down the street in Bangkok, wearing a coolie hat and traditional shift, bearing on her shoulder a pole with two suspended baskets of fruit. And on her feet were Reebok running shoes.

Thus, considerations of social stratification move us up and down among countries and societies in a Maslovian manner. Maslow is the source of a famous template; I have noticed that his hierarchy of needs is highly favored by students as one of the great explanatory devices of modern social science, and I grew up on it, too. It points to the consumer's need for basic satisfactions of feeding, security, love, and other sorts of intangible, ethereal, and emotional fulfillments, as well.

In forming the Grand Template, ideas about social stratification interact with ideas about the stages of the life cycle. People are born to the socioeconomic status of their families, and they absorb (and react against) the outlook and values provided by that social and interpersonal environment. These basic relations are paradigmatic, dramatized in the various famous Complexes of Oedipus, Electra, Orestes, and Tom Sawyer. They act as a matrix and initial filter for all social relationships. As people mature in age, they may remain at the same social level or change their position through upward or downward mobility. These two important forms of hierarchy, social status and age, imply increasing superiority with greater levels. Centrally, this increasing superiority refers to having more power, economically and socially. This power is the ability to control and command more resources, ultimately to make more choices. Even if one remains at the same socioeconomic level, growing up leads to an increase in resources and power, through the increasing capacity to make choices. The nature of the choices--of how to live, what to buy, what to consume--is the outcome of the interaction of social status and age-grading with other main influences. Intertwining with social position and the life cycle are gender and sexuality, group memberships (race, peers, education, occupation, etc.), the nature and events of immediate situations, and the features of products. That is, the person--and as a person, a personality with developed perceptual and motivational propensities--arrives at the Consumer Event; whatever it is, more or less prepared to interpret it and to decide what to do about it.

The definition of the situation at each given moment in time and place is in various ways

demanding, permissive, and constraining. It says what one can do, may do, might do, should do, must do, cannot do, etc., and we work, perhaps even struggle, to analyze scientifically how the consumer's selection among these possibilities is determined by a confluence of circumstances that makes the consumer's performance a necessary outcome. If we knew J. Alfred Prufrock well enough, could we predict how he will wear his hair and roll his trousers, or if he would dare to eat a peach?

The choice (the apparent choice?) is the result of being that physical person of specific age, sex, social level, trained role, personality facets (self-concepts and attributions) in a mood that is under the influence of the weather, what was previously eaten, being delayed on the expressway, the imminence of a parental visit, the pressure of marketing promotions, and being confronted by products, people, services, and/or ideas of high, medium, or low involvement.

The grand template is a highly ramified nomological network, and everyone who conducts consumer research works at filling in aspects of it, providing content about elements of its structure, its processes, its methods of inquiry, and philosophies about its science and its values. Now, rather than leaving the thought as a blank truistic generalization, I'll indicate some of the content that interests me in the template, ideas about consumers based on my education and the kinds of research in which I have participated.

I see consumers as goal-oriented and seeking, living out their destinies--that is, lifetimes of consuming--that have the potential for infinite variety. I don't know more than anyone else whether it is all random, determined, or allows for free choice. Taken in the aggregate, it may be as stochastic as the dance of sub-atomic particles seems to be; but we also analyze the Consumer Event as the necessary outcome of its antecedents; and even so, grant each other the dignity of believing we are responsible for our will and decisions. Perhaps consumer behavior, similar to light's being both wave-like and discrete, is both caused and free. Out to consume, people show several principles at work.

A fundamental attribute is memory. Memory refers to our ability to bind time, to be self-conscious, to know ourselves and others over time. Without memory we lose our identity and live sadly only from moment to moment. We older folks joke about it with gallows humor to show that we retain self-awareness--or I would joke about it if I could recall what I just said. Human memory means accumulating and handling knowledge in various characteristic ways. That is why the study of information processing is so important to us. Our research template is possible because we can put our knowledge together in our journals, our classes, and at conferences like this one. Perhaps even more remarkable than memory is our ability to think about the future, to plan, to anticipate, and to imagine the unfolding of possibilities. Beyond memory is the use we make of it to dream about it, to re-construct the past, to fantasize about the future. Quite wondrous is our need to yield ourselves up to music, pictures, and word-play, to keep explaining

through history, drama, fiction, biography, songs, movies, opera (both grand and soap), and through consumer research, the stories of our lives.

Keeping us powerfully in flux is the fundamental quality of ambivalence. Consumers are ambivalent about the Consumer Event; they are often uncertain, making inferences that vie with each other, as they try to decide in essence who they are, and what their decision will signify as to who they are. They must select actions in the template of possible meanings that will assert their position at the intersections of several dimensions. They are quick and relatively thoughtless in their decisions when these positions are well-established. However, more generally, ambivalence leads to some volatility, pendulum swings in consumer attitudes, and movement up and down the template as motivational devotions wax and wane in response to external pressures and opportunities.

Among the forces at work is insatiability. There is an open-endedness to human desires that allows us to keep wanting, that encourages us to innovate and offer endless novelty with the assurance that there will always be those who want this. Thus, out of every node in the consumer template, there grows a proliferation of alternatives, sometimes contrasting dramatically, sometimes extending tiny and, to the jaundiced eye, trivial differences. Yet, we have the capacity to detect them, and to find them worthy of making distinctions and preferences. The force of insatiability produces perpetual striving and the extremes of selfishness, greed, and boredom; it maximizes and enlarges the assertion of the individual's power and material substance.

Opposing insatiability is socialization, the pressure upon us to be virtuous, to comply with propriety, to be self-denying and altruistic in the interests of sharing. The goal is to be a good person, giving, nurturant, caring for others, and conserving of resources on behalf of our posterity. Extreme socialization may become rigid obedience, exalting the group requirements and submitting to its norms, consuming according to the prescription of authority; it may become tyranny and pathological consuming. When people go to the extremes, they show how utterly vile human beings can be, capable of the most egocentric gratifications in consuming nations, peoples, and even persons--whether in a Hitler Holocaust, a Dahmer dinner, or seeking sexual service on a sleazy city street.

We are all subject to the contention between the issues of individualism and sociality, and move between how much we care for ourselves and for others. I spent a year studying in a college social studies course called Freedom and Control, and to this day I still fret about how to resolve for myself the endless dilemmas posed by the conflict between my great American wish to maximize personal freedom, to stubbornly think my deviant thoughts and go my way, and my benevolent desire to live in harmony with my family, friends, and neighbors. Too often I fear I am obedient and conforming, yielding to wear what is in, eating what I am told is good for me, wanting to read

the latest highly touted book, and studying how large groups in the public do the same.

I speculate about the sources of these Consumer Events, the ambivalent human nature that motors the template, that makes us think some things are good or bad, desirable or not. I know some of you are familiar with the small piece of the template that I have offered (Levy 1986) in trying to account for the choices people make among all the beverages available to them. One might suppose that plain milk and water would suffice for us all; and I think they could. But no, we must have them processed, flavored, colored, textured, packaged and priced, to allow us to indicate the character of our distinct and changing social positions, our gender, our stage in the life cycle, our personality strivings, and subtle variations in mood. It is then striking to observe that as people mature from drinking milk as infants and from the healthy soups and juices that good parents provide to loved children, they break free to soft drinks with their festive carbonation, and perhaps to coffee and tea with their bitterness and caffeine. The fullest testament to maturity and freedom to choose among beverages comes with the addition of alcohol. It seems a telling commentary that people apparently aspire to the freedom to drink things that are strong in their effects and usually taste terrible, at least until we force ourselves to get used to them. Beverages are just an example; there seems to be a correlation between being more mature, having higher social status, and doing more or less bad things, because those bad things represent adulthood, independence, the freedom to stimulate one's body and mind, and to abandon the innocence and blandness of merely sweet and healthy things and the constraints that hamper lower status people. These issues relate to the large central problem of good and evil in consumption, about which we are in constant contention, explicitly or implicitly, on a local scale in our small daily choices, and on a grand scale in just giving lip service or in really worrying about consuming the resources of Earth.

Aristotle told us that all things come to be by nature or by making, and our competing feelings about nature versus culture have always plagued us. The higher social status represented by beverages that seem hard to take and unnatural to drink remind that the motivation of people toward higher social status is to gain increasing appreciation of culture, and what it creates. That means behaving in unnatural ways by making and acquiring objects, by competing to show one has superior economic power to own and accumulate objects that are rare, individual, costly to make. Thus, as one moves up the template, life becomes more deliberate, the array of choices widens, there is an increasing cachet to being able to make subtle discriminations that are unavailable to lesser mortals.

As I wondered about these matters, I thought that there was also a simple relationship with gender, that being aggressively individualistic and evil was a masculine thing while being well-behaved and compliant was feminine; and I know that much conventional thinking would agree with me because

that is one way we have been socialized. Pursuing that line, I thought that the beverage template implied that we are born innocent and virtuous, weak and feminine, and that as we progressed to consume ever stronger liquids, we could eventually become a mature, manly, high class scotch or brandy drinker, at the pinnacle looking down along a longitude line of the consumption template, on all the lesser lower class, youthful, female weaklings with their watery beer and milky pink ladies.

However, as I sought to generalize these ideas, seeking consistency and parsimony, to fit them to other realms of the grand template, I ran into trouble. Going up the template may indeed provide more variety, and the objects available to higher status people are often costly and rare. Color shifts show also some generality; for example, with clothing as with beverages, immaturity is represented by pure, simple, light pastel colors, youth and young adults by brighter colors, and maturity by depth, richness, and darkness. However, how can we reconcile that with the connection to social status and gender? Traditionally, for instance, dark breads were peasant breads, close to the soil and lacking refinement, so that going up the scale meant gaining access to white bread. To complicate the matter, dark breads lately have become attractive to higher status people.

A similar confusion arises with respect to gender. If going up the template by means of being socialized to free individual choices, to arrive at the sophisticated, high status, socially powerful male, how can we account for the traditional role of women as socializing the family, seeing to the lifestyle and consumption patterns correct for the position of the family? And how take account of women in newly powerful, high status roles? My earlier understanding seemed too simple, too parsimonious, too dominated by traditional stereotypes, not fundamental enough in being able to accommodate more varieties of Consumer Events as they arise.

Then a light bulb went on over my head, another one of those illuminations to which I am prone, when something I already know comes flashing back as a fresh insight. I realized that the innocent baby implies the goodness of Rousseau's human beings, uncivilized but noble in a state of nature, being corrupted by the powerful male consumerism and materialism of society and the evil city; and that this was only one theory or philosophy, one thread in reality. Another theory maintains that we are born bad, lustful, gross, egocentric, enslaved by the pleasure principle, and that the process of socialization is a benign one in which mothers domesticate and tame the brute, animalistic forces that drive us. Thus, women complicate and modify the beverage template with ideas of refinement, fine glassware, social events, and the notion of becoming more discriminating. They introduce a sense of aesthetics and manners, furnishing the home, the idea of caring for the young and sharing in the community. They foster temperance, compromise, and restraint, and encourage us to obey the social and medically authoritative pressures that tell us to cut out or cut

down on sugar, salt, caffeine, alcohol, fat, cholesterol, and nicotine.

I had arrived at a point in this intellectual journey where combining Rousseau and Freud in my fashion told me that men and women were equally important influences in affecting consumers to strive for cultured behavior, with the male principle being bad and the female good. The enjoyment I found in this thought seemed to demonstrate that it must be correct. But I could not stop there. I am an ardent feminist. My mother worked outside the home most of her life; my wife is a wonderfully capable professional woman; and my lawyer daughter has a sharp and realistic legal mind. My women colleagues and students show me their strong intellectual and managerial capacities. I am also realistic about all these women and do not merely romanticize them and their assets. I believe they will be free to be as good and as bad as males. But I don't think being feminist means ignoring gender, sex, and sexuality in their myriad of expressions and effects on consumer behavior, as we cope with working women, dual careers, expensive toys for children of guilty parents, and convenience foods when working becomes more important than eating.

So, pushing on, I was motivated to read and think more about these basic gender roots and roles in my template. I was reminded of the role of great heroes, good loving men, benevolent fathers, of Apollo, symbol of the Sun and the benign, curative traits in men. Conversely, there is the role of Eve as temptress, and Lilith, in some stories said to be Adam's first wife and symbolic of the Terrible Mother; and the many goddesses and witches with great and awful power. One can only conclude that there is ample evidence for the influence of the good father and the bad father, the good mother and the bad mother, and their respective roles in affecting what we find good and bad in our consuming. Marija Gimbutas on *The Language of the Goddess* (1989), Hans Peter Duerr on *Dreamtime* (1985), concerning the boundary between wilderness and civilization, where he explains the meaning of witches, and David Parkin's collection on *The Anthropology of Evil* (1985), help to illuminate for me some of these profound forces. Camille Paglia, in her book, *Sexual Personae: Art and Decadence from Nefertiti to Emily Dickinson* (1991), says men are responsible for that glorious erection called civilization, but in building their towers of transcendence they can never escape the primal pull of the earth mother. That sounds like an anxious situation for men, and they seek security. Paglia's thought brought to mind a little four year old boy I saw on a sunny day playing naked in the back yard. As he ran about, he clung to his penis. When someone asked him why he did that, he answered, "That's so I won't fall down."

The male and female principles take their different forms, both being inevitably bound together in our resultant mundane consumer actions. Each consumer has an idiosyncratic mix of experiences, prenatally, and from launching at birth, and pursues self-consciousness and identity, carrying these ultimate bi-sexualities and their mixtures of good and

bad, not as a simple ambivalence, but as a fourfold helix. Up the template they intertwine, determining who we are and what we do at moments of decision and consumer action. Each Consumer Event in the template is a summary at a point in time of the particular blend of gender forces, located in a particular cultural setting, expressing our motivations and perceptions directed toward some degrees of individuality and conformity.

The challenge we share is to contribute to the delineation of what I have presumptuously called the grand template in all its breadth and detail, with all our methods, intellectual power, and sympathy. I call it a *template* because that word packs into it so many of the thoughts I have tried to convey here to substantiate the seriousness and profundity of our subject matter. It refers to a *temple*, a sacred place that symbolizes the cosmos and its divisions, to the spiritual and virtuous elements of our aspirations and goals of our consumption of ideas, art, religion. It refers to *temptation*, the need to satisfy our animal selves and uncontrolled impulses. And it means that consumption is *temporary* and needs replenishment. The *plate* tells of our destiny as consumers, what is on our plate as workers in general, and as eaters in particular. The element *late* reminds us of the life cycle, that consuming is finite, that we can consume only so much before we too will be consumed. The *a*, *t*, and *e* form the word *Ate*, the name of a Greek goddess personifying foolhardy and ruinous impulse, telling us to be self-critical and to moderate our consumption. These letters also spell *ate*, reminding us that we indeed have eaten, and that this luncheon is now finished. I thank you for your kind attention.

**On Debts Due:
Presentation of ACR Fellow-In-Consumer-Behavior Awards
Jerome B. Kernan, George Mason University**

It is my great pleasure to introduce this year's FELLOWS IN CONSUMER BEHAVIOR -- Paul E. Green and Joseph W. Newman. Each of them has contributed significantly and over a number of years to our discipline and to our organization. We are proud to add their names to the pantheon of ACR Fellows.

PAUL E. GREEN

Paul Green is the S.S. Kresge Professor of Marketing at the University of Pennsylvania's Wharton School, where he has been since 1962, and from which he received his A.B., A.M., and Ph.D. degrees. Previously, he worked for Sun Oil, Lukens Steel, and duPont.

To say that Paul is a researcher is to allow that Nolan Ryan can throw a baseball. For more than 30 years, we have witnessed a prodigious stream of his books, monographs, chapters, articles, technical reports, and conference papers. He produces ideas quicker than most of us can digest them and it's no surprise that he's at the top of everyone's most-cited list. All consumer researchers have learned from him; indeed, if you've ever struggled with perceptions, preferences, measurement techniques, or quantitative analysis, it's likely that you've consulted Paul Green's work. Or you're from another planet.

But Paul is far more than his bibliography, overwhelming as that is. His direct imprint is on a galaxy of Wharton Ph.D.s and he has guided any number of other budding researchers as a fixture at the annual AMA doctoral consortium. He sits on more editorial boards than most of us can contemplate, yet his reviews read like tutorials. Add guest lecturing and consulting requests to everything else and we see one very busy person. Yet he *always* has time for even the least-connected among us and he *invariably* gives us words of encouragement. Indeed, if you're ever tempted to feel arrogant, just hang around Paul for a while; he'll show you what sincerity and humility are all about. And such a sense of humor!

Little wonder that Paul has received virtually every accolade on the horizon -- the Alpha Kappa Psi award, the Converse, Parlin, and O'Dell prizes and, earlier this year, the AMA/Irwin Distinguished Educator award. He's been elected to the Attitude Research Hall of Fame and he is a Fellow of the American Institute of Decision Sciences, the American Statistical Association, and now, I'm happy to proclaim, the Association for Consumer Research.

Paul's plaque names him an ACR Fellow "... for his legacy of contributions in consumer perceptions and preferences--as researcher, teacher, and mentor." I'm honored to present this award to a giant among us, who happens to be a wonderful person as well. And a dear friend.

JOSEPH W. NEWMAN

JOE NEWMAN is Professor of Marketing Emeritus at the University of Arizona's Eller School of

Management. He received his B.S. and M.S. from Kansas State and, after WWII service in the Navy, his MBA and D.C.S. from Harvard. Prior to his appointment as department chair at Arizona, Joe served on the faculty at Michigan, Stanford, and Harvard. He also worked as a newspaper man, sports information director, and media analyst.

One of the responsibilities of the Fellows' Committee is to evaluate nominees' contributions *in perspective* and, in the case of Joe Newman, that is especially important. His resume contains all the expected achievements--a fist-full of books, a score of papers; editorial-board membership for the JOURNAL OF MARKETING, JMR, and JCR; a legacy of Ph.D. students; significant consultancies; and distinguished service to both ACR and AMA. But we need to peel back that veneer of line-items to understand why Joe Newman is being honored today.

Here is a man whose career has spanned four decades. That's significant because, when Joe began his consumer research, the discipline *didn't exist*. Many of you remember or have heard about the skepticism we faced during the late '60s regarding the academic integrity of consumer behavior--the frustration that led to the formation of ACR in 1969. Just imagine how much *worse* it was in the '50s! There was no ACR; no JCR; not even a JMR; nothing to legitimize what we believed to be reasonable scholarship. Hostility was everywhere; the best we could expect was to be patronized. But then, as in all happy stories, we were rescued. We found our deliverance in 525-page book published in 1957 by the Harvard Business School. MOTIVATION RESEARCH AND MARKETING MANAGEMENT, which was based on Joe's doctoral dissertation, gave us respectability. People you might recognize had been working in qualitative research--Steuart Britt, Sid Levy, Burleigh Gardner, Pierre Martineau, Ernest Dichter, Darrell Lucas, to name a few--*but all these people were associated with the advertising business; none of them was a university professor*. As a result, it was easy for those so inclined to dismiss these efforts as the legerdemain of HIDDEN PERSUADERS. The preface to Joe's book advised us "... to get better acquainted with the behavioral disciplines, which are devoted to ... what man is and how he lives." He then went on to illustrate not only why, but *how* qualitative research yielded deep understanding of consumer behavior. Well, that was all we needed-- here was an *academic scholar*, whose message had a Harvard Business School imprimatur. Even the most stubborn academic administrator couldn't resist that combination. Joe was our hero and we were on our way. Momentum has never subsided and the rest, as they say, is history.

Joe Newman is a quiet man, who works away from the limelight. But don't be misled by his self-effacing manner; in innumerable ways that few of us will ever know, he knocked down a lot of professional

8 / Presentation of ACR Fellow-In-Consumer Awards

obstacles and showed us the path, as the consumer-behavior discipline came into being. So the next time you're doing qualitative research, remember--Joe Newman paved the way. Or when you research consumer-decision processes, realize that Joe's pioneering work in that genre dates from the early '70s. We're here to recognize our intellectual and professional debts to a man who has such personal grace and integrity that he's embarrassed by all this.

This plaque acknowledges Joe's pioneering investigations of consumer motivation and decision making--as researcher, teacher, and mentor--but in a larger sense, it confirms our longstanding debt to a gentleman who's made our field a lot more exciting and humane. I present this to you, Joe, with our deep appreciation and affection.

FELLOW'S AWARD SPEECH
Musings on Method in Consumer Research
Paul E. Green, University of Pennsylvania

INTRODUCTION

I'm deeply grateful to have been elected a fellow of the ACR. As an unabashed and sometimes outspoken methodologist, I was rather surprised to see my name added to a distinguished list of bonafide consumer researchers. As a tottering sexagenarian, I was particularly happy to join the ranks while I could still climb the stairs to the podium.

Even in an age of naturalism and postmodernism (Lutz 1989), traditional methodology still holds a place in consumer research. Indeed, alongside the venerable ANOVA and ANCOVA models, we are becoming increasingly familiar with the path diagrams and related tools of covariance structure analysis.

One early thought that I had was to regale you with a long list of technical advances in methodology—a kind of showcase of what may be in store for the nineties. (A 30-minute cap on the length of the talk fortunately quashed that notion.)

So, quite the contrary, my topic is on the role of *simple* models in consumer research. Over the past several years, I've become impressed with how good simple, robust models of decision making can be. But before getting into that subject, let me digress a little and talk about robustness in other contexts.

ROBUST QUALITY DESIGN

Today's quality control engineers speak almost as one voice in extolling the virtues of robust quality design, particularly Taguchi methods (Dehnad 1989). Quality engineers call the uncontrollable variables that cause characteristics of a product to deviate from their target values *noise* factors. These factors consist of: (a) external variations in the product's operating environment (e.g., temperature, humidity, or vibrations); (b) variations in product parameters during manufacturing; and (c) product deterioration over time and use.

Robust design engineers seek to produce a product that is robust with respect to all three categories of noise. This idea is operationalized by setting up experiments where the problem is to find engineering designs that maximize the signal to noise ratio while still keeping the parameters' mean values on target.

Conjoint analysts will be happy to learn that Taguchi and his followers are avid users of orthogonal arrays when designing the necessary experiments for building in quality robustness.

ADAPTIVE PROCESS CONTROL

My second example is also from the production sector. Since the early fifties, process engineers have been interested in response surface methods for optimizing productivity. Simple mathematical models—typically generalized quadratic functions—are chosen to represent the effect of a key set of control

variables on the yield of some chemical or physical process.

Experiments are set up to find settings of the control variables that optimize process yield. However, that's only a start. Processes change over time and generate the need for continuous fine tuning. This is where the methodology of *EVolutionary Operation* (or EVOP, for short; Box and Draper 1969) comes in.

EVOP is a management tool in which continuous investigation and experimentation serve as the basic mode for running a production facility. In EVOP, a process should be operated in such a way as not only to produce saleable product but also to produce information on how to *improve* the product in the future.

EVOP does this by carefully conducting on-line experiments in which process control variables are systematically varied during actual production runs. But they're varied in such a way that usable product is still produced. As environmental variables change, the control variable settings adapt in a more or less continuous approach to optimal response seeking.

The model of an EVOP process is (generally) a simple statistical, low-order polynomial representation that may have little relationship to the underlying chemistry of the process. In the words of the psychologist, Paul Hoffman (1960), it is a *paramorphic* model of the process. And, it's not unlike our simplified models for representing human judgment and choice. Again, highly fractionated factorial designs are used in implementing the EVOP experiments.

STATISTICAL ESTIMATION

My third example is from the statistics literature. Today's statisticians are becoming increasingly interested in robust methods for computing measures of location and dispersion (Huber 1981), as well as fancier estimation procedures for such multivariate techniques as discriminant analysis, factor analysis, cluster analysis, and multidimensional scaling (Spence and Lewandowsky 1989; Heiser 1987; Gnanadesikan and Kettenring 1972).

In statistics, the robustness of a procedure is defined as the property that makes the technique's answers reasonably insensitive to the kinds of departures from ideal assumptions that often occur in practical situations. When statisticians work with models, they are usually less interested in whether the model is "true" and more interested in whether it is illuminating and useful under a variety of contingencies.

Much of this research has focused on the modification of least squares estimation so that outliers have less influence on final parameter estimates. Order statistics, such as the median or quantile, and various kinds of trimmed means are typically employed. Much of the work on robust

statistical methods has gone on, in parallel, with computer intensive methods like flexible regression (Cleveland 1979; Rust 1989) and the bootstrap resampling method.

In sum, the development and application of robust models and methods is an ongoing enterprise in a variety of disciplines.

MULTIATTRIBUTE MODELS OF JUDGMENT AND CHOICE

One thing in which virtually all consumer researchers have interest is multiattribute models for judgment and choice. Over the years, the contributions of Paul Hoffman and colleagues in policy capturing models, the social judgment models of Hammond, and Norman Anderson's functional measurement have served as important underpinnings in today's consumer research.

One stream of research that has emanated from this earlier work has resulted in the development of pragmatic tools, such as conjoint analysis. Another stream of research has focused on non-compensatory models, such as EBA, lexicographic, and conjunctive/disjunctive models. What does model robustness have to do with the topic of multiattribute decision making?

In 1974 a now-classic paper by Dawes and Corrigan appeared. Their topic was as central then as it is now—namely, what is the role of linear models in decision making? For example, the problem context could entail predicting a graduate student's first-year grade point average, given knowledge of her scores on various aptitude tests, undergraduate record exam scores, peer ratings, years of work experience, and so on.

Dawes and Corrigan reported that a large number of empirical studies showed that simple linear, additive models performed well, typically better than the decision maker herself. In general, Dawes and Corrigan found that linear models predicted well when:

1. Part-worths are conditionally monotonic with changes in each attribute's levels. Hence, once a suitable ordering of the attribute's levels is found, the ranking of part-worths with changes in the levels of the attribute does not depend upon the levels that other attributes assume.
2. Errors in the measurement of the attribute levels themselves tend to linearize functions that may be originally highly nonlinear.
3. Relative weights in the model are not affected by increases in the general error term (as is the case in multiple regression).

Later, a fourth condition was added—that the predictor variables are positively correlated, on average (Green and Devita 1975).

Many judgmental and preference tasks approximate at least the first three conditions. If so, Dawes and Corrigan found that the quality of prediction (as measured by a product moment correlation) was little affected by the precision with

which the attribute importance weights were measured. Even equal weights worked very well.

MORE RECENT RESEARCH

Much has happened in multiattribute decision making since Dawes and Corrigan's 1974 paper. For example, the part-worth, ANOVA-type model has become popular in conjoint analysis. Even here, however, the main-effects, additive version often cross-validates as well as configural models that contain interaction terms.

Decision analysts have not given up, however, in seeking conditions that would topple the humble main effects, additive compensatory model. For example, in the context of multiattribute choice, as opposed to judgment prediction, the elimination of dominated options typically produces negatively correlated attributes. It is here where predictions would be expected to be more sensitive to the attribute weights.

Experimental evidence by several researchers (e.g., Levin *et al.* 1983; Green, Helsen, and Shandler 1988; Moore and Holbrook 1989; Elrod, Louviere, and Davey 1989) indicates that models calibrated in orthogonal environments *still* appear to predict well in more realistic validation settings where dominated options have been removed. The findings of Elrod, Louviere, and Davey are particularly compelling, since their validation sets employed maximally negatively correlated options.

Another facet of the model robustness problem involves the employment of non-compensatory models, such as the lexicographic, conjunctive, EBA, and phased models. These classes of models might be expected to pose a severe challenge to compensatory model approximations. Still, Johnson, Meyer, and Ghose (1989) found that compensatory models with selected interactions did fairly well in mimicking the results of non-compensatory processing, at least in the simulated environments of their experiments.

Overall, orthogonal designs and the relatively simple part-worth models of conjoint analysis appear to do a reasonably good job of preference modeling—at least in the practical world of commerce, where time pressures and less-than-docile respondents are the order of the day. In noisy and frenetic applications, the consumer researcher may simply not have the luxury of using more delicate models and more lengthy data collection techniques.

PLURALISTIC RESEARCH

What is the moral of this little stroll down robust modeling lane? For what they may be worth, here are a few observations:

1. Statisticians are now supplying us with an increasing array of tools for battling noisy data and for isolating outlier culprits. It behooves us to learn some of these methods and apply them to our own research.
2. From the quality control engineers and the process optimization chemists, we should appreciate the value of simple (but robust) models of complex processes. Orthogonal

- arrays play a major role in both of these experimental design strategies.
3. Closer to home, paramorphic models, like the linear models of Dawes and Corrigan or the part-worth models of the conjoint analyst, appear to provide robust ways for coping with the exigencies of applied consumer judgment and choice problems.
 4. But to be able to predict reasonably well is not necessarily to understand the phenomena being predicted. There's plenty of room in consumer research for seeking a deeper comprehension of the phenomena of interest to us.

So, what does this excursion into robust models mean for consumer research generally? It seems to me that consumer researchers will have to get used to both the esoteric and pragmatic side of our natures. There are constituencies out there who want robust models that can make reasonably good predictions. And, there is also a need for more delicate and sensitive models that can explain some of the nuances of decision making and other phenomena of interest to us. Like Rich Lutz earlier stated in his ACR presidential address, let me say that I'm all for research pluralism, too. But, then again, what red-blooded consumer researcher wouldn't be?

Sometimes these two motivations—the theoretical and the pragmatic—will merge and lead to a high-impact result; that is, an idea that is *both* intellectually exciting *and* appealing to the practitioner. More often than not, proponents of each approach will go their separate ways with (let us hope) mutual respect, if not endearment.

And what about the methodologist—that back room mole who always seems to be a step or two removed from the action? Not to worry. We'll continue to ply our trade as long as there's another variance to compute, another path diagram to draw, another hypothesis to test.

Some Observations of a Developing Field

Joseph W. Newman, University of Arizona

Being named a Fellow of the Association for Consumer Research is indeed a high honor. Receiving it is a moving and humbling experience. I feel very humble as I remember the contributions of the earlier Fellows - and those of Paul Green with whom I have the privilege of sharing the platform today.

In my career, I have had the opportunity to do many things and I have learned much from many people - students, colleagues, business executives and professional researchers. I am indebted to them. I shall be able to name a few of these people in the course of my remarks which will give special attention to the provocative behavioral scientists who ventured into marketing research some 40 years ago.

At this point, though, I would like to insert a personal note by acknowledging the all-important support of my family - my wife, Susan, and my daughters, Amy and Jane. Needless to say, they, too, provided me with a learning experience - a very rewarding one.

My academic career has been in marketing in schools of management. As you know, their faculties are expected to teach and do research which will help organizations function and, as a result, benefit the publics the organizations serve. Marketing is particularly concerned with how well products and services and the activities associated with their distribution satisfy the wants of consumers. It was in this context that I became interested in something called "motivation research" which was attracting a great deal of attention in the mid-fifties.

At that time, thinking in marketing was heavily influenced by economics. It emphasized the objective features of products and services. Marketers were aware that emotional aspects were important but had no systematic way of determining their presence in a given situation. So while consumer wants were seen as basic to planning, knowledge of buying motives was very limited. Marketing research produced many facts which showed what had happened but typically not why.

Also at that time, developments in the behavioral sciences prompted some behavioral scientists to see promising applications of their concepts and methods to problems of buying and consumption. They promised answers to the "why" question. That intrigued me, so I proposed finding out more about what was going on. The Harvard Business School, with Ford Foundation help, supported me in what turned out to be a two-year project. It resulted in the book, *Motivation Research and Marketing Management*, published in 1957.

When I began my field study, only a few organizations were engaged in what then was referred to as "motivation research." Their orientations differed somewhat, but typically they were exploring consumer motivations by the use of relatively nonstructured, in-depth interviews, projective techniques and, in some cases, measures of personality.

The prominent pioneer research firms were Social Research, Inc., of Chicago, and the Institute for Motivational Research of Croton-on-Hudson, New York. Social Research was headed by Burleigh Gardner, an anthropologist. Its interdisciplinary staff included Sid Levy who is well known to you.

The Institute for Motivational Research was headed by Ernest Dichter, a psychologist.

There were pioneers in several advertising agencies, too. In New York, Herta Herzog, a psychologist, had become Director of Creative Research at McCann-Erickson. Peter Langhoff had an interdisciplinary group in his research department at Young & Rubicam. Benton and Bowles was receiving behavioral input from Bill Wells who then was on the Psychology Faculty at Rutgers University.

In Chicago, Stuart Henderson Britt, a psychologist, guided research at Needham, Louis, Brorby. Also in Chicago was an influential promoter of "motivation research." He was Pierre Martineau of the *Chicago Tribune* which supported several landmark motivational studies by Social Research. One reason the introduction of behavioral research into marketing was possible was the backing of certain research directors and business executives like Martineau who were willing to try something new.

Also at this time, research of interest to marketing was going on at the Bureau of Applied Social Research at Columbia University and the Survey Research Center at the University of Michigan. The Survey Research Center was conducting surveys of consumer finances and other studies which provided data important to George Katona's development of the field of psychological economics.

For more insight on "motivation research," I refer you to Sid Levy's excellent President's Column in the March, 1991, *ACR Newsletter*.

By the early 1960s, other research organizations had moved in a behavioral direction and a few universities had begun to add behaviorally trained people to their marketing faculties.

The new research significantly broadened thinking in marketing. There were efforts to gain insight into the roles and meanings of products and services in the lives of people. The concepts of culture, social class, basic needs, life style, attitudes, self-image, brand image and others entered the scene. Psychological and social factors supplemented demographics. The concepts of less-than-conscious motivation, projection and free association impacted research methodology. More research was being undertaken to get ideas as well as to test them. So there was excitement and promise for the future.

By the mid-sixties, it seemed appropriate to take stock of just how much had come from the new research. A variety of approaches had been tried which drew on both the behavioral and quantitative sciences. Most of the research was private so findings typically were not published. And the researchers had been working independently. Stanford University, with the

financial assistance of Metromedia, made it possible to bring together researchers I mentioned earlier plus other leaders in the field. They met for a three-day symposium on the Stanford campus in October, 1964. The proceedings gave rise to the book, *On Knowing the Consumer*, published in 1966.

Before coming to the symposium, the participants were asked to review their work of the past decade or so to identify what could be offered as supportable knowledge of consumer behavior. At the symposium, they examined the nature of buying decisions, influences on consumer choice, market segmentation and consumer-brand relationships. They discussed the advantages of various behavioral concepts and mathematical models.

They did not claim many supportable general propositions about consumer behavior. However, there were a number of interesting findings. And there was agreement on an essential notion: that to understand consumer behavior, we have to understand human beings in toto and call on resources of all related disciplines to do the job.

Gary Steiner of the University of Chicago summarized the discussions. I can not go into detail here on his insightful commentary. But I will tell you that he concluded by giving three propositions he was sure all would agree were true in consumer behavior. Here they are:

1. "Some do, some don't"
2. "The differences are not very large"
3. "It is not as simple as that"

Those propositions, of course, still hold today. As Steiner pointed out, they also still hold for the older behavioral sciences.

While I was examining the behavioral research, I also was studying problems of relating research and management decision making. So I spent time not only with researchers but also with some of their clients.

My interest in consumer information search came in the late 1960s at the University of Michigan in response to encouragement by George Katona. Studies were undertaken with his valuable counsel and the partnership of Rick Staelin. They were supported by the Educational Foundation of the American Association of Advertising Agencies. That work led into research on consumer satisfaction with Bob Westbrook who went on to contribute much more in that area.

In 1973, I accepted the opportunity to lead development of the marketing faculty at the University of Arizona. We have enjoyed exciting years of growth. It has been very satisfying to have had a hand in attracting to the faculty an exceptional group of bright, well trained people and to see them contribute through their own research. My successor as department head, Dipankar Chakravarti, deserves special mention. He is an amazing individual who can manage a department, teach and provide research counsel to colleagues while concurrently maintaining his own high level of scholarship. Looking at consumer research today, one can not help but be

impressed by the tremendous growth. It came slowly at first, then accelerated. My earlier remarks focused on work in the 1950s which had begun even earlier. Interest in the academic community followed. The first Engle, Kollat, Blackwell consumer behavior text and the early theory books by Nicosia and by Howard and Sheth appeared in the late 1960s. The early 1970s brought the first ACR conference and the *Journal of Consumer Research*. Since then, there have been major advances in the quantity, quality and scope of research in the field.

A look back over the years prompts several observations.

First, an additional word about "motivation research." For some, the term has meant simply the use of certain techniques. While techniques are important, I view the early activity more broadly as the start of a development - that of interdisciplinary research coming into marketing in a major way. The real contribution has been that of furthering conceptual development. Progress in a discipline consists of evolving conceptual schemes - something Jerry Zaltman so ably emphasized in his presidential address a few years ago. We now have richer ways of thinking about consumers, products, brands, prices and communications.

Behavioral research was introduced into marketing by persons working in the business community. Their research addressed questions of concern to managements. Managers benefitted but so did the researchers. They found that working in applied contexts and seeing findings translated into action enriched their own thinking. Interdisciplinary efforts are important but they often are difficult to implement. People of different backgrounds do not automatically mesh well. In fact, they often clash. Significant findings are more likely to result when researchers become more interested in the issues being addressed than in their own disciplinary identities and bags of tools. It often takes a problem focus to encourage new ideas and willingness to go wherever the problem seems to lead.

We have learned that benefitting from other disciplines is not simply a matter of transplanting concepts and techniques, but of creatively adapting them in ways appropriate to the behavior under study.

Fortunately, the earlier thinking in terms of a dichotomy of behavioral vs. quantitative has largely disappeared with recognition that both are needed, often in combination. The training requirements for significant research have multiplied as scholarship in our field has evolved. Doctoral programs of today bear only faint resemblance to those of not very many years ago.

New thinking is not popular. It will be resisted because it typically threatens vested interests - either intellectual or financial or both. The early "motivation researchers" faced intense hostility, especially from survey firms whose clients had begun buying motivational studies. Hostility may be too strong a word for the receptions given the first behaviorists to join marketing faculties but it is safe to say that some of the newcomers were kept at a safe distance by their established colleagues. Fortunately,

times have changed. One of the more important contributions of the "motivation researchers" was their demonstration of the value of exploratory research. I refer to research which, at the outset, does not pretend to know what questions are worth asking - or, at least, not all of them. Instead, qualitative interviews can allow consumers to identify what is important to them and say how they feel about it. Such exploration can be valuable prior to drafting a questionnaire or deciding on research design, although it is too often omitted.

My last observation is the most important. It is that research efforts have not always been well directed. My biggest complaint over many years of reviewing manuscripts has been that many of them left me wondering why the research was undertaken in the first place. I am well aware of the strong, if not unreasonable, pressure for publication. Unfortunately, it often has promoted the expedient rather than efforts to make a difference. But I do not think it need do so.

You have heard pleas for greater relevance before. Yet I am adding another. Research on issues that really matter can result from different starting points. One is to identify an ongoing stream of inquiry which needs more work. Implications of future findings may not be clear but there must be some reason to believe that they will emerge and be important to someone.

Relevant research also can result from addressing issues of concern to managements of organizations. I refer to basic research which, in turn, will lead to better management and public policy decisions and, as a consequence, improve consumer welfare. For guidance to important streams of research, I cite two excellent references: the Quadrennial Review of Consumer Psychology by Joel Cohen and Dipankar Chakravarti published in 1990 and the 1991 *Handbook of Consumer Behavior*, edited by Tom Robertson and Hal Kassirjian. It is apparent from the coverage and depth of thought of these works that many scholars devoted much time to them and they deserve our thanks.

Another important source of guidance is the Marketing Science Institute's periodic listing of *Research Priorities*. MSI has contributed much to our field by stimulating and supporting research that advances basic knowledge needed for developing important practical applications.

The field of consumer behavior still is young and growing. It has produced many findings that we may tentatively accept as "knowledge." In addition, it has kept many faculty members employed. Hopefully, the results also are making life a little better for people in their role as consumers.

I have enjoyed being a small part of the consumer behavior scene. I thank you for the high recognition you have given me today.

Consumer Processing of Social Ideas Advertising: A Conceptual Model

Lalita A. Manrai, University of Delaware

Meryl P. Gardner, University of Delaware

ABSTRACT

A process-oriented approach is used to understand consumer reactions to social ideas advertising. Differences between social ideas and conventional products are discussed from a consumer's perspective. A model is developed to understand how these differences affect consumers' attention, cognition and affect upon exposure to social ideas advertising. Marketing implications and directions for further research are presented.

INTRODUCTION

Weibe (1952) asked: Why can't you sell brotherhood like soap? In this paper, we address this question by developing a conceptual model of consumer processing of social ideas advertising based on differences between social ideas and conventional products. Social marketing is defined as the "design, implementation, and control of programs seeking to increase the acceptability of a social idea in a target group" (Kotler and Armstrong 1989). The field of social marketing is thus a type of non-profit marketing that includes public health campaigns (e.g., those to reduce smoking, alcoholism, drug abuse, overeating); environmental campaigns (e.g., wilderness protection, recycling) and other campaigns (e.g., human rights, social equality) - (Kotler and Zaltman, 1971). Despite the phenomenal growth in social ideas advertising, very little is known about how consumers process these advertisements in comparison to the advertisements for conventional products.

This research takes a process-oriented approach to understanding consumer reactions to social ideas advertising. First, social ideas are compared to conventional products to understand how they differ from a consumer's perspective and what challenges are involved for marketers. Then, a model is developed to understand how these differences affect consumers' attention, cognition and affect upon exposure to social issues advertising. Implications of these relationships for marketing social ideas are discussed, and directions for future research are identified.

SOCIAL IDEAS VERSUS CONVENTIONAL PRODUCTS: A CONSUMER'S PERSPECTIVE

The term "social ideas" refers to social issues and social causes. According to Fine (1981):

"... issues are controversial; causes are generally not. One takes a position on an issue, but simply adopts a cause, such as joining a movement. Abortion and gun control are issues; the prevention of child abuse and forest fires are causes."

A list of social ideas as developed by Fine (1981) is given in Table-1. In some cases, organizations are listed rather than the associated causes, (e.g., United Way rather than volunteerism or nongovernment social service,) to maintain consistency with common usage. Social ideas are similar to products in that both involve consumption and need satisfaction. For social ideas, consumption involves taking a position on a social issue or adoption of a social cause and need fulfillment involves resolution of a social problem. As suggested by these similarities, product marketing and social idea marketing share a common underlying philosophy. Differences between social ideas and conventional products, however, necessitate adjustments in marketing actions. For example, although motivation to process advertising messages affects attention to both conventional product and social idea advertising, sources of motivation may differ in the two cases. An understanding of these and other differences could help marketers design more effective communications for social ideas.

There exists some -- although limited -- research investigating the differences between social ideas marketing and conventional products marketing. Brady (1984) points out that in the nonprofit sector (including social idea marketing) product offerings are vaguely defined and lack competition. Hupfer and Gardner (1971) investigated individuals' involvement with tangibles and issues. Their findings indicate that involvement with issues was higher than involvement with tangible products.

Rothschild (1979), however, suggests that involvement with social ideas follows a bi-modal distribution across ideas, with some having low involvement (e.g., the introduction of a \$2 bill) and others high involvement (e.g., drunk driving). In contrast, involvement with conventional products may be distributed over the middle of the continuum. In addition, involvement with social ideas may be bi-modally distributed across individuals - i.e., some people may have low involvement with almost all social ideas while others have high involvement. Fine (1981) compared the characteristics of individuals involved with social products (referred as "idealists") with those of individuals involved with ordinary goods (referred as "materialists"). His findings indicate that idealists tend to be older, married, females and members of racial minorities. Idealists were also less likely to own rather than rent their homes and spent less time watching television and on their jobs. No significant differences were found between the two groups on socioeconomic factors such as income and education.

TABLE-1
Some Current Ideas and Social Issues

55-mph speed limit	Foster parenthood	Pollution control
200-mile fishing limits	Franchising Fraternal Org.	Population control
911 emergency number	Free enterprise	Prayer in schools
Abortion rights	Freedom of the press	Prison reform
Affirmative Action	Fund raising	Product safety
Alcoholism control	Gay rights	Productivity in industry
Banking innovation	Gun control	Recycling wastes
Birth defects	Handicapped, employ the	Redlining
Blood donation	HMO	Reforestation
Blue laws	Health, value of	Religion
Buy American goods	Legalized gambling	Safety
Cancer research	Literacy	Save Chrysler
Care packages	Litter prevention	Save the Whales
Consumer cooperatives	Mainstreaming	Scouting
Car pooling	Manpower programs	Seat belt use
Child abuse	March of Dimes	Shoplifting control
Child adoption	Marriage	Smokending
Capital punishment	Mass transportation	Social security
Crime prevention	Mental health	Social welfare
Credit purchasing	Metric system	Solar energy
Divorce	Military recruiting	Space program
Draft registration	Minimum wage	Subsidies, government
Drilling, offshore	Motorcycle helmet	Suicide hot line
Drinking age	Museums	Tax reform
Drug abuse control	Nature conservation	Tax shelters
Drunk driving	Nuclear energy	Tourism
Education, continuing	Nudism	Two-dollar bill
Energy conservation	Nutrition	UNICEF
Equal Rights Amendment	Obesity prevention	Union label, buy
Euthanasia	One dollar coin	United Way
Exporting	Outdoor living	Urban planning
Fair housing	Peace	VD hot line
Family planning	Peace Corps	Vegetarianism
Fashion trend	Pet care	Veterans' rights
Fire prevention	Physical fitness	Vivisection
Fluoridation	Police, support of	Voter registration
Foreign aid	Politics	Wife abuse prevention
Forest fire prevention	Poetry	Women's rights

DIFFERENCES BETWEEN SOCIAL IDEAS AND CONVENTIONAL PRODUCTS: MARKETING IMPLICATIONS

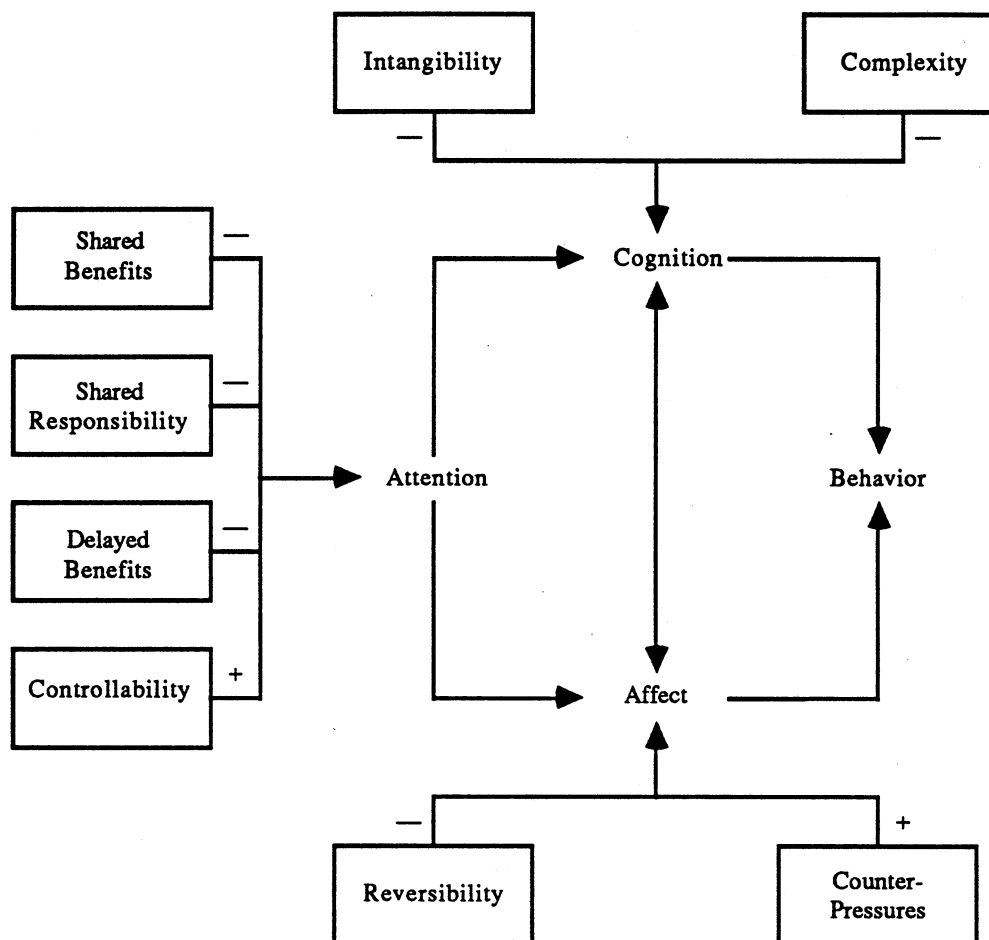

Based on the research discussed above and a general analysis of the nature of social ideas, we developed the model depicted in Figure-1. First we will discuss eight dimensions on which social ideas can be distinguished from conventional products.

Then the implications of these differences for attention, cognition and affect will be summarized.

1. Shared Benefits:

Benefits resulting from consumption of an idea typically accrue to society rather than to individuals per se (The term "individual" is used here to include such units as households and organizations.) (Fine, 1981, p. 148). These benefits are thus "Shared Benefits." Some health-oriented social action campaigns like "Quit Smoking" may benefit targeted

FIGURE-1
A Conceptual Model of Consumer Processing of Social Ideas Advertising

individuals more than other people and thus social ideas may vary in their relative emphasis on personal versus social benefits. However, any social campaign always has the basic objective of benefiting society and thus involves shared benefits.

Compared to this, consumption of most conventional products primarily benefits individual consumers. We thus propose:

Proposition 1: Consumers' perceptions of personal (in comparison to social) benefits would be lower for social ideas than for conventional products.

2. Shared Responsibilities:

Similarly, consumers view social causes and issues as concerns to be jointly shared by the entire society. In comparison, decisions concerning consumption of traditional products are viewed as personal responsibilities. There are instances of joint decision making, e.g., house buying, automobile purchase, etc. where multiple members of a household

may be involved but the personal element of responsibility is dominant in conventional products. Thus:

Proposition 2: Consumers' perceptions of personal (in comparison to social) responsibility would be lower for social ideas than for conventional products.

3. Delayed Benefits:

The adoption of a social idea may offer immediate intrinsic satisfaction to the adopter in terms of belonging to a cause to affect a societal or environmental change. But, the impact of such actions on society or the environment often cannot be seen immediately (Fine, 1981, p. 148). For example, the results of a campaign to preserve a rare species cannot be known for years to come. In contrast, most conventional products offer relatively immediate gratification.

Proposition 3: Consumers' perceptions of the time within which benefits of consumption will be realized would be longer for social ideas than for conventional products.

4. Controllability:

Consumers have more control over the consequences of their product purchases than the consequences of espousing a social idea or taking a social action (Fine, 1981, p. 148). For product purchases, the decision making unit includes the purchaser and the user. For social ideas, these roles are undertaken by very distinct, often very different, individuals. For example, consumers who buy food are reasonably sure that the food will be eaten by themselves or their families. In contrast, those who donate organs have no control over who will use their organs and whether a life will be saved.

Proposition 4: Consumers' perceptions of their control over the usage and consequences of consumption would be lower for social ideas than for conventional products.

5. Intangibility:

Services are, in general, less tangible than physical products (Shostack, 1977). For-profit services often involve services linked to tangible objects - e.g., restaurants serve food, airlines fly airplanes. In contrast, not-for-profit services, including social ideas, are less frequently associated with tangible objects. Thus, within services, not-for-profit services can be construed as more intangible than services for profit. To quote Assael (1990) who compared for-profit and not-for-profit services: "The benefits of air travel, telecommunications or bank services, are easier to convey than the benefits of religion, culture or knowledge." Thus

Proposition 5: Consumers' perceptions of the tangibility of social ideas would be lower than that of conventional products.

6. Complexity:

Not only are social ideas more intangible than conventional products, they are more complex too (Fine, 1981, p. 149). The term complexity is used here to refer to the multiplicity of relevant dimensions. First, consumers' own involvement may be higher (Hupfer and Gardner 1971; Rothschild 1979). Second, reference group influence may be more important and complex than it is for conventional products. Third, because social ideas may lead to social change, they have consequences in many different arenas. All these forces make social ideas more complex to comprehend and adopt.

Proposition 6: Consumers' perceptions of message complexity would be

higher for social ideas than for conventional products.

7. Reversibility:

In adopting a social idea, the commitment one makes has more long term implications than that for a conventional product. If a consumer does not like the article of clothing he or she has bought, it can easily be returned at the store. The same may not be possible for a social idea (Fine, 1981, p. 149). One cannot undo the support one has already given; one cannot get back donation dollars.

Proposition 7: Consumers' perceptions of the reversibility of a consumption decision will be lower for social ideas than for conventional products.

8. Counter-Pressures:

Consumers considering social ideas, especially social issues, are often faced with opposite pressures from different reference groups (Fine, 1981, p. 149). For example, a campaign on Drug Abuse Control points to the negative consequences of drug usage while peer pressure suggests that drug usage will provide wonderful experiences. This kind of counter-pressure will be far more dominant for controversial social issues than for conventional products.

Proposition 8: Consumers will experience more intense counter-pressures (opposing viewpoints) in decisions about social idea than in decisions about conventional products.

CONSUMER RESPONSES TO SOCIAL IDEAS ADVERTISING:

Attention to Content of Social Ideas Advertising:

As indicated in the model, the first four differences, i.e., shared benefits, shared responsibilities, delayed benefits and controllability would affect consumer attention to the content of social ideas advertising such that attention would be:

- 9a) negatively related to consumers' perceptions of the extent of benefits sharing.
- 9b) negatively related to consumers' perceptions of the extent of responsibilities sharing.
- 9c) negatively related to consumers' perceptions of the extent of delay in realizing benefits.
- 9d) positively related to consumers' perceptions of the extent of controllability.

The rationale for and implications of these are discussed next.

The effect of benefits sharing are related to consumers' reaction of "Why do it?" or "What's in it for me?". To overcome this, social idea advertising has to convey that what is beneficial to society is eventually beneficial to the individual. To convey this, the society-individual link should be emphasized. One example is the campaign of the United States Space Foundation - "Space Benefits - Find Out What's In It For You." This series of public service advertisements uses spokespersons who are polar opposites in some way (e.g., personal or political viewpoints, dress/lifestyle). These spokespersons state that all of us can benefit from the spin-offs of space research. The ads illustrate how technological accomplishments directly benefit Americans.

The effects of responsibility sharing are related to the reaction "Somebody else will do it" or "If I do not participate, it won't matter." Precisely the opposite message must be conveyed to overcome these reactions; social idea advertising must say, "You can make the difference." Once again, the link between individuals and society should be emphasized. One campaign that fosters a sense of "You Can Make the Difference" is the campaign of the National Association of State Foresters and the Forest Service, U.S. Department of Agriculture - "Only You Can Prevent Forest Fires." It is estimated that over \$420 billion in natural resources was saved by this program since the launch of the campaign in 1942. (An additional reason for the success of this campaign could be the use of Smokey Bear, a communication symbol with a recognition rate of 99%.)

The delay in realizing the benefits of adopting social ideas introduces uncertainty and skepticism. It may also make individuals procrastinate on social action. To overcome this, social idea advertising should offer immediate rewards. A campaign that capitalizes on the fact that the target audiences are already aware of the problem (and therefore would see more imminent benefits and would be more receptive to the idea) is Internal Revenue Services Campaign "File Now. File Early." This campaign is directed at over 100 million taxpayers and has the triple objectives of motivating taxpayers to file early, increasing public awareness of assistance programs and recruiting volunteers to help needy individuals with tax preparation. Almost everybody can relate to the immediate benefits of this social idea.

The fourth factor affecting attention - e.g., controllability - taps into individuals' desires to see and control the outcomes of their decisions. Since the action being sought is at the societal level, this control gets lost. Social idea advertising needs to restore this control to the individual. An example of social idea advertising which assures individuals that they have control is the "Reach for the Power. Teach." campaign of Recruiting New Teachers, Inc. This campaign, showing a teacher interacting with students in a classroom situation, was highly successful. In its first year, more than 184,000 individuals from 50

states responded, thus providing a large pool of potential teachers.

Cognitive Processing of Social Ideas Advertising:

Attention to social ideas advertising is expected to be negatively related to perceptions of extent of benefit sharing, responsibility sharing and delay in realizing benefits and positively related to perceptions of extent of controllability. This attention in turn is likely to affect consumers' cognitive processing of social ideas advertising such that comprehension of message content would be positively related with the attention.

In addition, as depicted in Figure-1, intangibility and complexity of social ideas would also directly affect consumers' comprehension of social ideas advertising. "Comprehension" is used here to refer to consumers' understanding of message content in the way intended by the advertiser. We propose that comprehension of social ideas advertising would be:

Proposition:

- 10a) negatively related to consumers' perceptions of the extent of intangibility.
- 10b) negatively related to consumers' perceptions of the extent of complexity.

In discussing the intangibility of ideas, Fine (1981) quotes Rogers and Shoemaker's (1971) report on rejection of the idea of boiling water in a Peruvian village:

Mrs. C. does not understand germ theory, in spite of Nelida's repeated explanations. How, she argues, can microbes survive in water which would drown people? "Are they fish? If germs are so small that they can not be seen or felt, how can they hurt a grown person? There are enough real threats in the world to worry about - poverty, hunger - without bothering with tiny animals one can not see, hear, touch or smell (p. 4).

The effect of intangibility of an idea is basically captured in one's inability to comprehend it using one's senses. A social idea marketer's job thus translates into the challenge of making an intangible more tangible. When the social idea is an "experience," this can be done by depicting the products used in gaining that experience. For example, the United States Army's recruiting efforts make extensive use of military equipment (e.g. planes, tanks) in their advertising directed at potential recruits. However, when the social idea is a desired action on part of the target audience, the task becomes more challenging. An example is the efforts of the American Red Cross to promote participation in CPR classes. Their campaign "If only they came with instructions" shows a baby holding a card with the following message, "IMPORTANT: Please hug me, feed me, keep me warm and PLEASE learn American

Red Cross Infant and Child CPR." The bold headline of the ad says "If only they came with instructions." Written in small print is the fear appeal-based message "Every year thousands of babies die of choking, suffocating or breathing emergencies. Don't let yours be one of them." The picture of a beautiful, smiling baby combined with the strong fear appeal message make the rewards of learning CPR very obvious and conveys the tangible results of this action.

The complexity of some social ideas may create information overload (Jacoby, Speller and Kohn 1974;) and affect consumers' ability to process the relevant information. Advertising for social ideas should be kept simple and consider target consumer's information processing capacity.

Affective Responses to Social Ideas Advertising:

In addition to its effect on consumers' cognitions (e.g., message comprehension), attention to social ideas advertising affects consumers' affective responses (e.g., feelings). Two aspects related to consumers' feelings need to be discussed - the valence or the pleasantness/unpleasantness of feelings and the intensity of feelings. Feelings are likely to be more intense when consumers devote more attention to the message than when they devote less attention. The second aspect concerns the valence of the feelings. As indicated in the model in Figure-1, lower reversibility of social ideas consumption decision and higher counter-pressures will directly affect affective responses to social ideas messages such that feelings would be:

Proposition:

- 11a) more pleasant when consumers' perceive greater reversibility.
- 11b) less pleasant when consumers' experience greater counter pressures.

The reversibility effect poses real challenges for the social idea marketer. The very objective of social idea advertising is to obtain commitment for a cause and issue and often these commitments are sought as a long-term action rather than a short-term one. This poses a threat to the consumer who sees himself or herself being "tied". This threat is associated with unpleasant feelings. The marketer of a social idea cannot really say that "they'll offer a refund" as in use of a conventional product. However, they can decrease the unpleasant feelings association with the commitment by emphasizing the high benefit to costs ratio: - i.e., emphasizing that benefits are far more and costs are nothing in comparison (without undermining the importance of the commitment). An example would be a television solicitation for children in poor countries which says that you can make the difference in the life of a child by "committing only 39 cents a day." These ads then go on to describe how the sponsored child will regularly write to you and how you will get pictures showing the difference your contribution has made.

The counter-pressures to social idea advertising arise from opposite and preexisting viewpoints. Conflicts resulting from such counter-pressures are associated with unpleasant feelings. To help consumers cope with such feelings, an ad should acknowledge these counterpressures while establishing the viewpoint advocated. The field of social idea advertising deals mostly with topics with which consumers are already familiar. Research suggests that when consumer awareness and knowledge are high, two-sided messages are more effective than one-sided messages (Faison 1961). Two campaigns of the American Cancer Society (ACS) demonstrate this point. ACS identified two high risk groups: leisure tanners and outdoor workers. The campaigns directed at these two target groups had a common theme but different executions. The common theme was "Cover up or face the consequences." The ad directed at leisure tanners showed a skeleton with a pair of sunglasses lying on a chaise lounge and carried the heading "Skin Cancer Can Ruin a Beautiful Tan." Thus this ad very indirectly acknowledges that "covering up" (the social idea in the interest of public health) prevents one from getting a tan but saves you from skin cancer. This makes viewers think about the choice they want to make. Similarly, the ad aimed at outdoor workers shows a brawny construction worker without a shirt. The ad headline says "Staying Cool on the Job Could Cost You Your Life." This time the social idea marketer is acknowledging that covering up may make you feel warmer, but it saves your life. Once again the target has to make a choice.

Consumer Behavior in Response to Social Ideas Advertising:

As the model in Figure-1 depicts, consumer behavior in response to social ideas advertising results from cognitive and affective processing of such messages. Further, the cognitive and affective responses are construed as mutually reinforcing rather than independent processes. The notion of behavior being a function of cognitive and affective responses is well supported by research related to the Theory of Reasoned Action (Fishbein and Ajzen 1975, 1981) which links the attitudinal or cognitive component and subjective norm or affective component to behavior. For example, research by McArdle (1972) suggests that behavioral intentions of alcoholics to sign-up for treatment in a Veterans' Hospital program were jointly predicted by their attitudes towards signing up for the program as well as their motivation to comply with referents (e.g., spouses, parents).

The area of cognition-affect relationships and their directionality has captured the attention of researchers in the area of consumer satisfaction/dissatisfaction. Several studies have established that cognitive responses such as attributions for product failure affect emotions or affective responses (Folkes 1984; Oliver 1989; Weiner 1985; Weiner, Russell and Lerman 1978, 1979). The reverse linkage, i.e., feelings affecting cognitions has been supported in the area of memory research (Bower 1981; Clark and Isen 1982; Isen and Daubman 1984). A cycle-recycle pattern of emotion-attribution-emotion was found in

two studies conducted by Stephan and Gollwitzer (1981). More recently, Manrai and Gardner (1991) suggest that emotional context of product failure affects attributions.

Taken together, this suggests that consumers' cognitive and affective responses to social ideas advertising affects behavior directly and that these responses are mutually reinforcing.

CONTRIBUTION AND FUTURE RESEARCH:

This paper makes two important contributions to the area of social ideas advertising research.

- 1) Eight basic dimensions were identified that differentiate social ideas advertising from conventional products advertising. These differences enable us to understand the true nature of social ideas advertising and the challenges involved.
- 2) A model is developed relating the eight differences to three aspects of processing upon exposure to social ideas messages: attention, comprehension and affect.

Future research can be directed in several areas. First, the differences between the social ideas advertising and conventional advertising require empirical investigation. Second, the propositions relating the eight differences to three aspects of processing also should be tested empirically. Third, other possible linkages should be explored. For example, the four differences that affect attention, i.e., shared benefits, shared responsibilities, delayed benefits and controllability may also influence affective responses directly.

The model presented here is very basic; future research could be directed at exploring more complex relationships and interactions. There appears to be wide scope for future research in this area. Such research efforts should enhance our understanding of this societally important topic.

Toward Articulating Theories, Triangulating Concepts, and Disambiguating Interpretations: The Role of Converging Operations in Consumer Memory and Judgment

Thomas K. Srull, University of Illinois at Urbana-Champaign

ABSTRACT

A variety of general methodologies for the study of consumer memory and judgment are outlined. Although each of them is useful in isolation, it is argued that researchers should strive to combine them, and collect converging evidence from widely divergent paradigms, whenever possible.

I have had a passing familiarity with the study of consumer behavior over the past decade and, more than anything else, two things have become apparent. One is that information processing theory has clearly become the dominant theoretical -- or metatheoretical -- approach to the field. Everything from introductory textbooks in consumer behavior to the pages of our most elite journals are filled with its fruits.

There are, of course, very good reasons for this. One is that information processing theory has been enormously successful in revolutionizing basic experimental psychology. A related but still distinct reason is that it has been nearly as successful in revolutionizing the study of consumer behavior as well. Without disparaging the impact of other traditions or viewpoints, the past decade has provided a virtual explosion of new scientific questions and, in many cases, quite subtle and sophisticated answers. The fact that this explosion of new knowledge has coincided with the field's adoption of information processing theory as the major guiding paradigm is no accident.

The second thing that has become apparent to me over the past decade, and this is in no way inconsistent with the first, is that we are still a very immature field in our approach. As I'm sure many of us do, I sometimes marvel at how researchers can tackle such difficult problems in such an elegant and sophisticated way. But then there are other times in which I become distraught over how many loose ends remain untied.

The field of consumer behavior is following a natural evolutionary course, one that has mirrored quite closely that of cognitive psychology. However, since cognitive psychologists have been active much longer, and have progressed much further, it is useful to examine some of the changes in orientation that have been responsible for their progress. In this way, we can avoid some of the mistakes they made and capitalize on some of their more productive achievements.

Anyone who reads both the cognitive psychology and consumer behavior literatures will be struck, above all, by the following: while researchers in consumer behavior typically use one experiment to test five or six hypotheses, cognitive psychologists typically use five or six experiments to test one hypothesis. This difference follows from a very basic orientation concerning how and when scientific inferences can be drawn from observed empirical data.

This point is worth elaborating in a slightly different way. Researchers in consumer behavior typically use a single experimental paradigm, and then draw inferences about several different cognitive processes. This is useful, and even necessary, in the early stages of investigation because meaningful theories require a data base that is both rich and descriptive. Cognitive psychologists working with virtually every psychological process traveled down this same path. Eventually, however, cognitive psychologists discovered that this is a very dangerous strategy in the long run because not nearly enough constraints are imposed on the theory. If one continues to follow this strategy, the theories will remain unspecified and unwieldy.

Having learned their lesson, painfully but well, cognitive psychologists now follow exactly the opposite strategy; they use many different paradigms to provide evidence that converges upon a single type of process or memory representation. As consumer behavior develops into a mature field, we will need to move in the direction of gaining evidence about a single memory representation from many different paradigms and dependent measures.

There is every reason to believe that those measures that have proved to be most useful in cognitive psychology will prove to be equally useful in consumer behavior. In the rest of this paper, I will try to outline in general terms what these measures are and when they can be used most easily. The point to keep in mind, however, is that they can and should be used in conjunction with each other whenever possible.

Free Recall Measures

A common type of experiment in consumer behavior is one in which consumers receive information about an object (e.g., a brand or category) with instructions to use it for a particular purpose (e.g., to learn the information or form an evaluative judgment). They are then asked at some later time to recall as much of the information as possible. A researcher might then compute any of six different indices: (1) the total *amount* of information recalled, (2) the *type* of information that tends to be recalled, (3) the *order* in which the various items are recalled, (4) the number of *intrusions* that are reported, (5) the *latencies* associated with the recall of each item type, and (6) the *implications* of the recalled information for a particular type of judgment or decision.

These indices are typically used to draw conclusions about three separate questions: (1) the extent to which the information was initially learned, (2) the content and organization of the mental representation that is formed, and (3) the particular aspects of the information that are used as a basis for judgments or decisions. These inferences can be made

in the context of (at least) four general memory models.

Associative network models. Many models conceptualize the representation of information in memory as an associative network of concepts and relations. Concepts in such a network are represented by nodes, and associations by pathways connecting them. However, the nodes themselves are assumed to have no internal structure. Associations are usually thought to be the result of contemporaneous representations of the concepts in working memory (rehearsing two items together, thinking about the concepts in relation to each other, and so on).

Two general types of retrieval processes have been postulated. One involves a serial directed search of the network. Once the concept represented by a particular node is activated, other concepts are retrieved by progressing from node to node along the pathways that have been established (see e.g., Srull, Lichtenstein, & Rothbart, 1984; Srull & Wyer, 1989). A second type of model assumes a parallel search of the network. This is best exemplified by various spreading activation formulations (see e.g., Anderson, 1976).

Retrieval models. It should be clear that associative network models tend to put all of the conceptual weight on the relations between concepts, and they deemphasize the internal structure of new episodes that are encoded into memory. Retrieval models take nearly the opposite approach.

As a general class, retrieval models make minimal assumptions about how a newly encoded episode is "organized" and represented in relation to other things that are known (see e.g., Ratcliff, 1978). That is, they deemphasize any relations that may exist between concepts. They do, however, make elaborate assumptions about the *internal* structure of any encoded event. In most cases, a vector or matrix format is used to represent the structure of new events that are encoded into memory. Each event is broken up into a set of elementary features (which include self-generated associations) and the "values" of such features are the components of the vector or matrix that is used to represent the event. Each vector or matrix is stored independently of all the others.

A common element of these models is that a retrieval cue (either presented by the experimenter or self-generated) can also be decomposed into more elementary features and represented in vector or matrix format. The effectiveness of any cue will be a function of the "similarity" of its own vector (matrix) with the vector (matrix) of the to-be-recalled event. This provides one explanation for why a cue is effective only if some or all of its features were thought about at the time of encoding (Tulving & Thomson, 1973).

Reconstructive models. A third type of model is particularly powerful in conceptualizing the dynamics that result in the intrusion of general world knowledge into the recall of specific information. There are two general versions of this model.

One postulates the existence of previously learned knowledge structures (scripts, schemata, etc.) that function as configural units and are used to interpret raw information whose features can be

instantiated in terms of them. For example, one may have a particular schema for health food. When specific information is received about a particular health food, this information is not directly stored. Rather, only a "pointer" to the schema is retained, along with equivalence rules for translating specific features of the new information into prototypic ones and back again. This representation is sufficient to permit the new information to be reconstructed later, even though its details are not uniquely stored. However, because of this same process, one would expect to find many intrusions of unspecified features in consumer's recall protocols as well.

A second general type of reconstructive model also assumes that new information is interpreted with reference to a pre-existing knowledge structure. However, it assumes that once the information is organized and encoded in terms of this prior knowledge, it is stored in memory as a conceptual unit rather than as simply a pointer to the prototype used to interpret it (see e.g., Wyer & Srull, 1986).

Amount-of-processing models. A fourth conceptualization places special emphasis on the amount of cognitive activity involved in processing information at the time it is encoded (see e.g., Burke & Srull, 1988). In general, these models assume that more extensively processed information becomes more accessible in memory and therefore is more likely to be recalled. This may be true because thinking more extensively about information leads it to be more elaboratively encoded in terms of previously formed concepts, thereby making these concepts more effective retrieval cues (Jacoby & Craik, 1979). Another possibility is that more extensively processed information becomes more strongly associated with contextual (situational) cues available at the time it is received, and therefore is more likely to be retrieved in any later situation in which those same cues are present (Tulving, 1983).

Cued Recall Measures

One of the most significant influences on the development of an information processing framework for the study of memory and cognition was the primary consideration given to retrieval and computational processes (e.g., Lichtenstein & Srull, 1985, 1987), as well as to instances of retrieval failure (e.g., Lynch & Srull, 1982). The use of cued recall tasks has become increasingly common as more and more theoretical issues concerning retrieval have been raised (see e.g., Keller, 1987, 1991).

It is important to distinguish between cued recall as a process and as an experimental procedure. Several theorists (e.g., Battig & Bellezza, 1979; Voss 1979) have argued that much of one's recall involves the use of self-generated cues. Thus, a free recall task might involve "cued recall" in terms of the underlying processes being activated. As an experimental procedure, however, a cued recall task involves a situation in which the experimenter provides cues (at the acquisition stage, retrieval stage, or both) that may aid the subject in recalling other material.

There are two major advantages to using cued recall as an experimental procedure. First, it can often be used to detect information available in memory that less sensitive methods (e.g., free recall) are unable to detect. The second advantage of cued recall is more subtle but even more important. Many contemporary theorists (see e.g., Raaijmakers & Shiffrin, 1980, 1981) postulate that all information encoded into long-term memory is potentially available from that point on, and "forgetting" is due to the inability to retrieve a given piece of information in a particular context. By experimentally varying the situational context, and therefore the nature of the cues available to the subject, one can examine under what conditions people will and will not be able to retrieve given information.

Recognition Measures

Measures of recognition memory like the free recall and cued recall measures discussed earlier, are often used as an index of learning and retention. However, the conclusions one draws from these measures are probably even more dependent on the theoretical assumptions one makes about the processes that underlie the responses being measured.

In a recognition paradigm, subjects who have previously been exposed to a set of stimulus items are then presented with each of several test items and asked to decide whether each item was among the ones they had seen earlier. Some of the test items were actually presented before, and others ("distractors") were not. Three indices are usually considered: (1) the probability of correctly identifying a stimulus item as having been presented (the *hit* rate), (2) the probability of stating that a distractor had been presented when it had not (the *false alarm* rate), and (3) the time required to make these judgments. I will focus here only on the first two measures (for a discussion of how response time can provide additional information in a recognition memory paradigm, see Srull, 1984).

Quite different theories exist concerning the processes that underlie recognition responses. One view is that free recall, cued recall, and recognition all lie along a single continuum. That is, they are not qualitatively different from each other (Watkins, 1979). While in a free recall paradigm there is only one cue and it is very general ("recall everything you can from the list"), in a cued recall paradigm there are many cues and they are necessarily more specific. According to this model, a recognition paradigm is very similar. In recognition, many of the cues that are provided to subjects to aid recall are duplicates of the original items (these are called *copy cues*). However, the underlying retrieval process is no different than in cued recall, or free recall for that matter. According to this model, the critical determinant of recognition responses (like all others) is the association of the stimulus items stored in memory with the retrieval cues available at the time of recognition. In other words, recognition involves a retrieval process that is no different from that in free recall.

An alternative view is proposed by Gillund and Shiffrin (1984). They postulate that the primary criterion for a recognition response to an item is the

item's subjective familiarity. That is, a test item will be responded to affirmatively if it is experienced as "familiar" in the situational and informational context in which the item is presented. According to this model, search and retrieval processes, which play the dominant role in free recall, are simply bypassed when recognition memory measures are used.

A third, less well formalized conceptualization incorporates features of both of the above models. According to this view, a subject who receives a recognition test item will first use its features as cues to probe long-term memory for an item that has these same features. If the search is successful, a "yes" response will be given. However, if the subject does not find an item, he or she will have to "guess" whether the test item was included in the original list. This guessing process will be based on some index of subjective familiarity, which is assumed to be a function of the similarity of the item in question to other items the subject does remember as having been presented.

The conclusions drawn from a given set of recognition data will often depend on which of these general sets of assumptions is implicitly made. Several detailed examples of the interpretive controversies that can result are provided by Wyer and Srull (1988).

True - False Verification Measures

It seems reasonable to assume that the time required to respond to a stimulus is some function of the time required to perform each of the component stages that underlie the generation of this response. Moreover, if one has a precise theory of the stages of processing that underlie judgments in a particular situation, and if one postulates factors that independently affect the different stages of processing, these factors should have independent and additive effects on overall response time (Sternberg, 1969, 1975). If the effects are not additive, it implies that either: (1) the experimental factors do not affect the stages of processing that one assumes, or (2) the stages themselves are nonindependent.

There is often an inherent ambiguity in interpreting response-time data. This is particularly true when the responses being made require assumptions about both: (1) the structure and organization of the cognitive material on which the response is based, and (2) the nature of the retrieval and use of this material. As Anderson (1976) and others have pointed out, it is often impossible to localize the logical source of response-time differences. In other words, a given pattern of response times can be accounted for equally well by: (1) postulating differences in the structure and content of memory, but assuming a single search and retrieval process for accessing it, or (2) assuming a single memorial representation and postulating different search and retrieval processes. In many instances, these alternative interpretations must be evaluated in terms of their relative plausibility or parsimony rather than (simply) their consistency with the data.

These considerations make it clear that the use of verification times as a memory index is highly

contingent on the a priori assumptions one wishes to make about the process that underlies them. When one is willing to make a particular set of assumptions, however, some useful conclusions can be drawn. An elegant example is provided by Sentis and Burnstein (1979) in an investigation of subjects' tendency to organize information in memory in a manner implied by cognitive balance theory. Subjects received sets of three affective relations among persons and objects that were theoretically either balanced or imbalanced. Then they were presented with configurations of one, two, or three relations from the original materials, and asked to verify whether they were among the relations they had learned.

Sentis and Burnstein postulated that subjects would store the relations in imbalanced triads independently of one another, and thus the time required to verify a configuration would increase with the number of relations presented. However, subjects were expected to organize the relations contained in balanced sets into integrated units rather than storing them as independent entities. They were therefore expected to verify a balanced configuration more quickly when all three of the relations it comprised were presented than when only a subset was presented. In short, the time required to verify the relations contained in imbalanced sets was expected to increase with the number to be verified, whereas the time required to verify the relations contained in balanced sets was expected to decrease with the number of relations presented. The results supported both hypotheses, and provide an elegant demonstration of the use of this type of methodology.

Ease of Retrieval Measures

A wide range of questions related to cognitive organization can be investigated by examining the ease with which material that is represented in memory can be accessed. The precise experimental paradigms that are used vary greatly; while some resemble yes-no verification tasks, others resemble free recall tasks, and still others fall somewhere in between. Three representative but very different examples are described below to illustrate the continuum.

One question that often occurs within the study of consumer behavior is how closely one item is associated with another (and how the strength of that association might be manipulated). For example, Fazio, Herr, and Powell (1992) examined different advertising executions that presented the same information; the only difference was that the brand name was identified very early in one case, and not until the end of the ad in the other (so-called Mystery Ads). They then presented consumers with a yes-no verification task in which they were to indicate whether a particular brand belonged to the product category designated (e.g., Crest - Toothpaste).

Fazio et al. found that the time required to make these verifications was much less when a novel brand was learned about via a Mystery Ad than in the more traditional executional style in which the brand name is presented first. This suggested that the brand-category associations were much stronger in the former than latter case. Moreover, Fazio (1990) has

shown that such verification times correlate highly with how early a brand is listed when consumers are asked to list all of the members of a given product category, providing just the type of converging evidence that one would hope to find more often.

Similar approaches can be used to determine when consumers can retrieve information directly, rather than compute it indirectly on the basis of other, relevant information that has been stored. For example, Kardes (1988) presented consumers with an advertisement in which the conclusion from an argument was stated directly or only implied. He then measured the amount of time required to determine that the conclusion was true.

Consumers who saw the conclusion directly stated could simply retrieve it from memory, and their response times were very fast. Kardes also discovered, however, that consumers who saw the conclusion only implied were equally fast to respond if they were in a high involvement situation. This indicated that these consumers drew the necessary inference at the time they acquired the information, and they too could retrieve the (in this case, inferred) conclusion directly from memory. In contrast, when consumers were in a low involvement situation, and the conclusion was omitted, the time required to respond was much longer, indicating that there was very little inferential activity at the time of acquisition.

Finally, there are many situations in which it is useful to manipulate rather than assess the ease of retrieval. For example, semantic categories that are primed often have a dramatic effect on how subsequent information is processed (for a review, see Wyer & Srull, 1989).

It also appears that the ease with which information is recalled influences the way in which its implications are used. In a very powerful study, for example, Schwarz, Bless, Strack, Klumpp, Rittenauer-Schaika, and Simons (1991) asked subjects to recall either six examples of their own assertive behavior (a very easy task) or twelve examples of their own assertive behavior (a very difficult task). Other subjects did the same with unassertive behavior.

Schwarz et al. found that subjects who recalled twelve examples of assertive behavior actually rated themselves as less assertive than subjects who recalled only six examples. In fact, ratings of assertiveness were higher after recalling twelve unassertive behaviors than twelve assertive behaviors. Based on these and other data, it appears that self-assessments only reflect the implications of recalled content when the ease of retrieval is high. Otherwise examples that are retrieved from memory are discounted.

Summary

Cognitive psychologists have developed a wide range of paradigms that can be used to study consumer memory and judgment. An overreliance on any one of them is dangerous because, as history has demonstrated, the data collected from any single paradigm do not impose enough constraints for a complete and well articulated theory. Thus, consumer researchers should strive to collect evidence from different paradigms that converge on a common set of

psychological processes. In this way, interpretations can be made less ambiguous, concepts can be triangulated, and theories can be (tentatively) fleshed out in a more bottom-up fashion. If the impressive progress that has been made in our understanding of consumer psychology is to continue, such an approach will need to be taken. There are already some signs that this is occurring, and the purpose of the present paper is to help accelerate that trend.

Do Hispanics Constitute a Market Segment?

Geraldine Fennell, Consultant

Joel Saegert, The University of Texas at San Antonio

Francis Piron, The University of Alaska Anchorage

Rosemary Jimenez, The University of Texas at San Antonio

ABSTRACT

Proponents seem not to have examined the implications for hispanics or marketing strategy of the notion that hispanics constitute a "market segment." A hispanic "market segment" implies that hispanics are homogeneous, and the implied recommendation that marketers should target such a segment leaves many questions unanswered, including attributes of the offering or, even, how to go about selecting such attributes, as well as the implications of such special targeting for the firm's overall marketing effort. The marketing concept states that brands are formulated on the basis of identified customer wants. Wants vary as a function of heterogeneity in the contexts in which prospects engage in a focal activity. Such contextual heterogeneity occurs among and within individuals and is not illuminated by the labels of demographic classes. Plainly, there is no basis for assuming that hispanic wants are homogeneous, that hispanics do not share the full range of human wants found among nonhispanics, or that producers may devise a simplistic strategy to appeal to hispanics.

INTRODUCTION

Judging from the recent number of journal articles and conference presentations on the topic of "marketing to hispanics," formulation of special marketing strategy for hispanic consumers would seem to be widely recommended by marketing theorists. However, a recent paper by Fennell and Saegert (1990) questions the logic of "segmentation," i.e., devising a single marketing strategy to appeal to a particular ethnic group, or indeed, to any class defined on the basis of a (relatively) enduring personal characteristic (e.g., demographic or personality trait, geographic location, or product ownership). This argument, based on Fennell's marketing model (e.g., 1982a, 1982b, 1985, 1989), takes as a point of departure the marketing concept, i.e., the notion that marketing strategy proceeds by systematically assessing the wants and desires of prospects, selecting brand attributes to address such wants and desires in a competitive context, while aiming to obtain a satisfactory return on one's investment.

FALLACIES IN THE CONCEPT OF A "HISPANIC SEGMENT"

Many factors contribute to recent interest in the notion of a "hispanic" (or other ethnic group such as blacks, orientals, etc.) segment. Unquestionably, hispanics make up a large part of the US population and contribute richly and distinctively to the character of the nation as a whole. Moreover, hispanics are recognized as minority group members who historically have been at economic and/or social

disadvantage compared to majority group members. Thus, much attention is focused on both the cultural contributions made by hispanics and other ethnic minorities, as well as the need to provide mechanisms to prevent social injustice and discrimination. However, none of these facts argues for regarding hispanics as a market segment.

Those who would regard hispanics as a market segment contribute, doubtless unwittingly, to confused thinking about both hispanics and marketing strategy. It may be helpful to reflect on the concept of market segment. In short, it is necessary to think of markets as segmented because demand is heterogeneous, and the producer's decision, i.e., in a competitive context, choosing brand attributes to appeal to at least some prospects, requires reducing the heterogeneity of varied individual contexts to a manageable number of homogeneous segments.

Regarding markets as comprising "segments" simplifies the producer's task of responding to the varied circumstances of the prospects for a product. On the *demand* side, there are individuals in a population who perform a particular activity, e.g., feed a dog, attend live theater. Having regard to such prospects for dog food brands and live theater performances, respectively, the context in which they engage in the focal activity varies across individuals, and within individuals over time, and what they value in an offering varies accordingly. On the *supply* side, looking for a return from investing his/her resources, there is a producer who wants to make offerings that at least some prospects will (repeatedly) pay for. The contexts in which prospects perform the focal activity are outside the producer's control, but the producer *has* control over the attributes of the offering. S/he hopes to choose attributes that at least some prospects will want on at least some occasions when they engage in the focal activity. Considering how to create the offering, the producer faces a wide range of options, and must choose in light of prospects' wants *and competitive offerings*. This enormously complex task is facilitated by investigating the contexts in which prospects perform their focal activity and reducing complexity on the demand side to a manageable number of roughly similar kinds of context. These are the segments of demand. When that information is combined with information on brand liking/use within segment, the resulting picture shows how the *market* is segmented. Empirically, both demand and market segments are independent of demographic classification.

For our purposes here it is obvious that a *market segment* implies within-segment *homogeneity* as regards wants. Accordingly, to suggest that hispanics, or any ethnic group, constitute a market segment implies that hispanic wants and desires are homogeneous within their ethnic group. Of course, no

one explicitly argues this and, in fact, many authors emphasize the need to distinguish among subgroups of hispanics, most frequently, for example, as a function of their country of origin (e.g., Mexico, Puerto Rico, Cuba, or other hispanic countries). Nevertheless, it is easy to see that distinguishing among such subpopulations merely extends a presumption of homogeneity to another level; that is, it presumes that Mexicans, Puerto Ricans and Cubans are homogeneous within their respective subgroups, an assumption, again, that none argues explicitly, or examines.

A related issue is the implied recommendation that a marketer should design a marketing strategy to "appeal to hispanics," i.e., the notion that it is possible to appeal to an entire ethnic group by a single marketing strategy. Let us examine this by considering formulating a brand to appeal to a given ethnic subgroup. Even searching for an example of such a brand strategy runs the risk of perpetuating ethnic stereotypes, an outcome to which advocates of "ethnic segmentation" appear oblivious. However, in the interest of illustrating the illogic of "formulating a brand for hispanics," we must conjecture a stereotypical trait. For example, a recent article has maintained that a major cosmetics firm employed a "hispanic market agency" (Brookman 1988), presumably to "target" prospective hispanic make-up buyers. Assuming some characteristic that may be pertinent to hispanic customers, for example, darker skin shade, let us imagine that the manufacturer considers producing a brand specifically formulated for this subgroup. However, the producer would undoubtedly be aware that dark skin tones are not present in all hispanic prospects, and moreover are also found among nonhispanics. Thus, identifying an ethnic group as a market segment fails to deal both with the heterogeneity of conditions within, and similarity of conditions across, ethnic groups. Finally, and perhaps most important in terms of marketing strategy, deciding to formulate a brand for dark-skinned prospects (hispanic or otherwise) leaves unaddressed prospects' heterogeneous motivations concerning the focal behavioral domain, which would be personal grooming in the present example (e.g., coping with dry/oily/blemished/sensitive skin, symbolic/aesthetic/intellectual considerations), not to speak of preferences among product forms and package sizes. As Fennell (e.g., 1990) points out, desirable attributes in brands vary, across and within individuals, as a function of enduring and transitory elements in the contexts for engaging in the focal activity. In line with the marketing concept, i.e., brands are formulated to respond to a subset of prospects' wants, the notion of a hispanic, or any other ethnic, "market segment" is an oxymoron. Similarly, the notion that it is possible to "appeal to hispanics" by formulating "the hispanic brand" or even "the hispanic strategy" does a disservice to marketing professionalism, no less than to the ethnic group that is to be thus stereotyped.

MARKET SEGMENTATION

Much of the confusion regarding hispanics as a "market segment" may follow from inappropriate

terminology widely referring to ethnic and other demographic subgroups as "market segments." In fact, market segmentation reflects variability, *within domains of human activity*, in the circumstances that result in specific human wants, (e.g., Fennell 1982b). As noted, specific human wants, i.e., at the level of individual acts and corresponding market offerings, are not reflected in demographic or other enduring personal characteristics, which cut across domains of activity. Recognizing such heterogeneity of human wants and desires *within activity domain*, producers have understood that "responding to customer wants" leads to a variety of brand formulations within a single product category. Opportunities for brand differentiation result from the varied circumstances, within a particular domain of activity, for which prospects may choose a brand to minister to their wants.

Developing a marketing strategy follows a number of steps such as those outlined elsewhere (e.g., Fennell 1982a), which it may be useful to recap here. Faced with the range of everyday human activities that include, e.g., "removing: soil from clothes, sensations of hunger, various kinds of pains, aches, and insecurities, as well as providing stimulation for the mind and pleasure for the senses" (Fennell and Saegert 1990), a producer identifies a domain that corresponds to his/her productive interest. Within that domain, the producer hopes to be able to put productive resources to good use by creating a brand that some prospects will favor relative to competitive offerings.

Fennell's model outlines categories of motivation that lay the groundwork for differentiating brand offerings and, more broadly, developing marketing strategy. These heterogeneous contexts for an activity, found across ethnic and other demographic categories, are the source of market segments, and of the attributes that segment-appropriate brands should possess. Briefly, the model describes five simple and two complex motivational classes that help marketers to identify the heterogeneous contexts in which people perform an activity. These contexts are illustrated as follows for an oral hygiene activity:

...observing an individual engaged in some activity related to oral hygiene, such as "brushing teeth," and bearing heterogeneity in mind, one may conjecture that the individual may be *escaping* from the unpleasant process of bacteria in the mouth creating bad breath, or damaging teeth, or from the ugliness of teeth discolored or stained from smoking cigarettes/drinking coffee; or *preventing* imagined criticisms from oneself/significant others on grounds that one is lazy, or careless of personal hygiene, or lacking in consideration; or *maintaining* a system that needs only routine attention; or *exploring* an interesting question related to brushing techniques; or *enjoying* the sensory experiences associated with bristle on gums, taste and tingle of dentifrice, and the sight of glistening pearly teeth; or doing any of the

preceding while trying to ignore the discomfort of water on sensitive teeth or painful gums (*conflict*); or while feeling discouraged at the unsatisfactory result that one has previously obtained from one's efforts (*frustration*). Accordingly, the qualitatively different kinds of circumstances to be found in the establishing operations of instrumental conditioning help a researcher to generate candidate personal and environmental elements that may be operative in any individual instance or on some proportion of a universe of occasions (Fennell and Saegert, 1990).

Elements such as the preceding guide the qualitative researcher in obtaining the necessary information from prospects for quantification in large scale surveys. As noted, to simplify the brand positioning decision, marketing researchers form segments of demand and, having regard to prospects' information about and reactions to competitive offerings, market segments (e.g., Fennell 1978, 1982a). The producer's positioning decision reflects a judgment concerning how productive resources can be used to best advantage by responding to some region of demand that appears to be not well served by existing offerings.

CRITIQUE: ARGUMENTS FOR THE CONCEPT OF A HISPANIC SEGMENT

Researchers who have studied hispanic consumer behavior have offered a number of justifications for doing so. Some of these include the large number of hispanics in the US, empirically found differences between hispanics and others (e.g., nonhispanics/general population), and hispanic preference for Spanish language media. As will be seen, however, none of these justifications for studying hispanics as consumers establishes a basis for regarding hispanics as a market segment.

Demographic Differences

Frequently, researchers have pointed to demographic characteristics of hispanics as the basis for developing marketing strategy (e.g., Valencia, 1989). These include, for example the large number of hispanics in the US, their comparatively high growth rate, large average family size, disproportionately low average age, etc. Also, the argument is made that even though their economic status may presently be lower than that of the population at large, hispanics' income levels are rising rapidly, thus providing them new wherewithal to purchase producer's brands. Such characteristics, in fact, do not provide a basis for developing brand strategy. Take family size, for example. Knowing that "hispanics have larger families than average" might be considered as guiding a marketer to position a brand accordingly, namely for "large hispanic families." Characteristics of such a brand might include, for example, larger package sizes of foodstuffs, or greater durability of furniture (to lessen breakage by youngsters). But "large family size" provides no information relative to other aspects of the focal activity and hence, no guidance for

choosing brand attributes in regard to the central task that the brand is to perform. For example, knowing that some hispanic prospects have large families provides no information about whether such families, *in regard to the focal activity*, are seeking to escape from current problems, prevent potential problems, maintain a stable state, avail of opportunities to explore, or to enjoy sensory pleasure. Moreover, is there any reason to believe that "large hispanic families," as regards a focal activity, are homogeneous in their motivations and different from large nonhispanic families? In other words, the motivations of prospects are still not addressed by knowing yet another demographic label. Furthermore, not all hispanics have large families, so a recommendation to regard hispanics as a market segment has now been transformed into one to regard hispanics with large families as a market segment without, however, achieving the homogeneity regarding wants that is the defining feature of market segment.

Different Brand Loyalty

A number of studies have been produced that identify particular consumer behaviors as a basis for differentiating hispanics from nonhispanics. One celebrated example is the argument that hispanics are found to be more brand loyal than the general population (e.g., Deshpande, Hoyer and Donthu 1986), although the data are mixed as to whether this is actually the case (Saegert, Hoover and Hilger 1985). According to the brand loyalty claim, to a greater degree than nonhispanics, hispanics are believed to choose the same brand in repeated purchases, and to have strong positive feelings for familiar brands. Here again, it is difficult to identify a marketing strategy that proceeds from such findings. A marketer might reasonably ask, given that hispanics are brand loyal, what characteristics are implied for brand development? The answer is plainly, none. Further research along the lines already described is needed and will reveal heterogeneous wants among hispanics. Furthermore, what strategy is recommended for gaining new customers? If a particular producer's brand is not currently favored by hispanics, the indicated strategy might simply be to refrain from making special efforts to promote that brand to hispanics. Marketers rarely choose to challenge on a competitor's strongest ground, e.g., the brand loyal customers.

Different Attribute Ratings

Another example of distinctive hispanic consumer behavior being taken as a basis for regarding hispanics as a "market segment" is presented by O'Guinn and Faber (1986). These researchers asked hispanics and nonhispanics to rate the importance of attributes that they might consider in buying two products, laundry detergent and a TV set. They found that compared with nonhispanics, hispanics rated two attributes (price and friend's brand preference) as more important for laundry detergent, and seven of eight attributes as more important (e.g., price, brand, quality, and credit) for television sets.

Putting aside the issue as to whether it is appropriate to compare the means of the two groups in this manner (see Wood and Howell 1991 for arguments to the contrary), producers may again ask how such information can contribute to their marketing efforts. Designing and promoting a brand that features "low price" as a predominant attribute would not appeal to hispanics for whom price was unimportant (it is surely not suggested that such hispanics are nonexistent), although it would, of course, be interesting to nonhispanics for whom low price is a consideration. And again, besides low price, what attributes should the brand possess?

Spanish Language Preference

Another unexamined reason for recommending ethnicity as a basis for marketing strategy is the characteristic preference for the Spanish language by many hispanics. For example, it is recognized (O'Guinn and Meyer 1983) that many hispanics use Spanish language media, primarily radio and television and thus, for a marketer to reach this "market segment," advertising messages must be communicated in Spanish. There are at least two ways to consider the issue here: (1) as a purely business decision, and (2) as a decision guided by considerations of social justice or public relations.

(1) Considering first a purely business approach, the advertising decision is properly just one aspect of overall marketing strategy. On the assumption that within-activity wants are similar across ethnic groups and that Spanish speaking targets will not be reached other than by Spanish-language messages, it comes down to conducting a media buy analysis, applying the same criteria that are applied for the campaign generally. Based on those criteria, analyses show how available funds are best spent--on general media, or some mix of general and special language media (including various mixes of special language media, given that there are a number of ethnic groups, some of whose members may not understand English). It should be clear, however, that one is not thus targeting "hispanics," but rather attempting to reach the Spanish speaking prospects who fall into one's targeted segment. (For example, if the marketing analysis described earlier shows that the best national strategy for our brand of laundry detergent is to be formulated for light laundry of delicate fabrics, then our national media selection is going to seek media vehicles believed to offer a high concentration of individuals who want such attributes. Extending the media buy to include Spanish speaking targets attempts, similarly, to locate hispanics who do light laundry.) If it seems that including Spanish speaking targets is feasible within the budget on a *ceteris paribus* assumption, before giving the final "go" decision, the assumption should be examined. For example, the presence of a well-entrenched regional or ethnic brand that has been formulated for light laundry might argue against the decision because, presumably, the national campaign is not geared to challenge a well-entrenched competitor. Thus, management might decide that although Spanish speaking targets can be reached economically, such

funds would be misspent in that the chances of achieving a return on the investment are reduced because of the special competitive conditions existing within the hispanic market. (To keep the analysis simple, we are making the point here for the most straightforward case, i.e., where it is assumed that some hispanics simply will not receive our message unless it is in the Spanish language. Given appropriate documentation, we would extend the present analysis to cases where it is shown that message registration among targets is likely to be improved because of, e.g., greater familiarity with a mother tongue than with a second language, or greater receptivity engendered by feelings of national pride or ego enhancement due to being addressed in one's mother tongue. We stress, however, that we do not regard anecdotal evidence acceptable and that we would require research submitted in support of such claims to meet commonly accepted professional standards.) (2) Secondly, if one has decided, for social justice or public relations reasons, that regardless of return, it is proper to divert funds to special language media, the economic implications of so doing should nevertheless be estimated.

Whether as a purely business decision (i.e., expected return on investment), for reasons of social justice, or, more ambiguously, for public relations considerations, if management decides to use Spanish-language media, the translated advertising message should be checked for communicative problems to achieve good registration of the message and to avoid running afoul of culturally-given meanings that might be counterproductive (Valencia, 1983). The attentional aspects of the ad should also be checked to ensure that it is well designed to achieve processing by the targeted segment within hispanics (Fennell 1979). Note that the present analysis does not suggest changing the ad's essential message. Before such a change could be made on sustainable grounds, it would be necessary to redo the marketing analysis described above, but now defining one's prospects as hispanics who engage in the focal activity. The likely cost of such an analysis could well approach that of the original nationally based studies, and should be assessed in light of the number of ethnic groups that are candidates for such special treatment.

It must be fairly clear by now that the cause of "hispanic marketing" is not well-served by such studies reported in the "marketing to hispanics" literature. Most basically, a research design that is chosen to show differences between hispanics and nonhispanics is irrelevant to how a producer should proceed in trying to find favor with hispanics, and it establishes nothing to show a producer that his/her scarce resources are going to be well spent by being diverted to a special hispanic effort. Even if "hispanics" differ from "nonhispanics" on a particular want, no information is provided about the extent to which the want is well satisfied by the brands available to hispanics. Between-group differences, even when they achieve statistical significance, are far removed from the considerations that are relevant to a producer. An offering stands or falls depending on how well its attributes, compared with those of

competing offerings, match the concrete physical and psychological contexts in which individual human beings pursue a task or interest. Goods/services are judged, chosen, used and evaluated, not by "between group differences," but by individual human beings, hispanics or nonhispanics, in real world circumstances.

Consider the case of a producer who has already decided to try to make inroads into the "hispanic market." The producer's task is to create and announce the availability of an offering that some hispanics will find appealing, relative to their other options, so that they will repeatedly select that offering over the competition, and do so at a rate that gives the producer a satisfactory return on investment. What is going to be relevant here are exactly the same considerations that any producer deals with in deciding to try to gain a share of some market--identify the characteristics of the contexts in which the focal activity is performed, form the segments of demand, investigate how well such segments are being served by existing brands, judge the probability that the producer can successfully claim to be more appropriate than the competition for some subset of the contexts in which people (hispanics here) perform the focal activity (e.g., Fennell 1982a). In other words, the hispanic market is, from the point of view of marketing analysis, exactly on the same ground as the national, or black, or oriental markets. At the widest definition, a market consists of prospects for a producer's offering--people in a naturally-occurring population (or population subgroup), who are likely to be interested in using a particular category of good/service (e.g., dog food, live theater). Such interest is usually indexed by their engaging in some activity for which the category of good/service could conceivably be used (e.g., feeding a dog, regularly patronizing entertainment outside the home). A market *segment* consists of individuals *within* a market, i.e., a subset of such prospects, whose wants *regarding the focal activity* are sufficiently alike as to be addressed by the same *brand* formulation (physical and psychological).

We are now in the fourth decade of an era in which marketers act on the assumption that the wants of individuals who engage in a particular activity, who form a "market" in the broadest meaning of that term, are heterogeneous to the extent that they cannot be well-served by a single brand formulation. Recall, again, that a marketer does not hope to appeal to the entire national population: for any product the market is always smaller than a naturally-occurring population. A first cut through a naturally-occurring population gives the outside limits of a market, for convenience usually stated in terms of individuals who perform some activity. Moreover, *within* a market as defined, a producer does not hope to appeal to all prospects. Similarly, no one producer can count all hispanics as prospects, only those who engage in a particular activity and, *within* that group, a producer does not expect to find favor with all hispanic prospects. In a word, a producer does not plan to appeal to the entire national market, or to the hispanic, or black, or oriental, market by means of an

undifferentiated marketing effort. And beyond the market as defined, there are other members of the national population, and of the hispanic, black, and oriental populations, who are not in the picture for any individual marketing effort.

CONCLUSION

As to wants, markets are heterogeneous, and market segments are homogeneous. Accordingly, there is no sense in which it is proper to speak of a hispanic, or black, or oriental market segment. Doing so tends to reinforce the notion that ethnic groups can be stereotyped. To suggest that producers and advertisers can readily "appeal to" an ethnic group by some simplistic marketing gesture does disservice both to ethnic groups and to marketing practice.

Such a conclusion says nothing about the value of hispanic studies in general, nor does it seek to discourage interest in studying cultural diversity and pluralism. Moreover, it does not minimize concern for addressing minority disadvantage. Rather, the intention in the present context is to focus on maintaining our integrity as consumer researchers and marketers. To that end, we must try to ensure that our terminology with reference to marketing strategy is coherent, and our recommendations to management are such that we can stand behind, as scientists and practitioners.

In that connection, issues under a number of headings should be disentangled, including:

Social justice According to hispanics and other ethnic groups their due place as part of the fabric of American life,

Marketing science Developing marketing science and formulating guidelines for marketing strategy that enable producers to use productive resources to good advantage in serving people's wants,

Marketing practice Equipping marketing practitioners with analytic tools to use in advising management and clients regarding--

(1) the claims made and research presented by representatives in support of diverting funds to ethnic (language) media;

(2) the bottom line implications of allocating funds, to according ethnic groups their due place as part of the fabric of American life on social justice grounds, as well as where the line is blurred between social justice and responding to pressure for reasons of public relations; the implications of alternative ways of achieving social justice/public relations in the context, e.g., use of minority spokespersons, buying space/time in minority media, etc.;

(3) legitimate, sustainable arguments to use in approaching advertisers in order to achieve due recognition for ethnic groups as part of the fabric of American life.

As marketing professionals, we are properly called upon to advise management, business and nonbusiness, in regard to the implications of engaging in marketing in a pluralistic society. In this paper, we have but traced the outline of the kind of formulations and analytic tools that must be developed. We look for further developments toward achieving these goals.

Cultural Value Orientations: A Comparison of Magazine Advertisements from the United States and Mexico

John A. McCarty, University of Illinois at Urbana-Champaign
Patricia M. Hattwick, University of Illinois at Urbana-Champaign

ABSTRACT

This paper suggests that the understanding of cultural value orientations may be important when marketing products and services to other cultures. Cultural value orientations represent the basic and core beliefs of a culture; these basic beliefs deal with human's relationships with one another and with their world. The study evaluated the extent to which value orientations were present in advertising from the United States and Mexico. The analysis showed that the majority of ads did not express core cultural beliefs. Furthermore, when value dimensions were displayed in advertising, the position expressed on the dimension tended to be related to the nature of the product advertised rather than the orientation of the culture in which the ad appeared.

A debate in marketing over the past few years relates to the issue of how to market products internationally. The central aspect of this issue is the level of standardization that can be achieved when marketing in different cultures. Levitt (1983) has argued that the world is becoming more similar and more Westernized, therefore, companies desiring to market their products internationally can realize economies of scale by marketing globally with a single strategy. While such a possibility is enticing, many major blunders in international marketing such as those outlined by Ricks, Fu and Arpan (1974) are still fresh in marketers' minds. Kotler (1986), among others, has cautioned against the extreme position held by Levitt. Keegan's (1989) discussions of global marketing management clearly indicate that a decision on how to market internationally is a very complex one and relates to all aspects of the marketing mix. Therefore, which direction to take with regard to the issue of global marketing versus more local marketing will likely relate to the nature of the product, the business environment, and the cultures where the product is to be marketed. Wind (1986) suggests that the level of standardization may indeed differ as a function of which aspect of the marketing strategy is being considered. Clearly, international marketing is complex process and it is likely that standardization across all the marketing variables will be a rarity.

Given that complete standardization will generally be an unusual case, it would seem that an understanding of culture and cultural differences will be important to those who desire to market internationally. Culture is the complex system of meanings that a group has in common and this set of ideas may be very different from the culture of another group. Culture pervades every aspect of a society and affects the thinking and acting of every member of a group. Yet because culture is so pervasive and basic to a group, there are subtleties about the culture that group members may know and understand, but are unable to articulate to others outside of the group.

This, in a sense, is the fundamental problem of understanding a different culture from one's own: members of the culture may not be able to clearly articulate the culture to an outsider since the culture is such a basic part of their lives.

McCarty (forthcoming) has suggested that a starting point for understanding a culture and differences in cultures may be cultural value orientations. Kluckhohn (1951) defined value orientations as "a generalized and organized conception, influencing behavior, or nature, of man's place in it, of man's relation to man, and of the desirable and nondesirable as they may relate to man-environment and interhuman relations (p. 411)." Cultural value orientations, therefore, represent the most basic and core beliefs of a society. These beliefs form the central understandings that members of the culture have and, as suggested by Kluckhohn, they relate to human's relationship with one another and the world around them. McCarty argued that an understanding of these core beliefs may be important for those who wish to market their products in different cultures.

Cultural Value Orientations

Different cultural value orientations have been discussed by numerous social scientists over the past few decades (Hofstede 1984; Kluckhohn 1956; Kluckhohn and Strodtbeck 1961; Triandis 1989). These authors have identified dimensions on which cultures may vary and several of these will presently be discussed.

Individualism-Collectivism. The dimension of individual-collectivism relates to human's relationship with one another and it has been investigated by several social scientists (Hofstede 1984; Kluckhohn and Strodtbeck 1961; Triandis 1989; Triandis, et al. 1988). Individualistic societies are those which value the individual relative to the group. Individual achievement, recognition, etc. are encouraged and rewarded. Collectivistic societies, on the other hand, place an emphasis on the group rather than the individual. Individuals are important only in that they are members of the group. Collectivistic cultures stress cooperation among group members and the importance of group goals rather than individual goals.

Research has generally shown many of the industrialized countries such as the United States, Sweden, Great Britain, and Germany are individualistic cultures, while Mexico, Peru, Thailand, and Chile are relatively collectivistic cultures (Hofstede 1984). Triandis (1989) has noted that cultures tend to evolve from collectivistic to individualistic as they become more industrialized. Therefore, it is likely that countries like Mexico are moving toward more individualism as time passes.

Masculinity-Femininity. The dimension of masculinity-femininity deals with the extent to which the characteristics of one sex are favored in the culture relative to the characteristics of the other sex (Hofstede 1984). Therefore, this dimension relates to the extent to which a particular culture values traits associated with males such as achievement, aggression, and dominance versus the extent to which the culture prizes such feminine characteristics as nurturance, helpfulness, and affiliation.

Mexico, Japan, Italy, and Switzerland are highly masculine cultures while Sweden, Norway, Chile, and Denmark represent feminine cultures (Hofstede 1984). The United States is somewhat in the middle on this dimension, but tends to lean toward being more masculine than feminine.

Time Orientation. Kluckhohn and Strodtbeck (1961) argued that cultures may vary in terms of whether they are primarily oriented toward the past, the present, or the future. Past oriented societies tend to have reverence for tradition and their cultural heritage. Such cultures are apt to believe that the way things have always been done is the way that they should continue. Future oriented societies tend to embrace the future and, in a sense, look forward to change and all that the future will bring. Other cultures live for the present and, as Kluckhohn and Strodtbeck note, consider the past as unimportant and the future as unpredictable. For these cultures, therefore, an orientation toward the present is the only one that makes any sense.

As Kluckhohn and Strodtbeck point out, the United States is a very future oriented society. Members of this society believe that the future will generally bring good things and members of the culture orient themselves toward that eventuality. The evidence suggests that most Spanish-American cultures, including Mexico, tend to have a present orientation.

Uncertainty Avoidance. Cultures vary on the extent to which they are willing to tolerate ambiguity and uncertainty (Hofstede 1984). As Hofstede notes, uncertainty about the future tends to create anxiety and stress and societies differ on the extent such uncertainties exist and the extent to which the uncertainty and resulting anxiety is avoided or tolerated. Generally speaking, high avoidance of uncertainty is more common among cultures which are experiencing a rapid change such as newer democracies while more advanced societies, such as the older democracies, tend to have more tolerance for uncertainty. Mexico, Japan, Spain, and Greece are examples of cultures which have relatively high avoidance of uncertainty, according to Hofstede, while the United States, Canada, Great Britain, and Hong Kong are cultures which tend to have a greater tolerance for uncertainty.

Activity Orientation. Activity orientation focuses on the stance which a culture takes with regard to action versus reflection. As Kluckhohn and Strodtbeck (1961) indicate, doing versus being as stances toward human activity have been discussed in much of the philosophical literature over the centuries. Doing cultures are those which place a

premium on activity and action. Accomplishment is considered important in these cultures and one can only accomplish something by acting or doing. Being cultures, on the other hand, focus on reflection and understanding.

The United States is a very doing oriented culture (Kluckhohn and Strodtbeck 1961). This is apparent in almost every aspect of the culture of the United States. Accomplishment and action tend to be rewarded in this culture. Traditional cultures tend to be more being oriented compared with advanced cultures.

Human's Relationship with Nature. Kluckhohn and Strodtbeck (1961) argue that how humans view nature and their relationship with it is yet another basic arena with which humans must deal. They identified three stances that a culture can take concerning nature. A culture can feel that it lives in harmony with nature, it is dominant over nature, or that it is subjugated to nature. Cultures which believe they are subjugated to nature feel that there is little they can do about the forces of nature, while cultures which hold a dominance stance believe that they can control and change natural forces. As Kluckhohn and Strodtbeck note, the culture of the United States tends to believe in dominance over nature while most Spanish-American cultures take a subjugation stance with regard to nature.

The cultural value orientations that exist in a culture reflect the general leanings of a culture as a whole. The beliefs of individuals within any given culture on particular value dimensions may vary and deviate from the general stance of a given culture. The extent to which there is homogeneity or heterogeneity of individual beliefs within a culture is itself a dimension on which cultures may vary. Triandis (1989) argues that there are "loose" cultures which tolerate differences in people and there are "tight" cultures which are relatively intolerant of differences. Tight cultures have stronger sanctions against norm violations, for example, than loose cultures.

It should also be stressed that value orientations may change over time. As previously pointed out as cultures become more Westernized and industrialized, they tend to become more individualistic. These changes may be apparent in advertising. Mueller (1987), for example, showed that advertisements from Japan tended to reflect the Western value of individualism rather than the traditional collectivistic nature of that culture.

The Present Study

The present investigation had several related purposes. The primary question was to what extent are cultural value orientations reflected in the advertising of a culture? Similar comparisons have been made previously by numerous authors (e.g., Belk and Bryce 1986; Mueller 1987; Tansey, Hyman and Zinkhan 1990; Tse, Belk and Zhou 1989; Wayne 1956) for a variety of cultures including Japan, the Soviet Union, China, Hong Kong, Brazil, and the United States. Most of these studies compared the advertising of different cultures, however, the comparisons were not always at the level of core cultural value orientations. The current investigation compared print advertising

in the United States with that of Mexico on the several value-orientation dimensions discussed.

One purpose of the analysis was to determine the extent to which value orientations are expressed in advertising. It has been argued that these basic value dimensions are important for marketers to understand if they choose to market internationally. This importance does not necessarily mean that value orientations will be expressed in advertising. That is, even though core beliefs are important to a cultural group, these beliefs may not represent the best appeal for products or services. It is expected, therefore, that while value orientations may be represented in ads, they will not necessarily be the main appeal. The analysis in the study evaluated the way in which the value orientations were present in the ads.

An additional aspect of the analysis related to the extent to which expressed value-orientation appeals are consistent with the stance of the culture or inconsistent with the cultural beliefs. Intuitively, it would seem that the values expressed in advertising would be consistent with a culture's beliefs. As noted, however, Mueller (1987) has suggested that value orientations expressed in advertising may tend to be consistent with the direction in which a culture is evolving rather than the traditional beliefs of the culture.

METHOD

Print advertisements in magazines published in the United States and Mexico were analyzed to determine the prevalence of cultural value orientations in the advertisements. This study was an initial exploration in the evaluation of cultural value orientations in advertising. It was designed to aid in identifying important issues and concerns for future work in this area and to evaluate whether the study of cultural value orientations in advertising is a fruitful research path. Therefore, the following represents a preliminary analysis based on the coding of values themes made by one coder. The coder, fluent in both English and Spanish, analyzed the advertisements in both the Mexican and American magazines. Therefore, this reports work in progress and the results and conclusions should be considered tentatively, given that multiple coders have not been used.

The value orientations of interest in the current study were individualism versus collectivism, masculinity versus femininity, time orientation, activity orientation, human's relationship with nature, and uncertainty avoidance.

Mexico and the United States were selected for investigation since these two cultures tend to differ on the value orientations that were investigated. The United States is very individualistic, future oriented and oriented toward doing. This culture tends to believe in mastery over nature and is relatively tolerant of uncertainty. Mexico is a relatively collectivistic society which is present oriented and oriented toward being rather than doing. The one dimension which these two cultures do not differ dramatically is masculinity-femininity. Mexico is a highly masculine culture while the United States is a relatively masculine culture. One hundred ninety-five

Mexican advertisements from eleven magazines were analyzed, while 100 advertisements from six magazines from the United States were analyzed. A variety of magazines in both cultures were used, including women's magazines, men's magazines, parenting magazines, and gossip magazines.

The analysis of cultural value orientations in the advertising was conducted in the following manner. An advertisement was evaluated to determine whether each of the cultural value orientations was present in the advertisement or not. If a value-orientation was present, it was further analyzed to see if the orientation was consistent or inconsistent with the culture. For example, if individualism was expressed in an advertisement from the United States, it would be coded as a consistent value-orientation. In a Mexican advertisement, an expression of individualism would be coded as inconsistent. A third aspect of the coding related to the level that value orientations were expressed in the advertisements. The three levels at which the value orientations were coded as present in an advertisement were 1) the value-orientation was the main appeal of the advertisement, 2) the value-orientation was an appeal in the advertisement but not the main appeal, or 3) the value-orientation was present in the advertisement, but was not used as an appeal.

RESULTS

Thirty-five percent of the advertisements from the United States displayed at least one of the value orientations that were investigated. Forty-one percent of the Mexican advertisements had one or more of the value orientations present. Table 1 shows the percentages of the advertisements containing each of the value orientations for the magazines from each of the cultures. The table also indicates the extent to which the displayed value orientations are consistent with the culture or inconsistent with the orientation of the culture.

As the table indicates, the individualism-collectivism dimension and the activity orientation dimension were the two value orientations that were displayed in the advertising most frequently for both cultures. All other value orientations were present in less than 10% of the ads in both cultures. In the case of individualism-collectivism, a slight majority of the advertisements were consistent with the culture. That is, 61% of the ads from the United States that dealt with this dimension were individualistic; 53% of the Mexican ads dealing with individualism-collectivism were collectivistic. Therefore, a sizable percentage of ads in both cultures were *inconsistent* with the dominant orientation of the culture.

For the activity orientation dimension, all of the advertisements from the United States dealing with this dimension were consistent with the doing orientation of the culture. For Mexican advertisements, nearly all of the ads relating to this value-orientation were also of a doing theme, thus being inconsistent with the dominant orientation of the culture. This doing orientation in the ads seems to relate to the nature of the products advertised. Most advertised products solve some problem for consumers

TABLE 1
Value Orientations in Magazines from the United States and Mexico

<u>United States</u>			
<u>Value Orientation</u>	<u>Percent Having Value</u>	<u>Percent Consistent With Culture</u>	<u>Percent Inconsistent With Culture</u>
Individualism/Collectivism	31%	61%	38%
Time Orientation	5%	80%	20%
Activity Orientation	21%	100%	0%
Masculinity/Femininity	3%	0%	100%
Human's Relationship with Nature	2%	0%	100%
Uncertainty Avoidance	3%	0%	100%

<u>Mexico</u>			
<u>Value Orientation</u>	<u>Percent Having Value</u>	<u>Percent Consistent With Culture</u>	<u>Percent Inconsistent With Culture</u>
Individualism/Collectivism	32%	53%	47%
Time Orientation	8%	50%	50%
Activity Orientation	14%	4%	96%
Masculinity/Femininity	3%	66%	33%
Human's Relationship with Nature	9%	100%	0%
Uncertainty Avoidance	4%	100%	0%

Note - Total number of ads is the base for the first column percentages. Percentages in the other two columns are based on ads having that value-orientation.

and thus action to solve the problem must be taken by the consumer. In other words, most products tend to relate to doing rather than being.

For other value-orientation dimensions, the percentages were too small to evaluate the importance of the level of consistency with the cultural orientation. It was noted during the analysis that the orientation expressed in the advertisements appeared to be a function of the nature of the product. For example, the majority of ads dealing with uncertainty avoidance were for pregnancy tests; the inherent nature of such a product is to alleviate uncertainty and anxiety about pregnancy.

For only 22% of the ads from the United States and 19% of the ads from Mexico, the value-orientation mentioned in an advertisement was the primary appeal. The value-orientation in the ad was a secondary appeal for 52% of those from the United States and 60% of the ads that showed a value-orientation in Mexico. The value-orientation was merely present in 25% of the instances for the United States and in 21% of the Mexican ads that displayed a value-orientation.

DISCUSSION

A number of tentative conclusions can be drawn from this preliminary analysis of advertisements from the United States and Mexico. Although it has been

argued that the core cultural value orientations are important in international marketing, the current results indicate that appeals to these values do not appear in advertising very frequently. A majority of ads from either culture expressed none of the value orientations. In only a few instances was a core cultural value the main appeal of an ad. Moreover, appeals to a value dimension were often inconsistent with the traditional stance of a culture.

While most cultural values are rarely represented in advertising, these tentative results indicate that individualism-collectivism may be an important dimension, relative to the other dimensions studied. This dimension was represented in nearly one third of the ads in both the United States and Mexico.

The analysis suggests that the nature of the products advertised affects the way a value dimension is portrayed in an advertisement, regardless of a culture's traditional stance on the dimension. For example, even in a being oriented culture where members prize reflection rather than action, ads tend to express a doing theme since most products are designed to help people accomplish something.

The analysis also indicated that recent trends in cultural beliefs may be important in advertising, regardless of the traditional beliefs of a culture. Although the United States is a culture that has traditionally believed in dominance over nature, the

recent greening movement is consistent with a harmony with nature stance. It is the harmony with nature position that was apparent in a few of the ads that displayed a theme related to human's relationship with nature.

These results do not mean that a knowledge of cultural values is unimportant for marketers. The results do show that for current advertising in the United States and Mexico, appeals to these core beliefs do not form the basis for most promotional appeals. This is not surprising, if one considers that fact that these cultural beliefs are very basic and, hence, are not likely to form the basis of effective advertising. Although not critical for promotion decisions, an understanding of the value orientations of a culture may be essential for the design of distribution systems, packaging and other product decisions, and other aspects of the international marketing program.

What It All Adds Up To: Culture and Alpha-Numeric Brand Names

Janeen Arnold Costa, University of Utah

Teresa M. Pavia, University of Utah

The majority of human behavior, including consumer behavior, is learned. Acquired solely through social contact with other human beings, this enormously complex system of learned ideas, beliefs, norms, values and behaviors is referred to as "culture." This paper explores culture in the context of a specific set of learned attitudes regarding the use of numbers and letters in brand names. Focusing on American society, the authors delineate and analyze patterns of learned associations and multiple meanings associated with alpha-numeric brand names and brand name components. Our data suggest that brand names send powerful, sometimes unintended messages to the consumer, thereby affecting perceptions and behavior.

At birth, the human animal is virtually a *tabula rasa*, waiting for that learned complex of behaviors called culture to provide understanding, sustenance and meaning. Among the messages to be socially inscribed are the interpretation of otherwise arbitrary symbols connected with the act of consumption. This paper explores the meaning of alpha-numeric brand names in American culture. The authors contend that, like other symbolic representations, brand names carry with them covert meanings. The American consumer receives powerful cues from the specific type of brand name under consideration here, alpha-numeric brand names. These cues are learned through experience with other products, gender constructs within the society, and other patterns of behavior and interpretation in American society.

CULTURE

Culture remains an underexplored topic in the field of consumer behavior. Although many theorists implicitly assume that culture affects consumer behavior, most scholars are either unaware of their own assumptions or choose not to explore fully the concept of culture. When culture is brought to the forefront of an analysis, it is often in the form of cross-cultural comparisons, a procedure which highlights differences among cultures but frequently fails to bring out the depth to which culture itself influences all human behavior. Prime examples of full, in-depth analyses of cultural effects on consumer behavior are few; Costa and Belk (1990), McCracken (1988, 1989) and Sherry (1990), for instance, represent exceptions rather than the rule.

Enculturation, Systems, and Cross-Cultural Comparisons

The influence of culture on the growing human being begins *prior* to birth through the eating, sleeping and other behavioral patterns of the pregnant mother. In the first few years of life, the human child is exposed to an elaborate system of shared understandings, "culture," which imparts meaning to actions, behavior, objects and existence. This process of acquiring culture is referred to as

enculturation (Durkheim 1895). Through both overt and covert means, the individual learns "that complex whole which includes knowledge, belief, art, morals, law, customs and any other capabilities and habits acquired by man as a member of society" (Tylor 1958, p. 1). Either through internalization of norms or through social pressure, members of a society understand and enact, or choose not to enact, the socially accepted behaviors and norms (Barrett 1984). Virtually all sensory inputs pass through the cultural screen, distorting the perception process selectively and skewing the interpretation of messages accordingly. Since the systems of meaning vary from one culture to the next, messages are interpreted differently. It is the purpose of this paper to determine the nature and extent of American cultural influences on the interpretation of messages encoded in alpha-numeric brand names.

Cultural anthropologists have described broad areas of cultural systems, the structure, function, meaning and interpretation of which vary from one society to the next. Among others, these broad areas include patterns of ownership, exchange and inheritance, social organization for production, distribution and consumption, and for decision-making, influence and control, ideas and beliefs concerning the cosmos and the nature of the world, social systems involving family size, form and function, extended kin and non-kin ties, gender constructs, and material culture.

Theorists in the fields of marketing, consumer behavior and international business have focused on several specific dimensions of human behavior as manifesting critical variations cross-culturally. Hall and Hall (1987, 1990), for instance, describe differences in speed, context, space and time. Harris and Moran (1987) deal with cross-cultural variations in leadership and management styles, communication, job expectations and performance, and work culture. Within consumer behavior, Wallendorf and Arnould (1988) have looked at object attachment and the meaning of possessions; other theorists have focused on specific cultures, describing them in depth and providing a basis for further cross-cultural comparison (e.g., Arnould 1989, Costa 1989, McCracken 1988).

Cultural Learning and the Interpretation of Brand Names

The case study presented here is concerned with alpha-numeric brand names. "Alpha-numeric" refers to those brand names which are mixtures of letters and numbers, the latter of which can appear either as digits or written out in word form. Examples include combinations of letters and numbers (e.g., WD-40; V-8; 3M) or words and numbers (e.g., Alberto VO5; Saks Fifth Avenue; Colt 45 Malt Liquor). In some cases, the numeric component actually describes a model or model number used by the consumer to identify the product. For example, in the case of "Porsche 911,"

the "911" is the model number. However, for the consumer, the number may be an important component of the brand name, identifying the specific product and distinguishing it from other brands such as the Porsche 914. In such cases, the model number itself is considered to be part of the brand name.

Excess Meaning

In the context of alpha-numeric brand names, three general areas of culture and cultural learning are implicated. First, numbers are a special category of symbols which carry "excess meaning." That is, a number is not just a number. Rather, like other symbols, a number evokes numerous thoughts and connotes many things beyond mere quantity, a fact which has been documented in many societies. In the United States, for example, three (3) is a "sacred" number (de Lys 1957), connoting Christianity and the triple God-head, strength and power (FBI, CIA are three-letter acronyms), and business acumen or quality (IBM, RCA). Euroamericans have numerous beliefs which involve numbers; 7 and 13 are thought to be "lucky" or "unlucky," for instance (de Lys 1957; Lasne and Gaultier 1984). According to a study by Knapp and Chen (1964), American respondents feel that small numbers are "simple, complete, and weak," whereas larger numbers (above three) are "smooth, powerful, complex and masculine." Similarly, odd numbers are seen as "lucky and powerful," while even numbers in American society are thought to be "smooth and feminine" (see also Battig and Spera 1962; Cockran and Wickens 1963). In many Native American societies, four (4) is a number with special meaning related to the four directions; in Chinese culture, eight (8) signifies good fortune:

"Eight indicates prosperity: on the 8 August 1988, 8-8-88, an unprecedented number of new businesses were registered or opened in Hong Kong in the hope that they would be blessed with this prized commodity...Likewise the number 4 is associated with death because the number and word death share a phonetic similarity...In Japan too the use of the number 4 is also to be avoided since the word for it, *shi*, is also the word for death" (McDonald and Roberts 1990, p. 13).

The "excess meaning" of numbers may be perceived at a subconscious level, as are perceptions of personal space invasion, territoriality and other aspects of the cultural code (Barrett 1984; Hall and Hall 1987, 1990). It should not be surprising to find that "excess" meanings associated with numbers in a particular society carry over into numbers used in brand names, thereby affecting individuals' interpretations and perceptions about the named products.

Gender Constructs

A second general area of cultural influence on the interpretation of brand names in American society is gender constructs. In all societies, the basic physiological differences of male and female are elaborated into complex gender schemata whereby

expected or "appropriate" modes of dressing, working, speaking and other behaviors, as well as personality characteristics, are attributed to individuals on the basis of gender. Because the enormous cross-cultural variation extant in gender constructs is not widely known among the general populace, these gender-based systems of differences are often perceived to be biologically induced rather than culturally created. In American society, learned gender constructs have included the *stereotypical* beliefs that, *in general*, males are "better" at math, more competent in technical matters, more quantitative in orientation, more impersonal and objective, less emotional and more "balanced." American women, on the other hand, are *stereotypically* considered to be less competent in math, less oriented toward quantitative perspectives, less able to handle technical equipment and technical matters well, more emotional and subjective (Bellah et al. 1985, Epstein 1988, Harris 1981, Kitzinger 1980). Careful scrutiny reveals an intimate connection between *learned* gender constructs and *learned* attitudes about numbers (see Deboer 1984; Markoff 1989; Marshall 1983, 1984; Marshall and Smith 1987; Newton 1986; Sherman 1983; Tracy 1987; Ware and Lee 1988). Discussion of the nature and origin of these stereotypes is beyond the scope of this paper. What is of importance, however, is that the stereotypes exist and seem to affect perceptions about alpha-numeric brand names; this connection is explored more fully below.

Learned Associations

The third area of culture critical to the interpretation of alpha-numeric brand names is learned associations of numbers, letters and names with specific products. It is important to recognize that this again is cultural learning that may result in sub-surface or unconscious awareness and interpretation. Thus, individuals are not always certain *why* they associate particular number and letter combinations with certain products. Our informants felt certain brand names seem to "fit" a product; other theorists have reported similar responses. Peterson and Ross' (1972) data indicate consumers may feel a certain product name is more suited to one product class than to another; their respondents felt "Whummies" was "remindful" of cereals, whereas "Nemlads" was not, for instance. Zinkham and Martin's (1987) study concluded that brand names which seem "typical" for a product category benefit from consumers' inferential beliefs. As a result, these products may be easier to promote than those in which the given name does not seem to "fit" the product (see also Anon 1985, Boyd 1985). In some cases, this perception of "fit" may be due primarily to learned associations of given brand names with particular products, rather than to gender constructs or other learned patterns.

As might be expected, it is difficult to separate the underlying bases of such responses from one another. This is at least partially the case because components of culture are so intimately related to one another. Like a complex woven tapestry, the various parts of culture are patterned and integrated. Thus, a respondent's interpretation of a brand name may be the

result of learned assumptions about certain sounds, letters or numbers, gender-based constructs, or associations with certain product categories. So, for example, the letter "X" may imply harshness and angularity, seem masculine to some informants, and remind respondents of fast, sporty cars through association with the Mazda RX-7 *all at the same time* (see Pavia and Costa 1991a; 1991b). We contend, in fact, that it is this patterning and integration, this mutual reinforcement of the various cultural facets, which makes some brand names seem so compellingly appropriate and others seem so dismally inappropriate.

Numerous studies indicate letters themselves may have subsurface or covert meanings to members of a particular society. For example, Dogana (1967), following Sapir (1929), found that speakers of Romance languages interpret certain vowels and consonants as "bigger." Taylor's (1963) work indicated English speakers associate G and K with largeness and T and N with smallness, while Korean speakers feel T and P imply largeness, and J and M indicate smallness. When studies such as these suggest the implied associations or meanings of the letters vary from one society/language to another, we can assume such variations are a product of learning and culture (see also Davis 1961; Heath, Chatterjee and France 1990; Schloss 1981; Schmitt, Leclerc et al. 1988).

The Enculturation Process

A final part of culture which deserves some attention here is the enculturation process itself. If, as we contend, members of American society learn that certain numbers and letters fit with certain products and that these numbers/letters/products have gender and other associations, at what point do such associations solidify in the individual? Our preliminary studies seem to indicate that these associations are largely congealed by the time American children enter adolescence.

INVESTIGATION AND INTERPRETATION

The Investigative Process

In order to examine more fully the 'excess' meaning of numbers and letters in alpha-numeric brand names, the authors used a combination of quantitative and qualitative methods. Literature searches and initial depth interviews helped define the parameters for eight focus groups of 6-10 participants each, using a total of 63 college-level informants. These qualitative methods were followed by a quantitative approach in which we administered open-ended questionnaires to 144 students. Presented with hypothetical alpha-numeric brand names, respondents were instructed to "describe the product that seems most appropriate to you to have this brand name."

In the most recent stage of the research, we attempt to determine the point at which children in American society begin to perceive and express an association between alpha-numeric brand names and particular products. To this end, the authors and

student assistants conducted 28 depth interviews with children aged 4 to 12. Based on the outcome of these interviews, questionnaires were designed and administered to 24 fourth grade children, 9 and 10 years of age (5 female; 19 male). The findings from these questionnaires were consistent with those from the depth interviews. All data bases are open and available for verification and perusal by other researchers.

Cultural Interpretation of Alpha-Numeric Brand Names

A brand name provides important information to the consumer which can affect consumer interpretations and purchase decisions. The data provided in our study support the contention that brand names send important culturally-based messages to the consumer; the content of the messages is determined by and interpreted through a cultural screen; it is, therefore, intimately related to and integrated with other parts of the culture.

Marketers generally agree that a brand name should be distinctive, descriptive, short and easy-to-say and remember (Kotler 1988). For cross-cultural effectiveness, McDonald and Roberts (1990), following Collins (1977) indicate the brand name should also be "easy to read in all the countries in which the brand is to be marketed" and "of such a verbal form as to have semantic and or symbolic associations, i.e. conveys feeling" (1990, p. 10). The latter recommendation is of particular interest to us in the context of this study. Our data indicate consumers often have strong, if subsurface, feelings about the brand names they encounter. These feelings have numerous sources, learned through association with other products, through shared cultural ideas about certain sounds and figures, or through other cultural contexts.

In American society, it is apparent that a clear, strong relationship exists between gender constructs and numbers. This relationship carries over into interpretations of alpha-numeric brand names. Our data indicate American consumers tend to associate alpha-numeric brand names with complex, technical products, such as computers, radios and stereos, cars and planes. Additionally, they believe alpha-numeric brand names are appropriate to express chemical content, scientific formulae and nutrient value. Both the qualitative and quantitative data support this finding. The focus group responses presented below are representative of consumer interpretations of alpha-numeric brand names as indicative of the technical and scientific (focus group number and informant gender indicated):

- (FG#3) F: I think anything scientific, something that denotes that it's higher technology is appropriate [for an alpha-numeric brand name].
- (FG#5) M: Well, they use a number because of science.
- (FG#5) M: ...any number denotes high-tech, in my mind, you know.

In the open-ended questionnaires, respondents were presented with hypothetical brand names and were asked to free associate, describing what types of products they felt would "go with" the presented names. The association of alpha-numeric brand names with cleaners, soaps or detergents and with cars and car-related items was strong and consistent. For example, fully 67% of the informants indicated "A 909" would be an appropriate brand name for such products. When the "A" was changed to an "X," the underlying association of certain *letters* with technicality became more evident; 84% of respondents felt "X 909" would be an appropriate brand name for soaps and cleaners or car and car-related items, for example. Those responses which could not be categorized as cleaners/soaps/detergents or car and car-related items nevertheless indicated items that are technical or chemical in nature: computer, CD player, scientific calculator, high quality mountain bike, and bug spray.

Informant responses to questions concerning what type of product would have an alpha-numeric brand name reinforced the gender-based association of products and alpha- numerics:

- (FG#1) M: Motorcycles or airplanes or computers or something that at least until recently were more a part of a man's domain, so therefore, more a man's product...
- (FG#2) F: I think, as far as cars go, the numbers are more for the masculine, because the higher they are, the more powerful the car is. Whereas women don't care as much about how powerful it is.

The data became increasingly interesting as we began to explore the meanings associated with *specific* numbers and letters. In this context, it became clear that underlying, often unconscious, meanings of particular numbers and letters are intimately related to gender constructs in American society. Thus, informants said:

- (FG#5) M: I don't know, a smaller number, twenties or teens, might denote a feminine number...
- M: Maybe the smaller numbers denote petites...
- (FG#8) M: I think larger numbers like four digit numbers, five digit numbers, seem more masculine, too, than, say, smaller numbers, like 55. And even triple digit numbers seem feminine, I don't know why. But larger, like 10,000, sound masculine, seems masculine to me.

In some cases, informants indicated the shapes and sounds of both letters and numbers are related to American gender constructs. Thus, "soft," "rounded," "flowing" numbers and letters are interpreted as feminine; while "harsh," "angular," "blunt" forms are suggestive of masculinity:

- (FG#5) F: I was thinking that 36 might be feminine...I was thinking of, like, when you said 88, the shapes of the numbers, I think make a big difference...
- F: Like 44, to me, seems masculine. It's very sharp, it's very cut, it's very precise, square...
- M: And the numbers that seem, that are rounder and softer, it makes a difference somewhat.
- (FG#6) F: I kind of think a number like 21 is kind of masculine because it's just kind of blunt, kind of like - - hard.

The association of angular form with technical, hence stereotypically male in American society, was further supported by the open-ended questionnaire data, as indicated above in the example of "A 909" versus "X 909" (see Pavia and Costa 1991a for further discussion). As number and letters are combined into brand names, the gender-related meaning is carried over into both the name and the product, then, if we accept the contention that Americans stereotype "technical," "powerful," "large" or "scientific" as more related to males than to females:

- (FG#5) M: It seems that like the number/letter combination names -- and I never thought of this before -- but, it seems like the majority of them denote some masculine product, or at least some masculine image when you think of them. I'd never thought of that before, but it seems like most of them are masculine. I don't know. Is there a reason to have more products in those categories [that] have a masculine image? Do you think of males when you think of technology, or advanced features, or those kinds of things?
- M: Yeah, kinda, only because I don't think women are pushed into science.

Our research with children indicated that the perceived association of alpha-numeric brand names with specific types of products is already manifest in some children by the age of 5 or 6. By 9 years of age, the associations are even more prevalent and predominate the fourth grade sample. Thus, "A 2"

consistently suggested the technical; responses included "robot," "scientific calling of something," "computer" and "plane," for example. On the other hand, "Whummies" was suggestive of softness, animals, candy and toys: "gross squishey things," "little animals," "toys that are soft to hit people with," and "a good!! food." While the alpha-numeric brand names were consistently identified with 'technical' products, however, the association of this type of products with masculinity is emerging, but not solidified by this age. For example, while some informants indicated "XV75" would be an appropriate name for "airplane, new and improved robot, car, a secret submarine, tank, a code word, VCR," and that such products are "boy" products; others felt "XV75" would suggest "car motor, car (2 responses), jet, robot (2 responses), computer, B-1 bomber, missile, radio station, explosive, code, license plate," but that these products had no gender distinction, being neither consistently "boy" or "girl" products. It appears that such gender associations, perhaps not surprisingly, may solidify during adolescence. By the time respondents reach college age, the age of the majority of those in our combined samples, gender-based interpretations were definitely forthcoming. It is important to recognize, as well, that American culture changes rapidly and that, despite a mere 10 years' difference in age between our college-level informants and the fourth grade sample, quite different gender stereotypes may be developing.

CONCLUSIONS AND IMPLICATIONS

It has been possible here only to consider briefly the numerous culturally derived connotations and interpretations associated with brand names. Our data indicate that alpha-numeric brand names carry "excess" meaning. A consumer in American society, confronted with an alpha-numeric brand name, is thus likely to receive messages about the product which go beyond the manifest, surface content and evoke underlying cultural constructs related to gender and product type. While we have focused on alpha-numeric brand names, our adjunct data and the studies of numerous other theorists indicate brand names in general carry meanings and evoke interpretations beyond those immediately evident.

Specifically, as the American consumer matures, he or she is exposed to numerous messages which indicate that gender and numbers are related in very specific ways. These messages are derived from past association of certain types of names with certain products, through cultural stereotypes regarding male and female expertise in science and math, or through other learned beliefs and attitudes about gender-based personality structures and behavioral patterns. In any and all of these cases, the gender-based meaning is transferred to various components of the alpha-numeric brand names, resulting in the phenomenon of "excess" or covert cultural meanings attributed to the brand/product.

In order to understand the full impact of culture on consumer behavior, it is appropriate to focus on very specific, context-bound examples. In this paper, we have attempted to provide a brief illustration,

elaborated upon elsewhere, of the ways in which culture is manifest in and affects consumer interpretation of brand names. Our analysis points to the complexity of culture and its effects, specifically delineating the patterned and integrated interactions of various cultural components and systems. Thus, in the case presented here, we have illustrated the interwoven nature of product category, cultural expressions of masculinity and femininity, and arbitrarily assigned symbols in the form of alpha-numeric brand names. It is clear that culture influences interpretation and behavior in numerous and varied ways. We conclude that culture as a construct is critical in understanding consumer behavior in general and that culture must be incorporated more fully into analyses by consumer behavior theorists. As meaning is created and shared by members of a society, they encode that meaning in and through various objects, persons and symbols. We have tried to show here that the components of alpha-numeric brand names are culturally encoded in this way.

Through the alpha-numeric brand name case presented, we believe we have shown both the analytical and theoretical importance of utilizing the concept of culture in consumer behavior studies. The way in which alpha-numeric brand names capture cultural themes has managerial implications as well; appropriate branding strategies can be undertaken only when the marketing manager understands the culturally derived meanings of the specific numbers, letters or other symbols utilized in the brand name. Given the cultural basis of the interpretation, the work presented here suggests that a thorough investigation of the covert or "excess" meanings of given characters is particularly important in the context of developing international brand names or brands for diverse ethnic groups, where products are expected to cross cultural boundaries.

Meaning Construction in a Cultural Gallery: A Sociosemiotic Study of Consumption Experiences in a Museum

Jean Umiker-Sebeok, Indiana University-Bloomington

ABSTRACT

The recent cross-fertilization of different semiotic traditions has resulted in a sociosemiotics that combines sophisticated textual analysis with a pragmatic, socially-situated approach to meaning and message reception, and this new form of sociosemiotics has proven a useful tool for investigating a wide variety of marketplace behavior. This paper presents a study of visitor experiences in a cultural gallery of the Indianapolis Children's Museum. The study made use of this methodology and perspective, along with Mihaly Csikszentmihaly's concept of optimal experience and George Herbert Mead's notion of the collapsed act of the artefact. It is argued that the meanings the gallery has for visitors are the product of a complex interaction between the pragmatic strategies visitors (and their partners) bring to the experience and the meanings implied by the ways the displays themselves are structured.

CHANGING PERSPECTIVES ON BEHAVIOR IN MUSEUMS

At the same time that a growing number of voices are demanding that increased attention be paid to the full range of human experiences in museums, and to the social and political contexts of those experiences (e.g., Annis 1986; Carr 1990; Grabum 1977; Karp and Lavine 1991; Kelly 1987; MacDonald and Alsford 1989; Véron and Levasseur 1989; Zunzunegui 1990), evaluative research done in museums, even when using naturalistic observation methods (e.g., Wolf 1980; Wolf and Tymitz 1979a, 1979b) continues to be dominated by a positivistic paradigm in which the transfer of educational content from curator to individual visitor is assigned a preeminent position (see, e.g., the review in Screven 1984). Based on an implicit Durkheimian split between the *cognitive*, seen as problem-solving, rational, and individual, on the one hand, and the *emotive*, seen as irrational and social, on the other, evaluation tends to take on the task of solving the curatorial problem of how to teach visitors for whom a visit to a museum is first and foremost a social experience, pursued as a leisure activity and with the primary goal of entertainment and self-enhancement. Screven outlines this situation as follows:

There is nothing wrong with free exploration and social interaction in exhibitions. There are very important natural elements of human behavior in museum environments and *probably are among their major attractions*. But if exhibitions are to serve educational purposes, these features must be *harnessed*. The challenge is to link communication objectives with these intrinsic exploratory, social and recreational interests. (1986, p. 113) [emphasis added]

In this perspective, human behavior that an android such as Data on "Star Trek" would have trouble understanding is lumped together and, to pursue Screven's metaphor, seen as the "baser" part of human nature that must be "harnessed" or "put to good use" in the interest of cultivating the "higher" human behavior of learning "substantive content" or "information-processing."

This model is not only hierarchical in terms of visitor "motivations" or drives, but also in terms of the social relationship between the curator, a content expert with specialized knowledge stored in his or her head, and the visitor, a fun-seeking novice whose head needs to be filled with new ideas, if only one can distract him long enough to "get through" the annoying filter of socializing, dreaming, status seeking, emoting, and the like; (cf. Karp and Lavine 1991; MacDonald and Alsford 1989). It is no wonder that, with this the model implicit in the majority of evaluative studies, "the interaction between viewer motivation, exhibit content, the museum environment, and visual design are complex and poorly understood by both psychologists and exhibit planners...[and] better information must be obtained about how viewers respond to and learn from the design and content of displays" (Screven 1986, p.118-19). As Miles and others have noted, most museum visitors are "casual" ones, who spend only a few seconds at each display and are "concerned with the consummatory rather than the educational use of knowledge, i.e., they are using it for pleasure and for passing the time in a largely passive way." (Miles 1987, p. 121). Before museums can accomplish their acknowledged educational goals, they "must above all begin to pay attention to their visitors' concerns, interests, expectations and so on, and make an effort to speak to them in a familiar language." (Miles 1987, p. 121)

This reorientation requires a radically different model of human behavior and society than the information-processing and information-transferring one. Carr (1990), drawing upon Polanyi's concept of "indwelling" and Jerome Bruner's narrative psychology, uses the metaphor of the museum as an

evocative text, a private mnemonic environment that summons a range of memories, thoughts, and meanings—images like those we find surviving in diaries and letters, in accumulated snapshots of enduring experiences, in fragments and allusions. The user carries permanent, evolving texts and an array of private captivities: visions, dreams, encounters without language. In the presence of objects we go beyond objects to recognize our continuous histories. Out of these continuities we articulate silent hypotheses, and as we gain new information, we alter them. Each new encounter in the museum means the

revision of one life: new understandings, even drastic or unexpected reorganizations expand the bursting backpack we carry. The museum is a place for the dreamer to see private dreams in public places, deep memories framed anew. The content of the museum has to do with choices and desires, with things that please the senses, satisfy values, and explore human fears. In museums we are living examples of Jerome Bruner's idea that 'perceiving takes place in a tuned organism' (Bruner 1973, p.92). The museum evokes those strands of experience and memory that human beings use to attune themselves, to remember themselves, to remember themselves as actors framed by the continuities in their lives. (1990, p. 368-69)

Learning in a museum must be *re-creation* "to create anew, to restore, refresh" (Quinn and Bedworth 1987; cf. Zunzunegui 1990), addressing on an equal footing the intellectual, sacred, and social needs of visitors (cf. Graburn 1977; Kelly 1987; MacDonald and Alsford 1989) rather than catering primarily to cognitive needs. Evaluation must involve investigative techniques that can provide what Clifford Geertz calls a "thick description" of visitor experiences in museum settings.

A SOCIOSEMIOTIC APPROACH TO BEHAVIOR IN MUSEUMS

Semiotics, like other human sciences, has been caught up in just such a shift from a positivist to interpretivist approach to human behavior. Culture is now viewed not as a stock of information transmitted passively from generation to generation, but as sets of strategies for transacting or negotiating meanings and thereby resolving dilemmas. Renouncing the Durkheimian split noted above, what is sought is the elaboration of a "theory of active social actors, located in time and space, reflexively and recursively acting upon the world in which they live and which they fashion at the same time" (Lave 1988, p. 8). Culture and cognition are seen as two aspects of the same phenomenon. Cognitive processes are culturally constituted phenomena.

...the central concept of a human psychology is *meaning* and the processes and transactions involved in the construction of meanings.... This conviction is based upon two connected arguments. The first is that to understand man you must understand how his experiences and his acts are shaped by his intentional states, and the second is that the form of these intentional states is realized only through participation in the symbolic systems of the culture. Indeed, the very shape of our lives—the rough and perpetually changing draft of our autobiography that we carry in our minds—is understandable to ourselves and to others only by virtue of those cultural systems of interpretation. But culture is also constitutive of mind. By virtue of this actualization in culture, meaning achieves a

form that is public and communal rather than private and autistic. (Bruner 1990, p. 33)

One of the byproducts of this shift in semiotics is the growing emphasis on meaning as a socially-situated process determined not by the code which enables a sign to stand for an object so much as the relationship of the sign to other signs which also represent that object, that is to the sign's interpretant signs. This Peircean view of semiosis "allows for a much more hermeneutic concept of interpretation, where meaning develops out of a continuing translation of the sign" (Liszka forthcoming, p. 18). As a pragmatic theory of semiosis, the intentions and problem-solving goals of sign users also become an indispensable part of the semiosis.

This view of semiosis as dialogic and interpretive implies a dynamic concept of communication, contrary to that of Ferdinand de Saussure, which, "based on Locke's theory of telementation,... was simply the transference of thoughts from one human mind to another by a process of decoding and encoding." (Liszka forthcoming, p. 18). Although Saussure saw semiotics as a part of the social sciences, he conceived of culture as a pool of *knowledge* and thus, in effect, did away with any serious attention to the socially situated nature of signs and communication. Over the last dozen years, there has been such a vital cross-fertilization of ideas between the Saussurean, code- and language-centered semiology and the pragmatic, interpretive, Peircean-inspired semiotics that it would be difficult to find any semiotician today who did not believe in the necessity of developing an interpretive, pragmatic sociosemiotics. This has been especially fruitful for the study of marketplace behavior and communication, resulting in a flowering of hybrid studies combining sophisticated narrative and rhetorical analyses not just of texts (in the broad sense this term has in semiotics) but of consumer responses to them. Pragmatic semiotic studies have ranged over a wide spectrum of consumer contexts—including subways, banks, museums, libraries, gift shops, swap meets, and hyperstores— and message forms—including print ads, TV commercials and programs, clothing catalogs, packaging, a wide range of consumer products, magazines, and newspapers, to name a few (see, e.g., Bachand and Cossette 1988; Defrance 1983, 1986, 1987, 1988, forthcoming; Floch 1988, 1990; Fouquier 1984, 1986, 1988, forthcoming; Fouquier and Véron 1985, 1986; Péninou 1972, 1983, 1988; Semprini 1990a, 1990b, forthcoming; Véron 1983, 1985, 1989; Véron and Levasseur 1989).

MODEL OF MESSAGE RECEPTION

The model of message reception chosen for the current study of museum visitors takes reception to be a form of social action and self-expression, rather than passive re-action. Summarizing this model for marketing scholars, Fouquier writes:

Reception hinges on a series of partial synthetic moments, namely *figures*. These

objects, which thus become the fundamental subject matter of analysis, are composite units, *arranged in chain-fashion*, partially or wholly combining three links, namely an operation, a motif and a resonance. These links need to be seen as experiential qualities of various kinds (subjectively felt experiences, cognitive contents, emotions, etc.), partly generated by the structure of the work, and partly by the receiver. Figures may differ in 'length', they may be more or less complete (some have only one link, others display all of them). These links are interlinked into a *dynamic*: a particular aspect of the work may stimulate a specific reading operation, which in turn triggers a given resonance, depending on some internalized disposition, and in the process the text is compared or contrasted with another particular text, which in turn gives rise to a judgement based on some internalized norm whose subsequent effect is to direct the attention — and hence the motifs one perceives — to this or that aspect of the text, and so on....subjects clearly hierarchize the different components of the figures that they experience...[and] the link that is stressed [is called] the *theme* of the figure. (1988, p. 341-42).

Operations may be behavioral, perceptual, or cognitive. *Motifs* are plastic (the physical, perceptual space of reception), worldly (the fabricated, sometime fictitious space of the message), or pivotal (a space where the receiver observes the worldly space from his or her own particular vantage point and takes a position vis-à-vis the message). *Resonances* include emotions, evocations or associations, cognitions, and incitements. The system of internalized skills, or *habitus*, against which reception of a particular message takes place includes: "a *repertoire* of forms, themes, knowledge, a background culture with the aid of which receivers classify, nurture, compare and complete what they read..."; *centers of interest*; *postures* or attitudes toward certain kinds of messages; and "the individual's *horizons of expectation*, personal 'canons,' or system of preferences, tastes, expectations with regard to forms, styles, languages, stories, rhythms..." (Fouquier 1988, p. 338). Reception, in this conception, is a "process of confrontation...a ceaseless process of comparison" between the message and [the] *habitus* (Fouquier 1988, p. 338).

OPTIMAL EXPERIENCE AS A PART OF *HABITUS*

One of the first goals of the study of visitor experiences in the Passport to the World gallery of the Indianapolis Children's Museum was to identify major variations in this confrontational process of interpreting gallery exhibits. This would include a description of visitors' expectations concerning optimal experiences, an important schema for structuring the gallery visit. The reception of the gallery's "messages" takes place within the lived

narrative of the visit itself, which can be looked upon as a form of social drama in which visitors seek out, as best they can given the particular circumstances of their visit, what Csikszentmihalyi calls "optimal experiences":

The optimal state of inner experience is one in which there is *order in consciousness*. This happens when psychic energy—or attention—is invested in realistic goals, and when skills match the opportunities for action. The pursuit of a goal brings order in awareness because a person must concentrate attention on the task at hand and momentarily forget everything else. These periods of struggling to overcome challenges are what people find to be the most enjoyable times of their lives. (Csikszentmihalyi 1990, p. 6)

In a crowded museum gallery, the achievement of optimal experience requires a willing plunge into the concentrated drama of personal (or, it should be emphasized, *interpersonal*) struggle within the context of a particular display, no easy task given the many sources of distraction or obstacles to an unimpeded approach to and interaction with an exhibit. Like any form of dramatic action, attention must be focused on the logic of the drama itself, with other interpretive schema, such as that of the ritualistic "doing" the museum and gallery, which the vast majority of museum visitors bring to their visits (Falk 1981), temporarily shifted into the background (which does not mean that they do not help to shape the optimal experience). (In fact, for want of additional pages, this paper is arbitrarily abstracting a visit to the Passport to the World gallery from the other events in which it is embedded, such as the visit to the rest of the museum, other activities planned for a Saturday afternoon, etc., all of which contribute to the meanings created for that gallery. See Umiker-Sebeok 1991a for a full discussion of this process of the intermeshing of narrative schema.) Optimal experience is a form of dramatic narrative, obeys the laws of narrative logic, and therefore different expectations about it may be described through application of narrative analysis. Since visitors organize their experiences in terms of stories, narrative analysis is an important part of this, or any, sociosemiotic study. The form of analysis used in this study, as a part of the description of message reception patterns, is described most succinctly in Courtés 1991. On the importance of narrative to the study of human behavior and for research interview analysis, see, e.g., Bruner 1990; Mishler 1986; Sarbin 1986.

THE TEMPORAL STAGES OF RECEPTION

A final layer of framing involved in visitor reception of the gallery is the temporal sequencing of the visitor's interaction with displays. Objects are assigned a privileged place in a sociosemiotic model of consumer interpretation since they are not defined, following McCracken's suggestion, as a mere "diacritic of culture" but powerful rhetorical devices

due to their concreteness, use as synecdoches, economic value, ambiguity, and ability to persuade below a conscious level (McCracken 1988). Meaning and identity are created as much through what George Herbert Mead (1934) called the "collapsed act of the artefact" as through interaction with generalized others:

As we interpret self from the perspective of the other, so we also take the perspective of the object. As we interpret the group from the position of the generalized other, so too we define our acts from the perspective of objects generalized (one might say contextualized) into a setting. As generalized, the setting becomes a constellation of acts collapsed into symbols which, like the generalized other, inform our actions and give them their particular character. (Richardson 1989, p. 174).

The three stages of Mead's collapsed act of the artefact provides a simplified model of the sequence of steps through which a consumer interacts with exhibits and transforms them into significant symbols. In the first, *perceptual*, stage, the visitor must perceive an invitation to engage with some possible world. In this future-oriented phase, what Peirce (1931-66) called "firstness" is dominant, with the object's iconicity signalling various possibilities for interpretation and action.

Assuming that the consumer accepts the invitation to engage the world represented by the object, the second, *manipulatory* stage is marked by the interaction of the consumer with the object, during which he or she experiences its "otherness." Here, in this emergence in the present, "secondness" reigns, as the consumer explores the indexical aspects of the exhibit, its links to "reality" and existence.

As a result of his or her preceding acts of interpretation, in the third, *consummatory* stage the consumer translates the exhibit into a symbol, or conventional sign. In this, past-oriented phase, "thirdness" (habit, law, or rule) predominates. The symbols that emerge in this third phase are the stuff of the visitor's *habitus*, and inform future acts of interpretation.

METHODOLOGY

In the study of the Passport to the World gallery of the Indianapolis Children's Museum, 41 visitors were randomly chosen from among visitors approaching the gallery. Ranging in age from 5 to 75, 21 subjects were male, 20 female. They were asked to visit the gallery in any manner that they felt was natural for them and their partner(s). They were then tracked through the gallery, with an observer noting on a floorplan where they went, paused, and stopped, as well as what they did and said. When visitors indicated that they had completed their visit to the gallery, they accompanied the observer to a nearby room where they were interviewed. The first part of the interview consisted of survey questions eliciting demographic and lifestyle information about them and their families as well as queries concerning their

overall visit to the museum. Subjects were then asked to "draw a map" of the gallery on a plain, 8 1/2 by 11 inch piece of paper. Following this, the observer initiated an open-ended interview, based on the model presented in McCracken 1988, which was structured around the visitors' narrative account of their trip through the gallery.

A first, sociosemiotic analysis was made of the maps and interviews. This included a structural-generative analysis, described in detail in Courtés 1991 and Floch 1988, 1990, for verbal texts, and in Semprini forthcoming, for the maps. A pragmatic discourse examination of these texts according to a model described in Fouquier 1988 was also made. For a more complete description of the methods used, see Umiker-Sebeok 1991. On the basis of these analyses, visitors were classified into four major groups, representing four primary reception themes or strategies, as described below.

With this classification in hand, each of the 54 permanent gallery exhibits was analyzed according to which types of visitors were attracted to it and which were not, and whether or not it provided different types of visitors with something approaching an optimal experience (as judged by their descriptions in interviews). Using the same sociosemiotic methods used for the analysis of interview narratives, a cross section of exhibits of varying degrees of attractiveness and success in providing optimal experiences was analyzed in detail in order to provide an explanation of visitor interpretations and experiences in terms of the three stages of the collapsed act. In other words, how successful were exhibits in attracting one or more groups through the three stages of interaction, and why?

RESULTS

The 54 permanent exhibits showed a wide range of levels of attraction and engagement, from those at which none of the visitors in the study stopped to one where 73% stopped. Less than half (24) of the permanent gallery exhibits attracted 50% or more of one or more types of visitor (as described below). Of these, twelve attracted 50% or more of only one of the four groups, five 50% or more of two groups, two 50% or more of three groups, and five 50% or more of all four groups. In all, only 10 exhibits attracted 50% or more of all visitors. Thus, most of the gallery permanent exhibits appear to have lacked the semiotic structures required to engage visitors, especially two groups (utopian and pragmatic), which constituted 61% of the visitors. Only 10 of the 54 permanent exhibits in the gallery attracted 50% or more of all the subjects, and only five provided an experience that might be called one approaching "optimal". 50% or more of the critical group—the smallest of the four groups—found fully 20 exhibits attractive, and the next largest, utopian group, was attracted to 11. The largest, diversionary group was attracted to only 7 exhibits, the next largest, practical group to only 9.

As Csikszentmihalyi (1990) has reported, people can create optimal experiences through a wide variety of activities, and individuals are not limited to one source of such experiences. The same was true in

the gallery under study, where visitors reported peak experiences in interaction with a number of diverse exhibits. On the other hand, from examination of the *habitus* visitors brought to bear on their gallery experiences (described fully in Umiker-Sebeok 1991), it was found that individual visitors tended to employ fairly consistently one of four basic strategies of reception — called pragmatic, critical, utopian, and diversionary —, each of which structures the gallery visit in a different manner. It is assumed that, given the socially-situated nature of all interpretation, a given individual might change his or her strategy in different contexts, depending on a number of variables such as the social relationship he has with his or her companion(s), his or her personality, mood, amount of time already spent in the museum, types of preceding and anticipated experiences in the museum, and so on (see Umiker-Sebeok 1991 for a discussion of these factors).

Figure 1 presents a schematic representation of these four reception strategies are described briefly below.

PRAGMATIC RECEPTION STRATEGY

29% of visitors, ranging in age from 7 to 75 (average age = 21), were classified as relying predominantly on the pragmatic reception strategy. The group was evenly divided between males and females. The average time spent in the gallery was 28 minutes, with visits varying from 6 and to 70 minutes.

For the *pragmatic* strategy, the primary figure of reception is utility, and optimal experience is defined as the efficient accumulation of a store of either new information which can be applied outside the museum setting, or new applications for existing facts. Utilitarian values are a key part of this strategy, with the gallery as a type of (work)shop for the acquisition of discrete skills or ideas.

For this group, the first, perceptual stage of interaction with an exhibit must be marked by the perception of the potential for the optimal experience, defined, again, as the acquisition of a useful idea or skill. Not only this "content" must be present, but it must be communicated in a way that is efficient and promises a timely manipulative stage, for this group of visitors will not "invest" time in interacting with an exhibit unless they can judge, during the perceptual stage, that there will be a concrete "payback" for spending time at the display. The musical displays in the gallery, for example, attracted this group by promising experience in learning to play a tune or communicate through music, an underwater scene through providing information about solutions to pollution, or a storytelling performance by furnishing examples of the skill of storytelling.

During the second, manipulatory stage, this group favors a rational verbal and visual presentation of easily-identified "information" or training in a practical skill, with emphasis on concrete problem-solving applications. The experience at this stage should be challenging, but with easy-to-reach and easy-to-operate exhibit elements. This group likes to engage in practice aimed at achieving a defined goal,

or manipulations which result in the concrete application of information to problem-solving.

If the first two stages have been successful, the pragmatic visitor will come away with the satisfaction of knowing that he has acquired a new piece of useful information, a new skill with which to solve the problems presented by the world. The experience of the exhibit will have become, within their narrative schema of the trip to the museum and gallery, a generalized symbol of a rational, utilitarian approach to life, with the visitor playing the hero of the drama and the museum the role of helper-instructor.

While space limitations make it impossible to describe in detail the interactions between the features of exhibits and their reading by different groups (for this, see Umiker-Sebeok 1991), we may briefly summarize some of the dominant elements of this type of reception framework (see Fouquier 1984):

The preferred image of the *message sender* (called the *constructed message sender*) (i.e., the positions the sender attributes to himself and including the relationship between the sender and what is said) is that of a experienced (but not necessarily professional) instructor.

The preferred image of the message receiver (called the *constructed receiver*) is that of problem-solving learner or apprentice. The preferred figure of *enunciation* (specifying the relation(s) (e.g., pedagogical, ludic, persuasive) within the message between the constructed sender and the constructed receiver) is pedagogical. The preferred figure of the world as represented in the message (i.e., *the constructed world*) is that of a reality to be controlled through the application of appropriate methods. The preferred figure of *modalization* (representing the type of relationship existing between the constructed sender and the reality about which he/she speaks) is that of a person who has mastered control of a part of the world. The preferred figure of *implication* (characterizing the relations that the constructed receiver is supposed to establish with the reality being shown in the message) is that of mastery of means-ends relationships with the world. The preferred figures of *expression* (translating the relationship that the sender maintains with his own message as a formal product (e.g., as the implied author, paid presenter of a message authored by someone else, etc.) is that of implied author or a professional communicator talking about someone else's mastery. The preferred figure of *perception* (constructing the relations between the constructed receiver and the message as an ensemble of signs, e.g., active vs. passive message reception) is that of passive receiver of information but in the interest of actively using the information outside the museum context. The preferred figures of *representation* (including the different "manners" or "forms" the message adopts in order to present reality (e.g., direct vs. indirect, as narrative or analytical discourse) are direct, factual descriptions and demonstrations with possibility for repetition by the visitor.

CRITICAL RECEPTION STRATEGY

17% of visitors, ranging in age from 10 to 49 (average age = 28 years), were classified as relying predominantly on the critical reception strategy. This was the only group where males constituted a significantly greater percentage (71%) than females. The average time spent in the gallery was 40 minutes, with visits ranging from 10 to 74 minutes.

The *critical* visitor favors the acquisition of ideas, which are valued for their form or place in an abstract order, whether or not this proves "useful" in any concrete way. The visit is evaluated in terms of non-existential values as well, as a principle of organization or abstraction rather than as a tool. For this form-, collection- and classification-oriented group, visits tend to be long and thorough in comparison with those employing other strategies. The metaphor of the gallery as a museum might evoke the interpretations of those employing this strategy. The optimal experience for this group is the production of new models of the world, either in terms of form or content.

During the first stage of interaction with an exhibit, the critical visitor is less concerned about the efficiency of the interaction than that it will involve an intellectual or aesthetic challenge. While the practical visitor might judge the musical displays on the basis of its being identified as a tool of communication or for the opportunity to learn to play a tune, the critical visitor was more likely to be attracted by the promise of identifying the geographical source of the music, the comparison of different aesthetic styles of the music, or for appreciation of the collections of musical instruments (with collections seen as objectival forms of classification). This first stage need not promise an efficient, economical approach to the optimal experience, but it must promise the challenge of ordering information in ways this group finds attractive.

During the second stage of interaction, the task of identifying a "proper" order is more important than the amount of time it takes to do so, within the constraints of the optimal experience as involving "reasonable" tasks, and so visits by this group on average lasted much longer than those of other groups. Critical visitors often spoke as if from the vantage point of a curator rather than that of a visitor, as they tried to relate particular exhibits to the general themes of the gallery in order to divine the overall schema of knowledge they assume the staff intended to communicate. Their manipulations of the exhibits tend to be thorough, doing most of the things that the exhibit suggests they do, including reading long written messages (a rare occurrence outside this group).

If the first two stages have been successful, the critical visitor will come away from an exhibit with a sense of satisfaction in having mastered a subset of knowledge, another chapter of a textbook, and the exhibit has become a generalized symbol of that knowledge as well as the visitor's skill in conquering its subtleties. The ideal visitor in curators' minds, the

challenge for this group is to assimilate the order imposed by the curator, rather than finding a person meaning.

The preferred image of the *message sender* is that of a professional lecturer. The preferred image of the message receiver (*constructed receiver*) is that of expert. The preferred figure of *enunciation* is pedagogical. The preferred figure of the *constructed world* is that of a reality to be understood or modelled. The preferred figure of *modalization* is that of someone who organizes and focalizes information about the world. The preferred figure of *implication* is that of evaluation. The preferred figure of *expression* is that of professional communicator. The preferred figure of *perception* is that of active organizer of information. The preferred figures of *representation* are the direct statement of rules or collections that exhibit logical system of classification.

UTOPIAN RECEPTION STRATEGY

22% of visitors, ranging in age from 8 to 40 (average age = 22 years), were classified as relying predominantly on the utopian reception strategy. This was the only group where females constituted a significantly greater percentage (67%) than males. The average time spent in the gallery was 24 minutes, with visits ranging from 7 to 42 minutes.

The *utopian* strategy defines the visit in terms of its expression of existential values, with the optimal experience involving an imaginative self-exploration, preferably as a joint achievement with significant others, either companions or friendly gallery workers. While those employing this strategy of interpretation as the gallery visit becomes an act of self-expression, including a kind of group expression in which the visitor and his or her companion are intent on an expression of their social relationship. The metaphor of the gallery as a hall of mirrors is appropriate for this group, and the experience of the gallery itself becomes one of the values sought in the utopian narrative schema.

During the first stage of interaction with the exhibit, the utopian visitor requires a promise of a reality and challenge that can be approached through conjoint effort with his or her companion(s) in the gallery and/or one that offers self exploration through interaction and imagining "the other". Musical exhibits were attractive to the utopian visitor, for example, if they promised a shared listening or communal dancing experience, the possibility of recalling significant, music-related events in the visitor's life, or the exploration of ethnic identity. An underwater scene opened up the possibility of imagining a new and different "world" and thus adding to their stock of experiences with which they may shape their identity through identification of their personal reactions to it.

The manipulative stage for the utopian visitor must provide indices of the visitor's self, and the challenge becomes one of achieving the recall of memories or the creation of self-reflective "other worlds" through acts of imagination. Manipulations of exhibits by this group are quite varied, in keeping

with the conception of the gallery visit as a form of self-expression rather than an assimilation of the messages intended by curators. This group, more than any other, engages in the joint manipulation of exhibits.

If the first two stages have been successful, the exhibit has become a generalized symbol of the social identity of the visitor, who plays the hero in a story about extending the bounds of the imagination and self-awareness, the visitor's companions and volunteer workers in the gallery being cast in the role of helpers-communicators.

The preferred image of the *message sender* is that of an empathic facilitator, professional or non-professional. The preferred image of the *constructed receiver* is that of sensitive companion. The preferred figure of *enunciation* is inspirational. The preferred figure of the *constructed world* is that of possible worlds to be experienced. The preferred figure of *modalization* is that of someone who explores possible worlds. The preferred figure of *implication* is that of increased awareness and appreciation. The preferred figure of *expression* is that of personal communicator. The preferred figure of *perception* is that of active beneficiary. The preferred figure of *representation* is that of direct, dramatic discourse.

DIVERSIONARY RECEPTION STRATEGY

32% of visitors, ranging in age from 5 to 51 (average age = 17 years), were classified as relying predominantly on the diversionary reception strategy. The group was evenly divided between males and females. The average time spent in the gallery was 28 minutes, with visits ranging from 13 to 72 minutes.

The *diversionary* strategy stresses the non-utilitarian values of the gallery as an amusement park. With sheer enjoyment as the kind of optimal experience sought, the visit is judged according to cycles of individual stimulation. This is the strategy most antithetical to that of most curators, but, at least in this study, characterizes the largest group of visitors.

Diversionary visitors are attracted to the promise of new physical or emotional stimulation. Musical exhibits were alluring to the diversionary visitor, for example, if they offered a chance to move rhythmically, sing, or dance rather than as a means of accumulating new ideas about the world or learning something new about himself. It is not necessary for these experiences to be shared with others. An underwater scene was interesting for its promise of a chance to crawl around under a dock and for the thrill of being in a dark, slightly threatening place.

The diversionary visitor is the least likely to practice the kind of exhibit manipulations desired by museum staff. While the critical visitor seems to be most interested in rules and laws that can be developed from the concrete experiences of the manipulative stage, and the pragmatic visitor is drawn to the practical "objects" or tools he or she can take home as a result of the gallery visit, the diversionary visitor, like the utopian visitor, is interested in the experiences of the gallery for their own sake rather

than as paths to the acquisition of something lasting. Unlike the utopian visitor, however, who is constantly re-creating him- or herself through these experiences, the diversionary visitor seems to take fun as simply a sign of itself. The challenge of this stage is to engage in physical experiences of one sort or another, and the forms of manipulation are more or less limited to such experiences. This stage tends to be shortest for this group, since the manipulation will continue only while the "fun" lasts.

This means that for this group the third stage is marked by the creation of the exhibit as a generalized symbol of action. Dancing is a sign of participation in dancing, drumming a sign of drumming, and so on. The visitor has become the hero in a story where success is marked by "getting to do or feel" something enjoyable despite whatever obstacles might have been put in his or her path. The fun is an end in itself, the thing of value to be achieved by the narrative contract.

The preferred image of the *message sender* is that of an entertainer. The preferred image of the message receiver is that of someone who is the beneficiary of the message (i.e., the experience). The preferred figure of *enunciation* is that of entertainment. The preferred figure of the *constructed world* is that of disconnected clusters of activities and spectacles. The preferred figure of *modalization* is that of professional entertainer. The preferred figure of *implication* is that of entertainment. The preferred figure of *expression* is that of professional organizer. The preferred figure of *perception* is that of active participant in activities and spectacles. The preferred figure of *representation* is that of nonverbal enactments of activities and scenes (i.e., "spectacles").

CONCLUSIONS

As curators are well aware, and this study demonstrates for the one gallery in question, there are a myriad of ways in which a display can fail to engage a visitor. In Umiker-Sebeok 1991, sociosemiotic analysis of a number of both successful and unsuccessful exhibits documents a variety of common errors. These flaws can usually be traced to a failure to take into account the *habitus* of different visitors, especially their needs concerning achievement of optimal experience. This failure can be total, affecting all of the figures mentioned above as well as many others which space did not permit us to mention. More commonly, only a portion of the message elements are a problem. Sometimes it is a question of adequately expressing the *habitus* of one or more groups during the first stage of the collapsed act of the artefact but violating it in the second stage.

Visitors *act upon* the museum, dynamically building meaningful "spaces" in which to move and maneuver to their own advantage. Exhibitors must understand these spaces in all of their complexity if they are to do more than merely try to force their own (typically pragmatic or critical) predilections on reluctant visitors, usually with unwanted results. Different reception strategies stem from as well as construct different perspectives on the world. It is not enough to clarify what these perspectives are, for

curators wish also to know how to engage the visitor who approaches with one strategy and invite him or her to adopt another. A clever invitation to adopt an alternative role must start from where the visitor starts, and can only "propose," never impose a new perspective. This is the primary challenge for museum staff, aided by a more highly developed sociosemiotic habitus.

Parallels Between Hypnotic Suggestion and Persuasive Marketing Communications: Insights for New Directions in Consumer Communications Research

Stephen J. Gould, Rutgers University

ABSTRACT

Hypnotic phenomena, especially suggestions and related waking state phenomena in everyday life, offer significant parallels to the effects of persuasive marketing communications. These parallels are developed in terms of consumers' states, roles and a stimulus-state-response model. Research implications are offered and finally a conclusion regarding the relative position of consumer research to hypnosis research is discussed.

A number of writers have presented views (either their own or others) which find in comparing the reputed powers of persuasive marketing communications, particularly advertising, to hypnotic suggestion that they are similar in effect (Fromm 1976; Packard 1957; Pollay 1986). But is this point of view valid and if so, in what ways do these two communications phenomena function similarly? This paper seeks to explore these questions by discussing the parallels as well as the dissimilarities between the two phenomena and to provide a framework for assessing them.

COMPARING PERSUASIVE MARKETING COMMUNICATIONS AND HYPNOTIC EFFECTS

In comparing the effects of persuasive marketing communications to hypnosis, it is appropriate to consider hypnotic-like states which reflect the fact according to Hilgard (1965, p. 312) that "there are many continuities between experiences outside hypnosis and those inside." Both hypnotic and hypnotic-like states involve the relative dissolution of everyday cognitive reality and a particularly focused orientation on a small range of preoccupations (Shor 1960). Similarly, persuasive marketing communications may be said to be 'hypnotic-like' in that they are said to involve focused absorbing states and/or heightened suggestibility (Hirschman 1985; Shor 1960). Persuasive marketing communications and hypnotic phenomena may also be viewed as part of a larger hierarchy of states involving variations in focus along a continuum which ranges from total absorption in a particular focus to being completely awake and aware of one's surroundings. Moreover, hypnotic-states have been found to involve conformity, role-playing, and impulsivity, i.e. in playing the hypnotic subject (Hilgard 1965; Sarbin and Coe 1972; Shor 1960), characteristics also found in relation to persuasive marketing communications and other consumer behavior phenomena (see Venkatesan (1966), MacInnis and Jaworski (1989), and Stern (1964), respectively). Thus, I expect that the consideration of hypnotic suggestive communications will inform our understanding of persuasive marketing

communications processes and models in several aspects by: (1) focusing on the consumer exposed to a persuasive marketing stimulus as experiencing transformed hypnotic-like states which may render him or her more susceptible to its message, (2) considering him or her as a conscious role player in such exposure, i.e. the consumer reception role, in which s/he has certain personally and socially derived expectations about how to react and behave, and (3) focusing on the relative importance and effect of these two on persuasion, i.e. states versus roles.

From a social psychological perspective, hypnotic-like phenomena may be viewed according to the degree of involvement they reflect with a situation (Sarbin and Coe 1972). For example, Sarbin and Coe note that a supermarket consumer would be at a very low level of involvement relative to a hypnotic subject. In this regard, persuasive marketing communications induced states might be seen as similar to waking states used in hypnotic persuasion experiments to contrast with actual hypnotic states. In one such study which may serve as a potential bridge between persuasive marketing communications and hypnotic phenomena, Malott, Bourg and Crawford (1989) found that that highly hypnotizable subjects generated more favorable thoughts and agreed more with a persuasive message than did less hypnotizable subjects, no matter whether they were in a waking or hypnotic state. Based on this study, it can be hypothesized that high hypnotizability should be positively related to advertising response, other things being equal (cf. Snodgrass and Lynn 1989 for a related discussion and study). It seems likely that an analogue to hypnotizability may exist, i.e. susceptibility to advertising which reflects an individual's capacity or likelihood of becoming absorbed in advertising. This analogue may actually be an intermediate variable between hypnotizability and response to persuasive marketing communications with highly hypnotizable individuals being being more susceptible to such persuasion than less hypnotizable individuals. There also may be more specific hypnotic-like susceptibilities such as susceptibility to ads with sexy models or emotive appeals or susceptibility to particular types of advertising such as television commercials.

SUGGESTION AND THE ISSUE OF INVOLUNTARINESS RESPONSE

So far we have considered persuasive marketing communications as a type of waking state phenomena which nonetheless may possess some hypnotic-like characteristics. Moreover, highly hypnotizable individuals may be more responsive to such communications than less hypnotizable individuals. These ideas lead us to consider the possibility that marketing communications are most related to

hypnotic phenomena in terms of waking state suggestions. Suggestions in general are said to be suggestive because the resulting effects are not thought to be voluntary acts (Weitzenhoffer 1980). Suggestion is the end product of hypnotic processes. A suggestion is a communication (or sequence of communications) delivered to a subject with the intent of bringing about some action (Weitzenhoffer 1989). It provides perhaps the most important link between various hypnotic-like and hypnotic experiences in terms of persuasive marketing communications since the results of hypnotic suggestion have been related to waking state or non-hypnotic suggestions (Weitzenhoffer 1989). For instance, the process of suggestion has been directly identified in the dynamics of the sales situation which may be likened to the effect of asking leading questions to provide particular answers sought by the salesperson and to exclude those not sought (Gheorghiu 1989). As Gheorghiu (pp. 101-102) observes:

The influential process initiated by suggestion, if indeed it is effective, preconceives a confrontation with the rival alternatives... If a suggestion does prevail, then the person concerned does not realize - at least not while responding - that at the same time other possible reactions have been eliminated... Suggestions always offer answers or solutions, so to speak, even when they create (suggest) the problem in the first place. They implicate proffered solutions as the only valid ones. Finally, the suggestions can be considered effective when they are able to eliminate rival alternatives whilst being unnoticed. The directedness which is put into effect in the suggestive situation turns into an unambiguous directedness within the subjects' own cognitive reality.

Weitzenhoffer (1980) further notes that there are waking state suggestions which occur when there is no formal hypnotic process occurring. Thus for instance persuasive advertising communications which affect consumers, especially under conditions of low elaboration and/or involvement (Petty, Cacioppo and Schumann 1983) may be seen as a form of waking state suggestion in which a thought or non-verbal cue is planted in the consumer's mind eventually resulting in purchase or other behavior later or also as a form of 'suggestive communication' in which the receiver of a message must 'read between the lines' or make inferences from the message's context (Fiedler 1989).

However, the degree of involuntariness of a response has been an important issue in suggestion research and the limits and boundaries of persuasion in that process remain problematic (Weitzenhoffer 1989). Weitzenhoffer (1980) notes some individuals will view their responses to suggestions as involuntary while others will take the view that their responses are more voluntary. Moreover, many people will probably be unwilling to admit that they made an involuntary response to persuasive marketing

communications or even be able to articulate or comprehend how they could make such a response. Furthermore, they might build elaboration around involuntary responses which obscure their real response. For example, Janiszewski (1988) found that a person would respond more favorably to a product if an ad for it was placed on one side of a magazine as opposed to another. Yet, if we were to ask that person why s/he (dis)liked the product, it is very unlikely that s/he would make such an attribution. Thus, suggestions made in advertising and other persuasive marketing communications stem from myriads of possible executional factors (Stewart and Koslow 1989) which may result in some or all of the following on the part of the message receiving consumer: central and peripheral cue processing (Petty, Cacioppo, and Schumann 1983), automatic behavior (Cialdini 1984), unconscious processing (Pratkanis and Greenwald 1988); classically conditioned learning (Allen and Madden 1985), and possibly even subliminal processing (Moore 1988). Regarding subliminal stimulation, it should be noted that its effects are not necessary for advertising suggestion to occur and thus the general consensus regarding its lack of positive marketing effects do not detract from our argument here. It is likely, in fact, that most, if not all, advertising suggestibility effects occur in response to directly perceivable phenomena, such as a central message point or a peripheral cue, processed more or less consciously, rather than in response to some covert cue deliberately embedded by an advertiser.

However, the concept of automatic behavior bears more discussion in that there are many tacit or scripted rules which consumers act upon and which those who understand them may use to manipulate others (Cialdini 1984). There are certain mechanistic, ritualistic patterns which comprise what Cialdini calls a "trigger feature." Likewise suggestion has been called the "potential trigger of responses." Thus trigger features in advertising and other marketing contexts as well (e.g. the sales situation) may be seen as suggestive mechanisms. Triggers are usually peripheral cues (e.g. a sexy model) which stimulate favorable responses to ads. However, even central cues may serve as trigger features. For instance, the acceptance of a central message may in turn trigger greater receptivity to peripheral cues and lead in turn to a favorable response to an ad.

NATURE OF HYPNOTIC/HYPNOTIC-LIKE STATES

Another important issue concerns whether hypnotic states are distinctive psychophysiological or altered states of consciousness or whether they are social psychological phenomena in which people engage in role playing, i.e. taking on the hypnotic subject role (Sarbin and Coe 1972). A compromise position on these views has been offered which suggests that some people respond to hypnotic suggestion by taking an active role while others respond more passively, i.e. allowing things to happen to them (Coe 1978). Hilgard (1985) provides another view which, involving the idea of

dissociation, he believes can account for differences in both hypnotic induction and "waking hypnosis." Such dissociation he finds to be amnesic in that there are various gradations of memory which occur in the hypnotic process and which can be explained without resorting to some altered state of consciousness model. Relatedly, it has been suggested that response to hypnotic suggestion involves two potentially dissociative parameters which need to be considered: (1) a respondent's skill or capacity for employing imagination, and (2) the believability or credibility a respondent has concerning the hypnotic situation and applies to any particular suggestion (Sarbin and Coe 1972). In a similar fashion, McGuire (1989) suggests that susceptibility to social influence involves a compensatory tradeoff between two compliance mediators: (1) comprehension (equivalent to imagination) and (2) agreement with the message (equivalent to believability). Assuming as he does that both are the function of a personality trait, such as intelligence or self-esteem, persuasion and/or behavioral compliance will vary negatively with agreement, since a variable such as intelligence reduces gullibility, and vary positively with comprehension, since intelligence facilitates comprehension. With respect to marketing communications, we can hypothesize that individual difference variables (e.g. demographics, beliefs toward advertising in general (Andrews 1989)) along with situational variables (e.g. attitude toward any particular ad, being in the market for a product) parallel the social psychological role-taking perspective on hypnotic effects. Indeed we should consider framing advertising response issues in terms of the dual model of imaginative capacity and credibility.

At the same time, altered state effects as indicated by distinct psychophysiological reactions cannot be ignored. For example, research in both the fields of hypnosis (e.g. Pagano, Akots and Wall 1988) and advertising (e.g. Rothschild, Hyun, Reeves, Thorson and Goldstein 1988) have investigated and turned up some brain laterality effects. Perhaps most intriguing was the recent study of Olson and Ray (1989) which found brain wave response to television commercials involved correlated alpha and beta waves, a finding which contradicted previous beliefs that the two had a reciprocal relationship. This finding suggests in consonance with hypnosis research in which both attention and relaxation occur together (Edmonston 1981) that there may be psychophysiological state parallels between response to at least some marketing communications and hypnotic ones. However, to my knowledge, no one has yet attempted to actually demonstrate such a parallel and thus the issue remains for future research. At the same time to hypothesize parallels should not be misconstrued as hypothesizing identical reactions. It seems more likely that families of states will be found which integrate persuasive marketing and hypnotic phenomena into a hierarchy or patterns of related but distinctive states.

A MODEL OF THE PERSUASIVE MARKETING COMMUNICATIONS SUGGESTIBILITY PROCESS

Hypnotic suggestibility involves the mechanisms involved in the formation of suggestive focus and its transformation into responses based on this focus (Gheorghiu 1989). In terms of the state processes and the actors involved, both hypnotic suggestibility and persuasive marketing suggestibility may be seen as fitting within the traditional sender-receiver model of communications. Hypnosis involves the communication of a persuasive message by a hypnotist to a hypnotized receiver through a trance. Suggestive response either during the hypnotic session or post-hypnotically represents feedback to the hypnotist and also to the hypnotized receiver if the response is shared by the hypnotist with the subject. Similarly, in persuasive marketing communications, the marketer communicates a persuasive message to a target audience through some medium with feedback coming in the form of attitude change, purchase and the like as in various hierarchy of effects models. Here, we might reformulate the persuasive marketing communications model in the following way:

- (1) *Persuasive Marketing Communication Stimulus*. This stimulus includes the source and medium as constituting what has been called the intended suggestion by Weitzenhoffer (1989) to distinguish it from the effective suggestion, i.e. the former is what the marketer intends the consumer to do while the latter involves the consumer actually doing it. The message and its medium should be viewed as equivalent to the hypnotist as source and medium in the hypnosis process.

With respect to the message, we might consider the notion of direct suggestions which are explicitly made and those which are indirect and alluded to or made by association (Weitzenhoffer 1989). Relatedly Fiedler (1989) has advanced the idea of suggestive communication which involves things inferred from textual cues rather than explicitly stated by the communicator. Such concepts parallel the idea of central (direct) versus peripheral (indirect) routes to persuasion (Petty, Cacioppo and Schumann 1983).

- (2) *Consumer State*. In reaction to seeing and/or hearing a persuasive marketing communication (i.e. receiving and decoding the message), the consumer has some affective cognitive reaction. This state is equivalent to the psychic-somatic effect resulting in hypnosis, most especially perhaps waking hypnosis (Wells 1965) in terms of process-specific somatic responses and the attenuation of external stimuli (Chertok 1986).

(3) *Consumer's Behavioral Response.* The consumer may also make a behavioral response to the persuasive marketing communication (e.g. making a purchase may be seen as a form of effective suggestion as well as representing feedback to the marketer). Such a response may be seen as equivalent to one of two hypnotic responses: (a) the consumer encounters a persuasive marketing communication, has a reaction defined in terms of his/her state, and engages in purchase behavior which may be likened to posthypnotic suggestion -- the suggestion to be acted upon by a subject after s/he awakens from an hypnotic induction (Weitzenhoffer 1989) (e.g. being persuaded by a commercial to buy a product and then later doing so sometimes with the aid of various processes such as sleeper [Hannah and Sternthal 1984], delayed [Burke and Edell 1986] and inoculation effects [Lessne and Didow 1987]), or (b) the person makes an immediate purchase while under the influence of a persuasive communication (e.g. responding to point-of-purchase display) which may be likened to an action taken by a hypnotic subject in response to a hypnotist while the subject remains in trance. An especially interesting case of immediate purchase concerns what Stern (1964) calls "suggestion impulse buying" which occurs when a person sees a product for the first time, visualizes a need for it, and purchases it. While we need not limit ourselves to first time impulse purchases as he did, we might consider nonetheless that Stern points out how the product itself as stimulus along with its packaging serve to communicate in a suggestible manner.

SUMMARY AND RESEARCH IMPLICATIONS

In summary, the process of hypnotic suggestion seems most parallel to the marketing communications process in terms of waking state suggestions which follow a stimulus, state and response model. On the other hand, hypnotic suggestions based on formal trance states probably differ from suggestions induced by persuasive marketing communications in terms of the nature of the reception state and role. However, the degrees of parallel and even possible equivalency between the two methods of inducing persuasive suggestion remains for future research to explore. Thus, the most important general implication of this paper is that consumer researchers should investigate the literature of hypnosis and related suggestive processes to identify phenomena which might help to explain consumer communication and persuasion processes. In support of that point and based on the previous discussion, the following research implications are offered:

1. The most basic level of research involving hypnotic-like effects in marketing communications will involve identifying, assessing and measuring the parallel effects, if any, between various forms of suggestion and those which seem implicated in marketing communications. Such research will involve looking both at potential stimulus, state and behavioral parallels, both psychophysiological and social psychological.
2. A subagenda to the first point would involve looking at various waking state phenomena for suggestibility parallels. For example, how can we model and investigate opinion leadership, sales and service exchange-interactions, and advertising in terms of suggestion as well as looking at non-marketing communications phenomena such as those involved in relationship formation. Moreover, within the various categories of persuasive marketing communications we might expect to find differences in conditions prompting suggestion effectiveness (e.g. central (direct) versus peripheral (indirect) suggestive cues; high versus low involvement situations; various media effects).
3. Consistent with Gheorghiu (1989), we need to discover the dialogical structure consistent with suggestion in advertising, sales etc. so as to better understand the depth of consumers' responses to cues. This suggests theoretical development and related experimental studies in which the language of leading questions is investigated and manipulated so as to be able to discover the tacit rules, if any, which exist. In doing so we can discover what sorts of people best deliver such suggestions, under what conditions and how consumers resist such persuasion.
4. Moderators of the suggestive process should be studied directly in relation to suggestibility as possible segmentation variables. These might include such variables as hypnotizability, trust, credibility, gullibility, intelligence, self-monitoring, self-consciousness, comprehension, style of processing, and absorptive capacities among others (Gould 1991; McGuire 1989).
5. Consistent with MacInnis and Jaworski (1989), research should be conducted which considers the six different levels of brand processing for different effects of suggestion and quite probably the different forms of suggestion which are related to each level. For example, their highest

level of processing involves self-generated persuasions which parallel auto-suggestion and which are very different from mood generated affect which may be present in their lowest level of persuasion. In particular we need to describe the underlying suggestive processes functioning at each level as well as the particular cues which prompt, invite, and stimulate these processes.

6. Apart from establishing parallels, future research will need to assess the effects on the public of the perception of advertising and other persuasive marketing phenomena as being 'hypnotic' since such research ala our experience with subliminal persuasion has a way of attracting public attention. The full implications of this issue are troubling and vexing as discussed in the next section.

CONCLUSION: A DILEMMA AND CHALLENGE

In this paper, we have considered the issues involved in assessing suggestive phenomena in relation to persuasive marketing communications and have provided a framework for future theory development and empirical research. Nonetheless deciding whether and how persuasive marketing communications are in any way hypnotic or provide waking state suggestions to consumers seems to pose a difficult although challenging focus of research attention for consumer researchers. However, there remains another issue to deal with which is just as fundamental and perhaps as vexing as the basic research problem. The social implications of linking advertising and other marketing communications with the concept of suggestion and the process of hypnosis is a disturbing prospect when we consider the fact that the popular imagination has already linked advertising with subliminal factors. Moreover marketers are not likely to be happy having their work so linked and we may conjecture that there may be legal, social and ethical ramifications. However, as researchers we cannot ignore this issue. For instance, as a consumer researcher, I was asked by a researcher in the field of hypnotic suggestibility to contribute a chapter on advertising and suggestibility to a book on human suggestibility (Gould 1991). In researching and writing the chapter, I discovered not only that many people had linked advertising and other marketing phenomena with the process of suggestion but also that a plausible case existed for doing so in terms of research in the field of hypnosis research. Given such studies in the hypnosis field which have compared the effects of communications under waking and hypnotic states, and also the interest shown in my contributing an advertising chapter to a book on human suggestibility, it seems inevitable that research will be conducted regarding the relationship of suggestion and persuasive marketing communications. However, if consumer researchers do not engage in such research and involve themselves

with the topic, then the framing of the central issues and the social agenda concerning such communications will be set by others.

Context Effects on Social Judgments: Implications for Measurement in Consumer Research

Geeta Menon, New York University
Barbara Bickart, University of Florida¹

ABSTRACT

This paper provides a summary of a special topic session that focused on context effects in survey judgments. The papers presented in this session showed conditions under which earlier responses to survey items affected later responses and provided theoretical perspectives to explain these results. The broader implications of this work for consumer judgment processes and questionnaire design were also discussed.

OVERVIEW

There has been a growing interest among survey methodologists about the mechanisms which underlie the survey response process and how contextual factors affect these mechanisms (see Hippler, Schwarz, and Sudman 1988; Jabine et al., 1984; Schwarz and Sudman 1991, in press). This work represents a shift from simply identifying response effects when they occur to attempting to understand the processes that underlie such effects. The development of a substantive theory of the survey response process holds important implications for questionnaire design and survey procedures. In addition, survey judgments are similar to other kinds of judgments and decisions people make on a daily basis. Therefore, this work holds implications for these judgment processes as well.

In both applied and basic consumer research, we often require people to answer questions about brand-related beliefs, attitudes, purchase intentions, and past behavior. In answering such questions, respondents must interpret the question, retrieve appropriate information from memory, integrate this information to form a judgment, and report their judgment in the format desired by the investigator (Tourangeau and Rasinski 1988; Strack and Martin 1987). There is substantial evidence suggesting that earlier survey questions affect later responses (see Schuman and Presser 1981 and Feldman and Lynch 1988 for reviews). The nature of these effects, however, is not well understood. Specifically, we lack an understanding of when information rendered accessible by earlier questions will be used to form a later judgment, and if so, how this information will be used. The papers in this session examine factors which influence the use of accessible information in survey judgments from a variety of theoretical perspectives.

Carolyn Simmons and her colleagues present the results of a test of the Feldman and Lynch (1988) model in a survey context. This model suggests that the use of inputs rendered accessible by the context

will be depend on (1) the accessibility of alternate inputs in the respondent's memory and (2) the relative diagnosticity of these inputs. They focus specifically on how an individual difference variables, prior commitment, affects a respondent's use of specific and general information rendered accessible by the context. The results of a survey about voting intentions in the 1988 presidential elections generally support the Feldman and Lynch model.

Leonard Martin and Thomas Harlow present empirical work suggesting that the use of accessible information is related to the amount of cognitive effort respondents expend in making a judgment. They find that people are more likely to partial out accessible inputs when they exert more effort in answering a question, resulting in a contrast effect. In this case, the type of judgment elicited (self versus proxy) appears to be related to the amount of cognitive effort expended in answering questions.

The work of Barbara Bickart and her colleagues shows how contextual factors influence the use of information about oneself in making judgments about others. Specifically, they show that earlier items can both render inputs accessible and suggest a comparison basis for making a later judgment. The combination of these factors appears to determine the extent to which the self report is used in making a proxy report. Further, these factors also affected the convergence between a proxy report and the target person's self report.

Finally, Norbert Schwarz and Herbert Bless present a comprehensive model of contrast and assimilation effects in social judgments. This model shows how categorization processes influence the emergence of assimilation or contrast effects in survey judgments and can account for effects related to important questionnaire and respondent variables. In addition, this model is also useful for understanding and predicting assimilation and contrast effects that occur in other marketing contexts.

In summary, the four papers together highlight how the response formulation process may vary depending on individual characteristics of the respondent and questionnaire design. Comprehensive models such as those proposed by Schwarz and Bless (in press) and Feldman and Lynch (1988) provide important insight into the measurement process. These models hold important implications for understanding consumer decision and judgment processes as well.

Context Effects in Proxy Judgments

Johnny Blair, University of Maryland¹

ABSTRACT

In many surveys, respondents are asked to answer questions about both themselves (self reports) and others (proxy reports). In this paper, we report the results of an experiment that examines the conditions under which respondents use their self report in making a proxy judgment. The findings indicate that the distance between the self and proxy report and the type of comparison strategy evoked by an earlier question affect both the weight given to the self report and the convergence between self and proxy reports. These results are consistent with a theoretical framework proposed by Schwarz and Bless (in press). Implications for reducing measurement errors in surveys via questionnaire design are discussed.

INTRODUCTION

In consumer research, we often ask people to report about both their own behavior and attitudes and those of other people. Reports about others are referred to as proxy reports. For example, one respondent may be asked to answer questions about the purchase and consumption behavior of all household members. Because household members are likely to be similar on these dimensions, a respondent's self report can be a diagnostic, or useful, input to such judgments.

The purpose of this research is to investigate how contextual factors, such as questionnaire format, affect the use of respondents' self reports in making judgments about their partner. In addition, we examine how contextual factors might affect the adequacy of proxy reporting. Specifically, we examine differences in convergence, which is the correlation between the proxy report and the target person's self report.

After a brief review of the relevant literature, we present the results of an experiment that investigates the effects of two contextual factors on (1) the use of one's self report in making a proxy report and (2) the convergence between reports. These factors include the distance between the self and proxy report and the inclusion of questions intended to evoke a comparison basis for making the proxy report. The theoretical and practical implications of these results are then discussed.

LITERATURE REVIEW

In many cases, summary judgments about respondents' own attitudes and behaviors may not be accessible (Lastovicka and Bonfield 1982). For example, while a respondent may go to a restaurant frequently, s/he may not be able to retrieve the number of times s/he visited a restaurant in the last month simply because the information is not accessible in memory. Therefore, it is unlikely that respondents have other people's global judgments regarding various issues and past behaviors stored in memory. Hence, judgments about others are likely to be constructed on the spot, using inputs retrieved from memory.

Hoch (1987) suggests that when making judgments about others, people can use three kinds of information: (1) their own judgment regarding the topic, (2) the perceived level of similarity between themselves and others, and (3) other relevant information, such as prior conversations or observed behavior. For example, Davis, Hoch and Ragsdale (1986) found that people relied heavily on their own preferences in predicting their spouse's preferences for a variety of consumer products. In addition, respondents appeared to use knowledge about their spouse's perceived level of influence in the purchase decision for the product in answering the question. Finally, Davis et al. (1986) found that couples would often be more accurate if they relied completely on their self report and did not adjust it at all based on other information (see also Hoch 1987). This suggests that when people are similar, a self report is a diagnostic input to a report about their partner. Thus, we might want to investigate strategies to encourage the increased use (or weight) of one's self report when making a proxy report.

Questions placed earlier in an interview have been shown to increase the accessibility of information used to answer a later question (see Feldman and Lynch 1988 and Tourangeau and Rasinski 1988 for reviews). Thus, an earlier self report should render self information accessible and increase the likelihood that the self report is used in answering a later question about one's partner. However, Davis, et al. (1986) varied the order in which self and proxy reports were elicited, and found no effect of question order on the weight given to one's own preference in predicting their partners'.

Earlier questions could also invoke a strategy that respondents may use to answer later items. For example, Menon et al. (1990) had respondents give both self and proxy reports of the favorability of political groups. In some conditions, the proxy report immediately followed the self report, and in other conditions, the items were separated by a series of unrelated questions. In addition, in some conditions a question querying the extent of agreement

¹This project was funded by the National Science Foundation, Grant No. SES-8821362. We thank Lauranne Buchanan, John Lynch, and Stan Presser for helpful comments on an earlier draft of this paper.

between the couple on political issues preceded the proxy judgments. They found that respondents were more likely to report using their self report in answering the proxy question when it was preceded by the agreement question. This only occurred, however, when the self and proxy reports were queried contiguously. Menon et al. (1990) suggest that the agreement question invoked a comparison-based strategy that resulted in the use of the self report *when it was relatively accessible* (e.g., it had been recently queried in an earlier question).

Our research extends this previous work in several ways. First, previous research has dealt only with judgments about purchase intentions and attitudes. We look at judgments about both attitudes and behavioral frequencies. The latter may be especially important in marketing research, since many market share predictions and forecasts are based on consumer reports of how often they purchase and/or use different products. Second, we consider the effects of invoking other types of strategies on the use of one's self report, such as comparisons to a norm. Finally, we explore the relationship between contextual factors and the convergence between the proxy report and the target person's self report.

HYPOTHESES

In this experiment, we attempted to manipulate two factors: (1) the accessibility of the self report, and (2) the comparison basis used in making the proxy judgment. The key dependent measure was the weight given to the self report in making the proxy report. We expected an interaction between the two manipulated variables on this measure. Specifically, invoking a self-based comparison strategy should only affect the weight given to the self report when it is relatively accessible. When the self report is not accessible, invoking a self-based comparison strategy should not affect the weight given to the self report in making the proxy judgment, because the self report is not accessible to the respondent to make this comparison. Assuming that couples are relatively similar in the queried domains, we expect convergence between reports to follow a similar pattern. Thus, convergence should be higher when the self report is accessible and a self-comparison strategy is invoked. Finally, invoking a norm-based comparison strategy should not affect the weight given to the self report under any condition. This is because the self report is not a diagnostic input to a norm-based comparison.

METHOD

This experiment was embedded in a larger study dealing with the cognitive aspects of proxy reporting (see Bickart et al., 1990, Blair, Menon, and Bickart, in press; and Sudman et al., in press). The survey included questions about a variety of topics, including media usage, consumption of alcoholic beverages, health status, political attitudes, and demographics. Most of these questions were taken from other surveys conducted by major survey research institutions. In this paper, we focus on the four questions shown in Figure 1: (1) TV viewing (TV), (2) beer consumption (Beer), (3) an overall health rating (Health), and (4)

attitudes toward the federal government's drug policy (Drugs).

Telephone interviews were conducted with 201 couples. A standard directory-based random digit dial sample design was used to select households (Sudman 1973). Couples were eligible to participate if they were either married or living together as married. Agreement to participate was secured from both partners before either was interviewed. Respondents were requested to ask their partner to leave the room during the interview, and not to discuss the survey until both interviews were complete. The interview averaged 20 minutes per person.

Two variables were manipulated in the questionnaire. First, the accessibility of the self report was manipulated by the distance between self and proxy questions. In half of the questionnaires, self reports on all topics were obtained before the proxy reports, creating a *buffer* between items (the *buffer* condition). In the remaining questionnaires, the self and proxy questions were obtained sequentially for each topic (*no buffer* condition).

Second, the comparison basis used in making the proxy report was manipulated by the addition of a question immediately preceding each of the items in Figure 1. We refer to this as a "priming" question, as the intent was to heighten the accessibility of certain comparison standards at the time the proxy report was made. As shown in Figure 2, there were three types of priming questions. First, in some conditions respondents were asked to assess the similarity between their own behavior or attitude and that of their partner. In a second condition, respondents assessed the *dissimilarity* between themselves and their partner on the topic. In both cases, the intent of the questions was to evoke the use of a strategy suggesting a comparison to the self report. Because there were no differences on the dependent measures when similarities versus dissimilarities were queried, these conditions were combined (the *Prime-Similar* condition). Third, some respondents were asked to compare their partner's behavior or attitude to "most other people". The intent of this question was to increase the accessibility of a "norm-based" comparison process (the *Prime-Norm* condition). Finally, no priming question was included in the *control* condition. Crossing these variables resulted in a 3 x 2 between-subjects design, with two levels of the distance between self and proxy report (buffer/no buffer) and three priming conditions (control, prime-similar, prime-norm). Treatment conditions were randomly assigned to couples. Because the similar and dissimilar conditions were combined, cell sizes varied between 45 and 105 respondents, although the number of observations included in the analysis of individual items may differ due to nonresponse.

RESULTS

The key dependent variable in this analysis was the weight given to the self report in making the proxy report. It was predicted in the no buffer condition, this weight should be greater in the prime-similar condition, compared to the control condition. In the buffer condition, the weight given to the self

report should not vary by priming condition. Finally, when norms were primed, the use of the self report should not vary significantly from the control condition.

Regression analysis was used to test these hypotheses. Separate regression models were estimated using OLS for each of the four key questions. In these models, the proxy judgment was regressed on the self report, one dummy variable representing question order (Buffer = 1, No Buffer = -1), two dummy

variables representing the priming conditions, all interactions, and gender as a covariate (Males = 1, Females = -1). The dummy variables for the priming condition were contrast coded to compare each priming condition with the control condition (X1: Control = -1, Prime-Similar = 1, Prime-Norm = 0; X2: Control = -1, Prime-Similar = 0, Prime-Norm = 1) (Cohen and Cohen 1983). Both the proxy judgment and the self report were centered on the mean for this analysis.

¹Self x Buffer x Prime-Similar interaction significant, $p < .05$

Pairwise comparisons are between the control and prime-similar condition within buffer groups for each item. Within these pairs, coefficients with different superscripts are significantly different from one another, $p < .05$.

The results of the regression analyses are shown in Table 1. For each model, the independent variables accounted for a significant proportion of the variance in the proxy report, ranging from 10% for reports about health status to 61% for reports about drug control policy. Not surprisingly, there was a significant main effect of gender in three of the four models (TV, Health, and Beer). This suggests that the mean level of reported proxy behavior or attitudes varied by gender. For example, women reported higher levels of beer consumption for their husbands. These differences are reflective of differences in self reports (e.g., men reported consuming beer more often than did women in their self reports). (See Bickart et al. 1991 for a further discussion of gender differences in proxy reporting.) In addition, the self report had a large and significant effect on the proxy report in each of the models.

We were most interested in whether the use of the self report varied as a function of the buffer and prime manipulations. This hypothesis is tested by the significance of the beta coefficient for the Self x Buffer x Prime interactions. A significant interaction suggests that the weight given to the self report varies as a function of the buffer and prime condition, relative to the control condition. The results of the regression analyses suggest that priming similarities, but not norms, affects the use of one's self report differently depending on the accessibility of the self report, compared to the control condition. For three of the four items (TV, Beer, and Health) the Self x Buffer x Prime-Similar interaction is significant,

while for the fourth item (Drugs) only the Self x Buffer interaction is significant. Priming norms, on the other hand, did not affect the use of the self report for any of the items (p 's $> .10$).

We then examined the nature of the Self x Buffer x Prime-Similar interaction. Our hypothesis suggests that the Self x Prime-Similar interaction should be significant in the No Buffer condition, but not in the Buffer condition. To test this, separate regression models were estimated within each Buffer condition, and the significance of the beta coefficient for the Self x Prime-Similar interaction was examined. Contrary to expectations, the weight given to the self report was more likely to vary as a function of the priming manipulation in the buffer condition (versus the no buffer condition).

These results are summarized in Table 2, which shows the unstandardized regression coefficients estimated within buffer and priming conditions. These coefficients represent the weight given to the self report within these conditions. In the buffer condition, greater weight was given to the self report when similarities were primed for both the TV ($E(1,186)=6.18$, $p < .05$) and the Health ($E(1,194)=4.17$, $p < .05$) items. For the other items (Beer and Drugs), the trends were in a similar direction, but were not significantly different. It appears that querying similarities increased the accessibility of self information, which had become less accessible due to the buffer of questions.

In the no buffer condition, the impact of the self report on the proxy report varied significantly as

TABLE 3
Convergence (Correlation Between Proxy Report and Other's Self Report) by Condition

Item	No Buffer			Buffer		
	Control	Prime-Similar	Difference	Control	Prime-Similar	Difference
# Hrs TV Weekday	.52 (47)	.31 (93)	.21 ²	.51 (47)	.35 (95)	.16
# Times Drank Beer Last Month	.91 (24)	.79 (42)	.12 ¹	.87 (17)	.64 (49)	.23 ¹

Attitude Towards Drug Control Policy	.36 (47)	.08 (98)	.28 ¹	.07 (48)	.29 (94)	<.22>

Note: Cell size in parentheses.

¹Dif. ≠0, $p < .05$

²Dif. ≠0, $p < .10$

a function of the priming condition only for the TV item. In this case, the self report received less weight when similarities were primed ($E(1,184)=4.72$, $p < .05$). A consistent pattern occurred for the other items, although the differences were not significant. Thus, contrary to expectations, priming a self-based comparison strategy seemed to result in a reduced use of one's self report in making a proxy report when the self report was accessible.

For the Drug item, the use of the self report varied only as a function of the buffer condition, as indicated by a significant Self x Buffer interaction. In this case, the self report influenced the proxy report more in the no buffer condition, that is when the self information was more accessible. The priming condition had no effect on responses to the drug item, possibly because respondents had not discussed the drug issue with their partner, and thus had little information on which to base their response to the priming question.

Finally, we were interested in seeing if the reduced anchor was associated with lower convergence between reports. Convergence is probably not a good indicant of accuracy in this case, given the social desirability biases that are likely for at least three of the items (TV, Beer, and Health). The convergence correlations, computed within the experimental cells, are shown in Table 3. The difference between correlations in the control and priming conditions within buffer conditions is of key importance. Correlations were transformed using Fisher's r to z transformation prior to significance testing. In the no buffer condition, correlations were significantly lower when similarities were primed compared to the control

condition for each of the items. Thus, priming a comparison-based strategy when the self report is accessible appears to be related to reduced convergence. In the buffer condition, priming a self-based comparison does not appear to affect convergence.

There are two important limitations to the convergence measure used here. First, convergence is likely to represent shared error between the self and proxy report (Bickart et al., 1991). Thus, both reports may be biased in the same direction, especially given the social desirability of the items. Second, convergence may also represent the actual similarity between the couple. Thus, differences in convergence can not be directly related to differences in the use of one's self report until actual similarity is considered.

DISCUSSION

There were several key findings in this experiment. First, when the self and proxy report were separated by a series of questions, people gave more weight to their self report when similarities were primed in a question preceding the proxy report. Priming similarities appeared to increase the accessibility of the self report, which may have been reduced due to the buffer.

When the self and proxy reports were elicited sequentially, the weight given to the self report was consistently *lower* when similarities were primed, compared to the no prime condition. Because the self and proxy reports were elicited sequentially, the self report should be relatively accessible. Thus, in this condition respondents appear to *reduce* the weight given to the self report. This runs directly counter to

the results reported by Menon et al. (1990), who used concurrent protocols as a dependent measure. It is possible that respondents' verbal reports of increased use of self information are a better indication of the accessibility of inputs, versus the actual use of inputs.

Earlier questions may have affected both the accessibility of inputs used to construct a judgment, and the strategy used to form the judgment. If a comparison strategy is activated, the increased use of the self report should be contingent on the similarity of the couple in the given domain. Modal responses on the similarity questions suggest that most respondents felt they were at least somewhat like (not very different from) their partner in the queried domains, with the exception of beer consumption, where people tended to rate themselves as being either very alike or very different. Because the self report was accessible (compared to the buffer condition), the priming question may have increased the salience of any differences between the couple. Thus, the self report may have been given less weight to account for such differences. Future analyses will take this contingency into consideration.

It is also possible that when a comparison strategy was activated and the self report was accessible (e.g., had recently been queried), respondents may have used the self report as a standard of comparison for making the proxy report, regardless of the content of the self report. A framework proposed by Schwarz and Bless (in press) suggests that this is likely to occur when: (a) respondents are aware that the information has come to mind due to a preceding task, and (b) respondents feel that their response will be redundant with earlier answers. The manipulations in this experiment may have produced such effects. Further, the Schwarz and Bless model suggests that if (a) and (b) do not hold, assimilation is likely to occur. Again, this is consistent with the results in the buffer condition, where respondents are less likely to realize that their self report had been rendered accessible due to the context.

Finally, preliminary results from this study suggest that convergence between the proxy report and the other person's self report was lower when a self-based comparison strategy was primed and the self report was accessible. Under these conditions, it appears that respondents may have discounted their self report in making the proxy report. Assuming that the self report is a diagnostic input for the proxy judgment, discounting the self report would result in a less accurate judgment. Because respondents are more likely to use their self report when it is accessible, eliciting self and proxy judgment sequentially may be the optimal strategy. It is important to note that convergence may not be a good indicant of accuracy in this case. High convergence may simply reflect shared error between the self and proxy report, particularly given the sensitive topics queried in this study (Bickart et al. 1991). Further research is needed in this area.

Assimilation and Contrast Effects in Attitude Measurement: An Inclusion/Exclusion Model

Norbert Schwarz, ZUMA
Herbert Bless, University of Mannheim

ABSTRACT

We present a theoretical model of context effects in attitude measurement that predicts (a) the conditions under which context effects are likely to emerge; (b) their direction (i.e., assimilation or contrast); (c) their size; (d) their generalization across related items; and (f) their dependency on the mode of data collection used.

Market researchers have long been aware that attitude measurement is context dependent, and that preceding questions may influence the responses given to subsequent ones. However, the conditions under which context effects may emerge are not well understood -- and when they emerge, it has typically been difficult to predict their direction. In the present paper, we present a process model (Schwarz & Bless, in press) that draws on current theorizing in social cognition (Barsalou, 1989; Kahneman & Miller, 1986) to identify variables that give rise to question context effects and to specify the conditions under which answering a preceding question results in assimilation or contrast effects on subsequent judgments.

ASSIMILATION AND CONTRAST EFFECTS

In short, we assume that individuals who are asked to form a judgment about some target stimulus first need to retrieve some cognitive representation of it. In addition, they need to determine some standard of comparison to evaluate the stimulus. Both, the representation of the target stimulus and the representation of the standard are, in part, context dependent. Individuals do not retrieve all knowledge that may bear on the stimulus, nor do they retrieve and use all knowledge that may potentially be relevant to constructing its alternative. Rather, they rely on the subset of potentially relevant information that is most accessible at the time of judgment. Accordingly, their temporary representation of the target stimulus, as well as their construction of a standard of comparison, includes information that is *chronically accessible*, and hence context independent, as well as information that is only *temporarily accessible*, due to contextual influences.

Whereas differences in the chronic accessibility of information reflect respondent characteristics, differences in the temporary accessibility of information are primarily due to questionnaire variables. Most importantly, information that has been used for answering a

preceding question is particularly likely to come to mind when respondents are later asked a related question, to which it may be relevant.

Assimilation Effects

How the information that comes to mind influences the judgment, depends on how it is *categorized*. Information that is *included* in the temporary representation that individuals form of the target category will result in *assimilation effects*. This reflects that the judgment is based on the information that is included in the representation used. Accordingly, the addition of some positive information results in a more positive judgment, whereas the addition of some negative information results in a more negative judgment.

Suppose, for example, that you are asked to report your opinion about the politicians of the Christian Democratic Party that governs Germany. To do so, you will presumably recall some relevant information from memory. This information makes up the "cognitive representation" of politicians of the Christian Democratic Party. Assuming some basic familiarity with German politics, the chronically accessible information that comes to mind may include that the CDU is a conservative party, that Chancellor Kohl is a member of it, and so on.

Other features of the target, however, will only come to mind on some occasions. These features are therefore said to be "context dependent". For example, if you were just asked a question about Richard von Weizsäcker, a particularly well respected member of the Christian Democrats, information related to Richard von Weizsäcker may come to mind later on. If you include this information in the cognitive representation that you construct of the Christian Democrats, you should evaluate politicians of this party in general more positively than if no question about Richard von Weizsäcker was asked.

Empirically, this is the case. In one of our experiments we asked subjects to recall the party of which "Richard von Weizsäcker has been a member for more than 20 years". Answering "Christian Democratic Party" should include Richard von Weizsäcker in the temporary representation that respondents form of politicians of the Christian Democrats. As shown in the first row of Table 1, this manipulation resulted in a more favorable evaluation of the party in general.

Contrast Effects

However, according to our model, the same piece of information may also result in a contrast effect. We propose that this is the case when the information is *excluded* from, rather than included in, your cognitive representation of the target.

For example, Richard von Weizsäcker has not only been a member of the Christian Democratic Party

¹The reported research was supported by grant SWF0044-6 from the Bundesminister für Forschung und Technologie of the Federal Republic of Germany to N. Schwarz.

TABLE 1
Evaluation of Political Parties as a Function of the Inclusion or Exclusion of a Highly Respected Politician

Target	Preceding Question about Richard von Weizsäcker		
	Party Membership	None	Presidency
Christian Democrats	6.5	5.2	3.4
Social Democrats	6.3	6.3	6.2

Note. N = 19 to 25 per condition. 1 = unfavorable; 11 = very favorable opinion about politicians of the respective party. Adapted from Schwarz & Bless (in press).

for several decades, but he also serves as President of the Federal Republic of Germany -- and the office of President requires that he no longer actively participates in party politics. The President as a representative figure-head of the Federal Republic is supposed to take a neutral stand on party issues, much as the Queen in the UK. This rendered him particularly suitable for the present experiment because it allowed us to ask other respondents, "Do you happen to know which office Richard von Weizsäcker holds, that sets him aside from party politics?".

Answering this question should *exclude* Richard von Weizsäcker from the representation that respondents form of Christian Democratic Party politicians. If so, it should result in lower evaluations of Christian Democratic Party politicians in general, although it may do so for different reasons, as discussed below. Empirically, this was again the case, as shown in the first row of Table 1.

This contrast effect may reflect either of two processes. On the one hand, Richard von Weizsäcker and his party membership may have been chronically accessible for some subjects who were not asked a question about him. If so, some of our control group subjects may have spontaneously included him in their representation of the party. In this case, the assimilation effect would reflect that the party membership question increased the number of subjects who did so. By the same token, the contrast effect would indicate that the presidency question decreased the number of subjects who did so. Thus, the obtained contrast effect would simply reflect that these subjects "*subtracted*" Richard von Weizsäcker from the database that they used in forming a judgment.

On the other hand, evaluations do not only require a representation of the target stimulus, but also a *standard* against which the target is evaluated. We assume that this standard is just as context dependent as the representation of the target itself, and includes chronically as well as temporarily accessible information. Accordingly, our respondents may not only have excluded Richard von Weizsäcker from their representation of his party, but may also have used him in constructing a standard of comparison against which his party was evaluated. Given that Weizsäcker

sets a high standard, such a *comparison* process would also result in a lower evaluation.

Thus, our model provides two different mechanisms for the emergence of a contrast effect, which are not mutually exclusive: Namely the subtraction of information from the representation of the target, and the possible use of this information in the construction of a standard or scale anchor. How can we distinguish these two processes? The most straightforward way to distinguish them is to assess the generalization of the obtained contrast effect across different stimuli to which the standard of comparison may be relevant. If the obtained contrast effect solely reflects the subtraction of Richard von Weizsäcker from the representation of the target category "politicians of the Christian Democratic Party", the presidency question should only affect the evaluation of politicians of this party. If respondents used Richard von Weizsäcker in constructing a standard of comparison or a scale anchor, on the other hand, the obtained contrast effect should generalize to the evaluation of politicians of other parties, such as the Social Democratic Party, to which this standard is also applicable.

To explore this possibility, we exposed other respondents to the same questions but asked them to provide a general evaluation of politicians of the *Social Democratic Party*. As shown in the second row of Table 1, neither of the questions about Richard von Weizsäcker affected subjects' evaluation of politicians of the Social Democratic Party. This suggests that the contrast effect obtained on the evaluation of Christian Democratic politicians reflects a *subtraction effect*, rather than a change in the standard of comparison or scale anchor.

The Impact of Category Width: Political Scandal Study

Our next study (Schwarz & Bless, in press) extends the inclusion/exclusion logic by demonstrating changes in the standard of comparison. Moreover, it bears on a different variable that may determine the inclusion or exclusion of information, namely the inclusiveness of the question asked.

Suppose, for example, that respondents are induced to think about politicians who were involved

TABLE 2
Evaluation of the Trustworthiness of Politicians in General and of Three Exemplars as a Function of Thinking About a Scandal

Target	Scandal Question	
	Not Asked	Asked
Politicians in General	5.0	3.4
Specific Exemplars	4.9	5.6

Note. N = 8 per condition. 1 = not at all trustworthy; 11 = very trustworthy. Adapted from Schwarz and Bless (in press).

in a political scandal, and are subsequently asked to evaluate the trustworthiness of politicians in general. According to our model, the politicians involved in the scandal are members of the general category "politicians" and are therefore likely to be included in the temporary representation that respondents form of that category. If so, their evaluation of the trustworthiness of politicians in general should decrease, reflecting an assimilation effect.

Suppose, however, that respondents are *not* asked to evaluate the trustworthiness of politicians *in general*, but the trustworthiness of a *specific politician*, Mr. Joe Doe, who was not involved in the scandal. We assume that in evaluating a specific person, this person makes up a category by him- or herself. If so, the politicians who were involved in the scandal should not be included in subjects' representation of Joe Doe. Rather, these politicians may be used in constructing the standard or scale anchor against which Joe Doe is evaluated. If so, Joe Doe may seem particularly trustworthy by comparison, reflecting a contrast effect. Thus, the model predicts that thinking about politicians who were involved in a scandal *decreases* judgments of the trustworthiness of politicians in general, but *increases* judgments of the trustworthiness of specific politicians, provided that they were not involved in the scandal.

To test this implication, we asked subjects to recall the names of some politicians who were involved in a recent political scandal in West Germany (the so called "Barschel Scandal", which bears some resemblance to the Watergate scandal), either before or after they answered the dependent variables. As shown in Table 2, thinking about the Barschel scandal resulted in decreased judgments of the trustworthiness of German politicians in general. This assimilation effect reflects that subjects included the politicians who were involved in the scandal in their representation of German politicians in general.

Other subjects, however, were asked to evaluate the trustworthiness of three specific politicians, who pretests had shown to be not particularly trustworthy to begin with, although they were not involved in the scandal under study. In this case, thinking about the Barschel scandal *increased* judgments of

trustworthiness of these specific politicians. This contrast effect reflects that subjects used the easily accessible politicians who were involved in the scandal in constructing a standard of comparison or scale anchor. Note that this contrast effect cannot be accounted for on the basis of a subtraction assumption. The information that was primed by the scandal questions was presumably never part of subjects' representation of the specific politicians they had to evaluate. Hence, the contrast effect obtained here reflects the use of the recalled politicians in constructing a relevant standard of comparison or scale anchor. This information could only be used in constructing the standard, however, when it was not perceived to bear on the respective target category in the first place.

These findings indicate that the same information may affect related judgments in opposite directions, depending on whether the respective target category invites the inclusion or the exclusion of the information that comes to mind. In general, our model predicts that assimilation effects are the more likely to emerge, the more inclusive the target category is. Accordingly, *general questions* that assess respondents' opinion about a wide target category, that allows for the inclusion of a variety of different information, should be most likely to show assimilation effects. On the other hand, *specific questions*, that assess respondents' opinion about a narrowly defined target, should be more likely to show contrast effects. This reflects that it is more likely that the information that comes to mind can be included in one's representation of a global rather than of a specific target.

On the substantive side, we would obviously draw very different conclusions about the impact of scandals on politicians' trustworthiness, depending on whether we asked a general or a specific question. In the light of these data, it also comes as no surprise that political scandals are typically accompanied by attempts to channel the public's categorization of scandal related information. To the extent that individual politicians, or groups of politicians, can dissociate themselves from the scandal, they may actually benefit from the misdemeanor of their peers,

TABLE 3
 Contrast Effects as a Function of the Dimension Tapped by Preceding Questions Context Stimulus

Preceding Question	Vodka	Beer
Consumption	5.4	4.4
Caloric Content	4.4	4.5

Note. N = 25 to 27 per cell; 9 = "very typical". The mean of ratings of three beverages (milk, wine, and coffee) is given. Adapted from Schwarz, Münkler and Hippler (1990).

although the impact on the perception of the profession as a whole is likely to be negative.

The Role of Salient Dimensions

So far, we have seen evidence for the emergence of subtraction based contrast effects in the Weizsäcker study, and for comparison based contrast effects in the scandal study. Under which conditions, however, are we likely to obtain one or the other? We propose that thinking about some stimulus does only evoke comparison processes in evaluating subsequent stimuli if the stimulus is linked to the relevant judgmental dimension. If the stimulus is thought about with regard to some other dimension, it is unlikely to be used as a standard or as a scale anchor for a later unrelated judgment. With regard to the preceding studies, this suggests that thinking about a political scandal was likely to bring the dimension of trustworthiness to mind. On the other hand, thinking about Richard von Weizsäcker's party membership or office may have been less likely to bring the evaluative dimension to mind that was relevant to subsequent judgments of the Christian Democrats.

In line with this assumption, one of our studies demonstrated that comparison effects do only emerge when the context dependent information is linked to the dimension of judgment (Schwarz, Münkler, & Hippler, 1990). Specifically, we asked subjects to rate how "typically German" a number of different beverages is, namely wine, coffee, and milk. Before they made this judgment, some subjects were asked to estimate the caloric content of a glass of vodka, or of a glass of beer, respectively. Other subjects, however, were asked to estimate how frequently Germans drink vodka or beer.

Both questions should make vodka or beer more accessible in memory. However, only the frequency of consumption question is related to the typicality dimension, whereas the caloric content question is not. If it is sufficient that an extreme stimulus comes to mind, both questions should result in contrast effects on subsequent typicality ratings. If the emergence of comparison effects requires that the extreme stimulus is linked to the relevant judgmental dimension, on the other hand, contrast effects should only emerge when subjects estimated the frequency of consumption.

Empirically, this was the case. When subjects estimated the frequency of consumption, they rated all

beverages as more typically German after thinking about vodka than after thinking about beer, as shown in Table 3. Estimating the caloric content of vodka or beer, on the other hand, did not affect their ratings. Accordingly, we conclude that the emergence of comparison or anchoring effects requires that the context dependent information is linked to the relevant dimension of judgment.

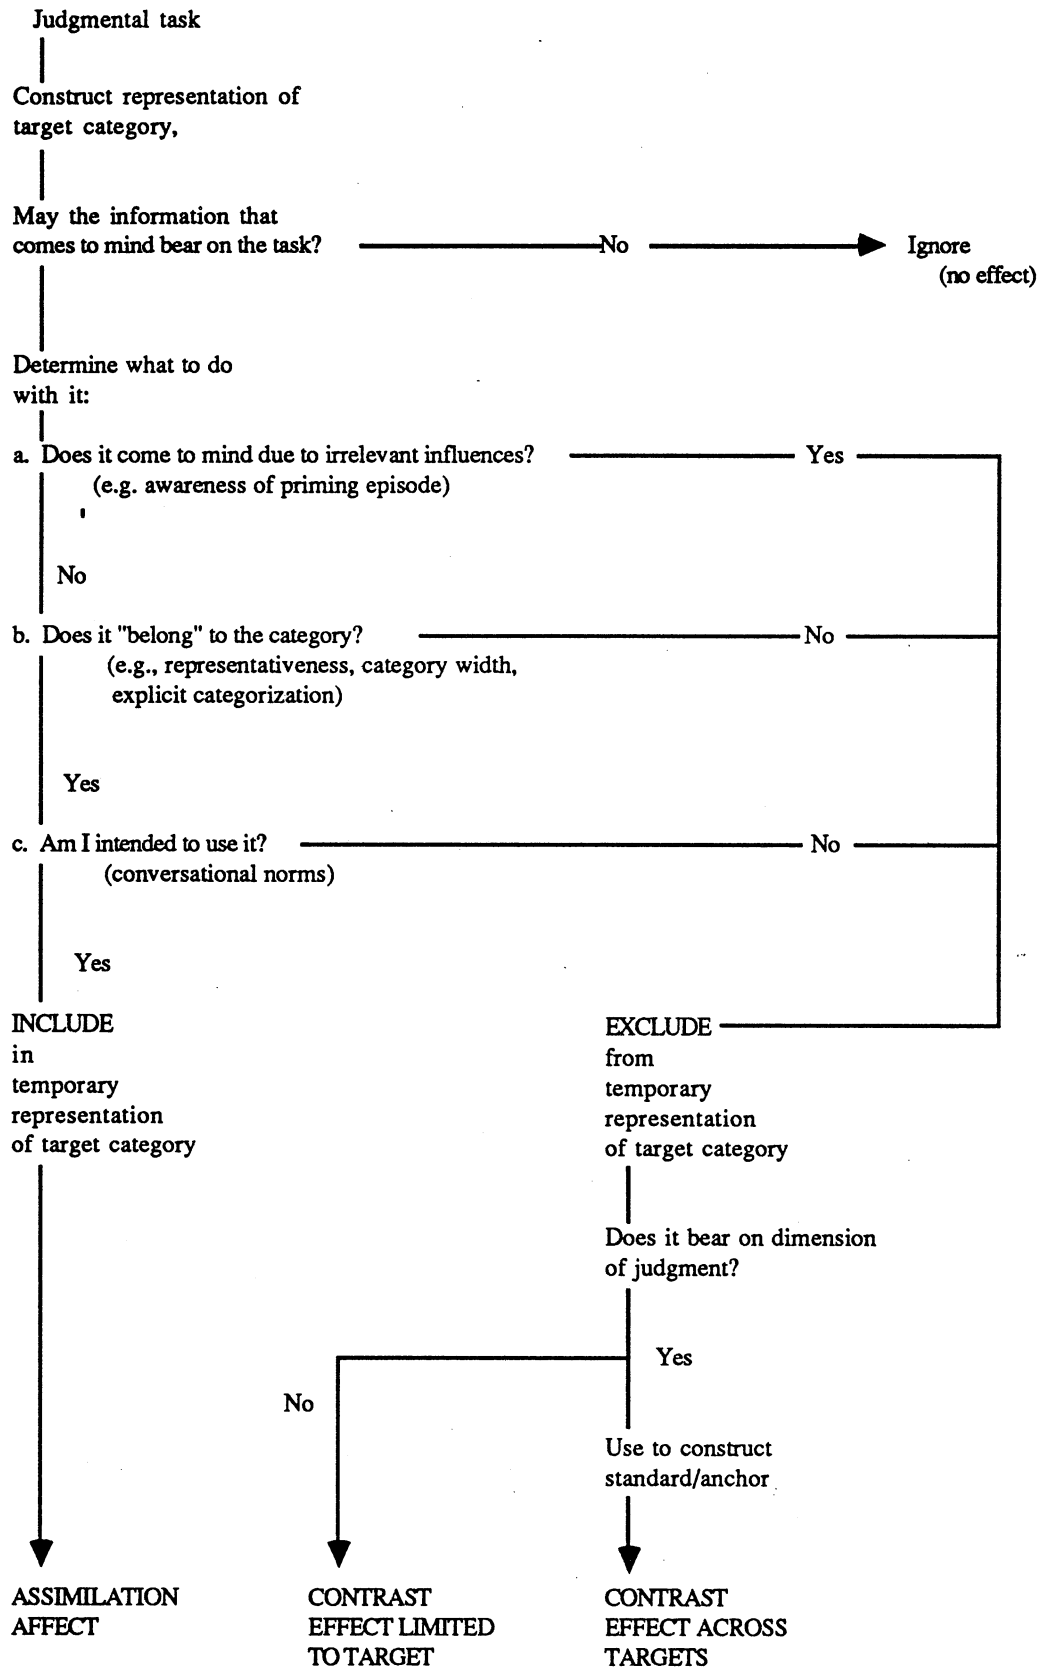

This suggests that we may only see comparison or anchoring based contrast effects when the excluded information is thought about with regard to the relevant dimension of judgment. In that case, it may be used as a standard of comparison or as a scale anchor, resulting in contrast effects that *generalize* across various target categories. If the excluded information is thought about with regard to some other dimension, it may still result in contrast effects, but only by means of a subtraction process. Accordingly, the contrast effects that emerge under this condition should be *limited* to the evaluation of the category from which the information was excluded in the first place, as was the case in the Weizsäcker study.

THE INCLUSION/EXCLUSION MODEL

In summary, when asked to form an opinion about some target, respondents will search memory for relevant information. Some information is likely to come to mind under all circumstances, and is hence called context independent. Other information will only come to mind because it has been used recently, for example, in answering a preceding question. How the information that comes to mind influences the judgment, depends on what respondents do with it. On the one hand, they may use it in constructing a cognitive representation of the target. On the other hand, they may use it in constructing a standard of comparison or scale anchor, against which the target is evaluated.

For which purpose the information is used, depends on a number of categorization decisions that respondents have to make. In the present paper, we have only discussed one of the three decisions shown in Figure 1. This decision reflects if the information "*belongs*" to the target category or not. This decision is influenced by the *content* of preceding questions, as in the case of the Weizsäcker study, and by the *width* of the target category, as in the political scandal

FIGURE 1
Inclusion/Exclusion and the Emergence of Assimilation and Contrast Effects

study, as well as related variables (cf. Schwarz & Bless, in press). If the answer to the "does-it-belong?" decision is YES, the information is included in the representation formed of the target category. This results in an *assimilation effect*. The size of this assimilation effect increases with the amount and extremity of context dependent information, and decreases with the amount and extremity of context independent information.

If the answer to the "does-it-belong" decision is NO, the information is excluded from the representation formed of the target category. This results in a contrast effect that may or may not generalize to judgments about other targets. If the information has NOT been thought about with regard to the underlying dimension of judgment, it is only excluded from the representation of the target category. This results in a localized contrast effect that does not influence related judgments of other targets, as we have seen in the Weizsäcker study. We call this type of contrast effect a *subtraction effect*. The size of subtraction effects again depends on the amount and extremity of the subtracted information, and on the amount and extremity of other information that is used in constructing the representation. If the excluded information HAS been thought about with regard to the underlying dimension of judgment, however, it is likely to be used in constructing a standard, which may be applied to other targets as well. This results in generalized contrast effects, as we have seen in scandal study and the study on drinks. We call this type of context effect a *comparison effect*. Its size depends on the amount and extremity of the context dependent and independent information used in constructing the standard.

In combination, the model predicts the *direction* as well as the *size* and the *generalization* of context effects. Moreover, it provides a framework for the conceptualization of the role of questionnaire variables, which influence the temporary accessibility of information and respondents' categorization decisions, as well as respondent characteristics, which influence chronic accessibility.

As shown in Figure 1, other decisions bear on whether the information comes to mind due to some external influence (e.g., Lombardi, Higgins, & Bargh, 1987), and on whether conversational norms do or do not prohibit its use (e.g., Schwarz, Strack, & Mai, 1991). We provide a detailed discussion of these steps, and a review of relevant research, elsewhere (Schwarz and Bless, in press). In general, these decision steps allow us to conceptualize the impact of introductions to blocks of questions, the presence of filler questions, and other aspects of questionnaire design, including the graphical lay-out of mail questionnaires. All of these variables have been shown to influence inclusion/exclusion decisions and hence the direction of context effects in some of our studies.

One additional point, however, deserves attention. Figure 1 seems to suggest that respondents are engaged in a lot of decision making in a very orderly fashion. Probably, this is not quite so. We assume that the default option is to include what comes

to mind and that decisions that may result in exclusion processes need to be triggered by some salient feature of the questioning process. This suggests that we should be more likely to see assimilation rather than contrast effects in survey measurement, reflecting that assimilation effects are based on the default option, namely the inclusion of what comes to mind. Moreover, exclusion processes require additional cognitive work. Accordingly, we should only see them when respondents are motivated and able to engage in this work (see Martin, Seta, & Crella, 1989). This suggests that contrast effects should be more likely to emerge the more respondents have a chance to engage in the necessary cognitive work, as is for example, the case under the leisurely conditions of responding to a self-administered questionnaire, but less under the time pressure of a telephone interview (cf. Schwarz, Strack, Hippler, & Bishop, 1991). Hence, the model predicts that the emergence of context effects may depend on the mode of data collection, although relevant data are not yet available.

Rationality of the Culture of Goods

M. Sahlins, University of Chicago

My paper is about the relationship between the two kinds of "rationality" involved in modern market economies: the pecuniary calculus of gain, or economic rationality proper, and the logics of meaningful properties by virtue of which goods become use values in the society. No doubt this is all too familiar. Even though the 500th anniversary of Columbus' feat is near, I do not pretend to bring you the startling anthropological news of the discovery of America. But would like to do a bit of archaeology on our disenchanting consciousness of rationality with a view toward suggesting that its supposed dominance over the symbolic dimensions of material life is a cultural prejudice.

Indeed the peculiar Western species called *Homo economicus* goes back to Original Sin. By pleasing himself instead of regarding God, man was condemned to the unhappy existence of a "self-pleaser" -- in a world of "thorns and thistles." The punishment, as Augustine said, was the crime. Man (Adam) put love of himself before the love of Him alone who could suffice, disobeyed god to satisfy his own desires, and thus became the slave of insatiable bodily needs: a limited and ignorant creature exiled in an intractable natural world to labor, to suffer, and then to die. This life, concluded Augustine, is a "hell on earth." No wonder that babies are born into it crying and shrieking.

Still, God was merciful: He gave us Economics. By Adam Smith's time, human misery had been transformed into the positive science of how to make the best of our eternal insufficiencies, the most possible "satisfaction" from means that are always less than our wants. It was the same Christian cosmology, only bourgeoisified, which is to say, a more encouraging prospectus of the investment of opportunities that are afforded by human suffering. And even though the neo-classical economists would go on to translate our primordial inadequacies--what Hume had called "the unnatural conjunction of infirmity and necessity"--into elegant mathematics of scarcity, the genesis was not forgotten. "We have been turned out of Paradise," said Lionel Robbins, in a famous determination of the object of Economic Science: "We have neither eternal life nor unlimited means of gratification. Everywhere we turn, if we choose one thing we must relinquish others which, in different circumstances, we would wish not to have relinquished." So Robbins is clear! The Economic Man that inhabits page one of our Economics 101 textbook, this character is Adam.

Robbins skips over a lot of things that happened between the Fall and its Economics, especially the Renaissance change of heart about the blessings of poverty and the contemptibility of this world. No time for that here either. Jump to the seventeenth or eighteenth century. Everything happened as if the developing empirical science together with the emerging market economy, the twin demiurges of the Western rational cosmos, would

complete man's banishment to a godless natural world. Whatever the pan-glosses the intellectuals were putting on it, the full consequences of the tragedy in Eden were becoming apparent to the European progeny of Adam. Even the headier Enlightenment schemes of human progress, insofar as they translated a faith in divine redemption and dogmas of social evolution--the "rationalist corruption of Christian eschatology," as Paul Ricoeur describes it --even these progressive schemes were grounded in a base human nature: a libidinous creature easily driven by continuous wants to viciousness and competitive strife. And at the same time that the *philosophes* were thus revealing the full scope of human imperfections (while talking of the perfectibility of the species), the economy was producing unparalleled "satisfactions" by capitalizing on "one thousand shocks the flesh is heir to."

In this regard, the Invisible Hand of the market place might well have been the wrathful hand of God, as it would create the wrath of the nation out of the sense of privation it visited on the person. If the collective wealth is best secured by each one maximizing his own, it follows that each must be in that recurrent state of insufficiency that is the beginning of economic wisdom--the aforementioned scarcity of material means relative to the possible ends of personal gratification. This was the great industrial revelation: that in the world's richest societies, the subjective experience of need increases in proportion to the objective output of wealth. Or rather, in greater proportion, since needs are presumed to be endlessly expandable: the unnatural conjunction is between infirmity and infinity. Suffice it to say that individual wants, by encompassing an international division of labor, became permanent and inexhaustible. Felt moreover as physiological pangs, like hunger and thirst, such need seemed to emanate from natural dispositions of the body, springing from human nature itself. The bourgeois economy made a fetish of human needs in the sense that needs, which are always social and objective in character, which are always then historical formations, had to be assumed as subjective experiences of bodily affliction. The corollary of Weber's iron cage of pure desire has been an exquisite sensitivity to pleasure and pain, duly installed as the hegemonic motives of people's actions. Sensitivity especially to pain, which is anyhow the condition of the possibility of pleasure and much more lasting -- as every Chicago Cub fan knows.

The development of bourgeois society thus liberated egoistic man from the prison house of Christian morality and allowed desire to parade shamelessly by the light of day. This was no fundamental revolution in the Western concept of human nature, only a moral reversal between the earthly and heavenly sides of man's double being, and exchange of the values of flesh and spirit. Self-love acquired a positive moral status. The original evil and source of vast sadness in Augustine, it became the

"necessary evil" of *philosophes* such as Holbach, or else simply "natural" as in Hobbes, to end in Adam Smith & Co. as the pursuit of happiness and the best thing, since the greatest total good came out of each one's total self-concern. What was slavery to Augustine, every person's endless and hopeless attention to his own desires, is now perceived as the essence of freedom, the sacred right of every individual to do just that.

The argument I would make is that the development of capitalism, by making individual need appear as the cause of collective institutions, motivated a folk consciousness of society that passed too easily for the science of thereof.

Every cultural order fashions representations of itself: modes of appearance that are taken as ultimate realities since they make up the people's awareness of their social existence. Yet this subjective experience of culture is not the same thing as the systematic relations and meanings that historically produced it. Following Karl Polanyi, the decisive institutional moments of modern Western history can be described as the commoditization of land and labor. Brought into the marketplace, land and labor then entered in pecuniary relations with the other goods of existence. But since, as Polanyi reminds us, "labor is only another name for man, and land for nature," this is also to say that all human existence became subject to the dispositions of the supply-demand-price mechanism.

Subjectively, then, a vision that began in the Renaissance (Pico, Manetti) was coming true: we could make ourselves whatever we chose, inasmuch as the whole universe had been commodified. Unfortunately, however, no one has been able to afford it. So the actual effect was to make the recurrent sense of *scarcity* or lack the necessary condition of life -- whether in the perspective of capital, labor or consumption -- the process of accumulation is the reproduction of an initial scarcity, an eternal return to a deficiency of means relative to ends, setting off another cycle of judicious economizing. As for livelihood (so-called), accumulation is a labor of Sisyphus, ever falling back to zero by the act of consumption. Or worse. Even with respect to its apparent satisfactions, livelihood is a tragedy that, beginning in scarcity ends in deprivation, since every acquisition is also a denial of something different that could have been had instead. The commodity (as Marx taught) has a double nature. On one hand, it appears as an abstract exchange-value or price, which is not a property of the object as such but an external mark attached by the market, so making it more or less accessible to us. On the other hand, the commodity is a use-value in virtue of its empirico-meaningful qualities, the content that makes it suitable to our "needs" as historical and social beings -- the way that a filet mignon, being suitable for a celebratory occasion, is not just chopped liver. Now in certain respects, this dualism of value is irreducible, however we try to synthesize it in terms of "satisfaction." For in choosing between different goods, presumably in the interest of maximum satisfaction, one in fact forgoes specific gratifications that in quality (or use-value) are incommensurable with those achieved. The

idea that economic activity is the rational maximization of satisfactions is a cultural *cum* academic mystification. It depends on the supposition that things unlike in their objective attributes and human virtues, their different meanings to us as use-values, are indeed comparable as quantities, which is actually and only true in their capacities as exchange values. Thus the economist is able to subtract oranges from apples and convince us that the remainder is all for the best. But what remains to haunt us in choosing, for example, between taking kids to see their grandparents in California or saving the money to send them to college is that either kinship suffers or else education.

This is where a certain social science comes in: as an academic reflection on the common experience that by satisfying our individual need we create society. Since all use-values are transacted through exchange-values, in people's existential awareness, cultural forms of any description are produced and reproduced according to the calculus of their personal desires. These needs to which scarce resources are rationally allocated, they are nothing less than the system of society perceived as ends of the individual. Society seems to be another trick of the Invisible Hand, a kind of ledger-domain. And in the event, the whole cultural organization of the economy remains invisible, or at least implicit, being explicitly perceived as the pecuniary rationality by which its arbitrary symbolic values are realized. All the idiocies of modern life -- from Walkmans, and Reeboks, mink coats and five-million-dollar-a-year left-handed pitchers, to MacDonalds, Madonnas and other weapons of mass destruction -- this whole curious scheme can appear to the participants as the transparent effects of a universal practical wisdom. Hence the great rationality-paradox of a social science derived from the same native consciousness: that though the society seems to be constituted by rational choice, it is not thus intelligible. Though the total cultural order is generated by acts of practical-material reason, the effects are anything but utilitarian.

For the practical rationality of the things American people need would be difficult to imagine, however prudently they go about getting them. Is the relative cost of filet mignon really a reflect of its superior nutritional values? Are mink coats really warmer? The current sexist dogma, is this the most effective way to organize a division of labor? The streams of five passenger cars on the way to O'Hare airport each occupied by one or two people, is this a rational system of energy use? To say that people are optimizing other ends than material utility does not resolve the problem but merely describes it, as the statement is either a simple tautology or it invokes principles of value different in kind from the means-ends relations of practical action itself. To allege there is no disputing people's tastes is merely a formula for ignorance, for then there can be no social or historical understanding of them. Nor will it do to put the onus on the production side, as if capital creates demand arbitrarily. Somebody or something has to educate the educators. Even the producers who may be perpetuating people's tastes have to be

informed by the order of cultural values, that is, by what sells -- or else they will discover the system of society by their loss. Producers surely expand and manipulate the cultural code, but to do so they have to work out its logical implications. Everything will then happen as if the market economy were a perverse form of Hegel's cunning of reason: a cunning of custom, rather which by harnessing an absolute mode of rationality to a relative logic of signs ushers in a truly golden (i.e., profitable) age of symbolic freedom.

I am not speaking of the "irrational factors" in demand or production, a phrase which recuperates within a traditional paradigm of optimization what is inexplicable by it and thus defends the territory of the economy as the kingdom of the rational. I am speaking rather of another kind of logic, more encompassing than the instrumental and just as systematic, by which the calculus of satisfactions is mobilized and organized. Always the instrumental logic is set in cosmic order of cultural values. Practical rationality is subject to a calculus of meaning whose operations are such as metaphor, identity, analogic proportion, synecdoche, deixis, inversion or negation, and whose effect is to symbolically conjugate a set of material goods with a world of social persons. So it is not only objects which are hard or soft but also persons, even as it is not only persons who are masculine or feminine but also objects. Yet masculinity and femininity cannot be discovered in the physical properties of things such as steaks and tomatoes. It is their integration in the cosmos of symbolic values, the function of their properties as signifiers, that makes goods masculine or feminine, sexy, dressy, not right to eat for breakfast, Californian, upscale, youthful or appropriate on Sundays but not on weekdays. (I am reminded of my teacher Leslie White, of his favorite illustration of the symbolic: no ape, he used to say, could tell the difference between holy water and distilled water.) Pardon me for being so simple. But it sometimes seems necessary to recall that we are one of the others: exiled to a world without immanent spirit, perhaps, yet living a life of things as enchanted as the practitioners of any totemism.

"Every commodity carries with it a practical philosophy and a doctrine of life," observes an historian of the old Asian silk route. Indeed to clothe oneself in silk is to participate in its social significance, a whole doctrine of life, which includes the differentiation of women as "soft as silk" by contrast to the courser manliness of wool. And yet this analogic of the elementary units of apparel -- the "clothemes" of texture, color, line, pattern and the like -- are the beginning only of a vast grammar of clothing whose systematic dimensions are yet to be adequately explored and described. Notice the fascinating structures on the higher levels of clothing "statements": if men are to woman as wool is to silk and trousers are to skirts, still women may legitimately wear woollen pants, although "real men" will not be caught dead wearing silk dresses. But then "unisex clothing" is generally male clothing. And all such examples of the grammar of goods correspond to

the markedness structure of the pronouns of our language, which likewise encompasses the feminine in the masculine and defines the former as a differentiated and opposed subgroup of the latter. A fact that at last allows me to return to the beginning of the paper, to justify it as archaeology, since in the Western mythology woman was indeed made from a part of Adam (Man). What I am trying to suggest, then, is that what we usually think of as a practical praxis, not only in the production of clothing, but food, shelter and everything else, that all this is only the objectification in concrete terms of a total historical and cultural "doctrine of life."

It may not be "you are what you eat" -- or if so, it is because of an *a priori* logic that connects what you eat with what you are. (A friend of mine doing ethnographic work in New Guinea with a people who had formerly practiced cannibalism asked one if he ate his enemies in order to become like them, to assimilate their powers. "You eat chicken, don't you?" The anthropologist nodded in assent "well, does that make you like chickens?") In any event, the studies of Mary Douglas and her colleagues have demonstrated an enormous set of relationships between main social distinctions in modern societies -- distinctions of gender, religion, ethnicity, region and status -- and patterns of food consumption.

The variations concern not merely types and properties of different foods, modes of preparation and the structures of meals, but also daily, weekly and seasonal consumption routines, culinary modes of celebration and ritualization, and much more. There is clearly a complex, heteroglossically expressed code connecting meaningful social and cultural distinctions with objects of properties of food and its preparation. Observations of Bourdieu and others have begun to explore the code, this cast cultural system of diet. But so much remains to be done, perhaps because it is not always appreciated that the task will have to go far beyond the ethnography of eating, into the history and constitution of the cultural order in general. If the outside of the animals is to the "innards" as culture or civilization is to nature, in the way that names of our meats suggest, we will have to open up the whole question of the culture-nature distinction and its connection to concepts of bodies as well as categories of persons. If meat is to vegetables (or steak is to tomatoes) as the masculine to the feminine, we will have to take notice of the historical fact that "meat" was once the generic term for "food," and the livestock, as opposed to the "deadstock" of fixed farm equipment, was the principle of increase in the domestic economy -- whence the well known connection of cattle with stock in the form of capital. And if meat is so mixed up with gender and wealth, let us not forget that we use the concept of inheritance -- which in our society is predominately patrilineal -- to refer equally to the transmission of biological and social identities (genes and names) as well as to the transmission of property. There is a peculiar relation of cultural domains involved in the meanings of food - - and more, there is a whole cultural cosmology.

Person Perception Carry-Over Effects: An Exploratory Look at How Our Partners' Traits Influence The Evaluation Of Ourselves

Therese A. Louie, UCLA

ABSTRACT

Research has investigated what traits individuals should possess to receive favorable evaluations. We extend this inquiry by exploring how the evaluation of individuals is influenced by the traits of their romantic partners. Subjects 1) read vignettes which portrayed partners who possessed varying degrees of status, personal warmth and attractiveness, and 2) rated the favorability of individuals associated with these partners. Individuals who had partners with high, versus low, personal warmth were judged favorably, with those who had partners with high personal warmth/low status rated highest. In addition, paralleling past research, males judged individuals by the partners' attractiveness more than females did.

A recent radio advertisement provides the listener with a conversation between individuals who are wondering why they lost out on a promotion. While one individual mentions, "I get along better with the boss than he [the promoted colleague] does," the other remarks, "My wife is prettier than his." The last remark suggests that individuals are evaluated not only by their own characteristics, but also by the traits of their spouse or romantic partner.

Similar to the manner in which the traits of a company spokesperson influence the image of a product, the attributes of a romantic partner may influence judgments about an individual. This "partner carry-over" has many applications in consumer behavior. For example, in the field of advertising, suppose that an advertisement is being constructed to show consumers what type of individual (e.g., a yuppie or a farmer) uses a given product. The inclusion of a romantic partner can be used to reinforce the desired image. In addition, in the field of public relations, individuals who are concerned about projecting a certain image (e.g., political candidates) might be interested in knowing how their partners' characteristics reflect upon themselves. In short, the partner carry-over effect is relevant to any occasion in which it is important that an individual project a certain image to consumers.

While researchers have long noted the potential impact of a partner's characteristics (Whyte, 1956) efforts to explore any carry-over effect have been limited to the examination of the trait of physical attractiveness. In real world situations information about variables other than attractiveness may be available for forming person perceptions. This research is an attempt to explore how personal traits combine to form a partner carry-over effect.

Past Research On Traits Which Influence Person Perception

Physical attractiveness. The partner carry-over effect has been partially examined by researchers investigating physical attractiveness. Past work suggests that individuals who associate with others

who are attractive are evaluated higher than those who do not (Strane and Watts, 1977; Sigall and Landy, 1973). However, other efforts suggest that this effect is dependent upon gender specific stimuli in that it occurs primarily for males who associate with attractive female partners (Harnett and Elder, 1973; Bar-Tal and Saxe, 1976).

When individuals describe one another they often comment upon factors other than attractiveness such as personal warmth (e.g., amicability) and status (e.g., success in professional or intellectual pursuits). When investigated separately these factors have been found to heavily influence the evaluation of individuals (see Sears, Freedman, Peplau, 1985). However, the simultaneous influence of multiple *partner* traits on individual evaluations has not been probed in past work.

Personal warmth. The extent to which an individual has a pleasant personality, or is personally warm, may be assessed by witnessing the degree to which he/she reacts positively to other individuals. Research (Folkes and Sears, 1977) has shown that individuals who have a positive attitude are perceived as having higher levels of personal warmth and more favorable evaluations than those who do not. This perhaps suggests that individuals who have partners with high personal warmth are evaluated more highly than individuals who have partner's with low personal warmth.

Status. An individual's status is often measured through his/her success in professional or intellectual pursuits. For example, individuals are often judged by what college they attended or by their job title. In general, individuals who have high status are evaluated more favorably than those with low status (Kinder and Abelson, 1981). Intuitively it seems reasonable to propose that individuals are more favorably evaluated when associating with a partner of high, rather than low, status.

To summarize, information about attractiveness, personal warmth and status has been shown to influence the evaluation of individuals. In general, when each of these traits is examined separately higher levels of each generate more favorable individual evaluations. This research shifts the focus of trait investigation from those possessed by the individual being evaluated to those possessed by the individual's partner. We attempt to begin exploring how the evaluation of an individual is influenced by a partner's level of attractiveness, personal warmth, and status.

METHOD

Subjects And Procedure

Due to the exploratory nature of this research a small sample was used. Ten female and 10 male graduate students were asked to voluntarily complete experimental questionnaires.

Stimulus Materials

Researchers have used written scenarios, or vignettes, to ascertain how subjects would react in given situations (Gross, Mason, and McEachern, 1958). In this study questionnaires were used which contained vignettes about particular target individuals interacting with their romantic partners.

To compose the vignettes, ten pretest subjects (who did not participate in the final study) completed a preliminary questionnaire in which they rated (a) the level of attractiveness of various physical descriptions (e.g., of a fashion model or of an individual who has a significant weight problem), (b) the level of personal warmth displayed by various actions (e.g., by giving a partner a thoughtful gift or by yelling at a partner in public), and (c) the level of status of various job descriptions (e.g., of a company vice president or of a fast food worker). All ratings were made on a scale of one (1 = low) to ten (10 = high).

Mean item ratings of below and above the arbitrarily chosen cut-off of five were respectively designated as negative and positive descriptions of attractiveness, personal warmth, and status. Then, questionnaire vignettes were constructed using the different descriptions to convey information about the target individual's romantic partner.

Below is a sample vignette with a partner who is of low attractiveness, personal warmth, and status. The target individual is John.

John's girlfriend stopped by to ask if he could give her a ride from the fast food stop where she worked to her Weight Watchers meeting that evening. When John agreed, she said, "Don't make me wait."

It should be noted that, departing from the procedures used in previous research in which information about attractiveness was presented visually, the presentation of all traits was standardized by being presented in verbal print form. This procedure, in addition to presenting the traits in an identical manner, allowed us in this preliminary effort to avoid some of the confounds which may stem from subjects' different opinions of what is considered visually attractive. In future research photographs or film may be used to more fully explore how physical attractiveness interacts with personal warmth and status.

Sixteen vignettes were written to rotate all combinations of the variables. Two randomizations of the vignettes were made to form two versions of the questionnaire. Finally, the gender of the subject was noted in order to examine any differences in evaluation style. Thus, this is a gender of target individual (2) X partner's level of attractiveness (2) X partner's level of personal warmth (2) X partner's level of status (2) X gender of subject (2) within subjects design.

Dependent Variables

After reading each vignette the subjects were asked to rate how favorably the target individual would

be evaluated on a scale of one (1 = extremely unfavorably) to ten (10 = extremely favorably).

RESULTS AND DISCUSSION

A comparison of means was conducted across the levels of attractiveness, personal warmth, and status, and across both the gender of the subject and of the target individual, retaining subject as a factor. An initial analysis showed that there were no significant effects of the gender of the target individual. Therefore, the data were collapsed across this variable and subsequent analysis were conducted across the factors of attractiveness, personal warmth, status, and the gender of the subject.

Target Individual Evaluations

There were two interactions in the data, one which highlights the differences across levels of personal warmth and status, the other which accentuates how male and female subjects differentially react to the attractiveness of the partner.

Level of personal warmth and level of status. As displayed in Figure 1, the evaluation of the target individuals differed significantly across the partners' levels of personal warmth and status: $F(1, 319) = 4.59, p < .001$.

This interaction qualifies a significant main effect of personal warmth whereby the subjects more favorably evaluated target individuals when their partners had high, versus low, levels of personal warmth: $M = 6.11$ and $M = 4.67$, respectively, $t(319) = 9.47, p < .001$. In addition, subjects evaluated target individuals more highly when their partners possessed high personal warmth and low status than when their partners possessed high personal warmth and high status: $M = 6.43$ and $M = 5.78$, respectively, $t(319) = 3.16, p < .05$.

According to the study findings, individuals who want to be evaluated favorably should associate with partners who have high levels of personal warmth. There also appears to be a hierarchy in the importance of different traits: While there was a main effect of personal warmth, status had only interactive effects.

Somewhat counter-intuitively, low rather than high partner status increased evaluations when paired with high personal warmth. To gain insight into this finding one subject was asked to explain verbally the reasoning behind his provided responses. The subject stated that the described target individuals who associated with partners of high status could be accused of using their partner to obtain prestige and power. In contrast, target individuals who had partners of low status were not as suspect; for this subject, high ratings were given to target individuals who had partners with low status and high warmth due to the assumption that the target individual was truly caring without ulterior motives. As we do not have open ended measures of the subjects' thoughts we can only speculate that perhaps the interaction of partner warmth and status conveys information about an individual's interpersonal motives and sincerity.

FIGURE 1
Evaluation of Target Individual: Level of Personal Warmth by Level of Status Interaction

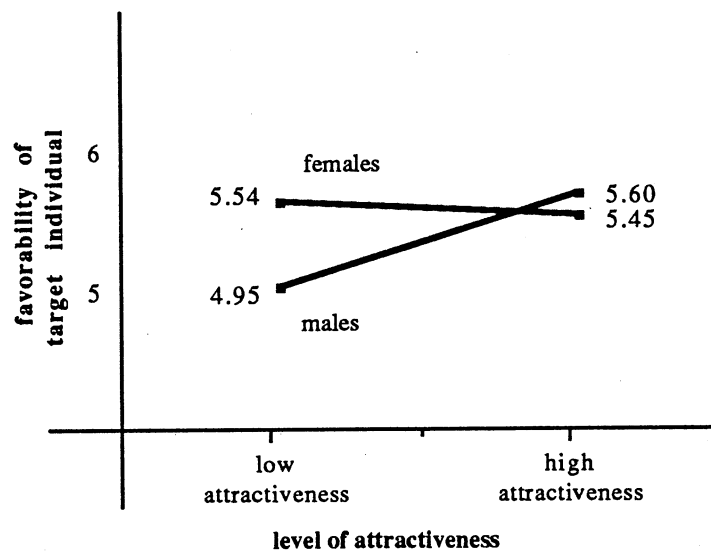

FIGURE 2
Evaluation of Target Individual: Gender of Subject by Level of Attractiveness Interaction

Gender of subject and level of attractiveness. As illustrated in Figure 2, the target individual was evaluated differently by the male and female subjects according to the level of attractiveness of the partner: $F(1, 319) = 9.84, p < .001$. Post-hoc comparisons reveal that males evaluated target individuals with partners who had low levels of attractiveness more unfavorably than did females: $M = 4.95$ and $M = 5.54$, respectively, $t(159) = 2.47, p < .05$. In addition, the male subjects evaluated target individuals less

favorably when the corresponding partners had low, versus high, levels of attractiveness: $M = 4.95$ and $M = 5.60$, respectively, $t(159) = 2.72, p < .05$.

Hence, male subjects were more likely than females to consider the level of attractiveness of the partner when evaluating the favorability of the target individual. This finding is similar to that of past research in which males place greater value than females on a target individual's physical attractiveness when selecting a partner (see Feingold, 1990).

However, as we found no differences based upon the gender of the *stimuli*, these research findings differ from that of past studies in which male individuals were evaluated more favorably when associating with attractive partners (Harnett and Elder, 1973; Bar-Tal and Saxe, 1976).

FUTURE RESEARCH

There are many ways to test the generalizability of these results by improving and expanding upon this initial effort. For example, while information about high and low traits levels was manipulated in this study the weight of these factors was not controlled. To convey high status in one vignette the partner was described as a company vice president, while the same trait was conveyed in another vignette by describing the partner as a student at an ivy league college. Some subjects might view the former as higher in status while others might favour the latter. In future research care can be taken to ensure that the weights of each factor are similarly valued for all individuals.

In addition to testing the generalizability of these results, having found some evidence of partner carry-over effects, another future endeavour is to investigate why the different findings occurred. For example, females were less likely to evaluate target individuals based upon the partner's attractiveness than were males. Perhaps the different genders truly do place different emphases on the value of physical attractiveness. If so, it would be interesting to investigate when and how this difference develops, how persistent and pervasive the difference is, and what can be done to lessen any negative consequences resulting from this discrepancy.

Or, equally interesting is the possibility that the genders similarly emphasize this factor but approach the evaluation task differently, with females trying particularly hard to be unprejudiced by responding to descriptions with attractive and unattractive partners as equivalently as possible. To test for this "matching" effect, these results may be contrasted with those of a study using a between subjects design in which subjects are placed in conditions to read about only attractive or unattractive partners.

In addition, these findings pertain to circumstances in which information is conveyed verbally (e.g., via print or radio media). Individuals may react quite differently to visual or visual/verbal data. For example, unlike the results of previous efforts (e.g., Bar-Tal and Saxe, 1976) the findings of this study do not differ across the gender of the target individual. That previous studies were conducted with visual stimuli suggests that individuals' evaluations are less sensitive to biases caused by gender-based stimuli when the information is provided verbally. This visual/verbal difference may have interesting implications for the manner in which information is conveyed in pictorial versus written/spoken materials. If the evaluation of an individual is less subject to gender biases when the information is conveyed via nonvisual media—even when the gender of the individual is identified—then this media should be used

when evaluations are to be made without regard to gender differences. It would suggest, for example, that the practice of attaching photographs to applications (e.g., as requested by some college admissions offices) should be eliminated. Insights into how information is conveyed visually and nonvisually can be gained by asking subjects to respond to open ended thought questions.

In short, many steps may be taken to improve upon this initial effort. These include constructing the stimuli with equal attribute weighting, using a between subjects experimental design, incorporating visual as well as verbal information, and requesting that subjects respond to open ended thought questions.

CONCLUSION

The findings of this exploratory effort suggest that the traits of partners carry over to influence the evaluation of individuals with whom they associate. The three traits of attractiveness, personal warmth, and status, and the gender of the evaluator all influenced the evaluations. Future research will attest to the generalizability of these findings across different evaluation tasks and different sources of trait information.

Effects of Involvement, Arousal, and Pleasure on the Recognition of Sponsorship Stimuli

M. Tuan Pham, University of Florida

ABSTRACT

This paper examines the effects of involvement with a sports event, and arousal and pleasure in reaction to this event, on the recognition of embedded sponsorship stimuli. A study shows that involvement with a soccer game has a curvilinear effect on the recognition of embedded billboards. Arousal in reaction to the game has a negative effect on this recognition. These effects are distinct from each other. Pleasure did not have the expected positive effect. It was also observed that the recognition of the sponsorship stimuli was significantly lower among females than among males.

INTRODUCTION

Sponsorship can be defined as "the provision of resources (e.g., money, people, equipment) by an organization directly to an event or activity in exchange for a direct association to the event or activity" (Sandler and Shani 1989, p.10). Sports Sponsorship as a communication tool has recently become very popular among marketers. According to Meenaghan, (1989), in 1987 in the United States, 35,000 companies spent \$1.75 billion to sponsor sporting events, and in 1989 worldwide sponsorship expenditures were valued at \$4.1 billion. Marketing practitioners' marked interest in sponsorship communication (e.g., Otker 1988; Ryssel and Stamminger 1988) is in sharp contrast with academic researchers' lack of attention (Gardner and Shuman 1986; Meenaghan 1983; Sandler and Shani 1989).

One of the main reasons for the practice of sponsorship is the achievement of media coverage (Abratt, Clayton, and Pitt 1987). Hence, sponsorship effectiveness is most often expressed in terms of the amount of media coverage generated through it (Waite, 1979; Mintel 1986). However, while sponsorship stimuli (e.g., billboards) embedded in sports events can receive dramatic exposure (see e.g., Welling 1986), there is evidence that attention to and memory for these stimuli are, in fact, very limited (Nebenzahl and Hornik 1985; d'Ydewalle et al. 1987). Therefore, there is a need to better understand the factors that affect the processing of sponsorship stimuli and, consequently, moderate the effectiveness of their exposure.

The purpose of this paper is to explore how involvement with a sponsored event, and affective reactions to this event, moderate the effectiveness of

exposure to embedded sponsorship stimuli. The measure of effectiveness considered here is the subsequent recognition of these stimuli. The effects of event-induced affective reactions are studied along two main dimensions, pleasure and arousal (cf. Mehrabian and Russell 1974). The literature about the effects of involvement, arousal, and pleasure is briefly reviewed, leading to three hypotheses. The results of a study testing these hypotheses are then reported and discussed.

SPONSORSHIP STIMULI IN CONTEXT

The selection of events to sponsor is partly determined by the assumption that sponsorship stimuli will be processed somewhat differently as a function of the events in which they appear. This issue parallels the stream of research that relates the context of an ad to its performance (e.g., Axelrod 1963, Thorson et al. 1985). For instance, Pavelchak, Antil, and Munch (1988) have recently investigated the effects of emotional experience induced by a Super Bowl game on the recall of embedded commercials. They found that arousal induced by the game decreases the number of commercials recalled. There is, however, a critical difference between commercials and the type of stimuli considered in this study: sponsorship stimuli (e.g., billboards around a soccer field, brand names on racing cars, logos on team players' shirts) *do not interrupt* the programs in which they are embedded. Therefore, the issue is to determine how factors related to the processing of a sports event affect the *concurrent* processing of sponsorship stimuli. Three variables are considered here: 1) involvement toward the sponsored event, 2) arousal in response to this event, and 3) pleasure when watching the event. Although involvement and arousal are strongly correlated, especially in a sports context, it is suggested here that they have distinct effects on the processing and subsequent recognition of sponsorship stimuli.

Effect of Involvement

Consumers' processing of a sponsored event is influenced by their motivation, ability, and opportunity to process this event (cf. Batra and Ray 1986; MacInnis and Jaworski 1989). These factors should also affect the concurrent processing of any embedded stimuli. Motivation to process information is often referred to as *involvement* with the informational object (e.g., Celsi and Olson 1988; Petty, Cacioppo, and Schumann 1983). This motivational state is governed by the perceived relevance of the target object (Greenwald and Leavitt 1984; Zaichkowsky 1985). Consistent with Celsi and Olson (1988) and Houston and Rothschild (1978), it is proposed that the phenomenological experience of involvement with a particular sponsored event results from the combination of enduring (or intrinsic) and situational sources of personal relevance. For

¹ The data reported in this paper were collected while the author was at the Catholic University of Mons (FUCAM, BELGIUM). The author is indebted to Michel Bomboir for his assistance at various stages of the study and to Richard Celsi, Christian Derbaix, Susan Fournier, Rich Lutz, Piet Vanden Abeele and Luk Warlop for helpful comments on earlier drafts of this paper.

instance, while an individual may be involved with soccer in general or with a specific team in particular (i.e., enduring involvement), situational factors such as the opponent (e.g., two teams from the same city), the stakes (e.g., a World Cup final), or the score (e.g., 3-3) can increase or decrease the perceived personal relevance of a given game. This perceived personal relevance, or "felt involvement" (Celsi and Olson 1988), will influence the processing of the event, and thereby, the processing of the sponsorship stimuli.

Consistent with Mitchell (1979;1981), (felt) involvement with a sponsored event is conceptualized as having both intensity and directional properties, each exerting a different effect on the processing of embedded stimuli. The more a person is involved with say, a soccer game, the more *intense* his/her processing of the game (cf., Burnkrant and Sawyer 1983). At low levels of involvement, little attentional capacity (effort) will be allocated to the event as a whole. Because they are inlaid in the event, sponsorship stimuli should also receive little attention. As involvement increases more overall attention is devoted to the event and also, as a result of their embeddedness, to the sponsorship stimuli.

However, involvement also has a *directional* property. Because of limited cognitive capacity (Kahneman 1973), as involvement or motivation to process reaches high levels, attention becomes more focused on the relevant source of information (Celsi and Olson 1988; MacInnis and Jaworski 1989), i.e. the game itself, and away from irrelevant information such as the sponsorship stimuli. Thus, at high levels of involvement, attentional selectivity should overcome the positive effect of processing intensity on the processing of sponsorship stimuli. Highly involved people are no longer "willing" to process irrelevant billboards when watching a soccer game. Therefore, a curvilinear relationship is hypothesized between audience involvement with a sponsored event and the processing of sponsorship stimuli. This should be reflected on people's ability to recognize the stimuli in a subsequent task.

- H1 Felt involvement with a sponsored event has an curvilinear (inverted-U) effect on the recognition of embedded sponsorship stimuli.

This curvilinear relationship between felt involvement and the recognition of sponsorship stimuli is essentially driven by people's *motivation* to process the event. It is argued that this effect is distinct from the effect of arousal, discussed here below.

Effect of Arousal

Sports events can induce intense affective reactions among audience members. The intensity dimension of affective reactions is often operationalized as arousal (e.g., Clark 1982; Pavelchak et al. 1988). Arousal refers to the activity of the autonomic nervous system, particularly in its sympathetic division (Mandler 1975). Its experience is defined as a feeling state varying along a single

dimension from drowsiness to frantic excitement (Mehrabian and Russell 1974, Humphreys and Revelle 1984).

In dual task studies, heightened arousal has been shown to impair performance on the secondary task (Eysenck 1982). Easterbrook (1959) suggested that heightened arousal produces an attention narrowing process, restricting the range of cue utilization. Primary task cues are attended to at the expense of secondary task cues. This attention narrowing process results from capacity limitations associated with high arousal. Two explanations can account for this increased attentional selectivity. First, it has been proposed that arousal cues arousal-related material in memory (Clark 1982; Clark, Milberg, and Ross 1983). Because more, and more diverse, material enters consciousness, there is a decrement in the amount of processing capacity available (Worth and Mackie 1987). It is also plausible that arousal in the autonomic nervous system generates internal cues that compete with external cues for the limited attentional capacity in the conscious field (Mandler 1975).

A parallel can be drawn between the dual task paradigm and the concurrent processing of a sponsored event and of embedded sponsorship stimuli. When watching sports event, limited processing capacity must be shared by the event itself (e.g., a tennis match) and other sources of information including sponsorship stimuli. As arousal increases, available processing capacity decreases. Because of this reduced *ability* to process information, attention is narrowed to the game itself. Therefore, arousal induced by a sponsored event will have a negative effect on the processing of embedded sponsorship stimuli. This reduced processing of the stimuli should result in a lower ability to subsequently recognize them.

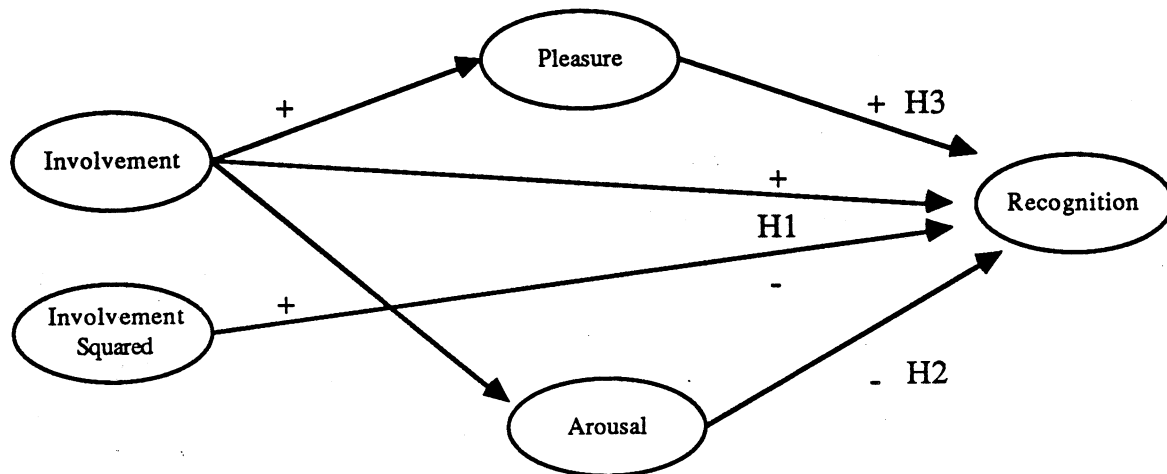

- H2 Arousal induced by a sponsored event has a negative effect on the recognition of embedded sponsorship stimuli.

High involvement with a sporting event should result in higher arousal in reaction to this event. People to whom the event is personally relevant should experience more intense affective reactions to it. Nevertheless, it is speculated that the curvilinear effect of involvement is distinct from the negative effect of arousal. Conceptually, whereas the former reflects people's motivation to process information, the latter results from their *ability* to process such information (Sanbonmatsu and Kardes 1988).

Effect of Pleasure

Besides their intensity, affective reactions can be characterized by their polarity (i.e., pleasure versus displeasure). Sporting events have the potential to create highly polarized affective states among audience members. It has been suggested that people learn more material when in a positive mood than when in a negative mood. For instance, Goldberg and Gorn (1987) observed that commercials were better remembered when inserted in a happy TV program than when inserted in a sad program. Mayer (1986) proposes that negative affective states impede

FIGURE 1
Hypothesized Relationships Among Involvement, Arousal, Pleasure, and Recognition of Sponsorship Stimuli

learning by decreasing motivation and inducing the interjection of negative thoughts. Isen (1984) suggests that positive affective states produce changes in cognitive organization that enable a more efficient processing. Specifically, people in a positive affective state categorize material in fewer but broader categories. This use of broader categories allow them to organize the material more efficiently and consequently to memorize it better. In line with these arguments, it is hypothesized that event-induced pleasure will have a positive effect on the recognition of sponsorship stimuli.

H3 Pleasure experienced in reaction to a sponsored event has a positive effect on the recognition of embedded sponsorship stimuli.

The path diagram in Figure 1 summarizes the hypothesized effects of involvement, arousal, and pleasure. Although they are not central in this study, the expected relationships between these independent variables are also presented. It is anticipated that both arousal and pleasure will be enhanced by an increase in felt involvement. As already stated, people to whom the sporting event is personally relevant should react more intensely than people to whom the event is less relevant. Also, although highly involved people might feel displeasure if their favorite team or player is losing, on average, watching a sporting event should be a more pleasurable experience to involved viewers than to noninvolved ones. Pleasure and arousal are depicted as uncorrelated because they are conceptually orthogonal constructs (Russell, Weiss, and Mendelson 1989). However, a positive correlation is sometimes observed between them (e.g., Pavelchak et al. 1988). An artificial variable, the square of felt involvement, is included to express the curvilinear effect of involvement on the recognition

of sponsorship stimuli (H1). Felt involvement and its square are described here as uncorrelated, which is expected if the former is normally distributed and expressed in deviation form. Arousal will decrease the recognition of sponsorship stimuli (H2); pleasure will increase it (H3).

METHOD

Overview. Eighty-five undergraduate students at a Belgian university took part in the study to fulfill a course requirement. They watched, in a single session, a 25-minute edited version of an unaired recent soccer game with embedded billboards. After viewing the game, subjects were administered a surprise recognition test concerning the embedded billboard.

Material. Given the objectives of the study, it was necessary to generate sufficient involvement, arousal, and pleasure among the subjects. The perceived relevance of the material to the subjects was enhanced in three ways. First, the selected game concerned a confrontation between two of the most prestigious Belgian teams. Second, it was known in advance that the game would not be broadcast prior to the study, except for short excerpts during TV news. (This was also essential for the internal validity of the study.) Finally, the study took place only six days after the actual game, and before either team had played another game. A full recording with original commentaries was made available by Belgian French speaking Television (RTBF). The recording was professionally edited in order to select the most interesting sequences (as in real televised summaries) and to control exposure to the billboards. In order to obtain sufficient power (Sawyer and Ball 1981), the edited program was 25-minute long (i.e., much longer than usual summaries).

Procedure. The study was run in a single session in order to minimize communication effects. The projection of the stimulus material took place in a

conference hall with excellent viewing facilities. The subjects were first assigned well-spaced seats, and then given the following cover story: "The Belgian Soccer League has recently observed a steady increase in the attendance at the matches of the Top League Championship (a slide was projected to support graphically this true assertion). The Soccer League attributes it notably to increased quality of the games resulting in a higher potential to interest the viewer. Our study aims at analyzing the ability of the matches to induce interest among TV viewers". They then completed a questionnaire concerning their possible "centers of involvement" (i.e., soccer in general, or a team in particular), their level of enduring involvement toward each "center", and their knowledge of soccer. They were also questioned about their acquaintance with the particular game (e.g., unseen, seen portions during TV news, attended the game).

After the first booklet had been collected, subjects were shown the game on a giant screen. They were instructed to imagine that they were in their living room watching sports news on TV.

After the projection, a second booklet containing the independent variables measures was distributed. Subjects were asked to report their felt involvement while watching the game and their affective reactions (pleasure and arousal) to it. To measure any demand characteristics, control questions were included about the objectives of the study. After the second booklet was collected, the recognition task was administered. After completing this task, subjects were asked to estimate how well they performed on it. They also explained why they thought that their recognition performance was good or poor.

Independent Variables. Zaichkowsky's (1985) 20-item PII scale was adapted to better capture the phenomenological nature of felt involvement. Zaichkowsky's antonyms (e.g., "important/unimportant") were inserted into small sentences such as "Watching this game has been important/unimportant to me" and "I have found this game boring/interesting." In order to measure experienced pleasure and arousal, the scales developed by Mehrabian and Russell (1974) were adapted in a similar way. For example, the 6-item pleasure scale included the item "While watching the game, I was happy/unhappy." The 6-item arousal scale included items such as "During the game I was jittery/dull". All three scales were presented in a single random order with end-points counterbalanced. Because the effects of involvement are easily confounded with the effects of knowledge, the latter was also measured in this study. Thirteen multiple-choice questions about soccer and the teams, with various degrees of difficulty, were developed. The measure of knowledge was simply the number of correct answers.

Dependent variable. Recognition of the sponsorship stimuli was measured on the basis of 8 billboards that were clearly visible during the program (mean duration of exposure = 118.5 sec). Each of these 8 billboards was projected to the subjects for 10 seconds among 3 other billboards that did not appear in the program. No other cue but the billboard itself

(e.g., a player, a portion of the stadium) was projected. The subjects were asked to indicate which of the billboards presented in groups of 4 they recognized as appearing during the program. They were instructed not to rely on their beliefs nor to attempt to guess. The recognition score was simply the number of correct answers.

RESULTS

Control of Artifacts

Control questions about the objectives of the study were asked just after the projection of the game and before the recognition test. They revealed that no subject guessed the true purpose of the study. After the recognition test, as a second control, subjects were asked to explain their recognition performance. Seven subjects explicitly attributed their good performance to their acquaintance with the stadium or with the home team; they were thus disregarded for subsequent analyses. Two other subjects were dropped because of evident carelessness. The final sample was composed of 76 subjects, 35 males and 41 females (mean age = 19.2). While 16 of these subjects had been previously exposed to small portions of the game broadcast during TV news, there was no significant effect of this previous exposure on the recognition score ($F(1,73) = .09$, $p > .77$). Hence, these 16 subjects were retained in the analyses.

Reliability and Discriminant Validity of the Independent Variables

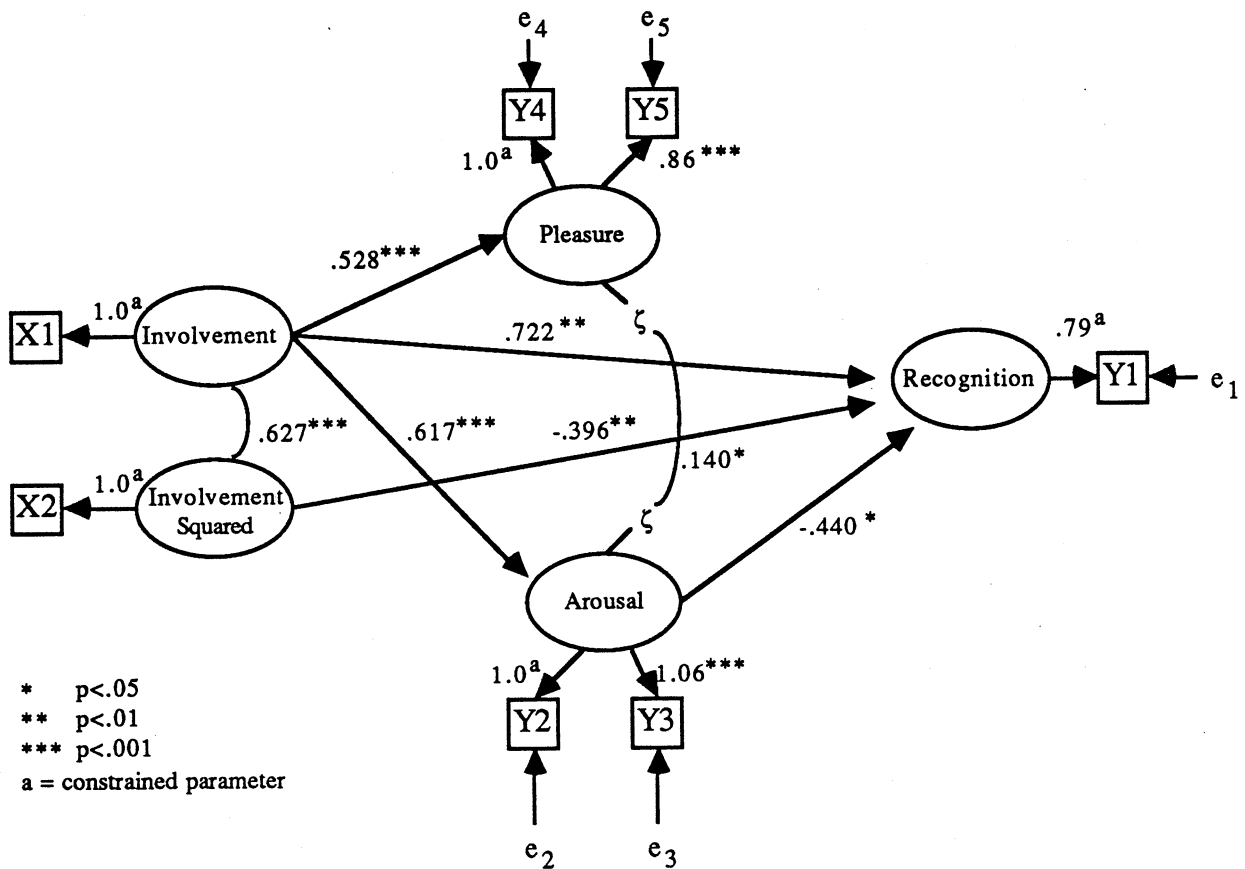

Scales for felt involvement (Cronbach's $\alpha = .98$), arousal ($\alpha = .86$), and pleasure ($\alpha = .88$) exhibited high internal consistency. To test the discriminant validity of the felt involvement, arousal, and pleasure constructs, the 32 items measuring them were factor-analyzed. Because involvement and arousal were anticipated to be highly correlated, an oblique rotation (OBLIMIN) was applied to the extracted factors. A three-factor solution accounted for 72% of the total variance.

The rotated factor loadings (not reported here because of space limitation, but available from the author) clearly indicated that three different constructs were indeed measured. All felt involvement items loaded on factor 1, pleasure items on factor 2, and arousal items on factor 3. As anticipated, factor 1 (involvement) and factor 3 (arousal) were strongly correlated ($r = .462$). The correlation between factor 1 and factor 2 (pleasure) was $r = .368$. Although pleasure and arousal are theoretically orthogonal (Russell, Weiss, and Mendelson 1989), factor 2 and factor 3 were positively correlated in this study ($r = .264$).

Effects of Involvement, Pleasure and Arousal

To review, felt involvement was hypothesized to have a curvilinear effect on the recognition of sponsorship stimuli (H1). Arousal was hypothesized to have a negative effect, distinct from that of felt involvement (H2). Pleasure was hypothesized to have a positive effect on recognition (H3). The hypothesized relationships depicted in Figure 1 were

FIGURE 2
Observed Relationships Among Involvement, Arousal, Pleasure, and Recognition of Sponsorship Stimuli

tested using LISREL-VI maximum likelihood procedure (Jöreskog and Sörbom, 1984). It is recognized that the inclusion of a squared variable (felt involvement squared) violates the assumption of multivariate normal distribution made by maximum likelihood estimation. However, a previous study (Hayduk 1987) also using a squared variable in LISREL, found maximum likelihood estimates to be little affected by this violation. Hence, maximum likelihood estimates are reported here. (generalized least squares estimates were very similar.)

Rather than directly path-analysing the observed summated scores (see e.g., Pavelchak et al. 1988), it was judged preferable to take measurement error into account. The recognition score had an estimated reliability of KR-20 = .62. Following common practice, this measurement error was introduced in the model by setting the corresponding factor loading equal to the square root of the reliability estimate and the measurement error equal to 1 minus this estimate. Although both pleasure and arousal were measured with good internal consistency (alpha = .88 and .86, respectively), it was decided to split each of the two 6-item scales into two 3-item scales to have two separate

measures of each construct. Finally, since felt involvement had a very high reliability (alpha = .98), it was assumed that the observed summated score was an error-free single indicator of the latent construct. This allows to consider the squared involvement score to be itself an error-free measure of the latent squared factor. (This is clearly a simplifying assumption, but it would also have been made had path analysis or multiple regression been used instead.)

The final estimated model is depicted in Figure 2. It shows a very good fit to the data (Chi-square (df=10)= 13.94, p > .18), goodness-of-fit index = .955, root mean square residual= .042). Felt involvement had a strong positive effect on experienced arousal (.617, t= 6.88, p < .001). It also increased subjects' pleasure experiences when viewing the game (.528, t= 5.39, p < .001). There was a residual correlation between pleasure and arousal that was not accounted by the structural model (.140, t = 2.01, p < .05). This is probably because, on average, subjects experienced more pleasure than displeasure in reaction to the game (mean = 27.07 on a scale from 6 to 42). This resulted in an overall polarized affective reaction that was accompanied by heightened arousal.

In support for the first hypothesis, the effect of felt involvement on the recognition of the stimuli was clearly curvilinear. The path from (unsquared) felt involvement to recognition was positive (.722, $t = 3.19$, $p < .01$), whereas simultaneously the path from felt involvement squared to recognition was negative (-.396, $t = -2.26$, $p < .01$). It can be observed that felt involvement, although expressed in deviation from its mean, was strongly correlated with its square. This unexpected correlation probably stemmed from the skewness of this sample's felt involvement distribution. Even when the effects of felt involvement and its square were accounted for, arousal significantly decreased the recognition of the stimuli (-.440, $t = -1.898$, $p < .05$). This effect of arousal corroborates the second hypothesis. However, it is possible that involvement has a curvilinear effect on recognition only because it has both a positive direct influence and a negative indirect influence mediated by arousal. To test that mediation explanation, the direct path from squared involvement to recognition was removed, resulting in a nested "mediation" model. This mediation model fitted the data significantly worse than the model depicted in Figure 2 (Chi-square difference ($df=1$) = 4.98, $p < .05$). Adding a path from felt involvement squared to arousal did not improve the fit of the mediation model (Chi-square difference ($df=1$) = 1.01, $p > .30$). Therefore, it appears that the curvilinear effect of felt involvement and the negative effect of arousal are distinct from each other. Contrary to the prediction of third hypothesis, the effect of pleasure on recognition was not significant ($t = .615$, $p > .25$). The corresponding path was consequently dropped. Felt involvement (squared and unsquared) and arousal accounted for 22% of the variance in the recognition of sponsorship stimuli.

Effects of Knowledge and Gender

An alternative interpretation of the data is that the effects of felt involvement are confounded with the effects of knowledge. Therefore, a measure of subjects' knowledge of soccer and of the teams was taken before they saw the program. This knowledge index had a strong internal consistency ($KR-20 = .84$). As could be expected (Celsi and Olson 1988; Sujan 1985), it was strongly correlated with felt involvement ($r = .595$, $p < .001$). To test for this potential confound, a knowledge factor (adjusted for measurement error) was included in the causal model as a predictor of recognition. Its effect on recognition was not significant ($t = .885$, $p > .15$).

Marked gender effects were also observed. As could be expected, females had less knowledge of soccer and of the teams than males ($F(1,74) = 27.465$, $p < .001$, Omega-squared = .26), and reported a lower level of felt involvement ($F(1,74) = 18.826$, $p < .001$, Omega-squared = .19). Females were also less aroused ($F(1,74) = 4.417$, $p < .039$, Omega-squared = .043), but their pleasure when watching the game did not differ significantly from males ($F(1,74) = 2.457$, $p > .12$). Females scored consistently poorer ($M = 2.65$) than males ($M = 3.80$) on the recognition test ($F(1,74) = 8.195$, $p < .01$). Unexpectedly, their performance was still significantly lower when; previous exposure to

the game, knowledge, arousal, felt involvement, and its square were entered as covariates ($F(1,67) = 4.053$, $p < .05$, Omega-squared = .037).

CONCLUSION AND DISCUSSION

In a recent editorial, Lutz (1991) called for more research on substantive consumer behavior issues that are important to someone other than the researchers themselves. Sponsorship communication is important to marketers. If they are to continue to rely on generated exposure as a measure of sponsorship effectiveness, understanding what happens *beyond* this exposure is clearly needed. In this study, extensive exposure to the billboards yielded only limited effects on recognition. On average, the billboards were visible for 118.5 seconds. Yet, on average, they were recognized by only 39 percent of the subjects (although the a priori probability to choose the correct billboard in a set of four is 25%). This replicates the findings of previous controlled studies (d'Ydewalle et al. 1987; Nebenzahl and Hornik 1985). That billboards achieved only limited recognition stresses the need to identify potential influences on the processing of sponsorship stimuli. Three of these were studied here, (felt) involvement, arousal, and pleasure. Felt involvement was found to have an inverted-U effect on the recognition of sponsorship stimuli, arousal a negative effect, but pleasure no effect. Involvement and arousal accounted for a fairly large proportion of recognition variance. This has some implications both for the selection of events for sponsorship and for the evaluation of sponsorship effectiveness. For a given audience size, highly involving and arousing events might not offer the sponsor his/her best advantage. On the other hand, it is also true that potentially involving and arousing events are likely to attract a larger audience.

Pleasure did not affect the recognition of the billboards. The effects of pleasure on memory for billboards may be too subtle to be captured in a recognition task. It may also be that the incidental learning of billboards does not lend itself to the processing efficiency principles suggested by Isen (1984). These principles may apply only to more goal-directed processing. In a related context, it was also found that pleasure experience when watching a football game did not increase recall for the embedded commercials (Pavelchak et al. 1988).

The distinction between involvement and arousal needs to be clarified, especially when involvement is defined as a state of arousal or activation (e.g., Cohen 1983; Mitchell 1979; Rothschild 1984). For instance, Thorson et al. (1985) purportedly measured and manipulated involvement with TV programs. However, both their manipulation of program involvement (sexual program segments) and their measurement of involvement (cortical arousal recorded by EEG) could be interpreted in terms of arousal. In this study, a distinction was drawn between (felt) involvement and (physiological) arousal. One difference between these two constructs is that involvement is object-specific (e.g., Celsi and Olson 1988; Mitchell 1979; Zaichkowsky 1985), whereas arousal is nonspecific (Derryberry 1988;

Eysenck 1976) and can be misattributed (cf. Schachter and Singer 1962). This distinction between involvement and arousal seems to exhibit construct validity, even in a context where these two constructs are likely to be confounded. A factor analysis indicated that distinct factors underlie the felt involvement and arousal scales. Moreover, this study shows, in a nomological sense, that involvement and arousal have distinct effects on a critical dependent variable. Conceptually, felt involvement reflects people's motivation to process the event and the embedded stimuli, whereas arousal affects their ability to do so (cf. Sanbonmatsu and Kardes 1988).

Males unexpectedly outperformed females on the recognition task. This gender effect remained significant when arousal, felt involvement, knowledge, and previous exposure to the game were controlled. A post hoc explanation can be suggested for this gender effect. As reflected by their knowledge scores, females were presumably less expert than males in processing soccer. A well known consequence of expertise in a task is a reduction of the amount of cognitive effort required to perform the task (cf. Alba and Hutchinson 1987). Therefore, processing the game (as demanded by the experimental task) should have been comparatively more effortful for females than for males. As females invested comparatively more effort in processing the game, less capacity was available for the processing the sponsorship stimuli. For instance, Navon (1984; Navon and Gopher 1979) has argued that an increased processing efficiency in the performance of a primary task should result in enhanced performance on a concurrent task that draws on the same pool of resources. This processing-expertise explanation of the gender effect is worth testing in future research.

Several limitations of this study deserve mention. First, the independent variables were not experimentally manipulated. Hence, third-variable explanations cannot be fully excluded. It should be noted, however, that a knowledge interpretation of the results has been ruled out. Second, the type of sponsorship stimuli investigated here is restricted to billboards. Other stimuli (e.g., brand names on players' shirts or on racing cars) that are closer to the audience members' "center of involvement" may be affected differently by involvement and arousal. For instance, in a racing context, it is possible that stimuli on the cars, provided that they are visible, may actually benefit from the increased focus of attention created by high involvement and arousal. In contrast, this study suggests that signs around the circuit should be negatively affected. The moderating effect of the proximity of the stimuli to the audience's center of involvement awaits future research. Third, no measure of focused attention was collected. Therefore, it is difficult to ascertain whether the observed curvilinear effect of involvement and the negative effect of arousal resulted, as hypothesized, from increased attentional selectivity. Fourth, background factors such as subjects' familiarity with the brands advertised on the billboards were not controlled. This is a common drawback of using real marketing stimuli instead of artificial ones. However, to have biased

these result, these background factors should have had very specific interactions with the independent factors. Finally, this study only considered conscious processing of and explicit memory for the stimuli. However, there is growing evidence that even nonattended material that is subconsciously processed can be influential (e.g., Janiszewski 1990). The subconscious processing effects of sponsorship stimuli deserve future research.

The Relationship Between Distractor Similarity and the Recognition of Print Advertisements

James W. Peltier, University of Wisconsin-Whitewater
John A. Schibrowsky, University of Nevada-Las Vegas

ABSTRACT

This paper reports the findings of an investigation of the impact that distractor similarity has on the recognition memory for print advertisements. Two issues are investigated. First, the direct impact of distractor similarity on brand and claim recognition memory scores is investigated. Second, the attenuating impact of distractor similarity on the study of other variables posited to impact memory is investigated. A method for assessing distractor similarity is discussed, along with implications for advertising research.

INTRODUCTION

The use of recognition as a measure of memory has increasingly become a prominent topic in both academic and applied research (Leckenby and Plummer 1983; Stewart et al. 1985; Singh et al. 1988). Much of this interest stems from the growing concern that recognition may be more appropriate than recall for assessing certain types of advertising effects (Bettman 1979; Krugman 1972, 1985; Singh et al. 1988; Zielske 1982). The fundamental difference between these two measures is that in a recall task an individual must describe a non-present stimulus, while in a recognition task a stimulus is judged on the basis of whether it had been previously seen or heard (Bettman 1979).

Critics of recognition contend that it is a less sensitive measure for detecting differential memory effects than is recall. This belief is based on the substantially higher memory scores and resulting ceiling effects that are often associated with recognition (Haber 1970; Krugman 1979; Shepard and Chang 1967). However, the ease with which a stimulus is recognized is partially a function of the similarity between the stimulus and relevant distractor items. Specifically, researchers in cognitive psychology have shown that stimulus recognizability decreases as distractor similarity increases (Jorg and Hormann 1978; McNulty 1965; Postman et al. 1948).

Despite the potential inverse relationship between distractor similarity and the recognition of an advertisement, this issue has been largely ignored in the marketing literature. The typical approach used by advertising researchers has been to arbitrarily assess the similarity between a target stimulus and its distractors. This subjective procedure for selecting distractors creates two major problems for advertising researchers. First, the level of difficulty for a particular recognition task can not be quantified. Second, and potentially more important, a similarity bias may exist due to the inability to equate distractor similarity across advertisements and/or experimental treatments. These are critical issues that must be addressed before recognition tests can be effectively employed in advertising research (Singh and Cole 1985).

We report the findings from an experiment that examines the effect that distractor similarity has on the recognition of brands and claims presented in print advertisements. In addition, an attempt is made to determine which level(s) of similarity is (are) most sensitive to memory differences. A simple method for equalizing distractors across advertisements and treatments is also discussed.

LITERATURE REVIEW

This section is organized into two separate parts. First, the different types of recognition tests are described. Second, the extant literature that has investigated distractor similarity is examined.

Types of Recognition Tests

In general, recognition tests involve exposing subjects to target stimuli, then, after a specific length of time, the subjects are asked to select those stimuli from a list of items, some of which are distractor items (e.g., they have not been previously seen). There are essentially three different ways to administer a recognition test:

Yes/No Test. Subjects are shown a set of stimuli one at a time. For each item, subjects are asked to respond 'yes' if they have previously seen that item and 'no' if they have not. Typically, there is one distractor for every item in the original list of stimuli.

Batch-Testing. In a batch-testing recognition test all of the original stimuli and all of the distractor items are presented at the same time. Subjects are asked to select those items that they had previously seen.

Forced-Choice. In this method, subjects are asked to identify a previously seen stimulus from a list containing one or more distractor items. This task is repeated once for every stimulus on the original list. Unlike batch-testing, there is only one 'correct' response per set. When one distractor is used this is called a two-item test, when two distractors are used it is a three-item test, and so on.

An additional measure that is often obtained along with recognition is to have subjects indicate the degree to which they are confident with their responses. Confidence ratings are typically obtained via a three- to five-point scale ranging from very confident that the response is correct to not confident at all. The confidence ratings are then used to transform correct and incorrect responses into a more sensitive multi-point scale. It has been argued that this procedure contributes considerable information for data analysis. In particular, statistical analyses can be conducted on the transformed data that are free of distortions (Singh and Rothschild 1983b).

Distractor Similarity Literature

While the issue of distractor similarity is of extreme importance for measuring advertising

effectiveness, it has received surprising little attention in the marketing literature. The work that has been done in this area has been of a conceptual nature. Specifically, Singh and Rothschild (1983a) suggested that recognition scores could be lowered, and thus made more difficult, by employing very similar distractors. More recently, Singh and Cole (1985) stressed the importance of equalizing distractor similarity across test ads and treatments.

There is a body of knowledge within the cognitive psychology literature that has examined how distractor difficulty affects recognition memory. Furthermore, each type of recognition test has been used as a dependent measure. Early work by Postman et al. (1948) using a four-item forced choice recognition test showed that subjects incorrectly selected similar distractors more frequently than dissimilar distractors. McNulty (1965) found analogous results via a batch recognition test--subjects performed more poorly for similar, rather than dissimilar distractors. Using a yes/no test, Dale and Baddeley (1962) showed that stimulus recognizability decreased as distractor similarity increased.

The robustness of the distractor similarity findings is evidenced by the variety of stimulus devices that have been used to manipulate this construct. Specifically, distractor similarity has been manipulated via nonsense syllables/words (McNulty 1965; Postman et al. 1948), numbers (Dale and Baddeley 1962; Shepard and Chang 1963), line drawings (Bahrack et al. 1967; Bower and Glass 1976; Jorg and Hormann 1978), and other pictorial stimuli (Bahrack and Bahrack 1964; Nagae 1980). In all cases, distractor similarity had a significant negative impact on stimulus recognizability.

Distractor Similarity and Advertisements

The degree to which the distractor similarity findings in the cognitive psychology literature can be generalized to an advertising context is not well documented. Part of this dilemma is in measuring the similarity between distractors and advertising stimuli. In particular, measuring the similarity between distractors and specific brand names and advertising claims is a much different process than for nonsense syllables, numbers and line drawings.

In general, the measurement of target-distractor similarity in previous research studies focused on the structural relationship (i.e., what they looked like) between a target stimulus and its distractors. Conceptually, when measuring distractor similarity for words (e.g., brand names) and phrases (e.g., claims), both the structure and the meaning of these items must be compared to the target stimuli. In principle, distractors and stimuli that share comparable meanings may be judged similar even if structurally they are not, and vice-versa.

HYPOTHESES

The research project reported here had two major objectives. One of the objectives was to explore the effect that brand and claim distractor similarity have on recognition memory. The

cognitive psychology literature provides insight into this phenomenon. The following prediction is tested:

- H1: An inverse relationship will exist between brand and claim distractor similarity and recognition.

The contention that recognition tests attenuate memory differences due to task simplicity (difficulty) and resulting ceiling (floor effects), suggests that an experimental manipulation may be judged unsuccessful when this not the case. Exposure time is manipulated in this study for the purpose of creating experimental conditions where recognition differences are expected to occur (Rothschild et al. 1989). If Singh and Rothschild (1983a) are correct, making recognition tests more or less difficult by manipulating distractor similarity should affect recognition within and across exposure time treatments.

This suggests the following hypothesis:

- H2: A significant distractor similarity X exposure time interaction will exist, with recognition memory differences being eliminated as distractor similarity approaches the extremes.

Each of the above two hypotheses are investigated in the study discussed below.

METHOD

Subjects and Design

Ninety-one undergraduate students were randomly assigned to conditions in a 4 (degree of distractor similarity: very similar, similar, somewhat similar and very dissimilar) X 2 (exposure time: 15 seconds and 10 seconds) within and between factorial design. Degree of distractor similarity was the within subject factor and exposure time was the between subject factor.

Procedure

The cover story given to subjects was that a local advertising agency wanted feedback on a number of print ads that they had developed. Eight test ads were then viewed via a slide presentation in small groups of approximately 15 subjects. Order effects were controlled for by developing four different ad presentation sequences. It should be noted that a significant order effect was found for the various memory scores.

After the slides were viewed, subjects completed a three minute distractor test. The dependent measures were then administered. In a response booklet, subjects were given a verbal description of each of the products promoted in the ads that they had viewed. They were asked to identify the correct brand and claim associated with each product and to rate how confident that they were with their responses. In the response booklets, each of the four distractor similarity conditions was assigned two different ads. Order effects were controlled through the use of four different response booklets that varied

TABLE 1A
Mean Brand Similarity Score By Condition

<u>Ad Number</u>	<u>Very Similar</u>	<u>Somewhat Similar</u>	<u>Very Similar</u>	<u>Dissimilar</u>
1	1.8	2.9	3.8	6.8
2	1.9	2.9	3.7	6.6
3	1.6	2.9	3.8	6.8

distractor similarity across the test ads. Finally, subjects were debriefed and were asked not to disclose the purpose of the study to others.

Stimulus Materials

Slides of color illustrated print ads were used in the study. Each of these ads had a character, a product illustration, a brand name and a claim. These ads generated differential recognition responses across exposure time in a different study.

Distractor Similarity Pretest

A relatively simple pretest was employed to develop recognition measures for each of the distractor similarity conditions. Several graduate students were given the task of generating distractor brands and claims for each of those to be used in the actual study. They were told that these distractors should fall along a similarity continuum ranging from very similar to very dissimilar. When developing these distractors, they were instructed to consider both the structural nature of the targets and their meanings. From this list 25-30 thirty brand and claim distractors were selected for each target stimulus. Using a seven-point scale (very similar to very dissimilar), a second set of pretest subjects rated these distractors with respect to specified target brands and claims. No conditions for judging target-distractor similarity were stated.

After analyzing these judgments, brand and claim distractors for each similarity condition were selected on the following basis (1=very similar and 7=very dissimilar):

1. The mean similarity score for each brand and claim had to fall in the range of 1.6-1.9 for the very similar condition, 2.6-2.9 for the similar condition, 3.6-3.9 for the somewhat similar condition, and greater than 6.0 for the very dissimilar condition.
2. Distractors with lower standard deviations were preferred.
3. For each ad, brand and claim distractors were equally similar.

Table 1A and Table 1B report mean similarity scores for brands and claims for each of the distractor conditions. There were no significant differences in similarity scores between ads within each condition. Differences in mean scores between conditions were significant.

Dependent Measures

As indicated above, each subject was exposed to one of two exposure time conditions and received

TABLE 2
F Values for Differences of Recognition Measures Across Four Levels of Distractor Similarity

	BSUM	CSUM	TSUM
Deodorant	.67	2.84	2.33

Ear Wax Remover	5.38	9.79	12.10
All Ads Summed	18.90	33.00	42.65
Significant Differences*	7/9	7/9	8/9

* $F(3,87)=2.72, p<.05$

all four distractor similarity manipulations for two ads each.

Brand and Claim Recognition: Using a five-item forced choice test, subjects were asked to identify the correct brands and claims that were in the ads that they had viewed.

Confidence Rating: Confidence ratings for brand and claim responses were assessed via a five-point scale ranging from very confident to not confident at all.

A forced choice recognition test was employed in the study to limit response biases that are often associated with yes/no and batch-testing procedures (Shepard and Chang 1963). A five-item test was selected as a compromise between a two-item and a nine-item test.

RESULTS

To investigate the hypotheses, the brand recognition, brand recognition confidence, claim recognition, and claim recognition confidence scores obtained from the subjects were used to compute three summary scores. A brand summary score for each ad (BSUM) was obtained by multiplying the brand recognition score (0 or 1) by the brand recognition confidence score (1 to 5). A claim summary score (CSUM) was computed by multiplying the claim recognition score (0 or 1) by the claim recognition confidence score (1 to 5). A total ad recognition score (TSUM) was computed by adding together the brand summary score and claim summary score.

Results for Hypothesis 1

Recall that H1 hypothesized that a significant inverse relationship exists between distractor similarity and brand/claim recognition. Table 2 shows the results of the investigation of this hypothesis. It contains F values for differences in the computed measures of recognition across the four levels of distractor similarity. In a total of 22 of the 27 conditions (81%) there was a significant difference in recognition scores across different levels of

distractor similarity. In each case, memory scores improved as distractor similarity decreased. In summary, these results provide strong support for H1.

Results for hypothesis 2

Recall that H2 hypothesized that recognition memory differences would be attenuated as distractor similarity approached the extremes. This prediction suggests that floor and ceiling effects would eliminate differences that would otherwise exist. To test this hypothesis, exposure time was manipulated as a between subjects variable. Exposure time was selected because it has a robust effect on recognition memory scores. As exposure time increases so will recognition scores.

To test H2, the impact of differences in exposure time (10 and 15 seconds) on recognition scores was investigated at four different levels of distractor similarity: very similar, similar, somewhat similar, and very dissimilar. The three computed measures of recognition, brand recognition (BSUM), claim recognition (CSUM), and total brand and claim recognition (TSUM) summed across all ads were used as the dependent variables. The results were comparable for all three measures. Figures A, B, and C show the effects of exposure time on the TSUM, BSUM, and CSUM measures of recognition in the four distractor conditions.

In each case the figures support H2. The differences in recognition scores for the different exposure times are reduced in both extreme conditions. Table 3 summarizes the results for each of the three different measures of recognition.

As table 3 indicates, the effect of exposure time on all three measures of recognition were attenuated at the extremes. In the extreme conditions only 2 of the 6 cases were significant, while in the middle conditions 5 of the 6 conditions were significant. In summary, the findings provide strong support for H2.

 Mean Recognition Scores (TSUM) for Different Exposure Times and Levels of Distractor Similarity

FIGURE B
 Mean Recognition Scores (BSUM) for Different Exposure Times and Levels of Distractor Similarity

DISCUSSION AND CONCLUSIONS

The results clearly show that distractor similarity affects brand and claim recognition memory. Brand and claim recognition scores for the within subject analysis across distractor similarity conditions varied considerably. In addition, the between subject analysis across exposure time showed that distractor similarity attenuated recognition memory at the extremes.

These findings suggest that when distractors are very dissimilar with respect to target stimuli, the

recognition task is too easy and that ceiling effects may occur. When this is true, the criticism that recognition tests are insensitive for detecting memory differences may be valid. In contrast, when distractors are too similar to targets, the task becomes very difficult and memory differences that otherwise may have existed may also be eliminated. It should be noted that the extreme conditions did not attenuate the results in every case; however, the likelihood of detecting memory differences is definitely reduced.

FIGURE C
 Mean Recognition Scores (BSUM) for Different Exposure Times and Levels of Distractor Similarity

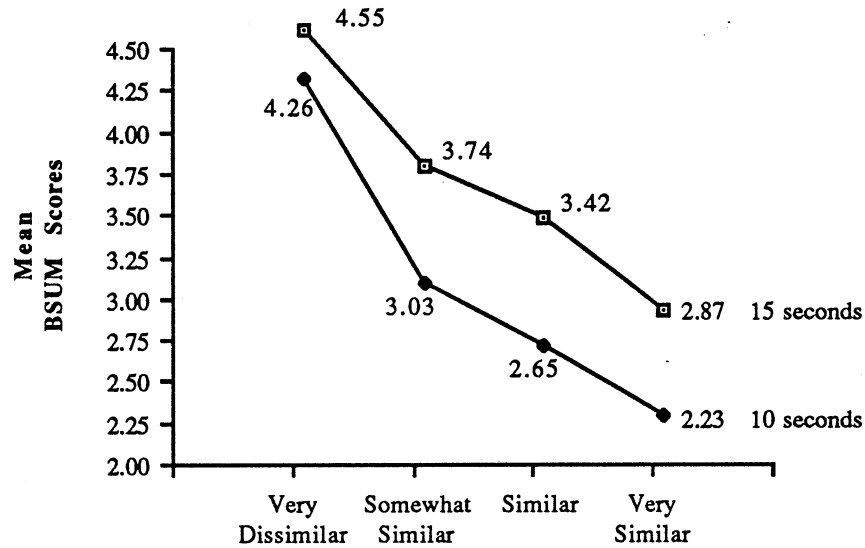

TABLE 3
 T-Values of the Effect of Exposure Times on Mean Recognition Measures for Each Level of Distractor Similarity

	Very Dissimilar	Somewhat Similar	Very Similar	Similar
BSUM	2.157*	4.117*	2.383*	1.500
CSUM	1.629	3.649*	1.202	.177
TSUM	1.613	2.489*	2.492*	2.160*

* $t > 1.96$, $p < .05$ 45 subjects per cell

Moderate levels of distractor similarity worked best for detecting recognition differences. While absolute recognition scores varied across distractors categorized as being similar or somewhat similar, differences across exposure time were relatively equal. Thus, either one of these two categories could be used as long as similarity is held relatively constant.

The procedure used here for equating distractor similarity is relatively simple and not very time consuming. While all levels of distractor similarity had to be developed for the current study, subsequent research need only focus on moderately similar distractors. Furthermore, over the course of the pretest the authors became quite proficient at predicting how similar distractors were to target stimuli. As such, a distractor similarity judgment learning curve for researchers should result.

Future research may wish to develop different ways to measure and control for distractor similarity

biases. In addition, the most efficient level of distractor difficulty across different types of conditions and task environments need also be tested.

Ask Not What the Brand Can Evoke; Ask What Can Evoke the Brand?

Stephen J. S. Holden, University of Florida
Richard J. Lutz, University of Florida

ABSTRACT

Research on consumer memory and choice has been dominated by paradigms that implicitly assume the availability of the brand, whether it is physically present in the choice situation or symbolically present in working memory as a member of a stable evoked set of brands in a product category. Research attention, therefore, typically has focused on the accessibility of brand information, given the presence of the brand. Recently, brand accessibility has attracted some attention, but only from the perspective that the product category is the stimulus activating brand retrieval processes. In this paper, we propose the alternative view that brand retrieval is more frequently stimulated by consumption goals or consumption occasions, and a model is developed that reflects this ecological dimension of consumer choice, using concepts of spreading activation and goal-derived categories.

INTRODUCTION

Prior to Lynch and Srull's (1982) influential article, the vast preponderance of research on consumer choice was conducted in a stimulus-based paradigm. Experimental subjects were presented with complete (i.e., brand-by-attribute) stimulus arrays, and the emphasis was placed on discerning the so-called decision rules used by subjects to combine the externally-available information and arrive at a brand choice. Lynch and Srull (1982) made the important point that few consumer choice processes are completely stimulus-based and introduced the notions of "pure" memory-based and hybrid mixed choice tasks; the latter referred to the situation in which some information is physically present, but other relevant information is stored in memory.

Lynch and Srull's (1982) insights both reflected and spurred increased attention to retrieval processes in consumer choice, and consumer memory became an important topic in its own right (Bettman 1986). However, most, if not all, of this research has implicitly assumed the presence of the brand in the choice situation, and interest has centered on the retrieval of brand-related information from memory (e.g., Biehal and Chakravarti 1986) with primary emphasis given to brand attributes, or benefits. Recently, inspired by Fazio's (1986) process model of attitude-behavior relationships, researchers have begun to consider the accessibility of brand attitudes in memory. Lynch, Marmorstein and Weigold (1987) have extended the analysis by introducing the diagnosticity construct to delineate the conditions under which brand attitudes or attribute information are more likely to influence decision making.

Oddly, until very recently, consumer memory researchers have not considered the ecologically important retrieval of brands themselves from memory. That is, in memory-based or mixed choice situations, it is not just attribute information, or

attitudes, that must be retrieved; in many cases, the brands must be retrieved from memory as well. Hence, the notion of brand accessibility becomes an important consideration. The retrieval of brands from memory is arguably the root of the evoked set concept, which was introduced by Howard and Sheth (1969) over two decades ago. However, most construals of the evoked set picture it as a static, relatively stable set of brands that is retrieved by the consumer in response to a category cue; recent research by Nedungadi (1990) suggests that evoked sets are more fluid and context-dependent. Therefore, it seems appropriate to apply the same sorts of ideas that have proven useful in studying information accessibility to the examination of brand accessibility. Such an analysis would yield a more complete account of consumer choice processes in "real world" purchase and consumption situations. The purpose of this paper is to begin the development of such a model by focusing specifically on situational antecedents of brand accessibility.

BRAND RETRIEVAL

As discussed in the previous section, researchers only recently have begun to turn their attention to brand retrieval. Before turning our attention to research focusing directly on brand retrieval issues, it is useful to contextualize the discussion by considering some of the historical antecedents to the concept of brand accessibility.

It is surprising that the notion of memory for brands has been a relatively neglected topic given that the concept of the evoked set, and its centrality to consumer decision making have been recognized for some time in both behavioral (e.g., Howard and Sheth 1969) and analytic models of consumer choice behavior (e.g., Silk and Urban 1978). A number of researchers have demonstrated that brand awareness is a particularly important concept relative to brand evaluation in predicting and explaining consumer choice behavior. For instance, Axelrod (1968), Haley and Case (1979) and Nedungadi and Hutchinson (1985) all demonstrated that top of mind awareness (i.e., brand recall) is strongly correlated with brand choice. Haley and Case postulated that brand awareness is more important than attitude. This notion was supported by Hauser (1978) who, using an information theoretic approach, reported that the probability of inclusion of the brand in the evoked set accounts for more variation in brand choice than does brand attitude.

Many researchers have highlighted the importance of distinguishing between brand awareness based on recognition versus recall (e.g., Alba and Hutchinson 1987; Baker et al. 1986; Rossiter and Percy 1987). More broadly, these measures are relevant to stimulus-based versus memory-based evocation respectively. The notion of stimulus-based versus memory-based judgment (Lynch and Srull 1982)

was a distinction originally offered, as a means of distinguishing between brand evaluations made where all relevant brand information was externally present versus evaluations based on recalled brand information. Recently, a number of researchers (Alba, Hutchinson and Lynch 1991; Nedungadi 1987, 1990) have recognized that the stimulus-based versus memory-based distinction also may be applied to brand evocation occasions where the brands are either present (stimulus-based evocation) or absent (memory-based evocation).

As pointed out by Alba et al., (1991), very few decisions in the real world are purely "stimulus-based." In effect, many consumer decisions include some memory component. For instance, seeing some brands may remind a consumer of some other alternative brands for which s/he may then physically search. With regard to evaluation, even though the package may contain all the relevant information, consumers appear to rarely examine information on the package (e.g., Hoyer 1984), suggesting that memory plays an important role in both the evocation and evaluation stages of most consumer decisions. The most important implication of this fact is that recall from memory will not always be accurate and, more specifically, will be systematically biased by accessibility.

Memory factors undoubtedly play a role in stimulus-based brand evocation (Alba et al. 1991) in terms of brand recognition (Rossiter and Percy 1987) and, perhaps more importantly, the ease of recognition (Alba and Hutchinson 1987). Nevertheless, the focus of the following discussion is on memory-based brand evocation, as the key aspects of brand retrieval are perhaps better understood in the simpler case of memory-based evocation. In stimulus-based evocation, both memory and physical salience factors can affect evocation and subsequent choice.

Memory-based evocation appears to correspond to what is typically referred to as "top-of-mind" awareness which has been reported to be a good predictor of brand choice and usage (Axelrod 1968; Nedungadi and Hutchinson 1985). However, Alba and Chattopadhyay (1985) point out a useful distinction between absolute and situational awareness, absolute awareness referring to brands that are known (i.e., recognizable) and situational awareness referring to brands that are recalled at any particular time. The concept of situational awareness highlights the fact that the brands recalled at one point in time may be different from the brands recalled at another point in time; therefore, the evoked set is more accurately construed as fluid and context-dependent rather than transsituationally stable.

Context Dependence of Evoked Sets

Recently, a number of researchers have criticized the fact that the evoked set has typically been thought of as relatively static (Alba et al. 1991; Nedungadi 1987, 1990). In general, evoked sets are conceived of as sets of brands that are generated or retrieved in response to a product category cue (e.g., Alba and Chattopadhyay 1985). Although a number of researchers have noted that cues other than product

category (most notably, attributes and benefits) may guide brand recall (e.g., Baker et al. 1986; Nedungadi 1987), most researchers and practitioners think in terms of top of mind awareness, which assumes that: (1) evoked sets are common taxonomic categories; and (2) evoked sets are relatively static and do not change in response to changes in context. We propose that these assumptions should be replaced by the notion that evoked sets are better described as goal-derived categories and vary by context. Considering evoked sets as goal-derived categories highlights the notion that brand evocation may be in response to some cue other than the product category. In terms of the influence of context, even if the product category is a salient cue, other cues salient in a situation may lead to evocation of a different set of brands.

In making a distinction between common taxonomic categories and goal-derived categories, Barsalou (1985, p. 633) points out that common taxonomic categories are often used for classification, whereas goal-derived categories are often used for instantiation. Thus, evoked sets, in which people generate (instantiate) alternatives in order to achieve some consumption goal, bear an important resemblance to goal-derived categories. When people shop in a supermarket for a meal for that evening, they may not think in terms of product categories, but rather in terms of different meals that satisfy their needs such as variety, economy, preparation and "fit" with things already at home.

The composition of an evoked set depends critically on the cues that are salient at the time of evocation. The idea that an evoked set is generated in response to a product category cue implies a static, context-free, common taxonomic category. Instead, evoked sets are generated in response to the far richer set of cues that are present ecologically. Even if the category is provided as a cue, other cues present within the situation affect the brands that are included in the evoked set relative to a retrieval situation where the category is provided as the only cue, or the category is provided within a different context incorporating different cues. For example, Roth and Shoben (1983) showed that the "graded structure" of the category of birds was changed if a context was added (e.g., "The hunter shot at the 'bird' flying overhead."). In the same way that categories vary by context (e.g., Barsalou 1985; Roth and Shoben 1983), so do evoked sets vary by situation (Nedungadi 1987). Ratneshwar and Shocker (1991) demonstrated that snack products recalled vary depending on (1) whether or not a usage situation cue is given and (2) the nature of the usage situation. They also showed that the graded structure (typicality) of the products varied across the two situational cues and the overall category.

Retrieval Cues

Before discussing the various cues that might serve to cue brands in choice situations, it is important to note that cues differ on at least two dimensions. First, retrieval cues may be either self-generated or externally generated (Lynch and Srull 1982). Internal cues are likely to be more characteristic of consumption situations rather than

purchase situations, but internal cues will be present in the purchase situation to the extent that the consumer uses the anticipated consumption situation as a cue at purchase.

Second, some cues may work directly to evoke the brand while others may work indirectly. For instance, thinking of the attribute, caffeine, may directly evoke Coke. A situation such as going to an early morning meeting may indirectly evoke Coke via a chain of associations: early morning meeting → need to stay awake → caffeine → Coke. Frequent instantiations of this indirect link may make the brand, Coke, more accessible in the cuing situation, i.e., early morning meeting.

Product Category and Other Brands. Two cues that are present in many retrieval situations and which have received consideration in consumer research are product category and other brands. First, evocation in response to a category label, or the "category production task," has sometimes been considered "the most relevant experimental paradigm in memory research for understanding product recall" (Alba et al. 1991, pp. 5-6). However, the value of this paradigm in exploring notions of evocation is limited, because product category represents only *one* of the constellation of cues present in retrieval situations. A broader view is needed which recognizes choice situations where the product category is not a cue at all (leading to goal-derived evoked sets) and/or situations where the composition of the evoked set is a function of product category *and* other cues present within the context.

The second cue that has received some consideration is the brand itself as a cue for other brands (e.g., Alba and Chattopadhyay 1985; Nedungadi 1987, 1990); however, the brand is probably an indirect cue which operates through the category. That is, the brand provided is likely to cue the category, which in turn cues other brands. In one sense, this cue does not move our thinking beyond the category production paradigm. Nevertheless, research examining the brand as cue has led to some new insights on possible retrieval interference effects. Alba and Chattopadhyay (1985) show that the provision of brands as cues can facilitate brand recall if the brand cues an unretrieved (sub)category, but inhibits brand recall in accessible categories (i.e., part-list cuing effect).

Nedungadi (1987, 1990) found that provision of a brand as a cue facilitates brand retrieval through both a "direct" and an "indirect" effect, but no part-list cuing inhibition effect was observed. Unobtrusive priming of a brand was found to increase the probability of evocation of the primed brand (direct effect). More subtly, priming a minor brand in a minor category increased the probability of retrieval of the major brand in that minor category (indirect effect); it appears that the minor brand cued the category, which in turn cued the major brand. This result did not obtain in the major category, presumably because the category itself was already highly accessible. For instance, priming with Dos Equis might be expected to increase evocation of both Corona and Dos Equis in recall of beer brands, both

representing the minor subcategory, Mexican beers. On the other hand, priming with Coors would not be anticipated to increase evocation of Budweiser. It is noteworthy that while priming had both a direct and indirect effect on brand evocation, it had only an indirect effect at the brand *choice* level, i.e., only major brands in minor (sub)categories were chosen more frequently as a result of priming.

The failure to find any inhibition effect was expected by Nedungadi (1987), as inhibition effects are typically in evidence in categories where there are large numbers of items in the category and where numerous exemplars are listed as cues. Subjects in Nedungadi's studies were asked to generate evoked sets, which tend to be constrained in size (see Hauser and Wernerfelt 1990). Subsequently, they were asked to recall as many more brands as possible. If an inhibition effect were to arise, it would be at this point. That is, the evoked set (which would be the same constrained size on average across cuing conditions) would provide a substantial part-list cue resulting in inhibition of subsequent recall; however, the priming of one brand would not be expected to lead to inhibition in generation of the evoked set.

Attributes, Benefits and Attitudes. Attributes, benefits and attitudes are typically considered in terms of their influence on evaluation (Keller 1991). For instance, attributes of the brand have been considered as a means of discriminating among alternatives (e.g., Alpert 1971). These so-called "determinant" attributes are defined as "those attributes projected by the product's image which lead to the choice of that product...they determine preference and purchase behavior" (Alpert 1971, p. 184).

Independent of the role of attributes in evaluating alternatives, Nedungadi (1987) argued that "certain attributes or properties of brands are activated by each usage [consumption] situation and are believed to underlie the process of retrieval set formation" (p. 35). Nedungadi (1987) distinguished between cues used in evocation versus cues used in evaluation by labeling the former "cuing attributes." He notes that cuing attributes may be independent of determinant attributes; that is, the attributes used to cue brands may be different from the attributes used to evaluate brands. Despite some difficulties finding cuing attributes via direct questioning, Nedungadi (1987, Experiment 2) set up some artificial stimuli (restaurants) in which the cuing attributes were uncorrelated with the determinant attributes and found support for his contention that cuing attributes influence brand evocation.

Benefits may be defined as the personal value that consumers attach to the product or service attributes (Keller 1991, p.7). In effect, to the extent that a product is perceived by a consumer to fulfill some particular purpose or function, it may be said to have the attribute of providing that specific benefit. Benefits may have a role in both evocation and evaluation.

Like attributes and benefits, attitudes are typically thought to be used to discriminate between brands. However, it should be apparent from the research in goal-derived categories that an evaluative

criterion can be used as a cue. Barsalou (1985) demonstrated that evaluatively valenced goal-derived categories can be constructed such as "personality characteristics in others that prevent you from being friends with them" and "foods not to eat on a diet" (Barsalou 1985, p. 651). Ecologically, it is likely to be exceedingly rare that a consumer would endeavor to recall brands that are associated with negative evaluations; consumers will automatically endeavor to recall favorable brands. This may offer at least a partial explanation why more preferred brands tend to be recalled earlier (e.g., Nedungadi and Hutchinson 1986; Ward and Loken 1986). At evocation, it appears that attitude plays a role as a coarse cue, virtually a filter, that ensures that no disliked brands are included in the evoked set. It is anticipated that attitudes will not offer a particularly useful cue for evocation because recalling brands associated with positive affect is likely to be virtually automatic; in effect, a positive attitude is a cue that is likely to be automatically salient in evocation of brands prior to choice.

Purchase and Consumption Situations.

Consumers make brand choices in both purchase and consumption situations. Both situations represent a complex of cues that may serve to guide retrieval of brands for inclusion in the evoked set. There is little dispute that brand choice varies by situation (e.g., Belk 1975), but the nature of the influence has not undergone thorough investigation. Most attribute the variation in brand choice by situation to be a result of changes in attribute importance by situation (e.g., Miller and Ginter 1979). However, some research has shown that brand recall varies by situation (Ratneshwar and Shocker 1991), confirming Belk's (1975) suspicion of situational influence through "subtle cueing effects" (p.161). Still, the particular cues need to be identified.

The important characteristics of choice situations are the motives underlying the consumer's choice. Thinking in terms of motives leads readily to consideration of goal-derived categories (Barsalou 1983, 1985). It is suggested that research aimed at identifying the situational goals that act as cues in the evocation process will provide more insight into the cues that guide consumer evocation. In particular, one element that represents an important cue and which has not been included in the associative model of brand memory is the consumer's underlying motives; that is, his/her needs and wants. Clearly, this should be a fundamental aspect given "marketing's first law: 'Don't sell what you happen to make; make what the consumer wants to buy'" (Fennell 1978, p. 38).

MEMORY AND BRAND CHOICE

Two interrelated models are necessary to fully understand the role of memory in brand choice. The first model is one of brand choice. Brand choice, as suggested by Nedungadi (1990), is composed of two separate stages--evocation and evaluation. The first stage, brand evocation, is necessary, and in the case of low involvement choice, may be sufficient, for choice. The second stage, brand evaluation, is

contingent on brand evocation in the sense that only evoked brands will be evaluated.

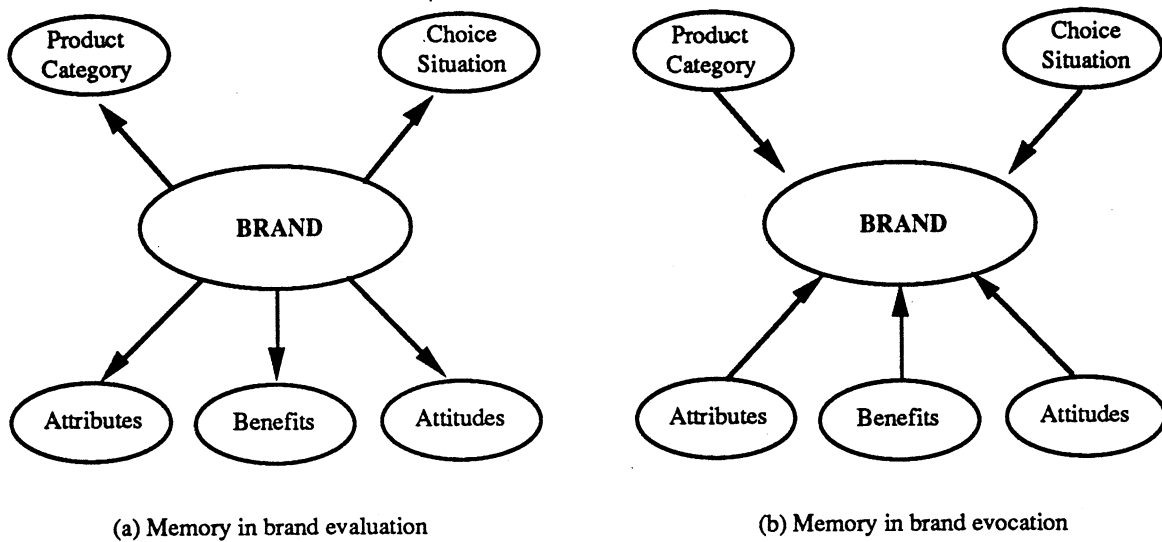

The second model is one of consumer memory structured as an associative network (see Anderson 1973; Collins and Loftus 1975). The brand is conceptualized as being the central node linked with a bundle of associates. Meyers-Levy (1989) uses the useful concept of an "association set" to refer to "the concepts that are meaningfully related to a target word or brand name" (p.197). Many researchers have cataloged a variety of associates that may be linked to the brand in memory (e.g., Aaker and Keller 1990; Brucks 1986; Keller 1991). Summarizing various conceptualizations, we propose that brand memory be considered an associative network with links to attributes (both unique to the brand and common to all or most brands in the category of which it is a member), benefits, attitudes, product category and choice situation (i.e., purchase and consumption situations). This categorization of associates is intended to be thought provoking rather than comprehensive. The associates included represent those that are considered to be most likely to have a role in brand choice.

Now we can put together the two models of staged brand choice and brand memory. First, considering the notion of memory in evaluation which has been the focus of most consumer memory research, choice is understood to be a function of the associates that are retrieved to support the evaluation stage of the consumer choice process (e.g., Alba et al. 1991; Lynch and Srull 1982; Meyers-Levy 1989). In this respect, the perspective taken by those investigating brand memory and evaluations is a *brand-to-associate* view (see Figure 1a). In this perspective, the attention is generally on the associates evoked rather than the cues doing the evoking; this is because the brand can be considered the central cue. However, Keller (1987) has demonstrated that memory for brand associates is facilitated by the provision of cues in addition to the brand; Keller provided advertising-related cues. The associates retrieved that receive most attention in the consumer behavior literature are attitudes and brand attributes (e.g., Biehal and Chakravarti 1986; Lynch et al. 1988).

We propose that a focus on brand evocation requires a reverse perspective on brand memory. That is, in examining the role of memory in brand evocation, it is necessary to examine those associates that lead to retrieval of the brand (see Figure 1b). Additionally, whereas brand evaluation focuses on what is evoked (namely associates such as attitudes and attributes) rather than the cues, research on brand evocation needs to focus on the cues, with the brand being the evoked object (i.e., the *associate-to-brand* links).

In terms of the different perspectives on brand memory, the brand evaluation perspective tends to dominate consideration of the influence of memory on choice. However, we argue that brand choice is more fully described as a function of the "brand-to-associates" links and by "associates-to-brand" links. Most prior research considers only the brand-to-associate links that underlie evaluations; modeling

FIGURE 1
Two perspectives on brand memory: evaluation versus evocation

brand choice as a function of associates evoked by the brand examines only half the issue--or less, given that many brands available are not included within the evoked set. In effect, it is proposed that the associate-to-brand links underlie evocation, while the brand-to-associate links underlie brand evaluation and, ultimately, associates of a brand will be retrieved and examined only if the brand itself has been evoked.

ACCESSIBILITY AND ASYMMETRY

An important notion in the memory literature is that the process of retrieval does not necessarily reflect what is "stored" in memory. Specifically, an item may be stored in memory, but may be retrievable only if a person is provided with the appropriate cues. That is, a brand may be "available," but is only "accessible" under certain conditions (Tulving and Pearlstone 1966). The notion of accessibility can be thought of as the strength of the cue-object link; a strong link facilitates retrieval of the object upon presentation of the cue.

Given studies that have shown differences in evocation as a function of different usage situations (e.g., Ratneshwar and Shocker 1991), and given the proposition that selective evocation is a function of the cues present in the situation, it is now proposed that the reason for variation in brand evocation is that different associates may have stronger links to some brands than others. The result is that any given associate evokes some brands with greater probability than others.

The model of brand memory as an associative network may suggest that brand-to-associate links are essentially the same as the associate-to-brand links. It has been pointed out that, in understanding memory in brand choice, a conceptual distinction must be made between the brand-to-associate and the associate-to-brand links (see Figure 1). However, even some of the

earliest work on the notion of spreading activation (see Collins and Loftus 1975) through associative networks recognized that "criterialities" or strengths of association may be asymmetric. Specifically, it may be highly likely that thinking about a particular situation will evoke a particular brand (e.g., something to drink while watching the Superbowl, Budweiser comes to mind), but thinking of the brand will not necessarily evoke that situation.

Similarly, categorization research has long recognized that the strength of the link from an instance to a category is not necessarily related to the strength of the category to instance link (e.g., Barsalou 1983). Barsalou and Sewell (1985) note that "a standard assumption in the memory literature [is] that relations can be asymmetrical in strength and that the direction processed more frequently develops stronger relations" (p. 650).

Already, some research in marketing may be interpreted as providing evidence of asymmetries in the strength of associate-to-brand links versus brand-to-associate links. Nedungadi (1987, 1990) showed that minor brands in a category are likely to lead to evocation of a major brand, but major brands are not likely to lead to evocation of the minor brand. Similarly, Herr, Farquhar and Fazio (1990) report preliminary evidence showing that the category-to-brand link is not necessarily equal to the brand-to-category link. However, their conceptualization and empirical work (see also Farquhar et al. 1990) consider only category-brand links. In line with our earlier suggestion of considering a wider set of retrieval cues, it is useful to extend this conceptualization (and empirical work) to consider the various associate-to-brand links that are likely to be activated in purchase or consumption situations.

Furthermore, due to the asymmetry that has been discussed, the link direction has different

implications for the two components of the choice process, namely evocation and evaluation. While the empirical work of Herr et al. (1990) highlights the importance of the strength of the category (associate) to brand links on brand choice, the focus is on the implications of the strength of the category-to-brand link for transfer of liking for that brand to brand extensions. An opportunity exists for extending this investigation to consider the influence of brand accessibility on brand choice independent of the influence of associate accessibility on evaluation.

IMPLICATIONS AND CONCLUSION

Recognizing the different roles of memory in brand evaluation and brand evocation has implications for a number of diverse areas in marketing. For instance, in measuring advertising effectiveness, the model highlights the need to assess effects on both evaluation (i.e., new, positively evaluated associates now evoked by the brand) and effects on evocation (i.e., new cues that are likely to evoke the brand). In particular, measures of brand awareness where the advertisement is provided as a cue are only appropriate if the advertisement is a salient cue at choice. In terms of segmentation, the substitution-in-use approach (e.g., Srivastava, Alpert and Shocker 1984) may be extended to distinguish segments based on brand preference versus segments based on systematically biased brand evocation. Finally, brand equity research, which frequently focuses on the associations evoked by the brand (e.g., Aaker and Keller 1990), could be extended by considering brand awareness, and more specifically, the role of associates as cues to brand evocation.

However, before the implications of brand accessibility can be explored in detail, it is necessary to establish the way in which brand awareness is a function of cues present at the choice situation. There is a critical need to identify empirically the associates that serve as cues to brand evocation. In addition, research is needed that extends Herr et al's (1990) findings by investigating the asymmetrical links between brands and associates, and determining the consequences of asymmetry on brand evaluation and brand evocation.

In summary, attention needs to be directed to the associate-to-brand links, because the associates act as "cues" for retrieval of the brand in the purchase or consumption situation. That is, brand choice is modeled as a function of the brand(s) evoked by specific associates. Evoked sets are likely to be a function of the complex of cues that make up the goal at the time of evocation. Consequently, an important priority is to investigate what are the cue constellations that instigate purchase and/or use of a specific brand. In effect, attention needs to be directed at the important issue of what evokes the brand in a choice situation rather than simply what the brand evokes.

A Revised Product Involvement Inventory: Improved Usability and Validity

Edward F. McQuarrie, Santa Clara University
J. Michael Munson, Santa Clara University

ABSTRACT

Four shortcomings of the Product Involvement Inventory published by Zaichkowsky (1985) are identified: usability, discriminant validity, criterion validity and construct validity. A revised ten-item inventory is shown to overcome these problems while maintaining good reliability. The Revised Product Involvement Inventory contains separate sub-scales that measure two facets of consumer involvement: perceived importance and interest. It maintains most of the strengths of the original PII while offering improved criterion validity.

We set out to modify and improve the Product Involvement Inventory (*PII*) developed by Zaichkowsky (1985). It should be emphasized at the outset that the *PII* is already a good measure by most standards of construct development. Our effort at modification has the goal of strengthening the *PII* through shoring up weaknesses and improving usability. The Revised Product Involvement Inventory (*RPII*) was developed to remedy four problems with the original measure: 1) difficulty and impracticability of use; 2) uncertain discriminant validity; 3) limited criterion validity; and 4) an overly narrow conceptualization of involvement.

Usability

The *PII* can be criticized for its polysyllabic vocabulary and its length (20 item pairs). The level of vocabulary (e.g., "mundane," "superfluous") may limit the applicability of the *PII* outside a university environment. Length becomes a problem when a researcher seeks to examine multiple products within a single study. Since earlier multi-item involvement measures had all been product specific (Bloch 1981; Tigert, Ring and King 1976), a key advantage of the *PII* is its suitability to comparing involvement across diverse products. Yet, the twenty item pairs in the *PII*, when applied across half a dozen products, might unduly fatigue respondents, making it difficult to measure other theoretical constructs of interest. A decisively shorter *PII* would have wider applicability while simultaneously offering greater convenience to both respondents and researchers.

Discriminant Validity

An examination of the content of the *PII* alerted us to a potential problem with discriminant validity. While there are some items in the *PII* that appear verbatim in commonly accepted scholarly definitions of involvement, such as "relevant" (Krugman 1965); "important" (Hupfer and Gardner 1971); and "interesting" (Mitchell 1979), the *PII* also includes items such as "valuable-worthless." These terms have a very different provenance: for over thirty years they have been shown to be among the best items for measuring the *evaluation* component of the meaning

of an object (Osgood, Suci and Tannenbaum, 1957, p. 190). Other items found in the *PII* which have been used to measure evaluation of an object include "useful" and "needed" (Osgood 1969), and "beneficial" (Burnkrant and Page 1982). Closely related in meaning -- although we could not find examples of their use -- are the terms "desirable" and "wanted." Thus, it would appear that between 20% and 30% of the content of the *PII* represents scale items whose typical use in the social sciences has been to measure a person's favorable or unfavorable evaluation of an object, and not involvement per se.

Inclusion of evaluative terms may confound the measurement of involvement with that of attitude. Hence, a measure of involvement ought to go to some length to exclude items which are predominantly evaluative in nature.

Criterion Validity

Behavioral criteria. Zaichkowsky (1985, pp. 346ff) specified five self-reported criterion behaviors as part of her validation efforts. Recent advances in the literature, however, cast doubt on the adequacy of the behavioral criteria used by Zaichkowsky. An examination of these five criteria (see Table 1) shows that they fall into two groups: three items are concerned with intensified information search or prolonged information processing, and the remaining two are concerned with commitment to a specific brand. Peter and Olson (1987) have argued persuasively that product involvement should be distinguished from brand involvement (cf. Rossiter and Percy 1987). An individual can be involved with the product category without seeing many differences between brands or having a preferred brand. This observation thus compromises two of Zaichkowsky's five items. Regarding the other three criteria, Zaichkowsky herself noted problems with the phrasing of the "reading about" information search measure (p. 347). Therefore, it would appear that the predictive validity of the twenty item *PII* rests on exactly two self-report items.

The non-brand related criteria used by Zaichkowsky (1985) measure the extent of information search and information processing -- activities that have continued to be judged in the literature as key concomitants of heightened consumer involvement (Beatty and Smith 1987; Bloch et al. 1986; Gensch and Jivalgi 1987). Information search can be indexed by activities such as reading about the product, attending to ads for it and discussing it with other people. Information processing can be indexed by activities such as comparing product characteristics, examining many factors for their potential relevance to purchase, and investing more time in the decision process. Any revision of the *PII* should have a demonstrated capacity to predict a wide range of such behaviors, and should be highly

predictive of a composite measure composed of multiple outcomes.

Situational discrimination. A second approach that Zaichkowsky used to establish criterion validity for the *PII* was to demonstrate its capacity to discriminate among products and among situations. The claim that the *PII* discriminates among situations is interesting but problematic. Zaichkowsky (1985) does not indicate whether the *PII* is intended to measure *enduring* involvement, *situational* involvement, or both (Houston and Rothschild 1978). Some authors would argue that different measures are required to assess these two types of involvement (Bloch and Richins 1983; Richins and Bloch 1986). On the other hand, the concept of *felt* involvement has been introduced by Peter and Olson (1987) to capture the net involvement produced in an individual by both enduring and situational factors. The tests reported in Zaichkowsky (1985) suggest that she intended the *PII* to be a measure of felt involvement. The support shown for this application of the *PII*, however, is modest: successful discrimination using one product (red wine) across one situational difference (private vs. socially visible consumption). Use of the *PII* to measure differences in felt involvement across situations could be better supported through an examination of multiple products across multiple types of situations.

Construct Validity

Theoretical definition of the involvement construct continues to be a contentious area. Clearly, allegiance to one or another theoretical position is going to have marked effects on how one measures the construct. While it is not our intent to present any new theories of involvement, we saw an opportunity to broaden the conceptualization that underlies the *PII*. Specifically, Zaichkowsky (1985) presents the *PII* as a measure of a single thing: involvement conceptualized as personal relevance. This is perhaps the most striking difference between the *PII* and the Involvement Profile developed by Laurent and Kapferer (1985). They insist that a measure of involvement must take into account multiple dimensions to be complete, and succeed in demonstrating the presence of at least four distinct factors in the analysis of their twenty item inventory.

The Laurent and Kapferer measure has its own problems, chief among which is whether *risk* (two of their four factors) is properly conceptualized as a dimension of involvement or as a separate construct (compare Chaffee and McLeod 1973; Bloch and Richins 1983; Rossiter and Percy 1987). If these concerns were to be placed aside, however, the two remaining dimensions (importance and pleasure) dovetail nicely with the two factor theory of involvement developed by Park and Mittal (1985). These authors argue that there exists both cognitively based and affectively based involvement. Heightened involvement can result either from functional consequences ("It is important that I attend to this product") or emotional consequences ("It gives me enjoyment to attend to this product"). This two factor conceptualization of Park and Mittal is consistent

both with subsequent work by Zaichkowsky (1987), and with an earlier tradition in the advertising discipline (Ratchford 1987; Vaughn 1980).

In this paper, we use the terms "importance" and "interest" to refer to these two aspects of the involvement response. Our position is that while the descriptors "important" and "interesting" are equally reflective of the felt involvement construct, they are *not* synonymous. Importance and interest represent correlated but distinct facets of felt involvement. Many products will strike a consumer as interesting and important to an equal degree; others will appear to be one but not the other. Hence, an involvement inventory needs to sample items from both domains, so that it can yield both an overall score and two subscores. This is particularly necessary if it should prove the case that the two dimensions differentially drive outcome behaviors such as information search, or vary in their effects across product categories. While Zaichkowsky (1985) did not make this distinction, the original *PII* appears to contain items from both the importance domain (e.g., "matters to me") and the interest domain (e.g., "exciting"). Our proposed revision will augment the interest domain (which appears to be represented by fewer items in the original *PII*).

METHOD

Sample and Procedure

Self administered questionnaires were completed by 146 students and 103 non-students; the total sample is 51% male and 49% female. The non-student sample consists of working adults over the age of 30; non-students were included to maintain comparability with Zaichkowsky's (1985) samples. Each respondent rated three products that were presented free of context (i.e., non-situated), and then a fourth product that was presented in two different situations. Ratings were made on a 22 item semantic differential that included the original *PII* plus two new item-pairs described below. Respondents also rated the three non-situated products on measures of attitude and information search and processing, as described below. Three different rating forms, each containing four products, were used in the research. The forms differed only in the specific products listed. The total of twelve products rated in the study include all the products used by Zaichkowsky with the exception of bubble bath (excluded in view of its gender-specific consumption). Within each rating form, one-half the respondents rated the products in one order, while the other half rated them in counterbalanced order. Across the three rating forms, *PII* scores for each group of non-situated products had been found to be roughly equal by Zaichkowsky (1985). After elimination of incomplete questionnaires, there were 1171 usable cases.

Measures

Involvement. Two new-item pairs were added to the *PII*: "fun-not fun" and "dull-neat". These were chosen by the authors to tap the interest facet of involvement, and to help alleviate the polysyllabic

EXHIBIT
Assignment of Items Used to Rate Involvement to the PII, RPII, and Discard Measures

Scale items	RPII		Discard
	Importance	Interest	
Important ... unimportant	X		
Not needed ... needed			X
Irrelevant ... relevant	X		
Means a lot to me ... means nothing to me	X		
Unexciting ... exciting		X	
Valuable ... worthless			X
Trivial ... fundamental			X
Beneficial ... not beneficial			X
DULL ... NEAT		X	
Matters to me ... doesn't matter	X		
Uninterested ... interested			X ^a
Significant ... insignificant			X
Vital ... superfluous			X
Boring ... interesting		X	
FUN ... NOT FUN		X	
Useless ... useful			X
Appealing ... unappealing		X	
Mundane ... fascinating			X
Essential ... nonessential			X
Undesirable ... desirable			X
Wanted ... unwanted			X
Of no concern ... of concern to me	X		

NOTE: Items listed under 'scale items' comprise the *PII* (Zaichkowsky 1985), with the exceptions of those in boldface capitals, which were added in the present study. Items listed under 'Discard' represent those items in the *PII* that we propose to discard. The order shown is the order in which the items were administered.

^a This item was excluded from analyses of the Discard measure. While it clearly measures involvement, it inappropriately duplicates the "interesting-boring" item, which was chosen for retention in the *RPII*.

character of the *PII*. For analytic purposes the 22 item pairs representing involvement can be characterized in several ways as shown in the Exhibit. The *RPII* consists of eight item-pairs drawn from the original *PII* plus the two new item-pairs. The *RPII* is divided as shown into two sub-scales referred to as Importance and Interest. The Discard measure consists of those items in the *PII* that we propose to eliminate. Since the *RPII* is largely a subset of the *PII*, most analyses compare the *RPII* to the Discard measure rather than the *PII*. The general hypothesis is that the items in the Discard set either serve no useful purpose or actually have a debilitating effect.

Attitude. Five item pairs (good-bad, ugly-beautiful, pleasant-unpleasant, awful-nice, positive-negative) were selected from the literature on the semantic differential (Osgood, Suci and Tannenbaum 1957; Osgood 1969). Each pair had very high ratings on the Evaluation factor in that literature. Coefficient alpha for the sum is .92.

Information Search and Processing. The five items used by Zaichkowsky (1985) and five additional items drawn from the literature were used to measure commonly accepted outcomes of a state of involvement (Table 1). In addition to examining individual items, the analyses also use the sum of those eight of the ten items that were not related to brand commitment (see note to Table 1; coefficient alpha for this sum is .94).

Situational Differences. Involvement with three of the products studied (red wine, calculators, and cameras) was examined across two situations. For red wine, this was the exact public vs. private situation distinction used by Zaichkowsky; for calculators it was self vs. gift purchase situation, while for cameras it was everyday use vs. use on an overseas vacation.

TABLE 1
Comparison of the PII, RPII and the Discard in the Prediction of Involvement Outcomes

Outcome	R ²		
	PII (20 items)	RPII (10 items)	DISCARD (11 items)
1. I would be interested in reading about this product	.59	.62	.55
2. I would read a Consumer Reports article about this product	.50	.52	.47
3. I have compared product characteristics among brands	.58	.58	.55
4. I think there are a great deal of differences among brands	.46	.48	.42
5. I have a most preferred brand of this product	.56	.54	.48
6. I usually pay attention to ads for this product	.52	.54	.48
7. I usually talk about this product with other people	.54	.58	.50
8. I usually seek advice from other people prior to purchasing this product	.49	.54	.44
9. I usually take many factors into account before purchasing this product	.51	.56	.47
10. I usually spend a lot of time choosing what kind to buy	.52	.57	.47

NOTE: Items #1 through 5 are the same as those used in Zaichkowsky (1985) with minor changes in wording. The remaining items were developed for the present study. Items 4 and 5 were eliminated to create the eight item summed measure of information search and processing discussed in the text.

RESULTS

Internal Consistency

Coefficient alphas for the *PII* and the *RPII* were computed over the nine products rated in the study, over the six situated products, and for each product and situated product individually. The reliability of both the *RPII* and the Importance and Interest sub-scales, when measured across multiple product categories, is very good in an absolute sense at .95, and almost as good as the *PII*, whose reliability is .98. In terms of individual products, the superiority to be expected from the lengthier *PII* is more apparent. In several cases reliability for the *RPII* and its sub-scales dips to the low or mid .80's, while that for the *PII* never dips below .92. Nevertheless, in about three-fourths of the individual product ratings the reliability of the *RPII* and its two sub-scales equals or exceeds .90. To measure test-retest reliability, three of the products (facial tissue, headache remedy and mouthwash) were rated a second time by 60 students after a three week interval. Over the three products, test-retest

correlations for the *PII* ranged from .59 to .85, and for the *RPII* from .53 to .78. As with coefficient alpha, the *PII* has a slight reliability advantage over the *RPII*.

Usability

The *PII* contains 143 syllables in 57 words ($\bar{x} = 2.51$), the *RPII* contains 66 syllables in 36 words ($\bar{x} = 1.83$), and the Discard contains 73 syllables in 24 words ($\bar{x} = 3.04$). The syllable-word ratio in the *RPII*, when compared item by item is significantly less than for the *PII* ($t = 2.62, p = .01$). A lower syllable count is often associated with greater readability and ease of comprehension (Locker 1989). As an additional test of usability, 65 undergraduates, predominately of Junior standing, rated each unique word in the *PII*. They were asked which of these words they used in speech or writing. Four words in the *PII* were found to be problematic: superfluous (77% did not use), mundane (62%), vital (23%) and fundamental (22%). These analyses strongly suggest the need to simplify the *PII* if it is to be applicable to broader populations outside of an elite university setting.

TABLE 2
Effectiveness of the PII and RPII in Discriminating Involvement Across Situations

Product Situation	PII				RPII			
	Mean	t	Wilks' lambda	% correct	Mean	t	Wilks' lambda	% correct
Red Wine								
Dinner party	103				52			
Everyday	65	12.7	.66	76%	34	12.9	.68	74%
Calculator								
Personal use	110				51			
Gift for friend	101	5.0	.92	64%	48	3.4	.97	57%
35mm Camera								
Vacation	112				56			
Everyday use	97	5.2	.92	66%	49	5.2	.93	64%

NOTE: All t test and Wilk's lambda values used in the discriminant analysis are significant at the .001 level. The "% correct" column indicates the number of cases correctly classified following a discriminant analysis.

Factor Structure

Principal components factor analyses with varimax rotation were performed on the *PII* and the *RPII* for the nine products taken in the aggregate, the six situated products in the aggregate, and over the 9 individual products and 6 situated products (Table 2). In both the aggregate analyses the *PII* revealed one major and one minor factor, exactly as reported by Zaichkowsky (1985). On an individual product basis the results for the *PII* are less clear. In 8 of 15 cases, the *PII* exhibited more than two factors, with as many as five in the case of automobiles and calculators purchased for a friend. This casts serious doubt on whether the 20 item *PII* really measures a single dimension of involvement as claimed by Zaichkowsky (1985).

The *RPII* had a two factor structure in both of the aggregate analyses. In the analyses of the 15 individual product ratings (nine non-situated, six situated), the *RPII* showed only a single factor in four cases, and two factors in the remaining eleven cases. The occasional absence of a second factor is probably a result of the high correlation between Importance and Interest ($r = .66$ overall).

Discriminant Validity

Surprisingly, both the *RPII* and the Discard measure have approximately equal correlations with the attitude measure ($r = .76$). This undermines our contention that the *PII* is more confounded with attitude than is the *RPII*. However, the results are somewhat more encouraging when the Importance and

Interest sub-scales of the *RPII* are examined separately. The sub-scale correlations with the attitude measure are .74 and .65, respectively. The latter correlation is significantly lower than the Discard-Attitude correlation of .76 when Steiger's (1980) test for dependent correlations is applied ($\bar{\chi}_1^2 = 5.41, p < .001$). It appears that the *PII* is not alone in having a high correlation with attitude. However, these findings also suggest that measures of interest are more distinct from measures of attitude than are measures of personal relevance (the Importance sub-scale). The sub-scale structure of the *RPII* thus offers some assistance to the researcher who seeks the greatest possible differentiation between measures of involvement with the object versus attitude toward the object.

Criterion Validity

This section compares the performance of the *PII*, the Discard and the *RPII* measures in the prediction of ten outcomes of involvement. To maintain comparability we first examine results for the five behaviors originally studied by Zaichkowsky (1985), despite the fact that two of these items probably measure brand involvement rather than product involvement. As shown in Table 1, the *RPII* is nominally superior to the *PII* in four out of five cases. The one exception concerns having a preferred brand. Even here, the five item Importance sub-scale predicts this behavior as effectively as the twenty item *PII*.

The next analysis examines the sum of eight items (three from Zaichkowsky, five added by us) which measure information search and processing (see note to Table 1). This sum provides a more reliable indicator of involvement outcomes than any individual behavior. Looking at the aggregate of nine products, the *RPII* is again superior to the *PII*, accounting for 45.2% of the variance in information search and processing, as compared to 40.3% for the *PII*. The difference between the two correlations is significant by Steiger's (1980) test ($\bar{Z}_i = 4.44, p < .001$). A more conclusive test is to examine the incremental contribution (I^2) in predicting information search and processing obtained by adding the Discard measure to an equation that contains the *RPII* measure (Cohen and Cohen 1983). This analysis shows no significant contribution by the Discard measure in a hierarchical regression analysis ($I^2 = .001, NS$).

Because the *PII* was found to be especially reliable on an individual product basis, this hierarchical regression analysis was repeated on a product by product basis. For eight of nine products, the addition of the Discard measure again failed to improve upon the prediction of outcomes obtained from the *RPII* (the exception is color televisions). These individual product analyses indicate that in most cases the items in the Discard measure perform no useful function from the standpoint of prediction of information search and processing.

Also of note are analyses of the attitude measure in prediction of information search and processing. Despite the high correlation between attitude and both Zaichkowsky's *PII* and our *RPII* measures of involvement, attitude is clearly inferior as a predictor of behavioral outcomes, accounting for but 27% of the variance in the eight item sum.

Discrimination Among Situations

Red wine, calculators and cameras were each presented to respondents in two distinct situational contexts. The *PII* successfully discriminated between two situations in the case of three different products examined in three different types of situations (Table 2), as would be expected of a measure of felt involvement (Celsi and Olson 1988; Peter and Olson 1987). We also found the *RPII* to be about as effective as the *PII* in this task. The *RPII* is also able to discriminate differing degrees of involvement across situations in all three cases; however, in a discriminant analysis it does not correctly classify quite as many cases as the *PII* (Table 2). On the other hand, in a hierarchical discriminant analysis where the *RPII* is entered first, the Discard measure does not add significantly to the *RPII*'s discrimination between situations in two of three cases (red wine and cameras). The roughly equivalent performance of the *RPII*, in conjunction with the limited incremental value of the Discard measure, suggest that the extra items in the *PII* may be of limited value when the goal is to discriminate degree of felt involvement with a product across multiple situations.

Construct Validity

Implicit in the Park and Mittal (1985) theory is the idea that the involvement response by an individual to a product may be a function of either the perceived importance it has, or its interest value, or both. This suggests an examination of the relative contribution of the Importance and Interest sub-scales of the *RPII* in predicting information search and processing. Using the eight item sum of information search and processing, and now looking at each product individually, Table 3 shows that for facial tissues, headache remedies, and laundry detergent, Importance is clearly a better predictor of involvement outcomes than Interest. In fact, for the first two products, Interest makes no incremental contribution to the prediction of outcomes. For automobiles, color televisions, instant coffee, and jeans, the reverse is true: Importance is less predictive than Interest, and affords no increment in prediction. For breakfast cereal and mouthwash, outcomes appear to be driven by both Importance and Interest. Taken together, the above analyses indicate the utility of distinguishing between the importance and interest facets of involvement.

DISCUSSION

One finding of this study is the strong performance of Zaichkowsky's *PII* across a number of validation tests. It is exceedingly reliable; it is highly predictive of a broad range of behavioral outcomes associated with involvement; and it is able to successfully discriminate felt involvement across several products and a variety of situations. The last two validation tests go beyond the evidence provided by Zaichkowsky (1985) in her original article. However, the *PII* also appears to suffer several limitations. It is unnecessarily long and elaborate; needlessly difficult to comprehend; insufficiently predictive of information search and processing outcomes; and unduly narrow in its conceptualization. The revised version of the *PII* examined in this paper appears to retain what is best in the original *PII* while offering a number of significant improvements and incurring no major liabilities. The ten item *RPII* is one-half as long as the *PII* while remaining very reliable; uses mostly short and simple words; is strongly predictive of information search and processing; and is effective at discriminating felt involvement across situations.

The most significant weakness of the *RPII* in comparison with the *PII* is its somewhat lower although still quite high reliability, as evidenced by both coefficient alpha and test-retest correlations. This weakness is most apparent at the individual product level. There are probably some situations, involving the correct classification of respondents into groups or with respect to some cut-off value, where this lowered reliability may argue for use of the *PII* instead of the *RPII*. However, even here the investigator will have to weigh the *PII*'s reliability advantage against its more polysyllabic character and the associated difficulties in comprehension. Similar comments apply when the investigator seeks to discriminate among situations.

TABLE 3
Comparison of Importance and Interest Sub-Scales of the RPII in the Prediction of Multiple Outcomes Across Products

Product	R ²		I ²	
	Importance	Interest	Importance	Interest
Automobile	.15	.26	.01 ^a	.12
Breakfast cereal	.37	.38	.04	.06
Color television	.16	.23	.00 ^a	.07
Facial tissue	.17	.06	.11	.00 ^a
Headache remedy	.19	.01 ^a	.19	.00 ^a
Instant coffee	.25	.30	.01 ^a	.06
Jeans	.28	.45	.00 ^a	.17
Laundry detergent	.26	.18	.13	.05
Mouthwash	.13	.12	.03 ^a	.02 ^a

NOTE: I² represents the increment in R² achieved when one of the sub-scales is added to an equation that already contains the other (see Cohen and Cohen 1983). The dependent variable for these analyses is the eight item sum of information search and processing outcomes (see note to Table 1).

^a Indicates a non-significant ($p > .05$) test result.

There is clearly a need for additional theoretical work on how favorability and involvement are related in the case of specific products. For the products we examined, both the RPII and the PII were highly correlated with the attitude (although the interest sub-scale is less so). The fact that the involvement measures are much better than the favorability measure at predicting information search and processing is certainly grounds for retaining the distinction between involvement and attitude. In future research it might be interesting to attempt to identify, on the one hand, products which are favorably regarded but uninvolved, and on the other, products which are unfavorably regarded but involving. Close examination of such products might help to disentangle the relationship between involvement and attitude.

The other conceptual finding of note is that involvement cannot be reduced to either personal relevance (i.e., importance) or interest. Most contemporary definitions (e.g., Bloch and Richins 1983; Cohen 1983; Mitchell 1979; Rothschild 1984; Zaichkowsky 1985) emphasize either the one or the other of these facets. Conceptualizations that identify the involvement construct with interest need to deal with product categories such as headache remedies where interest is quite unable to predict a wide range of behaviors typically associated with involvement. Similarly, conceptualizations that identify involvement with personal relevance need to grapple with product categories such as jeans, where importance is a weak predictor of outcomes. In the

meantime, the results reported here, in conjunction with theoretical work by Park and Mittal (1985) and also Laurent and Kapferer (1985), Ratchford (1987), Vaughn (1980), and Zaichkowsky's (1987) own later work argue for a multidimensional conceptualization of involvement. Whether importance and interest should be modelled as antecedents, or as facets, or as alternative expressions of involvement, is a task for future research. Here again it would be useful to examine some extreme cases: products that are important but uninteresting, or interesting but unimportant.

In conclusion, the findings indicate that the RPII represents a viable alternative to the PII for measuring involvement. Researchers who need a short measure with high criterion validity, and who can tolerate a slight decrease in reliability, may choose to use it in preference to the PII.

The Use of Multiple Methods to Explore Three-Way Person, Brand and Usage Context Interactions

Niraj Dawar, INSEAD

S. Ratneshwar, University of Florida

Alan G. Sawyer, University of Florida

ABSTRACT

Previous research on situational influences focused on two-way product-usage context interactions and generally employed single methods. In contrast, the present research investigated three-way interactions between person, product, and usage context, and used multiple methods. Specifically, we studied such interactions in the product category *bar soaps*, with gender serving as the relevant person-level segmentation variable. The results of three experiments provided converging evidence that males, in comparison to females, are less discriminating between different subcategories of soap, and are more likely to cross-use brands in those subcategories across different usage contexts.

INTRODUCTION

Consumers' choices of brand or product often depends on the situation or usage context for which the product or brand is desired. This finding has been established repeatedly in a number of studies that have emphasized the importance of product-situation interactions in explaining consumer choice and in determining market structures (e.g., Belk 1974, 1975; Dickson 1982; Miller and Ginter 1979; Srivastava, Alpert and Shocker 1984). It has also been argued (e.g., Dickson 1982) that in some cases it may be useful to examine person-situation-product interactions, where some product (or brand) choices (or attitudes) are influenced by the usage context and person variables differentially than other products (or brands). For example, a brand of soap may be designated by female users as a "shower" soap and another may be designated a "facial" soap, while male users may not make the distinction.

The person-situation-product interaction can be important since it has the potential for becoming a basis for segmentation if it can be shown that the groups identified by using this criterion have homogeneous within-group responses and heterogeneous between group responses (Dickson 1982). In the soap-brand example above, a person-situation-product interaction might identify two segments of consumers based on a person variable (gender) whose behavior (product choice) varies differentially across different situations or usage contexts (shower vs. facial usage). The behavior within each group or segment (females or males) is homogeneous in that the product x situation interaction can explain it.

While such three-way person x product x usage context interactions were conceptualized by previous researchers (e.g., Dickson 1982; Srivastava et al. 1984), to the best of our knowledge they have never been demonstrated *empirically*. Research in this area has invariably treated all subjects as replicate

experimental units; in other words, subjects were not "blocked" on the basis of relevant person-level variables. (This is not surprising, given that much of this research focused on the product x usage context interaction). In this present research we sought to investigate such three-way interactions in the product category *bar soaps*, with gender serving as the relevant person-level variable. Based on preliminary research, we expected to find systematic differences between male and female consumers in their category structures; that is, in their mental representations of the product category. More importantly, we also expected that these gender differences in category structures would be closely associated with differences in perceptions of appropriateness of various brands of soap for different usage situations (Ratneshwar & Shocker 1991).

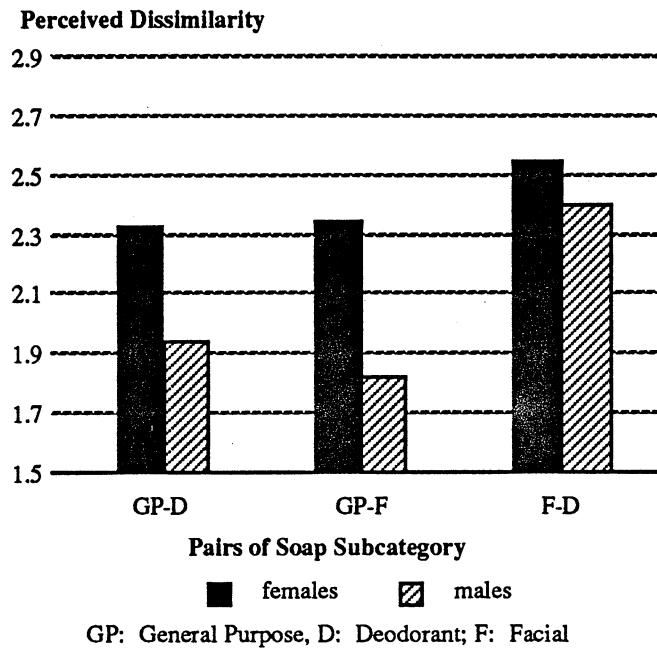

The present research had one additional unique feature, namely, the use of multiple methods. Previous researchers of usage situation influences on consumers' product preferences invariably adopted a single method: typically, one wherein all subjects rated a researcher-specified list of product alternatives across a set of usage contexts. There is some possibility that this method induces demand biases (Reingen 1976; Sawyer 1975). Specifically, Reingen (1976) suggested that the design of these studies (e.g. Belk 1974) may have cued subjects that they were "supposed to" shift their preferences across usage contexts. Hence, we decided on the use of multiple methods to examine whether converging evidence could be obtained on the three-way person-product-situation interaction.

We report three experiments. In Experiment 1, we explored whether males and females differ in their mental representations of various soap brands with the data being obtained from a categorization task. In a second experiment we investigated gender differences in terms of soap brands evoked from memory in different usage contexts. Finally, in Experiment 3 these gender differences were examined in a task where subjects rated a specified list of brands for appropriateness in different usages.

EXPERIMENT 1

A focus group (N=12) was first conducted to obtain some initial insights into gender differences in the manner in which consumers think about the product category. The discussion in the group suggested that in general males were not likely to be as sensitive as females to the usage situation for bar soaps. Concomitantly, males (vs. females) did not appear to discriminate as much between different subtypes of soaps. These conjectures led us to believe that males might differ from females in their mental representations of the product category, and that these differences might be associated with their respective

FIGURE
GENDER DIFFERENCES IN PERCEIVED DISSIMILARITY BETWEEN SOAP SUBCATEGORIES

perceptions of usage appropriateness of different brands. These speculations are consistent with recent research in categorization that suggests that category structures are not fixed across populations (Barsalou 1987), and that such cognitive structures can be goal-derived (Barsalou 1985; and see Ratneshwar and Shocker 1991). This implies that different subpopulations may use different categorization schemes to classify the same group of objects. For example, males and females may differ in the manner of classifying brands of soap because female consumers are more sensitive to usage goals, and are perhaps more expert in the soap category. As a result, they may use finer classifications than do males; that is, they may have more differentiated category structures. Also, the distinctions that they make among various subcategories of soap are likely to be clearer in that, as experts, they are likely to "avoid confusions between brands..." (Alba & Hutchinson 1987). In addition, as experts, their "basic" level might be more specific than that of novices and consequently, their categorical distinctions might be at a lower level than that of novices (Alba & Hutchinson 1987). Because of such differences in categorization, we expected that males might have a broader classification (fewer subcategories, with a larger number of brands of soap per subcategory) than females. Further, we expected that distinctions between brands belonging to different subcategories of soap might be coarser (i.e. less in magnitude) for males than females. Experiment 1 was designed to explore these issues.

Method

Twenty one brands of bar soap that were judged to be familiar by the focus group participants were utilized for the experiment (see Table 3 for the list of brands). A group of 32 female and 30 male undergraduate subjects participated. Subjects were asked to sort 21 cards, each carrying the name of a brand, into no more than eight groups based on perceived similarity. These data were converted into interbrand dissimilarity measures; these dissimilarity measures were computed at the aggregate level separately for each gender (see Ratneshwar and Shocker, 1991, Study 2, for details).

Results

The dissimilarity measures from the male and female groups were used as input to hierarchical cluster analyses and there were no major discrepancies between males and females as to the brands in each cluster. The results of this analysis indicated that both genders clustered the brands into three basic clusters. Based on packaging information, the brands in these three clusters closely corresponded to the usage subcategories Facial, Deodorant, and General Purpose soaps. By analyzing the differences between males and females on perceived dissimilarity of brands, we could determine if males did indeed perceive the brands to be less dissimilar than did females. The dissimilarity of brands that fell into different subcategories formed the data of interest. We analyzed these data to check for effects of Gender in perceived dissimilarity between soap subcategories.

The mean dissimilarity measures for both genders are presented in the Figure. Males and females

alike perceived a large difference between Facial brands and Deodorant brands, although females perceived the difference to be greater ($t_{58}=5.98$, $p<.0001$). With regard to the other comparisons, the General Purpose to Deodorant and General Purpose to Facial, the data show that males perceived greater similarity across categories than did females ($t_{118}=8.5$, $p<.0001$; and $t_{98}=14.64$, $p<.0001$ respectively). Thus, in all cases, females perceived greater dissimilarity across subcategories than did males.

Discussion

The results supported our expectation that males would differ from females in their perceptions of similarity of various subcategories of soap brands. Further, the extent of these differences apparently depends on which two subcategories are compared. Since males tend to perceive *all* brands of soap as more similar than females, they may be more likely to cross-use soaps than females. For example, males may be more likely to use a General Purpose soap for facial usage than females. Further, it is more likely that males may cross-use soaps across the Facial and General Purpose subcategories than across the Facial and Deodorant subcategories. The results of this experiment are consistent with the argument that as experts, females' distinctions among the subcategories of soap are likely to be clearer, and they are less likely to confuse brands. The category structures with which brands of soap are represented in memory apparently are different for males and females. This suggests that the principal cognitive tasks associated with such memory structures, such as brands evoked from memory, are also likely to be affected by gender differences. This issue was investigated in Experiment 2.

EXPERIMENT 2

This experiment examined potential three-way person x product x usage context interactions in the formation of evoked sets. As numerous studies demonstrate, the formation of an evoked set or consideration set, as some authors prefer to call it, is a necessary stage in the phased decision process (Alba & Chattopadhyay 1985, Bettman 1979, Howard & Sheth 1969, Ratneshwar & Shocker 1991, Wright & Barbour 1977). Most previous research into the effects of usage-context on consumer behavior has not considered the evoked-set formation stage, as subjects in these studies were provided with lists of product alternatives (see Ratneshwar and Shocker, 1991, Study 3 for an exception).

Evoked sets are subsets of a larger pool of brands or alternatives represented in category structures in memory (Alba & Chattopadhyay 1985, Bettman 1979). The products that make up these category structures vary in how typical they are of that category, and typicality is a major determinant of recall of category members from memory (Medin & Smith 1984). Recent research has found that typicality may vary as a function of context and of subject population (Barsalou 1985, 1987, Roth & Shoben 1983). That is, categories are now thought to

be flexible enough to allow for different instances to represent those categories depending, among other things, on the context in which they are evoked, and on the population evoking them (Dawar 1991). Evoked set formation is equivalent to the retrieval of instances of a subcategory from memory in a particular usage context (Ratneshwar & Shocker 1991). We can, therefore, expect that evoked sets may vary across subjects based on some subject variable as well as across usage context. In this experiment we examined how evoked sets differ across subject populations *and* usage contexts. Specifically, we investigated gender differences in the types of soap brands evoked by males and females in two different usage contexts (facial usage and shower usage).

Method

Subjects were two different groups of undergraduate students. The first group was made up of 68 marketing majors while the second was composed of 81 psychology majors. Subjects were later blocked on the basis of gender. All subjects evoked soap brands in both usage contexts, making usage context a within-subjects factor. Subjects were asked to name "brands of soap that you might use regularly to wash your face (on your body while taking a shower)". Order of presentation of usage context was counterbalanced across subjects. Subjects were asked to limit the number of brands listed to a maximum of three in each usage context. This was done so as to obtain only those brands that subjects were most likely to retrieve from memory in that usage context.

Subjects' brand listings were classified by the researchers into three types of soap subcategories based on Experiment 1: (1) General purpose, (2) Facial, and (3) Deodorant. A cross tabulation of the brand recall frequencies into the 24 cells generated by crossing Usage Context (two levels) with Groups nested in Gender (four levels) and Soap Subcategory (three levels) was analyzed using Analysis of Variance (ANOVA).

Results

The mean frequencies with which brands were evoked in the different subcategories in each usage context are shown in Table 1. An ANOVA was conducted using "group" as the experimental block. Since there are replicate groups within each gender, we can test all main effects and interactions including the three-way interaction of person-product-usage context. The three-way interaction of gender, usage context and brand recall was marginally significant ($F_{2,4}=5.8$, $p<.07$). Some clear trends are apparent in terms of gender differences. For facial usage, females (vs. males) are much more likely to use facial soaps, and much less likely to use deodorant soaps. For shower usage, females (vs. males) are much more likely to use general purpose soaps, and much less likely, again, to use deodorant soaps. Other interactions were significant too. The significant interaction of Product x Usage Context ($F_{2,4}=42.85$, $p<.01$) confirms previous findings (Ratneshwar and Shocker 1991) that brand recall is dependent on usage context, this time in the category of bar soaps. The significant

interaction of the Gender and Product variables ($F_{2,4}=10.33$, $p<.05$) shows that brand recall in this product category also depends on the gender of the consumer -- males and females differ in their recall of different types of soap. The lack of significance of the Usage Context x Gender interaction ($F_{1,2}=.02$, $p>.75$) indicates that the number of brands of soap recalled does not vary by gender with usage context. Further, the lack of significance of the main effect for Gender ($p>.50$) shows that variance due to gender may, in large measure, be accounted for by the Gender x Product and Gender x Product x Usage Context interactions.

Discussion

The results provided a confirmation of previous research by demonstrating the importance of the two-way usage context x brand interactions. However, the marginally significant three-way interaction is probably the most crucial aspect of the present results. Prior studies have generally not looked at the manner in which usage context differences may occur at the stage of evoked-set formation. The results obtained here suggest that differences between segments of consumers may arise at the evoked-set formation stage of the choice process. This implies that later stages (evaluation, choice) may all be affected by the interactions at the evoked-set stage. In Experiment 3 we examine brand appropriateness ratings for a three-way person x product x usage context interaction. This is the method traditionally adopted in studies of situation effects on consumer behavior.

EXPERIMENT 3

The previous two experiments attempted to examine the three-way person x product x usage context interaction by examining differences in perceived dissimilarity and brands of soap evoked in various usage contexts. In this experiment we adopted a method that has traditionally been used in the study of situational effects on buyer behavior (Belk 1974,

Srivastava et al. 1984). In this method subjects are asked to rate the appropriateness of a set of product alternatives for each of a number of usage situations. This yields a Product x Situations x Subjects experimental design. The data so obtained can be analyzed to estimate the contribution to variance of each effect and their interactions. But as noted previously, in past research all subjects have been treated as replicates and individual difference variables have been typically ignored. However, judging by the results of Experiments 1 and 2, it would appear that Gender is an important person-level variable on the basis of which one might expect a person x product x usage context interaction in the bar soap category. Note that the earlier two experiments dealt with earlier stages of the consumer choice process, namely, representation of alternatives and evoked set formation. This experiment is different from the previous two in that the dependent measure used here is much closer to actual behavior (Wicker 1972). In this study we examine the three-way interaction and its magnitude in consumers' ratings of appropriateness of brands of soap to each of three usage contexts.

Method

The 21 brands of soap chosen for the study were generated in a focus group and selected based on subjects' familiarity with them (see Experiment 1). The usage contexts used in this experiment were also generated in the focus group. The three used in this study were: (a) a brand of soap that you might use regularly to wash your face; (b) a brand of soap you might use regularly to wash your hands; (c) a brand of soap you might use regularly on your body while taking a shower. A total of 82 (48 male and 34 female) undergraduate students participated in the experiment for course credit. Subjects rated the appropriateness of each brand (on a seven-point scale) in each usage context, making both brands and situations within-subject factors. The order of

presentation of the three usage contexts was counterbalanced across subjects.

Results

The analysis aims to estimate the relative contribution to variance in appropriateness ratings of each of the main effects and interactions. This is accomplished by using the expected mean squares of each of the effects (see Belk 1974). The relative contributions of each of the effects and interactions are presented in Table 2. As anticipated, the three-way Gender x Brands x Usage Context interaction was significant ($p < .001$) with 2.9% contribution to overall variance. However the most important sources of variance are the Brands x Usage Context interaction (26.8%, $p < .001$), and the main effect for Brands (14.9%, $p < .001$). The contribution of the main effects of Gender and Usage Context are small. These results are consistent with earlier research on the topic of situational effects, even though the alternatives used in these earlier studies were products rather than brands, and the person variables used were different. Table 3 presents the means of the appropriateness ratings. These means show clearly that males and females tend to have a different pattern of response with regard to brand usage appropriateness ratings.

Stated simply, the data appear to suggest that females are more discriminating than males in their judgement of soaps, and that their judgements depend on the usage context. Males, generally, perceive fewer differences between soap subcategories and would be more prone to cross-use. For example, females rate deodorant brands as most appropriate for shower usage (mean=5.99), only moderately appropriate for use for washing hands (mean=5.19), and not very appropriate for facial use (mean=2.29). While males follow the same ordinal pattern in terms of appropriateness ratings, the mean ratings do not differ as much across usage context. For example, males rate deodorant soaps as reasonably appropriate

for all three situations (mean=6.24 for shower, mean=5.81 for hands, and mean=4.08 for facial use).

GENERAL DISCUSSION

The three experiments reported here provided converging results pointing toward the importance of an interaction between person variables, usage context, and alternatives, in explaining consumer behavior. The three-way interaction of Gender, Usage Context, and Brands was marginally statistically significant in Experiment 2 and statistically significant in Experiment 3. An examination of the cell means for Experiment 3 shows that males tend to rate deodorant brands as being more appropriate in all usage contexts than do females. This is also reflected in the result from Experiment 2 in that males tend to recall more deodorant brands across usage contexts than do females. The results from both experiments seem to show that males' preferences for deodorant brands show very little variations across contexts, while females tend to judge their brands with regard to specific usage context. It is further apparent from the results of both Experiments 2 and 3, that females have a stronger preference than males to use general purpose brands for showering. These findings are corroborated by the results of Experiment 1, which investigated the perceived similarity of brands across subcategories. Females tended to discriminate more between brands based on the typical usage of those brands, while males tend to view these subcategories as more similar.

Unlike previous research in this area (e.g. Belk 1974, Srivastava et al. 1984), we employed multiple methods to assess the impact of three-way person-usage context-brand interactions. In the first Experiment, we examined differences in perceived similarity of brands across gender, using a card-sort task to generate dissimilarity measures. The second experiment used a method that asked subjects to generate alternatives from memory for different usage

M=Males; F=Females

Note: Appropriateness Ratings were obtained on a 1-7 scale.

contexts. Finally, in Experiment 3, we reverted to the traditional method, wherein subjects rated a set of brands across different usage contexts. Thus, each of the three experiments in this study examined the three-way person x product x usage context interaction at a different stage of the consumer choice process. Our results show that the three-way interaction can explain differences in the mental representation of soap brands for males vs. females (Experiment 1); differences in the evoked set of soap brands considered in different usage contexts (Experiment 2) and differences in the evaluation or appropriateness judgements (Experiment 3). Previous research has generally only examined the last of these stages of the consumer choice process.

In addition, our operationalizations of the person, product, and situation variables differed

somewhat from those used in previous research. The person variable used in this study was gender, the product variable was brands of soap, and the usage context was three usage situations for soap. In spite of these differences, the results of Experiment 2 and especially Experiment 3 are remarkably consistent with the results of earlier studies. Specifically, the importance of the two-way interaction of Brands x Usage Context, and Brands x Person, is evident in this study as it has been in previous studies. Further, the converging pattern of results -- notwithstanding the differences in method -- from three experiments suggests that such interactions are "real," and not due to methodological artifact (cf. Reingen 1976).

Previous research has pointed out the importance of usage context interaction in

determining customer segments and defining market structures (Belk 1974; Dickson 1982; Ratneshwar & Shocker 1991). The three-way person x product x usage context interaction has the potential for becoming a basis for segmentation if it can be shown that the groups identified through this criterion have homogeneous within-group responses and heterogeneous responses between groups (Dickson 1982). The results in this study indicate that this can indeed be the case. As the results show, the person by situation segments that could be identified on the basis of these results are more homogeneous within segment than across segment. Specifically, these results suggest that the mental representations, evoked set formation, and appropriateness judgements are specific to gender x situation groups. It is useful for marketers to understand that some segments (e.g. women) may be more sensitive to usage context differences than other segments (e.g. men) for some products. In addition, some brands (e.g. deodorant brands) may be more influenced by person x situation factors than others (e.g. facial and general purpose brands).

Categories and category structures, especially in marketing situations are often goal-derived. Usage contexts may serve to "frame" or define consumer goals by specifying the specific benefits sought. Thus, perceptions of usage appropriateness may depend on the extent to which females or males perceive that a particular brand will provide the specific benefits sought in that context. These usage appropriateness perceptions, in turn are likely to impact on the mental representation of categories.

Finally, we note that the present research attests to the importance of research on the interaction between person, usage context, and product variables at various stages of the consumer problem-solving process. Future research may be able to verify whether there are systematic differences in the kinds of interactions that explain each stage of the problem solving task, across a person variable such as experts vs. novices. For example, experts may take into consideration a greater number of factors than novices in making their evaluations, but may be just as heuristic as novices in the creation of evoked sets.

Chernoff Faces: A Useful Technique for Comparative Image Analysis and Representation

Linda L. Golden, University of Texas at Austin
Mayur Sirdesai, University of Texas at Austin¹

ABSTRACT

While consumer researchers often measure image in a decomposed attribute-by-attribute manner, it is easy to recognize that image is greater than the sum of its parts. Brand image is an important concept for consumer behavior and its relationship to choice behavior is being established in the literature. This paper presents a new approach for globally representing quantitative image impressions (data) and demonstrates its usefulness empirically. Using Chernoff face icons, the consumers' perceptions of multi-dimensional, multi-object attributes can be readily displayed for visual analysis.

Consumer researchers recognize the important relationship between consumer image perceptions and purchasing behavior. In fact, it has been said that most individuals base their purchasing actions on the type of image a product portrays (Jacoby and Mazursky 1984). Thus, because of the importance of the idea, consumer researchers and strategists have developed many ways to measure consumer image perceptions.

Image measurement and analysis techniques range from the traditional quantitative multi-variate ones, to qualitative data collection and analysis (see Zimmer and Golden 1988 for a review and content analysis application), to the recent introduction of information theoretic analysis for scaled image data (Golden, Brockett and Zimmer 1990). However, irrespective of analytical approach, the effective display of multidimensional findings is often very cumbersome and its meaning difficult to represent.

Brand and retail image is generally recognized to be multi-dimensional (Golden, Albaum and Zimmer 1987) and researchers often wish to compare image results across alternative product offerings. Indeed, one way of comparing images of competitive products is to substitute competitors' brand names with your own and evaluate the relative consumer responses across multiple attribute dimensions in order to develop a comparative assessment of consumer perceptions (Jacoby and Mazursky 1984). However, sometimes the informational analysis desired goes beyond the "Are the differences statistically significant?" to focus on "What does this mean?" and "How can I interpret or present it?"

This paper develops and empirically demonstrates the idea of using icons, specifically

geometrically derived Chernoff faces, as a tool to comprehend and display multi-variate image data (in this case, retail store image data). Via SYSTAT the Chernoff face analysis program is now readily available and this technique has been shown to be more effective than many other icons for similarity comparisons (Wilkinson 1983). Chernoff faces can help behavioral analysts and strategists represent the results of image data in a simplified and comprehensive manner. In addition, Chernoff faces can be used as the sole method of analysis or combined with other statistical techniques to assess statistical effects, depending on the consumer analysts needs at the moment of inquiry.

The conceptual underpinnings of Chernoff faces are highly mathematical in nature (see Chernoff 1973), but the results allow for immediate visual comparisons across alternative image objects (such as stores or brands). No previous research has explored the usefulness of this technique for consumer behavior or image perceptions.

CHERNOFF FACES

A typical Chernoff face is a cartoon-like caricature of the human face developed through a series of highly mathematical and geometrical relationships (see Figure). Chernoff surmised that individuals can distinguish the subtle differences in each facial feature and can develop an image of a person based on these differences. He used this idea to create an image of multi-variate data sets where each variable was assigned a particular facial feature. Depending on the relative magnitudes of the data, the facial characteristics create a unique image for a given multi-variate data set.

Some studies using Chernoff faces have been conducted in the political, psychological and medical areas (see Wang 1978). One published paper, related to business, developed the faces as a representation of the mathematical results of the financial performance and future predictions for various types of businesses, using faces as a visual indicator of past performance and current status (Huff, Mahajan and Black 1981). However, most of the work has been conducted in the area of statistics, using Chernoff faces as a method of clustering multidimensional data (Jacob 1983, Jacob et. al 1976). In fact, this was the original purpose behind the development of Chernoff Faces: Visual clustering of multi-dimensional statistical data. This paper focuses on a useful consumer behavior application of Chernoff faces and the mathematics of the theoretical framework behind the technique is left to its discussion in other literature (see Chernoff 1973).

¹We gratefully thank New York University who contributed financially to the data collection, the University of Texas Research Institute and Mary R. Zimmer of the University of Georgia for her involvement. Sincere appreciation is also extended to Robert T. Green and the University of Texas Graduate School of Business for their support.

comparison). Thus, the usefulness of the technique for image display is not limited to inter-brand comparisons but also includes intra-brand comparisons across specific consumer segments of interest (in this case, segmentation by purchase/store trip frequency).

METHODOLOGY

Data Collection and Description

Chernoff faces were developed from the quantitative results of a nationwide survey of 453 consumer mail panel members. The final sample generally represented the geographical distribution of the United States and was 58.1 percent female. The respondents' annual household income distribution was: 17.5 percent earned less than \$10,000 per year, 25.8 percent earned between \$10,000 and \$19,999 per year, 23.1 percent earned between \$20,000 and \$29,999 per year, 15.7 percent earned between \$30,000 and \$39,999 per year, 7.7 percent earned between \$40,000 and \$49,999 per year and 10.2 percent earned \$50,000 or more per year. Nearly 16 percent of the respondents were under 30 years old, 22.7 percent were between 30 and 39 years, 16.8 percent were between 40 and 49 years, 19.0 percent were between 50 and 59 years and 25.8 percent were over 60 years old. Ten percent of the respondents had less than a high school education, 35.9 percent were high school graduates, 26.6 percent had some college education and 27.5 percent had four or more years of college.

In the survey instrument, respondents were asked to indicate their perceptions of both Sears and K-Mart on a seven-point numerical comparative scale (see Golden, Albaum and Zimmer 1987 and Golden 1991), an economical semantic differential-type scale format for image comparisons across multiple image objects and dimensions. The numerical comparative scale has also been shown to result in good quality data (Albaum and Golden, forthcoming).

The image dimensions used in this study were identified through an exhaustive literature review. The retail store image dimensions retrieved from the literature were then culled to:

- (1) reflect a comprehensive array of image attribute dimensions,
- (2) represent attributes most frequently investigated in the literature, and
- (3) reduce redundancy in attribute dimensions.

This process resulted in the isolation of nineteen image attributes whose bi-polar scale construction translated to: inconvenient/convenient location, low/high price, dirty/clean, hard/easy to get credit, cluttered/spacious, unpleasant/pleasant atmosphere, low/high quality merchandise, dull/exciting, bad/good selection, unsophisticated/sophisticated customers, unfriendly/friendly salespersons, low/high caliber, dislike/like, unhelpful/helpful salespersons, bad/good reputation, uncongested/congested, not enjoyable/

enjoyable, hard/easy to exchange merchandise, bad/good value. In the numerical comparative scale presented to respondents, the left most extreme point of each bi-polar adjective pair was represented by "1", with the right extreme being represented by "7".

Respondents were also asked to indicate how frequently they shopped at Sears and K-Mart. For the intra-store Chernoff face analysis, responses to this question were divided in order to represent Infrequent Shoppers (once a year or less), Moderately Frequent Shoppers (two to twelve times a year), and Frequent Shoppers (more than twelve times a year). The survey queried respondents about other issues and scale formats not relevant for this paper.

Chernoff Face Analysis

The mean and variances were computed for all nineteen attributes across the three shopping frequency categories. Based on these data, Chernoff faces were constructed using the SYSTAT software (Wilkinson 1988, pages 380-381). Twenty variables can be included in a single Chernoff face analysis; thus, the nineteen image attributes were within the possible computing range. Chernoff faces were developed for each store and each patronage frequency group separately.

Since an individual can perceive changes in some facial characteristics better than in others, it is feasible to assign the most important variables to features such as the curvature of the mouth, half-face height, half-length of eyes, and length of brow (Soete and Corte 1985) to get a better understanding of the image created. The Figure displays summary information on the mathematical construction of a Chernoff face and the particular facial characteristics that have been associated with each image attribute in this research.

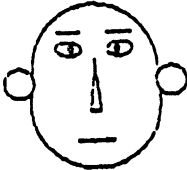

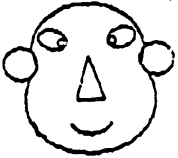

RESULTS

Tables 1 and 2 present the results of the analysis for Sears and K-Mart, respectively. Mean ratings for each image attribute and the group size (n) are presented, as well as the resultant Chernoff face compilation.

Instructive of the usefulness of Chernoff faces is for the reader to place his or her hand over the faces and try to interpret the comparative image of Sears and K-Mart for the various shopping frequency groups from the numerical data alone. The comparison becomes very cognitively complex and difficult to summarize. However, when one's hand is removed from the Chernoff faces, a visual comparison of the image across stores and shopper frequency categories becomes immediately apparent. In addition to being a sophisticated mathematical representation, Chernoff faces provide a very quick and lucid image analysis when compared to the process of analyzing numerical results across each attribute. Thus, the resultant usefulness of Chernoff faces for image analysis and comparative image representation.

Focusing on Table 1, it is immediately apparent from the Chernoff faces that image perceptions become more "favorable" as one moves from the "infrequent shoppers" group to the "frequent

shoppers" group. The association between shopping frequency and image perceptions is very quickly visualized.

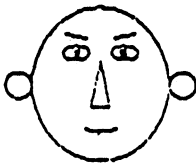

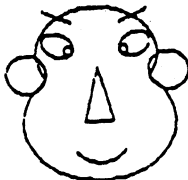

These same general results hold for Table 2, K-Mart. However, comparing the results for Sears (Table 1) and K-Mart (Table 2), Chernoff faces also demonstrate that the constellation of image attributes for K-Mart within the moderate and frequent shoppers is somewhat stronger than for the same shopper groups at Sears. Referring to the Figure which lists the facial characteristics associated with the various image dimensions, the mouth is associated with perceptions of location convenience. Thus, the up-turned mouth for K-Mart in Table 2 illustrates a stronger positive image perception of location convenience vis-a-vis that perceived for Sears (as shown in Table 1).

Likewise, two other important facial characteristics are the position of the pupils and the

slant of the eyes. These are associated with the overall affect toward the store (dislike-like) and perceptions of the customers' sophistication, respectively. For both Sears and K-Mart, persons who shopped more frequently at the stores liked the stores better and perceived the stores as having more sophisticated customers. These results are depicted by the pupils moving inwards as the perceptions of positive affect increase and the eyes slant more outward as the perceptions of customer sophistication increase. The direction of change for each attribute represented by a given facial feature is indicative of the direction of the attribute rating on the numerical comparative scale results.

An attribute-by-attribute analysis can be conducted in this manner; however, this is not the primary advantage of Chernoff faces because an attribute-by-attribute analysis can also be seen rather readily from the tables. The advantage of Chernoff

TABLE 2
Perception of Kmart through Shopping Frequencies

faces is the rapid visualization of the global image represented by the constellation of attributes. For example, across all attributes, the perceptions of K-Mart among moderate shoppers appear to be more positive (looking at the constellation of attributes represented by the whole face) than do the perceptions of Sears among its moderately frequent shoppers. The same can be said about the "frequent shoppers," as the K-Mart frequent shoppers display slightly more general enthusiasm than do the Sears frequent shoppers.

In using Chernoff faces to graphically represent multi-variate data, the researcher should keep in mind that an attribute-by-attribute comparison may mislead the viewer into believing there are strong differences where no statistically meaningful differences exist. For the brand image example presented in this paper, the appropriate focus is on the rapid visualization advantage of the *global* image and

not on over-emphasis of attribute-by-attribute comparisons. Otherwise, the value of Chernoff faces analysis may be obscured or the usefulness abused.

CONCLUSION

A brand or a store's image is greater than the sum of its parts (Zimmer and Golden 1988). Similarly, the constellation of a person's facial expressions is greater than the sum of its parts; thus, faces can be a useful mechanism for globally representing image response data. As consumer researchers continually recognize the relevance of image perception for choice behavior, it becomes more important to be able to accurately and precisely portray the results of image analyses. Facial representations provide a useful mechanism for so doing.

Although highly mathematical in nature and originally developed by Chernoff for the purpose of visual clustering, Chernoff faces do not circumvent the

usefulness of other statistical analyses to discern meaningful differences in response data. Chernoff faces do provide a quick and accurate technique for the depiction of comparative image data, and the main advantage comes from the fact that each data point does not need to be compared with others in the same category, rather, an overall image gestalt can be illustrated for visual comparison purposes.

Extending the usefulness of Chernoff faces, this paper showed the development of Chernoff faces for image comparisons both within and between brands. Inter-brand comparisons allow immediate visualizations of image differences between or among consumer choice alternatives. However, focus on comparisons of specific segments of interest within a brand (intra-brand) quickly reveals the relationships between image perceptions and behavior.

This study focused on retail store image (between and within alternative brands of mass merchandisers), but the same technique can be used for any other type of image portrayal situation for which the researcher has voluminous data and an accurate visual representation of results is desired. In addition, Chernoff faces can be used to augment other types of statistical analyses that focus on significant differences between image attributes. They provide consumer researchers with an additional tool for more complete analysis, understanding and representation of the relationships between image perceptions and behavior.

Cocaine As Innovation A Social-Symbolic Account

Elizabeth C. Hirschman, Rutgers University

A social problem exists primarily in terms of how it is defined and conceived in a society... A societal definition determines whether the condition exists as a social problem. The societal definition gives the social problem its nature, lays out how it is to be approached, and shapes what is done about it.

--Blumer, 1971, p. 300

INTRODUCTION

Cocaine is currently used by an estimated 6,000,000 consumers in the United States (U.S. Department of Health and Human Services 1987), an increase of 150% since 1980. Its use has exacted a high social cost: 3,308 deaths and 62,141 emergency room admissions during the past year have been attributed to cocaine consumption (King 1989). But producing and distributing cocaine is an extremely profitable enterprise; in 1988 the Colombian cartel based in Medellín grossed an estimated 5 billion dollars (Gugliotta and Leen 1989), despite a record number of cocaine seizures in the United States ("Cocaine Avalanche," 1989, p. 42).

As the opening passage from Blumer (1971) suggests, current metaphors in the popular culture view of cocaine are instructive in characterizing its present social meaning. The media typically characterize cocaine use as an *epidemic* (Washton 1987), a *disease* (Lewis 1989; "So Little Time, So Many Cases," 1989), or a *plague* (Massing 1989; O'Rourke 1989). Producers and distributors are variously described as *drug lords* (Morgenthau 1989a; Shannon 1989), *drug barons* (Serrill 1989), and *drug kingpins* (Morgenthau 1989b; Morgenthau 1989c). Those members of the law enforcement community who *battle* or *make war* (Morgenthau 1989b; Serrill 1989; Waldman 1989) against them are referred to as *troops* (Schwartz 1989), *soldiers*, and *warriors* (Waldman 1989). Those who use cocaine are termed, within this same ideology, as *addicts*, *abusers*, and *victims* ("Cocaine Babies," 1989; Cole 1989; Massing 1989; Miller 1989; Morgenthau 1989d).

This metaphoric imagery obfuscates several significant aspects of cocaine consumption. First, by depicting cocaine as a *disease*, we ignore the fact that it possesses several positive attributes which attract the consumer to it in the first place. Cocaine is perhaps the most powerfully reinforcing chemical available to man (Allen 1987); in initial use and sometimes for time periods extending over several years, it creates positive feelings in the consumer (Byck 1987). Diseases, typically, do not do this. To understand the etiology of cocaine then, we must begin to recognize and deal with its positive, as well as destructive, attributes.

Second, cocaine users are typically characterized as either *addicts* and *victims* of the disease or cocaine or as *abusers* of an illicit substance. The first viewpoint is premised upon the assumption

that the user is essentially blameless and has become 'infected' with cocaine. In this view, medical treatment and rehabilitation is the appropriate remedy (Bratter and Forest 1985).¹ The view that cocaine consumers are drug *abusers* leads to a more punitive policy which advocates criminal penalties such as imprisonment, fines or both (Musto 1987).² What both of these perspectives lack, however, is the recognition that persons who use cocaine are, in essence, *consumers* who through some reasoning process have *chosen* to ingest cocaine. By ignoring the dynamic of choice behavior, we may overlook valuable clues as to why some people do consciously seek out and consume cocaine. By viewing cocaine users as consumers we may gain useful information not only about the underlying choice processes preceding the decision to use the drug, but also about the effects of initial and continued use of the drug on the consumer's choice processes regarding this product.

Third, by casting cocaine producers and distributors as evil, powerful lords and barons, we may overlook one of the most basic aspects of the cocaine phenomenon. The cocaine cartel, however illegal its activities may be, is in fact a *business* (Gugliotta and Leen 1989; Williams 1989). Just as any other enterprise, it thrives on sound marketing strategy. As a business, the cartel will concern itself with sensing what consumers want and with supplying new products to meet shifts in demand and to attract new users.

Finally, by depicting efforts to reduce cocaine consumption as a *moral war* of good versus evil, we cloud issues that are grounded in consumers' life styles and socio-emotional preferences, with normative notions of right and wrong. As is widely acknowledged, consumers do not necessarily make decisions regarding drug consumption on moral grounds, and the morality of drug consumption itself is often situation specific and dependent upon historical context (Bakalar and Grinspoon 1984; Inglis 1975; Walker 1981). As Gusfeld (1967, p. 187) observes, "... Deviance designations have histories;

¹Use of the disease metaphor to conceptualize drug use implies the corresponding metaphor that drug users are *sick* (i.e., addicts or victims). As Gusfeld (1967) observes, "... the designation of a person as ill changes the obligations which others have toward the person... [The sick person] has now become an object of welfare, a person to be helped rather than punished... The sick person is not responsible for his acts" (p. 180).

²As Gusfield (1967) has noted, "crimes of vice" such as gambling, alcoholism, prostitution, and drug addiction are often portrayed in the mass culture (as well as the scientific one) as examples of moral corruption. They are seen as *crimes* against both God and the social order and, hence, are to be treated punitively.

the public definition of behavior as deviant is itself changeable. It is open to reversals of political power, twists of public opinion, and the development of social movements and moral crusades." As I will show, both the modality and the morality of cocaine consumption have shifted radically over the past 100 years in the United States.

THE INNOVATION PARADIGM APPLIED TO COCAINE CONSUMPTION

To supplant the current disease-and-war metaphors used to conceptualize and formulate public policy regarding cocaine consumption, I develop a model based upon the innovation-diffusion paradigm. The innovation-diffusion paradigm has a well-established acceptance within marketing and consumer research (Arnould 1989; Gatignon and Robertson 1985; Hirschman 1980; Midgley 1976; Robertson 1971), as well as several ancillary disciplines (Rogers 1983). The distinct advantage of utilizing this paradigm, as compared to the disease-and-war metaphors now commonly applied to cocaine usage, is that by viewing cocaine as an innovation which follows a diffusion pattern through various societal strata and subcultures, we can better understand why the demand for cocaine exists, how individual and group adoption practices come into existence, and based on this knowledge, formulate more effective demarketing strategies for reducing destructive forms of demand for this substance.

Cocaine is not a disease; it is a *product* with distinctive positive and negative attributes which determine its impact not only upon individual consumers but upon entire subcultures and societies. Most significantly, it is a *symbolic* as well as technological innovation (Hirschman 1981), which has been introduced and reintroduced in a variety of symbolic and chemical forms over a period of at least 5 millennia (Walker 1981). By comprehending cocaine as a product innovation, we can come to better understand not only why it is consciously, purposefully and willfully adopted by consumers, but also how to best aid those consumers for whom its use has become destructive and dysfunctional.

THE ORIGIN OF COCAINE: AN INNOVATION IS DISCOVERED

South American Indians discovered the stimulant qualities of the leaves of the *Erythroxylon coca* bush growing in the high Andes two millennia before the Inca Empire (Walker 1981). Coca leaf chewing as a remedy for fatigue and as medication for a variety of sicknesses endemic to the high altitudes was common in the Andes in pre-Columbian times (Walker 1981) and continues unabated to the present day (Allen 1987a). The product form of cocaine used in this context is a wad of fresh leaves which are formed into a ball or cud in the mouth and chewed together with potash, an alkaline substance which facilitates the release of cocaine hydrochloride from the leaf and aids its absorption by the body (Grinspoon and Bakalar 1987).

This practice continues in the Andes to the present day. As Grinspoon and Bakalar (1987, p. 188) note, "In many parts of the Andes and Amazon today, coca is the everyday stimulant drug, used more or less like coffee, tea, chewing tobacco, and *khat* are used in other areas of the world... In the form of leaf powder or tea, coca is taken for toothache, ulcers, rheumatism [and] asthma... Coca is also a local anesthetic. The juice of the leaf can be applied to soothe eye irritations or gargled for hoarseness and sore throat. Coca contains minerals, vitamin C and some B vitamins, and... is an important source of these nutrients in the Andean diet." Thus, in its earliest form as a product innovation, cocaine was, and continues to serve, not as a disease, but rather as a *cure*.

The Andean Indians had been using coca leaves as a stimulant prior to their conquest by the Inca Empire. In contrast to the *profane* (Belk, Wallendorf, Sherry 1989) use to which the plant was put by the Indians, the Incas regarded coca as having divine origin and believed it served as a sacred linkage to the gods. "They believed that they were the direct descendants of the god Inti, who had created the coca leaf to alleviate hunger, thirst, and to ease the burden of their life" (Allen 1987a, p. 7). As a result of their view of coca as a *sanctified product* (Belk, Wallendorf, and Sherry 1989), the Incas restricted its use to those having high social position or political rank; its use came to be prohibited among the general population (Allen 1987a). Thus, the first known *reduction* in the previously widespread adoption of this innovation came as a result not of cocaine's perceived destructive or immoral effects, but rather because it was seen as representing divine power and goodness, and was therefore appropriate only for certain consumers.

The Catholic Spanish, arriving in the 1500's, initially viewed cocaine consumption as a form of spiritual evil and devil worship and attempted to eradicate its use (Inglis 1975). However, even as the Church began its campaign to outlaw coca on the grounds of what was perceived to be its immoral and ungodly nature, a second -- secular -- force was already at work in the Spanish colonial culture. The Spanish colonialists who had opened vast tracts of Bolivia, Peru and Colombia to cultivation noted that their Indian workers performed much better when permitted to pursue their habit of coca leaf chewing. As was a frequent occurrence in colonial empires, the secular interest of the State in increasing its wealth won out over the sacred interest of the Church in salvaging Indian souls. "So the Indians, though they were punished if caught using coca in religious observances, were allowed to take it while working, in order that they might be able to put in still longer hours" (Inglis 1975, p. 51). Thus, coca leaf chewing was allowed to re-diffuse throughout the Indian (and to some extent, the Spanish) population of South America from the mid-1500's onward. Now purged of its sacred meaning as a religious symbol, it was reborn as a socially acceptable secular stimulant. *El coqueo* continues to serve these adopters in this capacity to the present day.

COCAINE AS AN INNOVATION IN EUROPE AND THE UNITED STATES: FIRST DIFFUSION CYCLE

From the time of its discovery in the New World, the cocaine innovation had periodically been brought back to Europe. However, because of the long, damp ocean voyage, the batches of coca leaves frequently lost their potency. Hence, the reports of cocaine's stimulant and euphoric qualities upon Indian consumers were viewed with some skepticism by Europeans (Allen 1987a). In 1855, Friedrich Gaedecke, a German chemist, succeeded in isolating the alkaloidal form of cocaine from the coca leaf, and in 1859 Albert Niemann named the alkaloidal substance *cocaine*. Also in 1859, Pablo Mantegazzo published a significant scientific essay which credited this new product with the ability to reduce fatigue, increase strength, elevate spirits, and increase sexual desire (Allen 1987a) -- a significant set of positive innovation attributes.

Between 1863 and 1865, Angelo Mariani developed the first commercial product containing cocaine, a beverage called Vin Mariani, which contained cocaine dissolved in a wine base. An instant success, Vin Mariani was consumed by such celebrities as Robert Louis Stevenson, Henrik Ibsen, Thomas Edison, Pope Leo XIII, Ulysses S. Grant and Sarah Bernhardt (Erickson *et al.*, 1987). An advertisement for the product claimed that it "nourishes, fortifies, refreshes, aids digestion, strengthens the system, is unequalled as a tonic-stimulant for fatigued or overworked body and brain, and prevents malaria, influenza and wasting diseases" (Byck 1974, p. 11).

The pharmaceutical properties of cocaine came to the attention of Sigmund Freud, who believed it might be useful in curing the morphine addiction of a close friend (Byck 1974). Freud adopted the innovation, himself, and wrote a scientific paper, "Gber Coca," describing its many positive benefits for the consumer: "One senses an increase of self-control and feels more vigorous and more capable of work. One... finds it difficult to believe that one is under the influence of any drug at all... Long-lasting, intensive mental or physical work can be performed without fatigue; it is as though the need for food and sleep... were completely banished... (1885 [1974], p. 60).

Freud's enthusiastic endorsement of cocaine enhanced the innovation's scientific and social status. It was quickly incorporated in a variety of pharmaceutical and over-the-counter medical preparations. By 1885, the Parke-Davis Company had prepared a monograph for physicians, which promoted the use of cocaine for medical applications (Byck 1974).³ Several American scientists and physicians encountered medical information regarding cocaine's beneficial properties and began to

experiment with the innovation. One of them was Dr. William Halsted, a preeminent physician and founder of the Johns Hopkins Medical School. Halsted discovered cocaine's effectiveness as a nerve-block anesthetic, but unfortunately began injecting himself with the drug. His resulting addiction to cocaine ruined his career (Allen 1987a; Byck 1974). Halsted's negative experience, however, did not stop the commercial diffusion of a plethora of cocaine-containing new products. Erickson *et al.* (1987, p. 8) report: "A market for cocaine had been created and the patent medicine industry wasted no time in taking advantage of the opportunity. Various remedies containing cocaine were soon available, not only at the drugstore and corner store but through the mail and door-to-door. Assorted tonics and powders containing cocaine were sold as cures for a range of ailments, including headaches, colds, toothaches, asthma, piles, impotence and diseases of the blood."

In 1885, John Styth Pemberton, a Georgia pharmacist, concocted his own innovative tonic, designed to compete with Vin Mariani as a nerve and brain stimulant. Made from a secret syrup containing both cocaine and caffeine, the new brand was christened Coca-Cola and became a widespread success (Allen 1987a).⁴ A number of competing beverage brands including Care-Cola, Dope Cola, Kola-Ade, and Wiseola soon appeared on the market. In addition to tonics and beverages of various concentrations, cocaine was available over-the-counter in drugstores in a powder form, which was ingested nasally (Erickson *et al.*, 1987).

LEGISLATION TO RESTRICT COCAINE DIFFUSION

At the time of cocaine's first diffusion cycle in the United States, there was no legislation prohibiting any drug from being consumed or used in commercial products (Musto 1987). In essence, cocaine and a variety of other drug innovations (e.g., opium, marijuana, hashish) were circulated in an unrestricted and unregulated marketplace. Their adoption and diffusion patterns were entirely determined by consumer demand.

Despite growing concern that cocaine could be addictive and racist fears by whites that its consumption was creating a crime wave among intoxicated blacks, cocaine consumption increased (Allen 1985; Musto 1987). It is estimated that Americans consumed *as much* cocaine in 1906 as they did in 1976, with only half the population base (Walker 1981). However, the diffusion of cocaine peaked in 1906 -- twenty years after its introduction. Public attitude had begun to move against the innovation and this sentiment was socially formalized in 1906 with the passage of the Food and Drug Act (Musto 1978). By 1908, cocaine importation had dropped to one-half the 1907 level, and public attitudes now changed toward cocaine consumers. Users were now viewed as "cocaine fiends" and the best

³It is significant to note that at the time Parke-Davis was extolling the value of cocaine, the Bayer Pharmaceutical Company was promoting its own brand of innovative drug recently isolated from the opium poppy--Heroin (Walker 1981).

⁴Cocaine was removed from Coca-Cola in 1903 (Phillips and Wynne 1980).

course of action was believed to be letting them die (Musto 1978). Cocaine usage among the general population began to decline dramatically, but its consumption and diffusion remained strong and even increased among one segment of users -- intellectuals and writers, who believed it enhanced their creativity (Allen 1987b).

By 1914, laws regulating the consumption and sale of cocaine had been passed in 46 states; that same year the Harrison Act was passed, which placed a complete national ban on cocaine (Grinspoon and Bakalar 1987; Walker 1981). Passage of the Harrison Act and an even more restrictive amendment to it in 1919, further reduced the diffusion of cocaine by giving it a negative social sanction (Gusfeld 1967) and increasing its price by 300 percent (Musto 1978). Now a prohibitively expensive product and labeled as a symbol of social deviance (Gusfeld 1967), cocaine consumption became restricted to the bohemian-jazz counterculture and to the black ghetto (Allen 1987b). Cocaine consumption remained secluded in these two marginal subcultures through the 1960's. And then, something happened.

THE SECOND COMING OF COCAINE: AN INNOVATION RE-INVENTS ITSELF

The 1960's were an era of enormous social and political upheaval; groups which previously had felt disenfranchised and disempowered burst forth with demands for equality and social recognition. Within the hippie counterculture which flowered during the late 1960's and early 1970's, forbidden drugs, such as cocaine, marijuana, and the hallucinogens, were not only a way to transcend bodily boundaries and achieve states of altered consciousness, but were also a conscious political effort to undermine the existing dominant (and, in their view, repressive) social order (Bakalar and Grinspoon 1984; Blumer 1971; Gusfeld 1967).

Within this radically restructured societal context, cocaine experienced a resurgence as an innovation, albeit one with a different symbolic significance than in its first diffusion cycle sixty years earlier. Now the product became identified as an icon of affluence, power, and success. As Allen (1987a, p. 10) writes, "In the 1970's cocaine hydrochloride, the white powder form of cocaine... became a symbol of affluence and glamour. Increasingly a main attraction at swinging parties, it was mentioned in films and used by intellectuals and professionals. In keeping with the ambition of the culture to be cool, confident and successful, cocaine euphoria seductively and temporarily provided these feelings."

In this second diffusion cycle, cocaine was viewed not as a medical tonic, but rather as a status symbol and as a vehicle to self-perceptions that the consumer was, indeed, powerful and successful. Cocaine was "the champagne of drugs" (Erickson *et al.*, 1987). Its use was associated with numerous motion picture celebrities (e.g., Richard Dreyfus, John Belushi, Richard Pryor, Chevy Chase), rock and roll musicians (e.g., Ringo Starr, Mick Jagger, Keith Richards), and sports figures (e.g. 'Hollywood'

Henderson, Lawrence Taylor, Daryl Strawberry). It was enshrined in films and popular music:

"When your day is done and you want a run,
Cocaine,
When you got bad news you want to kick the
blues, Cocaine.
She's alright, she's alright, Cocaine.
If your thing is gone and you want to ride on,
Cocaine.
Don't forget this fact, you'll get it back,
Cocaine.
She don't lie, she don't lie, she don't lie,
Cocaine."

Writer J. J. Cale
(c) 1975 by Audigram Music

Not only did cocaine have different social-symbolic qualities during its second diffusion in the United States, it was consumed via a different modality -- i.e., 'snorting' versus drinking. Consuming cocaine in this modality also required a different set of surrounding rituals. While imbibing cocaine as a beverage at the turn of the century had generally been a solitary activity, inhaling the drug generally occurred in the context of a leisure social setting (e.g., a party, date, discotheque) and often served as a precursor to sexual intercourse (Erickson *et al.*, 1987). Cocaine had become a *recreational* drug, facilitating group congeniality and accompanied by rituals of gift-giving and sharing (Anderson 1981; Murray 1984). Hosts were expected to provide cocaine 'lines' for their guests, much as they provided wine, beer, or liquor (Murray 1984). Hence, cocaine in the 1970's was a markedly different innovation than in 1906, both symbolically and technologically (Hirschman 1981).

Diffusion as a Media Phenomenon

In its second diffusion cycle, cocaine became more than just a novel product, it also became a media phenomenon; its spread through the population was documented by its spread through the mass media. In the 1970's, cocaine came to national prominence not just as a drug, but as a *concept*, a topic of public interest. A comparison of the number of cocaine-related magazine articles published in the United States from 1969 to 1988 (compiled from the *Reader's Guide to Periodical Literature*)⁵ with the actual and estimated usage data for cocaine from the President's Commission on Organized Crime (1986, p. 18) for the period 1976-1984 shows that the actual usage of cocaine by consumers closely mirrors documentation of cocaine in the popular media; a pattern that has also been found for marijuana and heroin (Beniger 1983).

Cocaine consumption more than doubled from 1977 to 1979, when the peak of the second diffusion cycle was reached. Also in 1979, public attitudes toward cocaine had begun to shift dramatically as a result of mass media stories on its destructive effects

⁵For additional analyses of the *Reader's Guide Index* for tracking drug diffusion, see Beniger (1983) and Erickson *et al.* (1987).

and governmental efforts to demarket the drug (Erickson *et al.*, 1987). As a result, cocaine came to be perceived as a social and personal liability rather than an asset (Blumer 1971; Gusfeld 1967). De-adoption began to occur by 1980, just as had occurred seventy years earlier.

The Supply-Side Responds

However, there was a significant difference between the marketplaces for cocaine in 1979 and 1909, a difference which would permit the drug to reassert itself in an even more potent incarnation in only three years -- the *marketers* of cocaine. Seventy years earlier, cocaine use had been curtailed simply and effectively by cutting off the *legal* sources of supply (Erickson *et al.* 1987). No black market was present and demand was decreasing, so commercial producers simply dropped cocaine products from their inventories and turned their attention to other, more lucrative products. By 1979, the supply-side nature of the market had changed radically. During the 1970's, cocaine became a cash crop in South America. In Peru, Bolivia, and Colombia where the coca plants are grown and processed, it had become *the* primary export; in Colombia, national income from cocaine exports had grown to exceed even that of coffee (Gugliotta and Leen 1989).

Further, the cocaine production infrastructure now encompassed hundreds of thousands of workers in these three countries alone -- from rural peasants who grew, harvested and dried the leaves, to chemists and industrial workers who processed the leaves through various stages of manufacturing (Gugliotta and Leen 1989). Further, extensive distribution networks had been established to transport the finished product from Colombia to a variety of U.S. destinations over air, sea, and land routes (Gugliotta and Leen 1989; President's Commission on Organized Crime 1986). The product was enormously profitable for all concerned, providing an estimated \$1 billion profit for the Colombian cartel controlling it in 1979 (Gugliotta and Leen 1989; President's Commission on Organized Crime 1986). Such a marketing apparatus does not die easily -- *it innovates*.

The Colombian Cocaine Cartel

According to the President's Commission on Organized Crime (1986), the Colombian cartel began as a loose confederation of drug processors and smugglers centered in Medellín, Colombia.⁶ During the late 1960's, the cartel used Cubans living in Miami to 'retail' their shipments of cocaine powder to U.S. consumers. Realizing there were vastly more profits to be made in direct marketing their product, the Colombians eliminated (literally) their Cuban middlemen and by 1978 had gained complete control of the U.S. cocaine market (PCOC 1986). They had also evolved a sophisticated transportation network

encompassing land, air, and sea routes. Logistical support along these routes came from a variety of sources including the corruption of transshipment country politicians and American pilots willing to fly contraband loads of cocaine into clandestine air strips in rural Louisiana, Georgia, Texas, and Florida (Gugliotta and Leen 1989; PCOC 1986).

By the early 1980's cocaine production and distribution by the Colombian cartel had grown so efficient that the retail price of the product began dropping -- from \$50,000 per kilo (2.2 lbs) in 1980 to \$14,000 by 1983 (Gugliotta and Leen 1989). The drop in market price began to put downward pressure on the industry's profits and management began investigating other cocaine-based products that would enhance profitability. The answer to their dilemma was generated through a novel use of cocaine powder by current adopters. This novel product usage was *freebasing* (U.S. Department of Health and Human Services, 1987, p. 143). Freebasing had a product advantage over cocaine hydrochloride powder in that the cocaine was absorbed more rapidly, producing a more intense and longer lasting euphoric effect on the consumer.

However, it also had a serious product disadvantage. Ether or another combustible solvent was required to release the cocaine alkaloid from the base. In the process of heating this mixture, serious accidents could occur (recall the severe burns suffered by free-base consumer Richard Pryor). However, from the cartel's perspective, the free-basing innovation was a highly desirable one. The freebasing 'high' effect was a much more intense one than that generated by cocaine hydrochloride powder. Consumers who adopted the freebasing practice demanded much larger amounts of the product.

CRACK COCAINE: THE THIRD WAVE

To overcome the product disadvantages of freebasing, cocaine dealers in the United States (and other countries, e.g., the Bahamas, Allen 1987), made two significant production decisions. First, they began transforming cocaine hydrochloride powder into a more safely smokable product, which they named "crack" or "rock." Second, they began pre-packaging crack cocaine in small amounts that could be purchased for \$5 to \$20, i.e., they made the product innovation more 'divisible' (Rogers 1983) and, hence, more easily adopted via a policy of penetration pricing. Thus, the introduction of the crack form of cocaine was based upon sound marketing strategy by cocaine powder producers and dealers; they effectively transformed their product from one consumed by a small segment of elite adopters to one desired -- and financially obtainable -- by the mass market. As Cohen (1987, p. 28) writes, "What the ready-to-wear industry did to tailoring and fast foods did to cooking, crack did to freebasing. The strategy is one of low cost, high volume operations."

Also similar to fast food marketing was the innovative form of retail outlet from which this new cocaine product was sold: crack houses. Crack houses typically are run-down or abandoned buildings in poor neighborhoods. (Williams 1989). Dealers operating

⁶By 1990, many of the managers of the Medellín cartel had been killed or imprisoned. Colombian cocaine production and distribution is now organized in Cali (Shannon 1991).

FIGURE 1
Number of Drug Articles in The Reader's Guide, 1969-1989

crack houses offer their product at low prices and provide fast service and excellent quality. They offer extended business hours, as well, most commonly what is termed a "24/7" selling period (i.e., 24 hours a day; seven days a week). In order to rapidly build a loyal customer base, crack house retailers will generally sell first-time triers \$40 worth of crack for only \$20 the first few weeks. Once consumer loyalty has been generated (i.e., the adopter has become addicted), the price is increased to 'full-cost' level. Customer complaints are few and in case of the rare police raid, the retailers are well-prepared; one crack house dealer told Williams (1989, p. 53), "We have nine millimeters (i.e., automatic rifles) and a machete. We have two bodyguards." The decentralized, multiple outlet nature of crack retailing makes legal proscription of the product extremely difficult; if one crack house is "busted," another (or more) will soon open in the same vicinity to service the pre-existing (and utterly loyal) customer base (U.S. Department of Health and Human Services, 1987).

Diffusion in the Media

Media attention began to accrue to this novel form of cocaine in 1984 and 1985. Crack cocaine was a cover story in both *Time* and *Newsweek* in February 1985 (Gugliotta and Leen 1989). Although the media for a time confused this novel product with its predecessor, freebase cocaine, national attention became intently focused upon the powerful effects of this form of the drug upon the death of Georgetown University basketball player, Len Bias, in 1986.

The pattern of crack diffusion as a popular culture concept is depicted in Figure One, which is based upon the number of articles on cocaine in the *Reader's Guide to Periodical Literature*. The data in the figure illustrate that the third (crack) diffusion of cocaine has vastly surpassed that of the second (powder), which peaked in 1979. It also indicates that the social-symbolic impact of crack cocaine has surpassed that of marijuana and heroin and is now equal to that of LSD/psychedelic drugs, the primary iconic drugs of the 1960's hippie culture. By 1988, at least six million Americans consumed crack cocaine regularly; further, on average three users died every day

(Gugliotta and Leen 1989). These statistics help to communicate the *breadth* of the diffusion of cocaine in its third wave through the United States, but they do little to reveal the *depth* of consumer adoption -- a matter to which we now turn.

ADOPTING CRACK: THE ULTIMATE PRODUCT LOYALTY

Crack is consumed by igniting small cocaine-base 'rocks' with a cigarette ash and then inhaling the vapors through a water pipe. Eighty percent pure cocaine vapor reaches the brain in eight seconds, causing a feeling of intense euphoria unlike any the user has likely experienced before. "The resultant euphoria is extreme, much like that produced by direct electrical stimulation of the reward centers of the brain... On subsequent highs, users describe being able to 'see' the first high, but being unable to reach it" (Allen 1987b, p. 17).

Intensely desiring to reach their prior state of euphoria and being burdened with increasingly dysphoric, depressive moods when the drug wears off, crack users often become unable to control their seeking and consumption of the drug. "Compulsive use, despite disastrous effects on the user's social and physical well-being, is common" (U.S. Department of Health and Human Services, 1987, pp. 144-145).

Psychological Effects of Crack Cocaine

As a product innovation, crack cocaine possesses both positive and negative features for its adopters. It is the unique nature of this drug that only the *positive* attributes are experienced at the beginning of the adoption process. Among these are (1) intense euphoria, (2) increased energy, (3) enhanced mental alertness, (4) feelings of mastery and competence, (5) increased sociability, (6) decreased hunger and fatigue, (7) indifference to pain, and (8) heightened sexuality (Beaubrun 1987, p. 171).

These characteristics prove so powerfully reinforcing that many trial adopters will be unable to discontinue product use, despite the severe negative consequences which result from continued use. Among the most destructive of these negative effects is a chronic syndrome termed *cocaine psychosis*, which includes these symptoms: (1) anxiety, dysphoria, and suspiciousness, (2) insomnia, (3) hallucinations, (4) paranoid delusions, (5) violent, bizarre behavior, and (6) homicide (Beaubrun 1987, p. 171). Chronic use of the product may lead to death (Beaubrun 1987, p. 171). Despite these negative consequences, adopters continue to use the drug in an effort to resume their previous euphoric state and to escape withdrawal. Withdrawal symptoms include depression, anhedonia, drug craving, tremors and muscle pain, eating and sleep disturbances, and EEG irregularities (Department of Health and Human Services 1987, p. 146). Thus, the physical agony of abandoning the product provides sufficient motivation for many users to continue its consumption, despite the resulting physical disintegration or even death.

Social Effects of Crack Cocaine

The initial social effects of crack follow the same positive patterns as for its psychological effects; consumers typically feel more sociable and gregarious. They experience more intense sexual arousal and feel more sexual attraction to others. However, continued use of the product transforms these benefits into ironic parody. Social gregariousness disintegrates into the desperate use of others to obtain the drug, and sexual arousal transmutes into promiscuity and depravity. Crack consumption may have catastrophic consequences on the adopter's family, as well. Adopters may manipulate and steal from family members and close friends to obtain more of the product. Crack use also is associated with increased family violence, child abuse, and child neglect (Allen 1987b). Ultimately, crack consumption destroys not only the welfare of the user and his/her family and friends, but may lead to an overall increase in community crime and violence. Hence, the negative social effects of this innovation radiate outward from the adopter to the surrounding society.

SOME IDEAS FOR DISCONTINUING COCAINE ADOPTION

Cocaine is one of the most complex and long-lived product innovations ever investigated in a consumer behavior context. Its complexity derives from the myriad of personal, social, and historic factors surrounding its adoption and use. Merely acting to interdict supply or arresting and criminally prosecuting consumers will not eliminate its diffusion (President's Commission on Organized Crime 1986). Supply -- in the face of decreased demand -- is likely to continue to innovate novel product forms which will be demanded. Demand -- in the face of lessened supply -- will likely raise the potential profitability of cocaine production, drawing more dealers into the market. In the present author's view, the only viable solution lies in deactivating both the supply and demand sides of the cocaine market concurrently.

Some clues as to how this may be accomplished are provided by considering the origins of cocaine and its two earlier diffusion patterns in the United States (i.e., 1909, 1979). Cocaine is an integral part of social, political, and economic life in the three primary countries which produce it -- Colombia, Peru, and Bolivia. It is extremely doubtful that a product whose cultivation and use extends back 5,000 years can be eradicated. It is also questionable that the eradication of cocaine in these countries would be a moral or ethical objective for the United States, even if it were politically feasible (which it currently is not). Cocaine is the primary cash crop of the majority of indigent peoples in the Andes (Walker 1981). It is a useful and virtually costless folk remedy for many ailments for which their government is not, and likely cannot, provide adequate professional medical care (Walker 1981). The use of cocaine -- in the product form of chewing coca leaves -- permits many to alleviate the impoverishment and fatigue of their daily lives, with no apparent negative consequences on their health or social life (Walker 1981); for these

consumers and in this product form, cocaine must be considered a positive innovation.⁷

In this regard, it is rather damning to note that neither the United States nor the governments of Colombia, Peru or Bolivia, despite their extensive and expensive efforts at interdicting cocaine supplies, have attempted to operate on its root source -- the poverty of the Andean Indians. Until crop substitution programs are successfully implemented and Indians are more fully integrated into the economic, social, and political culture of these countries, there is little likelihood that coca production will cease. Indeed, as Gugliotta and Leen (1989) report, poverty and social inequality are two of the primary forces undergirding the creation and continuing power of the Colombian cartel. Cartel members are not drawn from the educated, affluent classes, but rather emerge from the hard and violent slums endemic to South American cities. Although no one would condone the brutal methods and destructive activities of the cartel, two facts must be recognized if progress is ever to be made toward eradicating its influence.

First, cartel members are not merely criminals and thugs. To label them as such severely limits our view of how to reduce their power. They are *also* highly sophisticated, intelligent, and self-taught international businessmen (see Shannon 1991). Their ability to construct elaborate transnational marketing channels, transfer billions of dollars in foreign currencies, and maintain organizational coherence *despite* a multinational police effort to destroy their business must be recognized. Much like the American mafia, such organizations are generated because persons with great entrepreneurial drive are prevented from entering socially acceptable and legal forms of enterprise. Since the socioeconomic conditions which gave rise to the present cohort of cartel members are still very much in effect (i.e., poverty, socioeconomic disparity, unmanageable inflation and debt), it is probable that killing or capturing the current cartel leadership will not eliminate the cartel; it will only permit new leadership to emerge -- much as in American organized crime. (Indeed, this is exactly what has happened; the elimination of the Medellín cartel has given birth to the Cali cartel (Shannon 1991).

⁷Although some readers may be disturbed by my present advocacy of the consumption of a stimulant, they may wish to consider the current widespread acceptance of such practices in North America. Many, perhaps all, readers imbibe coffee, tea or cola beverages regularly, all of which contain the powerful (and physically addictive) stimulant, caffeine. Several readers also, no doubt, enjoy alcoholic beverages on occasion. Others may smoke cigarettes or marijuana. Thus, what to us appears to be an objectionable vice, i.e., chewing coca leaves, is no different in function from our own society's accepted drug consumption practices -- it is simply unfamiliar.

Analogously, we find the same conditions existing for both suppliers and consumers in the United States (Morgenthau 1989d). Williams (1989, p. 8) describes the entrepreneur-dealers he encountered in New York City: "At the retail level, the distribution and sale of cocaine involves mostly African-American and Latino boys and girls under eighteen. In general they come from families whose income is below the poverty line, and from neighborhoods where there is little chance to rise above that line. It is difficult to say how many young people are engaged in this trade, but certainly there are many thousands in the metropolitan area... Many teenagers are drawn... simply because they want jobs... [Thus], the drug business is a safety net of sorts, a place where it is always possible to make a few dollars..."

It is easy with a product as socially threatening as cocaine to reach for easy and fast solutions, such as arresting and imprisoning the teenage dealers described by Williams (1989). But, just as with the Colombian cartel, such actions are not likely to eliminate the rush of others to fill their positions. The United States, just as Colombia, Peru and Bolivia, suffers from poverty and social inequality. So long as these conditions exist, there will probably be many eager applicants for vacant jobs in the cocaine trade.

There will also be eager consumers, as well. "If all you have in life is bad choices, crack may not be the most unpleasant of them," stated a U.S. congressman, recently (Morley 1989, p. 13). Although crack adoption is now diffusing to all socioeconomic strata (PCOC 1986), its original customer base and continuing consumption stronghold is among minority members of the underclass (Cole 1989). Although many affluent cocaine consumers continue to use the powder form of the product (i.e., cocaine hydrochloride), because of its more elite image and less ominous reputation (Cole 1989), an increasing number of white collar professionals are now adopting crack, due to its low price and widespread availability (Cole 1989).

As in the first cocaine diffusion in the United States (1889-1909), the association of crack with black and other ethnic minority consumers has promoted strong racist imagery in the mass media and even in governmental documentation. The official report to Congress of the U.S. Department of Health and Human Services (1987, p. 18), for example, stated, "The 8th National Household Survey on Drug Abuse conducted interviews with 8,037 individuals 12 years old and older... The survey differs from its predecessors in that it contains an over-sampling of interviews with blacks and Hispanics, so that more reliable estimates of drug use by these population groups can be obtained."⁸ The racist depiction of crack as evidence of endemic weakness or evidence of moral dysfunction (Raybon 1989) among blacks is reminiscent of the popular culture imagery employed

⁸If the survey had oversampled, say, Republicans, suburban housewives, or corporation executives to better estimate their drug use, no doubt a public outcry would have ensued.

during another recent drug 'epidemic' -- heroin. The July 5, 1971 issue of *Newsweek*, for example, carried a cover story on heroin use and observed with alarm: "Heroin is spreading in epidemic proportions out of the ghetto [and] into white suburbia" (p. 3). As we have argued, to view crack as an innovation that originated 'in the ghetto' and then diffused to white, middle-class America, is not only simplistic, it is fallacious. It is more historically accurate to view cocaine as an affluent product that 'trickled down' to the poor when it was reformulated and repackaged from powder to crack. In essence, from the second to the third cocaine diffusion cycle, it has been affluent white consumers, together with shrewd marketers and retail dealers, who have 'infected' poor, black consumers.

Regardless of whether the rich or the poor are responsible for introducing crack cocaine into U.S. society, it is now here, and effective responses to its growing diffusion must be developed. The approach advocated here is to attack it from an innovation rejection perspective. That is, we must identify what benefits crack appears to offer its potential adopters⁹ and supply alternatives or substitutes capable of providing those same benefits. In the author's discussions with cocaine addiction treatment personnel, I was impressed by a constructive distinction they made between crack users. One category of user is typically poor, uneducated and unemployed. This *Disadvantaged Adopter* category uses crack cocaine as a means of erasing a negative, deficient personal environment and replacing it with one in which the self is seen as powerful, competent and in control of events.

In contrast, is the *Advantaged Adopter* group which is composed of well-educated, upwardly mobile, professional and managerial class consumers who use crack cocaine to help them perform their jobs more effectively and compete more successfully with their peers. For example, one affluent tax accountant became addicted to crack in the early months of 1989 because of career pressures in helping several important clients file their tax statements. For each adopter group, crack offers a different set of benefits and, hence, its adoption can only be avoided by offering a different set of incentives.

Advantaged Adopters. An important disincentive for potential advantaged adopters is to vividly inform them of how much they stand to lose if they begin to consume crack. The high rate of addiction resulting from crack trial needs to be communicated to this group, together with a rendition of the many serious negative personal and social consequences resulting from chronic use. Many professional people may view crack as something they might use to get through a 'tough time' in their careers or to help them cope with an unusually heavy workload. They must be informed in clear and direct fashion that crack adoption is *not* a short-term action -

- it may result in long-term addiction, and the loss of their careers, income, family and, perhaps, life. It is not something to be experimented with even once. At the present time, none of this information is being conveyed to potential advantaged adopters, and they are not even targeted as a high-risk group.

Disadvantaged Adopters. Disadvantaged adopters are presently featured nightly on the evening news, where they tell in disjointed language their legacy of despair and ruin. Standing at the periphery of the camera's range are usually scores of potential disadvantaged adopters. The surrounding landscape is inevitably one of burned-out, boarded-up buildings, junked cars, and small stores with metal bars across the windows. Unemployment runs at 70%, the drop-out rate hovers at 60%, legitimate job opportunities are scarce, and hope is eroded by cynicism (Morgenthau 1989d; Williams 1989). To tell these consumers to "Just say no" to crack appears naive at best, and possibly even patronizing.

For this group of adopters, Morley's (1989, p. 13) dictum may be appropriate: "If all you have in life is bad choices, crack may not be the most unpleasant of them." I am *not* recommending that impoverished, uneducated and unemployed consumers take up crack as a meaningful response to their troubles. But I am calling upon consumer policymakers to recognize the meaninglessness of parading the traditional blandishments against drug consumption, e.g., they're 'bad' for you; they won't solve your problems, in front of such people. The truth which many of us -- members of the educated, affluent elite -- do not wish to recognize when formulating public policy for disadvantaged consumers, is that much of what these people experience every day is 'bad' for them -- being without a job, living in a crime-ridden neighborhood, not having access to adequate housing or medical care. We also fail to acknowledge that although taking a drug like crack 'won't solve their problems,' few other solutions to their problems are readily apparent.

Crack cocaine will not be rejected by this group of potential adopters unless viable substitutes for its use can be found. The answer for this consumer group, then, is the same as that advised earlier for the original adopters of *el coqueo* -- the Andean Indians. For five millennia they have chewed coca leaves, depending on them to provide each generation with the strength to carry on, despite pressing poverty and socioeconomic exclusion. They still await their full and equal incorporation into the surrounding society. So do the disadvantaged American consumers of crack.

Further Findings on Self-Gifts: Products, Qualities, and Socioeconomic Correlates

David Glen Mick, University of Florida
Michelle DeMoss, University of Florida

ABSTRACT

This article reports new quantitative findings on self-gifts from two surveys. The first shows that some product classes (e.g., clothing) are more prevalent as self-gifts in certain contexts (reward versus therapy) and, also, self-gift qualities (e.g., memorable, inexpensive) are differentially associated with self-gift contexts. The second study shows that propensities to engage in self-gift behaviors (e.g., rewarding, cheering up) are correlated with socioeconomic variables such as age, current financial condition, and gender. Results are discussed and future research is suggested.

INTRODUCTION

Understandably, gift-giving theory and research have been primarily dyadic or interpersonal in nature (see, e.g., Belk 1979; Fischer and Arnold 1990; Sherry 1983). A few researchers have noted, nonetheless, that people may sometimes give gifts to themselves (see, e.g., Schwartz 1967; Levy 1982; Mick 1986). Empirical evidence has now begun to appear that not only substantiates self-gifts, but also suggests that the self-gift phenomenon may be widely occurring in American society (Mick and DeMoss 1990a, 1990b; Mick et al. 1991; Sherry and McGrath 1989).

Mick and DeMoss (1990b) define self-gifts as personally symbolic self-communication through special indulgences that tend to be premeditated and highly context bound. Typical of the self-directed messages are celebration, congratulations, or consolation; all are intertwined with self-concepts (how consumers define themselves) or self-esteem (how consumers feel about themselves). Often cited contexts include public holidays (e.g., Christmas) and birthdays as well as situations of success (e.g., graduation, promotion) and failure (e.g., low exam grade, divorce). Mick and DeMoss (1990b) have suggested that self-gifts reflect consumer behavior in some of its most flexible, dramatic, and personally meaningful forms.

Most of the early empirical insights on self-gifts have been qualitative. As Mick and DeMoss (1990b) noted, however, various research approaches will be necessary to understand self-gifts comprehensively, including quantitative inquiries. In this article we report some new quantitative findings on self-gifts emanating from two surveys. The results contribute further foundational knowledge about self-gifts, notably the types of self-gifts acquired (including differences between reward and therapy contexts), the qualities of self-gifts deemed most applicable in four different contexts, and socioeconomic correlates of consumers' propensities to engage in self-gift behavior in eight different contexts. As an additional contribution, moving past beyond the exploratory and descriptive nature of past

self-gift studies, the surveys also allowed us to test several propositions that Mick (1991) derived from a semiotic analysis of self-gifts.

STUDY ONE

Overview

Data from this first study were collected as part of a previous survey on self-gifts (see Mick and DeMoss 1990b for full details). In that project 392 critical incident reports on self-gifts were collected from a convenience sample of students and non-student adults ($n = 287$), ages 21 to 82, mostly from the Gainesville, Florida area. Two-thirds of the respondents were asked to describe a personal acquisition "as a reward for having accomplished a personal goal" and then, on a subsequent page, to describe a personal acquisition "to cheer yourself up because you were feeling down." The other one-third of the respondents were requested to describe a personal acquisition "for your birthday" and then another "when you had extra money to spend." These four contexts had been identified through previous exploratory research, with the first two (hereafter called reward and therapy) potentially representing the two predominant contexts of self-gifts. Further rationale for the four chosen contexts and their disproportionate distribution in the survey are discussed in Mick and DeMoss (1990b).

After completing the critical incident reports, respondents answered two scaled items about premeditation and guilt over each reported self-gift (see Mick and DeMoss 1990b). Then all respondents completed a series of adjective ratings regarding the qualities of self-gifts they perceived to be most applicable to each of the four self-gift contexts addressed in the survey (reward, therapy, birthday, extra money to spend). On each of four separate pages, under the heading of a self-gift context, twenty qualities were listed (e.g., practical, inexpensive). Using a 5-point scale, respondents indicated how much each quality applied to the kind of product, service, or experience acquired in the given context. The adjectives were taken partly from Belk's (1979) prior work on dyadic gift qualities and partly from insights generated during our prior self-gift research.

A few of the qualities related to propositions about self-gifts developed by Mick (1991). He suggested that, compared to self-gifts in the extra money context or the therapy context, self-gifts as rewards or on birthdays (a personal holiday) would more likely be sought for their temporal durability, i.e., to continue physically existing in the person's life or remaining mentally salient. His argument was based on the reasoning that rewards are sought as testaments to effort and achievement, while birthday gifts are usually chosen to befit a very special (once a

TABLE 1
Types of Self-Gifts Reported Across All Four Contexts

Type of Product	Frequency	Percentage

Totals	392	100%

year) personal occasion. Hence, consumers should desire self-gifts in those contexts that are more likely to last physically or otherwise remain memorable. Mick (1991) also proposed that reward and therapeutic self-gifts represent consumers' attempts to uplift themselves (self-esteem, moods, etc.). Thus, he suggested that, compared to extra money self-gifts or birthday self-gifts, reward and therapeutic self-gifts are more likely to be sought for their perceived inspiring quality.

Analysis

The critical incidents were content analyzed according to the type of product, service, or experience mentioned as the self-gift. This analysis was conducted independently by two doctoral students using a pre-established list of potential types of self-gifts. Coding agreements occurred in 86% of the cases; disagreements were resolved by a third judge.

Of the 392 reports, 134 were rewards, 145 were therapeutic, 39 concerned birthdays, and 74 concerned extra money to spend. Key cross-tabulations were constructed for types of self-gifts in relation to the self-gift contexts. Cross-tabulations involving the birthday and extra money contexts were generally less reliable due to low cell frequencies in light of the lower number of self-gift incidents reported in those contexts. Thus, only the cross-tabulation involving reward and therapy contexts is reported. As suggested by Mick and DeMoss (1990b), these may represent the two predominant contexts for self-gifts.

To determine whether the self-gifts varied according to the 20 qualities (Qs) across the four different self-gift contexts (Cs), a series of analyses were performed. First, the interaction of Qs and Cs was tested and found to be highly significant ($F = 21.8, p < .0001$). Then the simple main effects of the four contexts (Cs) were tested for the 20 qualities and all were statistically significant ($p's < .05$), with the exception of one quality ("simple"). *Post hoc* Tukey

comparisons were then performed on the remaining 19 qualities to test for significant differences between self-gift contexts.

Results

As Table 1 shows, across all four contexts the most frequently cited self-gifts were clothing, fast-food/grocery food, non-fast-food restaurants, music products (e.g., tapes), personal care services (e.g., hair styling), recreational products (e.g., tennis racquet), and electronic equipment (e.g., radio). As Table 2 shows, compared to the therapy context, the reward context was more likely to involve clothing, non-fast-food restaurants, recreational products, and travel, and less likely to involve music products, fast-food/grocery food, personal care services, and entertainment outside the home (e.g., movies).

A few qualities of self-gifts were shared among self-gifts across the four contexts (see Table 3), these qualities being exciting, fun, and satisfying; taken together they substantiate the indulgence and specialness of self-gifts (see Mick and DeMoss 1990b). Several of the qualities varied across the contexts examined. Compared to the other contexts, among the qualities especially applicable to reward self-gifts were inspiring, memorable, and lasting; by comparison, less applicable qualities to this category were unusual and silly. Among the qualities especially applicable to therapy self-gifts were inspiring and relaxing; these self-gifts were less likely to be practical, prestigious, memorable, elegant, perfect, irresistible, or lasting. By comparison, the qualities more applicable to birthday self-gifts were memorable, fashionable, thoughtful, perfect, and lasting; they were less likely to be inexpensive or relaxing. The quality perceived more applicable to the extra money context was inexpensive, with practical and irresistible comparatively higher as well; the less applicable qualities were inspiring, memorable, magical, and warm.

5-point scale: 1 = Does not apply at all; 5 = Applies very highly

All means in a given row that are not identical are significantly different at $p < .05$, unless noted as follows:

- a = Not different ($p > .05$) from Reward Context, in same row
- b = Not different ($p > .05$) from Therapy Context, in same row
- c = Not different ($p > .05$) from Birthday Context, in same row
- d = Not different ($p > .05$) from Extra-Money Context, in same row

Discussion

The results of study one are insightful, though it must be acknowledged that they are based on a convenience sample. With this limitation in mind, it appears that some types of self-gifts are more prevalent overall, though there is obviously considerable variety in self-gift selections since nearly one out of every four fell outside of the main prespecified categories appearing in Table 1. Also, some types of self-gifts are more likely to be acquired depending on the specific self-gift situation. When consumers are rewarding themselves (as opposed to cheering themselves up) they are more inclined toward clothing, non-fast-food restaurants, travel, and recreational products; whereas when they are cheering themselves up, they are more likely to select fast food/grocery food, personal care services, music products, or outside entertainment (Table 2). These findings make some intuitive sense and align with prior insights on self-gifts. That is, in reward contexts consumers are probably more likely to feel they *deserve* something special due to an achievement (Mick and DeMoss 1990b), thus they favor self-gifts like travel or pleasant full-service restaurants. On the other hand, in therapy contexts consumers are more likely to be seeking expedient relief or escape from life's problems (Mick and DeMoss 1990b); thus, these self-gifts are often just temporary diversions such as fast food restaurants and out-of-home entertainment.

Several of the results about qualities of self-gifts lend support to Mick's (1991) propositions about temporal durability and inspiration in self-gifts. For example, as he suggested, reward self-gifts are apparently more likely to be selected for their ability to inspire the individual, perhaps toward further achievement behavior. They are also more likely to be selected for their memorable and lasting qualities, as Mick also suggested, probably to serve as a reminder of the past accomplishment or victory. As he also proposed, therapy self-gifts are also sought for their inspiring quality, perhaps to restore one's sense of self-worth, but they are not as sought for the quality of memorableness or lastingness since the memory related to the self-gift is probably negative. In contrast, birthday self-gifts are not sought as much for their inspiring quality as for their memorability and lastingness, as Mick also suggested.

STUDY TWO

Overview

This study was part of a statewide (Florida) consumer survey that is conducted monthly by the Bureau of Economics and Business Research at the University of Florida. The survey is taken by telephone, with respondents contacted through a probability sampling procedure based on random digit dialing. In essence, we were given the opportunity to include a limited number of self-gift items that could be formatted to a telephone survey method.

One major gap in the understanding of self-gifts concerns which types of consumers are more inclined to engage in varied self-gift behaviors. To

gain some initial insights on this matter, within the constraints of the telephone survey method, we constructed eight separate items on the extent to which consumers are inclined to acquire products, services, or experiences for themselves in specific self-gift contexts. Respondents replied with a number from 0 (Never) to 8 (Very Often). The stem for each item was: "In the past when you have acquired products, services, or experiences for yourself, how often have you felt you acquired them" and this was followed by one of the following eight phrases:

- (1) to reward yourself
- (2) to cheer yourself up
- (3) because it was a holiday
- (4) to relieve stress
- (5) as an incentive to reach a personal goal
- (6) because it was your birthday
- (7) just to be nice to yourself
- (8) because you had extra money to spend

These eight contexts were identified based on focus group discussions and prior qualitative survey research (Mick and DeMoss 1990a, 1990b).

Seven socioeconomic variables (routinely measured by the bureau in its surveys) were highlighted as potential predictors of the propensity to engage in self-gift behavior:

- current financial condition compared to a year ago (worse, same, better)
- education level
- marriage status (currently married or not)
- age
- whether anyone else lives in the same household with the respondent (no/yes)
- income level
- gender

These predictor variables were selected based on prior research or for strictly exploratory purposes. For example, based on Belk's (1988) work, Mick (1991) proposed that older individuals should have lower propensities to engage in all forms of self-gift behavior; in general, older individuals are thought to be less concerned with acquiring new things, as compared to younger to middle age individuals, because they are more focused on their existing memory-laden possessions. Mick also proposed that people with better financial conditions may be more inclined to engage in all forms of self-gift behavior, especially for the genre of self-gifts he termed Romantic (which includes self-gifts just to be nice to oneself and when one has extra money to spend). Also according to Mick, since the expectations and norms for gifts are highly established for holidays (public and private), in those contexts the propensity for self-

TABLE 4
Multiple Regression Analyses

Dependent Variables	Independent Variables							R ²
	CFC	EDU	INC	MAR	ANYELS	AGE	GEN	
Reward	.10 (.02)	ns	ns	ns	-.09 (.08)	-.19 (.001)	ns	.08
Cheer Up	.06 (.12)	ns	ns	ns	-.08 (.12)	-.15 (.003)	.11 (.02)	.06
Holidays	.09 (.04)	-.09 (.12)	ns	ns	ns	-.19 (.001)	ns	.07
Being Nice to Self	.10 (.03)	ns	ns	ns	ns	-.11 (.03)	.18 (.001)	.07
Extra \$ to Spend	.10 (.03)	ns	ns	ns	ns	-.28 (.001)	ns	.10
Birthday	.09 (.04)	ns	ns	ns	ns	-.16 (.003)	ns	.04
Incentive to a Goal	.11 (.02)	ns	ns	ns	ns	-.23 (.001)	-.11 (.03)	.10
Relieve Stress	.05 (.14)	-.11 (.04)	ns	ns	ns	-.24 (.001)	ns	.09

All eight models (F-values) are significant at $p < .05$. All parameter estimates are standardized. T-tests on parameter estimates for current financial condition (CFC), marital status (MAR), whether anyone else lives in the household (ANYELS), and age (AGE) are 1-tailed tests, given the directional nature of the propositions discussed; all other t-tests are 2-tailed. Subsequent p values are in parentheses, except where ns means that $p > .15$.

CFC = Current Financial Condition (worse = 0, same = 1, better = 2)

EDU = Education Level

INC = Income Level

MAR = Marital Status (Currently not married, including single, divorced, or widowed = 0, Currently married = 1)

ANYELS = Whether anyone else lives in the household besides the respondent (no = 0, yes = 1)

AGE = Age

GEN = Gender (male = 0, female = 1)

gifts may be less impacted by current financial condition, i.e., consumers may be more likely on holidays to override any reluctance for self-gifts due to diminished financial conditions. Finally, Mick also proposed that people with less available intimate relationships (e.g., not currently married, living alone) should have higher overall propensities to engage in self-gift behavior (as a replacement for the missing interpersonal gift-giving in their lives), most especially for holiday contexts.

Analysis & Results

Multiple regression analysis was used to determine whether the socioeconomic descriptors were predictive of the propensity to engage in the eight different self-gift behaviors.

Approximately 500 individuals participate in the statewide survey each month, though due to

refusals on certain questions (e.g., income), the sample in our study was 398. Among them, 158 were males and 240 were females, with an average age of 46 (range 19 - 88). Table 4 shows the regression models for each of the eight separate contexts of self-gift behavior and the set of socioeconomic predictor variables.

Results show that the amount of variance explained by each model is low, R^2 s ranging from .04 to .10. These multiple coefficients of determination are probably attenuated by the range restriction resulting from the single item measures; this is an issue over which we did not have complete control since we were limited in the number of dependent variable items we could insert in the survey, and the independent variable measures were established by the survey bureau.

Table 4 shows that age is negatively associated with each self-gift propensity without exception; older individuals in this sample are less inclined to engage in self-gift behavior. Current financial condition is positively related to every self-gift propensity. However, the propensity for self-gifts on holidays (in general) and on birthdays are not more strongly associated with current financial condition, as compared to the other self-gift contexts. In addition, those respondents who were not currently married did not have any higher self-gift propensities, while those who lived alone (no one else in the household) had higher propensities only for reward and therapeutic self-gifts.

The results also indicate that females are more likely to engage in self-gift behavior in therapeutic and nice-to-self contexts, whereas males are more inclined in situations where the self-gift serves as an incentive to reach a goal. Education was negatively related to the propensity for self-gifts on holidays or to relieve stress. Income itself was unrelated to any of the self-gift propensities.

Discussion

The results from study two are provisional due to the fact that the dependent and independent variables were all single-item measures. Quite simply, the reliability of the measures is not known. However, to the extent that the results have some trustworthiness, the probability sampling procedure enhances their generalizability. Still, some will question altogether the appropriateness of using a telephone survey to study self-gifts. However, it is our continuing conviction that a multimethod approach to self-gifts is necessary to comprehend thoroughly the various facets of this phenomenon, particularly for building and testing self-gift theory (cf. Mick and DeMoss 1990b).

The results of study two are informative and partly supportive of Mick's (1991) propositions about consumers' propensities to engage in self-gift behaviors. Older respondents did report lower propensities to engage in self-gift behaviors. However, whether this finding is truly suggestive of an aging-related phenomenon, as implied by Belk (1988), or instead a specific cohort-related outcome (i.e., the older generation at this time may be less indulgent and more ascetic) cannot be resolved by these cross-sectional data. The results also showed that those with better financial conditions are generally more likely to engage in all self-gift behaviors, as Mick (1991) predicted, though this relationship was not strongest for public holiday and birthday contexts as he proposed. Given that self-gifts are forms of consumer indulgence that reflect intensive participation in a consumption-oriented and economically stratified American society, the financial condition findings can be interpreted in terms of the exercise of social and consumer power by those currently privileged within the existing socioeconomic structure (cf. Sahlins 1972).

With respect to other results, living alone does seem to predispose consumers to a higher propensity for reward or therapy self-gifts, though not for other

self-gifts, as Mick also suggested. Women reported higher propensities to engage in nice-to-self and therapeutic self-gifts, perhaps because they are more likely to use dyadic gift-giving as a means to express empathy or sympathy for other people (Cheal 1988). Men, on the other hand, are socialized to be more competitive and achievement-oriented, rather than human relations-oriented, and this gender difference seems to emerge in the males' higher propensity to use self-gifts as an incentive to reach a personal goal. Whether these differences will dissipate as women increasingly enter male-dominated arenas (e.g., career paths), and if men adopt more of the traditional women's roles, remains to be seen.

GENERAL DISCUSSION

This article contributes additional knowledge about self-gifts by reporting quantitative findings from two large scale surveys. In the first study certain products were seen to be prevalent self-gifts overall, while some were significantly more likely to appear in certain self-gift contexts (e.g., clothing as reward self-gifts, fast food/grocery food as therapeutic self-gifts). Also in study one, qualities of self-gifts were seen to vary depending on the self-gift context (e.g., *inspiring* reward self-gifts, *relaxing* therapeutic self-gifts, *thoughtful* birthday self-gifts). In the second study, the propensities to engage in eight self-gift behaviors were seen to vary negatively with age and positively with current financial condition. In a subset of contexts these propensities were also correlated with gender, education level, and whether the person was living alone. Taken as a whole, these findings tell us more about (1) which types of self-gifts are preferred overall, and between two predominant contexts; (2) which qualities are applicable to self-gifts in four major contexts; and (3) which types of consumers (based on socioeconomic criteria) have higher propensities to engage in different self-gift behaviors.

More research is needed on the types and qualities of self-gifts in such contexts as public holidays (e.g., Christmas, Valentine's Day), when relieving stress, when establishing an incentive to reach a goal, and when just doing something nice for oneself. Basic research is also needed to compare types and qualities of self-gifts with those of dyadic gifts in similar situations (e.g., birthdays, rewards, therapy) and with dyadic gifts differentiated by the relationship of receiver to donor (e.g., whether the receiver is part of the donor's extended self; see Belk 1988). Also, other individual differences besides socioeconomic factors could be considered for their ability to predict propensities for self-gift behaviors (e.g., personality traits such as need for achievement or self-esteem).

Self-gifts have been a relatively little understood phenomenon within consumer behavior, though their manifestations in everyday American life seem widespread. Using multiple methods while developing and testing both a priori and emergent propositions seems a fruitful strategy for ascertaining this phenomenon. Although a detailed understanding and general theory of self-gifts remain yet at a

considerable distance, some first steps have been taken in that direction.

Symbolic Communication Among Consumers in Self-Consumption and Gift Giving: A Semiotic Approach

Anil Pandya, Northeastern Illinois University, Chicago
A. Venkatesh, University of California, Irvine

Using Leach's (1976) communication framework, this paper explores how products symbolically communicate in different consumption contexts. It examines the non-verbal role products play when consumers communicate through purchase and consumption, to clarify the symbolic differences between products like clothing when used for personal and visible consumption and products like silverware used for gifts. It examines how expressive consumption communicate symbolic meanings and makes two key points: first, consumers use different types of symbolic communication in different contexts; and second, an analysis focusing on communication instead on objects leads to a richer understanding of consumer behavior.

Consumers use products to seek distinction, self-definition, identity extension; and communicate these to others (Belk 1988, 1990). Objects have being or movement in human society only by the significance men give them (Sahlins (1976). Consumer behavior would be difficult to fathom without understanding the meanings consumers attach to possessions (Belk 1988). This centrality of product symbolism in consumer behavior was first recognized by Levy (1959) and Grubb and Grathwohl (1967) and has been extended by Levy (1981) and McCracken (1986, 1988) on consumption anthropology; Hirschman (1985) on ethnic consumption; Holbrook (1986) on consumption of aesthetics; Belk, Bahn and Mayer (1982) and Belk, Mayer and Driscoll (1984) on symbolic decoding; Belk (1979, 1981) and Sherry (1983) on gift giving; Holbrook (1985), Holman (1983), and Mick (1986) on the semiotics of consumer behavior.

While, this literature has made major contributions, some important and unexplored areas remain to be investigated. It has mainly examined a consumer's relations with the objects of purchase (Belk 1990). The symbolic role of products in mediating relations among consumers as yet, remains an unexplored area. The mechanics of product based communication also remains unexplored. Leach (1976) maintains that cultural artifacts function as a nonverbal language system, with the important distinction between artifacts that work as *signs* and those that work as *symbols*. This terminology differs considerably from that of Charles Pierce. For a comparison see Barthes (1983 a).

Signs communicate by making reference to a shared code (Leach 1976). A code affords a general set of possibilities for sending particular messages (Douglas 1972). In a sign a part refers to a whole, to which it belongs -- like a cross for Christianity, or a crown for royalty. This part/whole mechanism of sign includes two relations: metonymy and synecdoche. Metonymy juxtaposes contiguous terms that occupy a distinct and separate place within a single semantic or perceptual domain. "You will read in Homer," the

agent (Homer) replaces the act (Iliad) (Sapir 1977). Synecdoche draws its terms from a single domain but one term always includes the other. The presence of a term refers to the absent whole as in crown (part)/royalty (whole).

Symbols on the other hand, communicate metaphorically to explain complicated ideas or emotions. Metaphors equate terms from different domains (Sapir 1977) like, "Put a tiger in your tank." Metaphors are meaningful only in particular contexts because equivalence can work only on the presumption of shared knowledge of one domain of experience to explain something quite different. Communication occurs through analogies and parallels.

The paper first defines *signs* and *symbols*, and discusses four categories of communication -- *self-consumption* as a *sign* or *symbol*; and *gift* as a *sign* or *symbol*. *Self-consumption* as a *sign*, is illustrated by the example of the clothing system; and gift-giving as a *symbol* is illustrated by consumer self-reports. The two remaining categories-- *Self-consumption*, as a *self-gift* and obligatory or unauthentic gift as a *sign*, are briefly discussed. The final section summarizes the contributions of the paper.

DISTINCTIONS BETWEEN SIGNS AND SYMBOLS

A culture is a complex of significations created by non-verbal sign systems (Leach 1976). People give meaning to things by using them. When artifacts are patterned in sets of coded information, products in use become elements of a non-verbal, symbolic language. Understanding such a language requires knowledge of its constituent elements and its grammar which organizes the elements in a coherent system of meaning producing structures; and accordingly, the information coded in styles of clothes, architecture, and automobiles are similar to coding implicit in sounds, words, and sentences with the important difference that the syntax of non-verbal language is simpler than that of natural language. Unlike the more dynamic natural languages, non-verbal communication tends to be customary and conventional (Leach 1976 p.11).

Leach (1976) uses a simple communication model consisting of a sender and a receiver. A sender sends a message bearing entity to a receiver who in receiving the entity, interprets the message. Thus Leach separates the message bearing entity (A) from the message (B), the entity carries. A is the "signifier" and B is the "signified." This act of separation is called opposition. The relationship between A and B is represented as A/B and is called a "structure." The relationship between an entity and the meaning it carries is represented by the equivalence model: Signifier/Signified :: A/B. A is the signifier and B is the signified. A product can function either as a sign or as a symbol. Signs and

symbols are produced when the message bearing entity A through cultural or causal associations stands for a message B.

SIGNS

In a *sign* the A/B correlations are cultural such that A (the signifier) stands for B (the signified) as a part stands for a whole. The receiver infers the whole B by observing the part A. A crown is a sign of royalty because in our minds it is a part of a royal costume. Only an arbitrary convention can explain this inclusion. There is no natural necessity for a crown to be a part of royal regalia. The repetition fixes the associative relationship between objects like a "crown" and a message like "belonging to royalty." This strong association causes royalty to be evoked by the mere observation of a crown.

The part/whole relationship is always contextual. In London a man's striped tie may suggest affiliation with a prestigious public school like Harrow or Eaton or the man's regiment. By implication, the tie may also indicate his standing in the British class system. But in the United States striped ties may have no such meaning. In Boston however, a Harvard tie would perform a similar social function, making signs context specific.

A sign is always a member of a set of contrasted signs. For instance, to infer from a school tie a person's wealth and status requires the tie to be observed along with clothes, car, accent and so on. This characteristic of signs is metonymic where contiguity of other signs helps the observer to interpret the message. A married Hindu woman puts a red dot on her forehead, wears red and green bangles on her hands, and wears a string of black and gold beads. The presence of all these signs testify to her married householder status in Hindu society. The absence of the dot alone on a woman's forehead may indicate she is a non-Hindu, but the absence of all other signs may suggest an unmarried Hindu woman. The absence of some and presence of the other signs together convey contextually specific messages. Each sign has more or less precise meaning only in relation to the other signs.

SYMBOLS

In a symbol the relationship between the signifier A and the signified B is also culturally and/or causally determined. But instead of a part/whole relationship of a sign, a symbol represents a whole/whole relationship. When A as a signifier is a whole and it stands for B the signified as a whole, then A symbolizes B. A zigzag road sign symbolizes the curvy character of the section of the road ahead. But this interpretation calls for an act of imagination. The interpreter must imagine that A represents B.

Symbolic representations can be of two kinds, "arbitrary" or "planned." Leach uses "arbitrary"/planned opposition to distinguish between different types of symbolization (Leach 1976). Symbols are "arbitrary" when the relation between the symbol and the message is relayed through repeated cultural assertions, as in the choice of an apple to represent temptation, or in the choice of the serpent to represent

evil. Here the symbols are "arbitrary" because there is no inherent relationship between the symbol and the message. The correlation is learned through repetition. Symbols are of "planned" similarity when some salient attribute of the message resembles the chosen symbol or its attribute as in the zig-zag road sign. Here the choice of symbol is planned to be similar to the intended message.

Leach (1976) further categorizes these two types of symbols as standard symbols, which most people in the culture understand, and nonce or private symbols which cannot generally be understood by most people. Symbols either become standard symbols by public discourse, as in the case of the frequently advertised Merrill-Lynch corporate symbol, or remain private as in poetry and can be understood through a deliberate contextual effort.

A TYPOLOGY OF EXPRESSIVE COMMUNICATION

A typology of expressive communication is organized as a two dimensional matrix shown in Figure 1.

The first dimension dichotomizes the context: self or the other. A product can be expressively used either for the self or for a significant other. The second dimension contrasts the expressive function of the product: the product can function as a sign or as a symbol. This results in four categories of communication: self-consumption as a sign in quadrant A; gift to others as a metaphoric symbol in quadrant B; self-gift where a person gives gifts to one's self which functions as a symbol in quadrant C; and obligatory gift giving where the gift to the other functions as a sign in quadrant D.

Self-consumption as sign (A) and gift to others as symbol (B) occur most frequently. These two types of communication, along the left-to-right diagonal are discussed first in greater detail. This is followed by the discussion of communication in (C) and (D) along the right-to left diagonal. These occur less frequently and are derivatives of (A) and (B); and their discussion is less exhaustive.

COMMUNICATION IN QUADRANTS A & B

The role of signs in self-consumption is discussed, using Sahlins (1976) work on American clothing as an illustration. The discussion on the role of symbols in gift exchange based on consumer self-reports, follows.

SELF-CONSUMPTION

The tendency to make inferences about others based on their choices of consumption objects is a universal cultural phenomenon. Research on coding and decoding confirms a considerable congruence between images of the self and images of the acquired products and that consumers communicate information about social status, life style, personality, age, sex, type of occasion, education and profession by making visible consumption choices (Belk, Bahn, and Mayer 1982, Holman 1980, 1981a, 1981b). Children, college students, and adults make remarkably

FIGURE 1
Typology of Expressive Communication

	SYMBOL	C Self-Gift	B Authentic Gift

consistent inferences and judgments about status and non-status based on peoples' ownership of houses and cars which improve over time (Belk, Bahn and Mayer 1982, Belk, Mayer and Driscoll 1984).

Taken together, six conclusions emerge from this research on visible consumption or expressive self-consumption, as it is called here: (1) consumers make inferences about themselves and others based on their possession and use of a variety of goods; (2) these products tend to be visibly used; (3) as experience with the use of these goods increases, the ability to make inferences also increases; (4) certain product attributes are more important for symbolic communication than others; (5) a product does not continue to convey the same information forever; and (6) consumers strategically use the fact that products communicate life styles and status. This literature does not answer how consumers attach meanings to things or how they decode such meanings. These gaps are addressed here.

QUADRANT A: SELF-CONSUMPTION AS A SIGN

Clothes convey a variety of messages and illustrate the role of sign in self-consumption. Sahlins' (1976) analysis of the clothing system, based on a master distinction between leisure and work, illustrates how sign based communication occurs. Sahlins (1976) uses the sign characteristics of clothing to reveal the structure of the dress code. It shows how products acquire meanings through the operation of a socially shared code where each type and style of clothing, when worn at different times and occasions, communicate specific things about the people who wear the clothes.

Deconstruction of the American Clothing System

The American clothing system, according to Sahlins (1976, p.179-209), is a complex scheme of semantic production of cultural categories in which women's slacks are evaluated in opposition not only to skirts, dresses and men's pants but also to other slacks on attributes of color, patterns, texture and cut. The outfit as a whole, made by particular arrangement

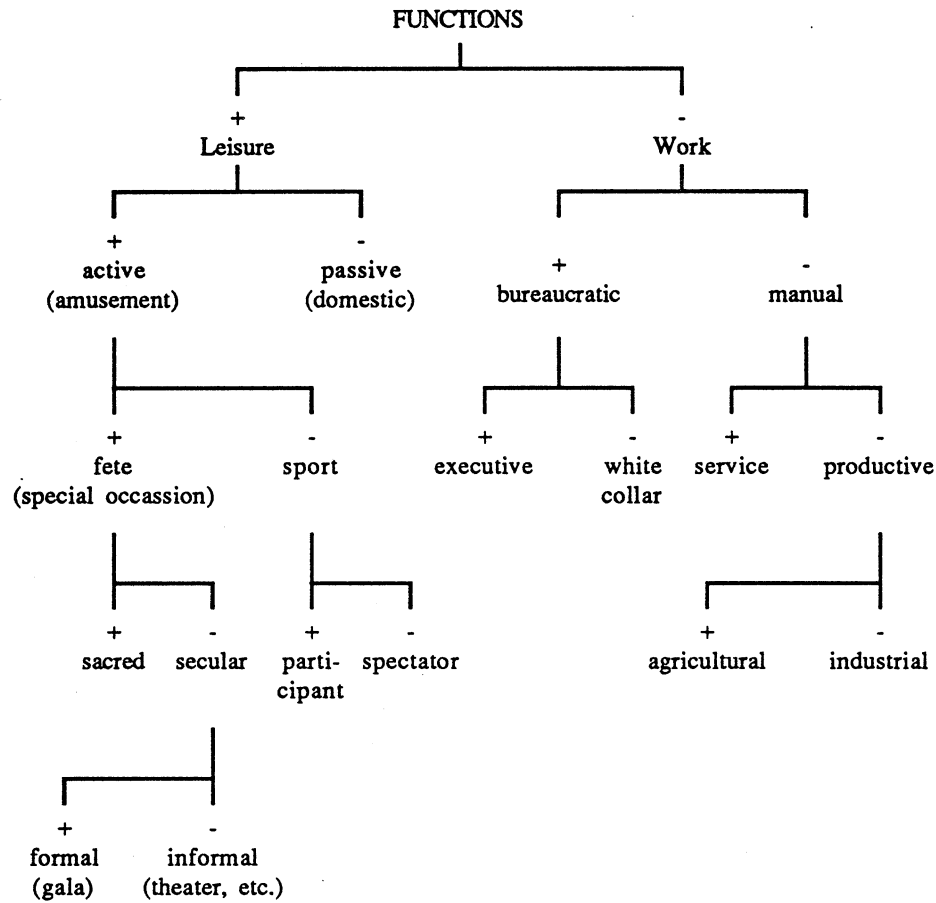

of parts and contrasted to other outfits makes a statement. The differences in clothing for men and women, for day and night wear, for around the house and in public, for adults or children reveal the underlying syntax: categories of time and place signify classes of activities and status to which people are ascribed. These notional coordinates of clothing mark the basic cultural notions of time, place and persons. Order of things correlate to the order of culture. When these correlations get disturbed, events appear as incongruous and out of place, as for example, the incongruity of seeing men in dress suits or women in evening gowns at work. Figure 2 illustrates this deconstruction.

At the top of the tree, the pair of functions, Leisure/Work form the master opposition. At the next level, work is subdivided into bureaucratic work and manual work. Bureaucratic work is further categorized into executive work and white collar work. Manual work is further divided into manual service and productive manual labor. The latter is further bifurcated into agricultural and industrial labor.

Leisure in Figure 2 is classified into active leisure where people go out and seek activities that provide amusement and domestic leisure which has no defined project like staying home and taking it easy. Active leisure is divided into special occasions and sports activity. Special occasions are subdivided into secular and religious occasions. Secular occasions are further subdivided into formal occasions like going to a concert or informal occasions like going to a movie. Sports activity is further categorized into participatory sports or spectator sports.

In Figure 2 the (+) sign represents leisure related activities and is placed on the main left branch and the (-) sign represents work related functions and is placed on the main right branch. At each subsequent level of the tree within each main activity-leisure/work, the left branch is marked and is considered more ceremonial and privileged and the right branch is unmarked and considered more workmanlike and less ceremonial and privileged. Thus beginning with the master opposition of leisure/work, the diagram at each level reveals a series of functional oppositions like active leisure/passive leisure,

FIGURE 2
 Schema of Function Signified in American Clothing

| ceremonial | workmanlike |

bureaucratic work/manual work, executive work/clerical work, agricultural work/industrial work and so on. The tree of oppositional pairs thus reflects the logic of clothing differentiations and allows Sahlins (1976) to identify two systematic, observable regularities- one, the rule of ceremonial correspondence and two, the rule of ceremonial exaggeration.

According to the rule of Ceremonial Correspondence, the terms of any oppositions correspond to the terms of any other, such that the ceremonial costumes of any two classes resemble each other by an analogous differentiation from their corresponding non-ceremonial classes. In the-

bureaucratic (+)/manual work (-) and service worker (+)/ productive worker (-) opposition the difference in clothing between say a waiter's uniform (color, style, epaulets) and the factory worker's blue overalls is the same as the difference between that of an executive (pin-striped suit) and the clerk (sports jacket).

The ceremonial clothes of the leisure functions, according to the rule of Ceremonial Exaggeration, will be more marked than those of the workmanlike functions. The uniform for an active sport like skiing has more color and dash than the uniform of a waiter. The clothing for special occasions is more exaggerated than executive suits in the bureaucratic function. The rule suggests that ceremonial

oppositions are exaggerated in the opposite directions. Spectators at a game wear more casual clothes than the clothes industrial workers wear to work. The exaggeration occurs in both directions: more ceremonial at its marked (+) and less workmanlike at its unmarked (-) poles.

The physical contrasts in clothing appear as differentiations reflecting differentiations in classes of time (day/night) and place (home/outside); and relate to classes of activities (leisure/work); and situations (formal/informal) and ascribe persons (male/female, adult/child) to classes of status (high/low). Products reflect the social order to indicate social status, activity and situation, realizing their utilities through the meaning attached to them in consumption. Barthes (1983 a) and Baudrillard (1981) extend these insights to explore how people express individuality, taste and style and how they manipulate the code to their advantage.

A dialect modifies the way some people pronounce vowels without changing the linguistic structure such that the language remains intelligible to all speakers. Barthes' (1983b) model for generating different utterances in clothing fashions consists of a combination of values taken on by an object (O), the object's supports (S) and a variant (V). Thus: a Sweater (O) With An Open (V) Collar (S) can take combinatorial values: the variant (V)- the state of the collar- can assume values (open/closed, high/low) in relation to the support (S)- the collar- or the object (white/color, pattern/plain), giving rise to many possibilities for expressing individuality.

People constantly manipulate the code to their strategic advantage. Business students dress up for job interviews and conform to corporate norms. Teenagers dress down in funky and bizarre outfits to distance themselves from their parents' world (Baudrillard 1981).

GIFT GIVING AND RECEIVING IN CONSUMER BEHAVIOR LITERATURE

Researchers have given gift giving considerable attention (Banks 1979, Belk 1974, 1979, 1982, Clark and Belk 1978, Gronhaug 1972, Heeler, et al. 1979, Pandya 1985, 1987, Ryans 1977, Scammon, Shaw and Bamossy 1981, Shapiro 1970, Sherry 1983). A gift is not a free good and in the anthropological sense it is the basis of a reciprocal system of exchange in a network of households (Mauss 1974, Polanyi 1957, Sahlins 1972). Only this sense of gift is retained here. The meanings of gift as bribery and gift as donation are excluded.

The empirical research on gift purchase describes it as a complex social activity, a form of expressive consumer behavior for communicating feelings, gratitude, emotions and closeness or distance in relationships (Belk 1979, Sherry 1983). Gift selections depend on the giver's ideal self-concept, the nature of the occasion and the relationship to the recipient (Belk 1979) and consume a lot of time in selection. Obligatory gifts on the other hand, tend to be less personal, less time consuming and simpler (Scammon, Shaw and Bamossy 1981). Gifts giving

normally involves at least two people but one can also give gifts to oneself (Levy 1981, Mick 1986).

Consumer involvement in buying products for one's own self (for self-consumption) and in buying gifts for others, differs. Consumers search for more alternatives, shop in more stores, seek more advice and get more information while buying silverware as a gift for others but are more cursory in their search when buying silverware for themselves (Gronhaug 1972, Clark and Belk 1978). For the purchase of small appliances as gifts consumers go to high status stores but spend less time in selecting a gift but while buying for themselves they go to discount stores and spend more time in selecting small appliances (Ryan 1977, Heeler, et al. 1979). Belk (1982), also found that gift situations varied substantially and other factors like expectations attached to gift giving played a confounding role and "Involvement" as a mediating variable could not explain the observed differences.

GIFT GIVING AS COMMUNICATION IN A RECIPROCAL EXCHANGE NETWORK

Gift giving is a form of reciprocal exchange where members of a network are obliged to give and receive gifts (Mauss 1974, Polanyi 1957). The obligation to give or receive gifts is usually implicit (Harris 1978). Gifts are exchanged among friends and relatives and rarely among strangers, and the closer the relationship the less explicit the rules governing the transactions (Sahlins 1972). Gift giving is more than a system of material exchange supplementing or substituting markets or hierarchies. It is also a system of communication (Bourdieu 1979) binding a community and yet allowing individuals and groups to retain independence and maintain individuality (Sahlins 1972).

Gifts are exchanged in a network of households and maintained by a regular flow of gifts (Bourdieu 1979). In urban communities the network consists of both relatives and friends with whom frequent contacts are maintained through gifts of food, hospitality, goods and services to strengthen the bonds of the network. A strong network becomes a system of support and a source of strength and comfort in times of need in an uncertain world. The maintenance of such networks, representing commitments of rights and obligations, requires substantial material and symbolic effort. Time becomes the most precious of gifts because the value of symbolic effort can only be defined with reference to the time spent on the maintenance of alliances (Bourdieu 1979).

Gift functions as a communication symbol precisely because its message is ambiguous (Sahlins 1972). The giver must match intentions and feeling with what receivers would appreciate in a given context. On the other hand, a meaningful gift makes the interpretation of the message imprecise. This ambiguity allows contradictions of economic and social interests to coexist and fuse and allows the expression of individual and social values and prevents their coming into overt conflict. Social and self-interest exist in what Sahlins calls a "diplomatic truce." The ambiguity of the gift exchange makes

allowances for unintended assumptions and permits a retreat from them.

QUADRANT B: GIFTS AS SYMBOLS

In over one hundred self-reports collected for this research, consumers support the contention that products operate symbolically in gift giving, where respondents describe their personal experience with gift giving and receiving. Two typical self-reports illustrate that gifts act as metaphoric symbols. Exchange of Gifts create ambiguity and tension and bring richer interpretations to the relationship. The self-reports illustrate the importance of concepts of time, obligation, ambiguity and the coexistence of economic and social interest.

SELF REPORT 1

"A high school friend whom I had not seen for many years was going to have a baby. When the baby was born I bought a baby ointment with a plant in it as a gift and went to see her. The gift was very inexpensive. I was a little nervous, a little anxious. When I entered the room she was so overjoyed that I almost forgot to give her the gift. She said that it was thoughtful of me to visit her and bring her the gift. Seeing her happy was the best part of the visit. I feel that if you give someone something it is not what you get out of it that matters. You are giving a part of yourself."

The narrator feels tension and anxiety prior to the encounter with the friend because it has been a while since the two have met. People change and forget old friendships. The uncertainty is real. The narrator knows that frequent contacts sustain relationships. But it has not been the case here. Moreover, the encounter is emotionally charged by the birth of the child. The choice of the event is strategic; but the gift is inexpensive. It is quite possible that the narrator's true gift, the gift of time, may not be appreciated. But the anxiety is dispelled by the warmth of the greeting and the friend appreciates the true gift, the visit. The gift now symbolizes this reunion and speaks metaphorically with its own voice as a *nonce* symbol.

Self Report 2

"When I was two my father became an alcoholic, and in the next few years lost his business, became bankrupt and left the house. Our family dropped from a comfortable middle class status to below the poverty line. The year my father left I was told that he had to leave for a while. But as time passed I realized that he was not coming back. Soon December 25th arrived. There were a few packages under our pine tree. As my brothers and I started unpacking the gifts I saw my mother looking very unhappy. The suspense of what was in the package was burning inside me. I wanted to unwrap the package, yet I felt this strong urge to be close to my mother. I ran to her and kissed her. She embraced me and began to

weep. I don't think my mother has ever held me tighter in her arms than on that day in year 1965. Since then our family has progressed. Nevertheless I will never forget that day in my mother's arms. We gave each other something we will never be able to purchase in a store. We gave each other a hug that brought love and security."

The gifts symbolizes the absence of the father, and the need for the mother and daughter to be close to one another. The narrator reciprocates the mother's gift and responds to the mother's need by hugging her, strengthening their bond. The gift now symbolizes the absence of the father and the bond between the two women, and a determination to face the future. The daughter recognizes the mother's sacrifice and pain and accepts the father's permanent absence. The family's need for security and closeness is fulfilled by gift giving. The gift speaks within the context and becomes a *nonce* symbol.

These self-reports substantiate Belk's (1979) findings that gift selections depend on the giver's ideal self-concept, the nature of the occasion and the relationship to the recipient. These considerations make gift giving a more complex choice act than the selection of comparable products for personal consumption. Gifts mediate the relationship between the self and the other in specific contexts. The context makes the giver aware of the need to make an effort to select an appropriate gift to symbolizes the occasion, the relationship and the emotions. It makes the participants anxious and creates feelings of ambiguity. The gift succeeds if the recipient appreciates it. The context provides opportunities for meaningful communication. The interpretation of this communication requires that the gift giver and the receiver both simultaneously and reciprocally interpret the gift through a shared knowledge of circumstances making the gift choice difficult and time consuming.

COMMUNICATIONS IN QUADRANTS C & D

Self-consumption normally functions as a sign. But sometimes it functions as a symbol when we give a gift to ourselves (C). Similarly, gift normally, functions as symbol. But sometimes it can become a sign and refer to a code (D).

QUADRANT C: SELF-GIFT

Normally a gift involves two people: the giver of a gift and its receiver. But sometimes a person can also give a gift to one's own self (Levy 1982; Mick 1986). As symbols of self-dialogue such gifts differ from self-consumption of products. An individual can give a gift to the self as a reward for the accomplishment of a task, to reassure the self, or to assert personhood. Thus what may appear as self-consumption (a sign) indicating social function, position or status, may in fact function as a personal symbol.

In the film "Crimes of the Heart," Diane Keaton, a lonely middle aged single woman, thinks

her family has forgotten her birthday. She gets a cookie for herself, lights a candle on it and sings "Happy Birthday" to herself. She gives herself a birthday party the others forgot to give her. Her gift to herself accentuates her loneliness but also affirms her selfhood. There are many such examples of self-gift in real life like the vacations as a reward after a year of hard work. But when families discuss their vacations with their friends these often become signs of their status, competition and success.

Self-consumption thus communicates in two contexts simultaneously. In one, the dialogue is private, with the self, and has a personal meaning. The self-gift becomes a *nonce* symbol (C), but conspicuous consumption is a sign, a part of the code to be interpreted by others in a fixed way (A).

QUADRANT D: OBLIGATORY GIFT AS A SIGN

Obligatory gifts to others function as signs rather than symbols (Quadrant D). Sending obligatory greeting cards and thank you notes to friends is an example, where the cards act as a reminder of events and the self and become a gesture of social mannerism. Scammon, Shaw and Bamossy (1981) found that flower purchase patterns differed for people buying flowers to fulfill obligations and those buying flowers as spontaneous gifts. The obligatory purchase was less personal and simple. Ryan (1977) and Heeler, et al. (1979), found that obligatory gifts were purchased more quickly than products for self use. A thoughtless gift often leaves one feeling cheated. When people without investing themselves give gifts to meet an obligation, the gift becomes a mere gesture, and acts as a sign of unauthenticity. A respondent echoing this sentiment said: "although I enjoy giving gifts on birthdays and other occasions, I much prefer giving something when it is not expected".

Sometimes people assert their dominance and status through gifts. Such gifts are often resented. The hand-me-downs which rich relatives bestow on their poorer cousins is one such example. Once Richard Lee, an anthropologist while working among the Kalahari bushmen announced his intention to present them with a fat ox on Christmas. His announcement was met with ridicule. They said his gift was a poor and thoughtless choice. At the feast however, the ox was devoured with gusto. Lee perplexed at this behavior asked for an explanation and received this response: "Yes, we knew what the ox was like but when a young man kills much meat (and distributes it to others) he thinks of himself as a chief and (looks at) the rest of us as his inferiors. So we always speak of his meat as worthless...(to) cool his heart and make him gentle." (Harris 1978, p.107-108). Gifts such as these assert dominance in relationships and become gestures of power or prowess and may seek to humiliate the recipient. Such gifts violate the spirit of reciprocity and the norm of equality in close relationships. Eskimos have a proverb: "[Such] gifts make slaves, just as whips make dogs," (Harris 1978).

SUMMARY

Communication in self-consumption is based on a generalized code. A sign activates a set of prior perceptions and attitudes generalized in the code. The character of sign requires that consumers use a set of related products for successful communication. The deterministic character of signs encourages people to manipulate the stereotypes to their strategic advantage. The fixity of the generalized code makes self-consumption easier to interpret.

The gift giver makes gifts unique to communicate the complexity and ambiguity of relationships. Not all gifts are equally complex. The authenticity of the relationship determines the extent of sacrifice of time and money involved in gift giving. Gift communication is harder to interpret. The gift object requires fresh and unique interpretation in each new context. The giver must communicate the investment of time and effort without being explicit. The dynamics of the relationship rather than the fixity of the partners, makes gift giving possible and meaningful.

Retrieval Inhibition and Related Adaptive Peculiarities of Human Memory

Robert A. Bjork, University of California, Los Angeles

Marc Vanhuele, University of California, Los Angeles

ABSTRACT

The functional properties of the human as an information-processing device differ in significant ways from the corresponding properties of the standard digital computer. One such important difference is that items in human long-term memory (e.g., names, numbers, facts) differ greatly in accessibility--that is, in the likelihood that they can be retrieved (recalled) when needed. Retrieval of information from long-term memory is erratic, probabilistic, and context dependent in ways that would seem intolerable in the search of a computer's memory.

From one perspective, the unreliable nature of the retrieval of information from human memory seems nothing more than a weakness of the system. From another perspective, however, the retrieval failures we suffer are a by-product of a system that is, overall, adaptive. Given the virtually unlimited storage capacity of human memory, and the relatively slow rate of neural transmission, we do not *want* everything in our long-term memories to be accessible, particularly when that information is irrelevant or out of date (such as where we left the car *yesterday*, or the address where an important business associate *used* to work).

We argue herein that the pattern of accessibility across items in memory changes in dynamic and adaptive ways as a consequence of input (presentation) events, output (recall) events, and shifts in environmental, social, and mood-state cues, and that inhibitory processes (and recovery over time from such inhibition) play a central role in such changes.

INTRODUCTION

In general, we have a poor understanding of how our own memories work. Our assumptions, usually implicit, about how we store (or do not store) and later recall (or do not recall) information are wrong in most important respects. As a consequence, we do not use our memories efficiently, nor do we have appropriate expectations as to what our friends, family members, and co-workers will or will not remember on the basis of our interactions with those individuals. Faulty assumptions about human memory also result in poorly designed instructional programs in educational, industrial and military settings and--in the consumer domain--less than optimal marketing and advertising programs.

It is surprising, from a trial-and-error standpoint, that we do not learn more about the characteristics of our own memories. Our experience would seem to provide each of us with extensive feedback as to the circumstances in which our memories succeed and fail. There are two reasons, in our opinion, why individuals do not gain a good understanding of human memory based on experience alone. First, there is the simple fact that

introspection, as demonstrated across many fields in psychology, is of limited value in learning about ourselves. Second, and of more importance for present purposes, is that people understand the basic characteristics of man-made devices, such as a tape recorder, or the memory in a computer, better than they understand the characteristics of human memory, and they assume, (implicitly) that human memory works in roughly the same fashion. Given that the characteristics of human memory differ in most important respects from the characteristics of such man-made devices, we end up with a seriously flawed mental model of our own memory system.

Among cognitive scientists, there is a growing realization that they, too, like the hypothetical layperson referred to above, may have been misled by an inappropriate analogy between man and machine. For several decades, the information-processing approach to the study of human memory, based on the assumption that the processing of information by humans is roughly analogous to the way programs run on a serial digital computer, dominated research on human memory. (For a good example of such flow-chart models of memory, see Atkinson and Shiffrin 1971; and see Bettman, 1979, for an elegant extension of such models to consumer behavior.) In the last half of the 1980s, however, a variety of empirical and theoretical developments in the behavioral, brain and clinical research domains have convinced cognitive scientists that the basic information-processing architecture in humans differs dramatically from the processing architecture in the typical computer. It is beyond the scope of the present paper to summarize those developments in any detail. A major factor, however, was the emergence of PDP (parallel distributed processing) models based on an analogy to neural networks (see, e.g., McClelland, Rumelhart, and Hinton 1986). In general, it became increasingly apparent that the sequential nature of symbol processing in typical computers limits the extent to which they can simulate the complex cognitive processes characteristic of humans. Theorizing in the human-memory field has entered an era in which a brain metaphor is replacing a computer metaphor.

One consequence of the long-term dominance of the computer metaphor was to bias the types of processes researchers hypothesized within their theories. It was natural to postulate buffers and more permanent storage systems of various types, and to postulate processes such as scanning, sorting, chunking, transferring, and filing. Among the processes it was *not* natural to postulate, are the inhibitory mechanisms that are the focus of this symposium. Across the last several years, researchers in several fields, particularly attention, memory, and language, have begun to argue that inhibitory processes are fundamental to human cognitive processes (see, e.g., Bjork 1989, Hasher and Zacks

1988, and Tipper 1985). It is the goal of the present paper to argue that the inhibition of retrieval access to items in memory, and recovery from such inhibition over time, play an important and adaptive role in the everyday functioning of human memory. Before we pursue that argument further, it is necessary to describe some important characteristics of storage and retrieval processes in human memory.

RETRIEVAL PROCESSES VERSUS STORAGE PROCESSES

Retrieval

A fundamental property of human memory, one that is highly familiar to all of us, is that the retrieval of information from our memories is a fallible process. Names, numbers, and facts that are recallable without apparent effort on one occasion can be impossible to recall on another occasion. There is something erratic and probabilistic about the processes by means of which we attempt to gain access to items of information that, in fact, exist in our memories.

One source of such variation is that retrieval processes are cue-dependent: what we can and cannot recall at a given point in time is strongly influenced by the cues available to us, where such "cues" include not only stimuli bearing an associative relationship to particular items in memory, but also aspects of one's current environmental, emotional, interpersonal or body-state context. As Smith (1988) has pointed out, such contextual cues can be so powerful that we can be virtually a different person in different contexts--at a class reunion, for example, or a place of worship, or attending a little-league baseball game.

It is tempting to consider the fallible nature of retrieval processes as simply a weakness of the human memory system. When viewed in the context of the other characteristics of human memory we summarize below, however, and in terms of the real-world demands on our memories, the retrieval failures that are so typical of human memory are but one reflection of a system that is, overall, adaptive.

Storage

In contrast to the limitations on gaining access to stored information in memory, there appears to be essentially no limit on storage per se. Storing new information in long-term memory appears to be a process of interpretation--of relating the new information to existing knowledge. Items are stored in terms of their meaning, as defined by their semantic relationships to other items. For all practical purposes, there appears to be no limit on how much information can be stored via this process. In fact, rather than thinking of long-term memory as any kind of container, which would imply that there would be less room for new information the greater the amount of information already stored, it is more accurate to think of prior knowledge as creating additional capacity; The more that is already known in a given knowledge domain, the more ways there are to store additional information in that domain.

There is another sense in which the capacity of human memory is essentially unlimited: Once information is successfully embedded within the knowledge network that defines long-term memory, it appears to remain in storage essentially forever. Even the most overlearned and heavily used item of information, such as a prior home phone number or street address one may have had, eventually become non-recallable with a long enough period of disuse, but such forgetting is a matter of loss of retrieval access to such items, not a loss of their representation in memory per se. Such items can typically be recognized at a rate that greatly exceeds chance levels, can be relearned at an accelerated rate, and can often be recalled in special circumstances that reinstate certain cues from the past--all of which constitute evidence that such items have not been lost from memory in any absolute sense.

The storage and retrieval dynamics described thus far illustrate that it is inappropriate to think of memory representations as varying on a unidimensional strength dimension. In a so-called "New Theory of Disuse" Bjork and Bjork (in press) have argued that an item's *storage strength* (how well it has been learned or interrelated with other items in memory) must be distinguished from its *retrieval strength* (how accessible or activated the item's representation is at a given point in time). The retrieval strength of a given item can wax and wane as a function of events involving that item or its competitors.

RETRIEVAL DYNAMICS IN HUMAN MEMORY

Retrieval as a Learning Event

In devices such as a tape recorder and computer memories, retrieving stored items leaves those items in the same state they were in prior to being retrieved. In human memory, on the other hand, the act of retrieval is itself a potent event: The information retrieved becomes more retrievable in the future, and other items bearing certain types of similarity relationships to the retrieved items become less retrievable in the future. The successful retrieval of an item from memory is, in fact, considerably more potent as a learning event than is a presentation of that item for study, and the potency of an act of retrieval increases with how difficult or involved the process of retrieval is (see, e.g., Gardiner, Craik and Bleasdale, 1973, and Landauer and Bjork, 1978).

As certain members of a set of items associated to a given cue are made more accessible--that is, have their retrieval strength increased by virtue of further study or retrieval practice--other items in that set become less recallable. Providing some members of a set of items to be recalled, for example, impairs rather than helps the recall of the remaining. Such "inhibition from part-set cuing" (Nickerson, 1984) has been demonstrated with brand names in product categories (see below) as well as with the members of natural categories and lists learned in the laboratory. Retrieval practice on certain items associated to a given episodic or semantic cue impairs subsequent

recall of other items associated with that cue (see Anderson and Bjork 1990, and Bjork and Geiselman 1978). There is also evidence that the process of recall itself is a "self-limiting process" (Roediger, 1978); that is, in the process of recalling a set of items, the items recalled earlier become more accessible at the expense of yet-to-be-recalled items.

Retrieval Inhibition in the Updating of Memory

In assessing our own memory performance, we tend to think of remembering as good and forgetting as bad. Efficient use of our memories, however, depends, in a sense, as much on efficient forgetting as on efficient remembering. In a variety of different ways, on a range of time scales, we must update our memories. We need to remember our *current* phone number, where we left the car *today*, and how *this* word-processing program works, and so forth; it is not helpful to remember, instead, our old phone number, where we left the car yesterday, and how an old word processor worked. That is, we need some means to erase, set aside, or inhibit out-of-date information.

In man-made memory devices, we typically replace out-of-date information by an over-writing process that is efficient from one perspective (the out-of-date information cannot intrude if it has been obliterated), but is less than optimal from another perspective (what if we happen to need that information again?). In human memory, the primary updating mechanism appears to be retrieval inhibition. As we learn new information to replace old information, retrieval access to the old information becomes inhibited. Because recall of that old information is inhibited, it does not interfere with the recall of the new information, but the old information remains in memory to be recognized or relearned (at an accelerated rate), should that be necessary.

The foregoing characterization of the updating process in humans emerges from research on interference processes carried out decades ago (for a thorough review, see Crowder 1976), and from research on "directed forgetting" carried out more recently (see, e.g. Bjork, 1989, and Geiselman, Bjork and Fishman 1983). The typical procedure in the interference tradition involves having a subject learn a new response (e.g., words) to each of a set of stimuli (e.g., nonsense syllables) after having learned other responses to those stimuli. There is a clear, but implicit, instruction to subjects that they should suppress the original responses once the new learning phase begins. In the directed forgetting paradigm, subjects are typically signalled, at some point in learning a list of items, that they should forget the items they have tried to learn thus far--that these items were the wrong list, or practice list--and that they should memorize the upcoming list instead. In addition to the evidence from such procedures that implicit or explicit instructions to forget inhibit subsequent retrieval access to the to-be-forgotten items, there is also evidence that with time and intervening events there is a recovery of access to those items.

Regression and Recovery

A type of regression effect appears to be fundamental to human memory. When there are alternative or competing memory representations, one constructed more recently than the other, a period of disuse of either representation results in an increase in retrieval access to the earlier representation at the expense of the most recent representation. Thus, having known a woman friend by her maiden name prior to learning her married name, one may get to the point of recalling her married name without apparent competition from her maiden name, but after an extended period of being away from that friend it will tend to be her maiden name, not her married name, that is most recallable. The memory representations underlying motor skills are also subject to such regression. One may have practiced a new and different golf swing, for example, but after a period of not playing it is one's original swing that will be most dominant. The full dynamics of such regression effects are not completely understood. They show up in many types of behavior, in animals as well as humans, and are more pronounced under conditions of stress (for a more thorough discussion of such effects, see Bjork and Bjork, in press). It is also clear that the nature of the situational context cues--and their overlap with the conditions present at the time the earlier or later memory representation were constructed--plays a role. One factor that clearly contributes to memory regression, however, is recovery from retrieval inhibition. As a consequence of constructing and using a newer representation, access to the older representation is inhibited, but with disuse of either representation--and a loss (possibly rapid) of retrieval access to the newer representation--the dominance relationships will change, especially if the older representation was better learned and more highly practiced initially.

ADAPTIVE ASPECTS OF THE SYSTEM

Looked at in isolation, each of the characteristics of human memory discussed above seems unusual or peculiar when compared to the characteristics of man-made recording devices. Taken in combination, however, and viewed in terms of the memory problems the world poses for us, there are some clear adaptive features of such a system.

If we take as a starting point that humans are remarkable as storage devices, and that there are obvious advantages of having virtually unlimited capacity in that domain, the limitations on retrieval access can be viewed as a necessary filter. In the interest of speed, accuracy and avoiding confusion, we do not *want* every item in our memories to be accessible. When asked for our current home phone number, for example, we retrieve that number without entertaining alternatives, even though prior home phone numbers exist in our memories. We could, as certain computer routines might do, retrieve all the numbers with a home phone tag in our memories and then engage a decision process to decide which one is our current number. Such a process would be slower certainly, and more error prone as well.

The fact that retrieval access is heavily cue-dependent, and that retrieving an item makes that item more retrievable in the future, means that, in general, the most accessible items are those we need in our current situation. On the one hand, cues of various types will tend to enhance access to memory representations that are most relevant to the current context. On the other hand, the most accessible items in memory will tend to be those we have been accessing the most in the recent past, which--statistically--will tend to be those we need the most in the near future as well.

The fact that it is retrieval access, not the item's representation in memory per se, that is lost as a function of subsequent learning has adaptive aspects as well. Because the item remains in memory, it will often be recognized and identified as an old item, which can be useful in various ways. Should that old item become pertinent again (the hypothetical woman friend of yours referred to earlier gets divorced, e.g., and returns to her maiden name), regaining full retrieval access to the item is a very rapid process.

Finally, the regression and recovery phenomena referred to above can have adaptive aspects as well. What will it tend to mean if one stops using the more recent of two competing memory representations? Suppose, for example, to pick quite multifaceted memory representations, that you have spent a year in England driving a leased automobile. To drive successfully during that year, and to stay alive, there are many aspects of your earlier habits (corresponding to driving your own car in the United States) that you need to inhibit. When you stop driving in England, however--which we can presume means that you have returned to the United States--it will be very useful if those inhibited habits recover in strength. As that example illustrates the conditions that result in our ceasing to use more recent representations will often also result in less recent representations becoming relevant. It will be adaptive, therefore, if access to those representations recover.

IMPLICATIONS FOR CONSUMER RESEARCH

Marketing

Several recent studies suggest how marketers can use advertising and point-of-purchase displays to activate inhibitory mechanisms in memory. This may help them gain a competitive advantage in situations where recall is a major determinant of consumers' choices, such as when none of the alternatives are physically present (e.g., when writing down a shopping list or choosing a restaurant) or when not all competitors can be found at the same location. Having subjects think about one or more particular brands not only increases the salience in memory of these brands, and the likelihood they are considered for purchase, but also can inhibit the recall of other product category members that otherwise would be candidates for purchase (Alba and Chattopadhyay 1985a, 1986; Miniard, Unnava and Bhatla 1990). This retrieval inhibition phenomenon--referred to

earlier as the part-set or part-category cuing effect--has also been demonstrated for recall of product attributes (Alba and Chattopadhyay 1985b). Marketers apparently can choose the product dimensions on which they want to be judged *and*, at the same time, inhibit consideration of alternative dimensions on which their competitors are superior.

In a similar vein, Keller (1991a, 1991b) shows how recall of the communication effects for a particular advertisement--that is the content of the advertisement and the responses to this content--can be impaired by the presentation of advertisements for competing brands in the same product category (see also Burke and Srull 1988). This inhibition effect even occurred within a group of advertisements of the same valence, presented in the same experimental session (Keller 1991b).

Because successful retrieval of an item strengthens the representation of that item in memory, a marketing campaign that initially influenced recall may have prolonged effects. From a memory perspective, each new purchase and usage of a brand further inhibits consideration of its competitors. Because retrieval of an item is a more potent learning event than the mere exposure and processing of that item, advertisers may want to trigger retrieval attempts in their audience during the presentation of commercial information. A campaign with a series of consecutive commercials in which each, implicitly, refers to the previous "episode" of the series can stimulate recall activities. Similarly, radio messages may contain cues that trigger the recall of the visual elements of a television commercial in the same campaign. These synergistic effects should enhance memory retrieval of the focal brand and inhibition of its competitors.

Consumer Memory

As explained above, memory inhibition may be considered as a fundamental weakness of our memory systems, making us vulnerable to marketing influences that lead to suboptimal consumer decision making. From a more general perspective these effects can be looked upon as an--unfortunate--by-product of a complex of mechanisms that, given the constraints of our memory structure, serves our overall needs. The global advantages of the combined mechanisms of activation and inhibition are most apparent when one follows the memory representation of interrelated sets of knowledge across an extended period of time. Unfortunately, memory researchers have little hard evidence to offer to enhance our understanding of storage and retrieval of complex information in a long-term perspective. Traditional memory research methods (in particular the proverbial memory experiment with a study trial, distractor task and memory test in a single session with simple materials, such as nonsense syllables, to be remembered) do not address these dimensions. It is more important to examine the acquisition of knowledge on the basis of experiences which are distributed in time. During intervals between these exposures, access to the knowledge of interest will be impaired as a consequence of previous and new

presentations of related information. An interesting and unique attempt to follow these cycles of acquisition, loss, and reacquisition over time can be found in Bahrack (1979).

To illustrate our general claim about the adaptive features of inhibition, we have to resort to the description of a hypothetical case, which the reader probably can link to personal anecdotal evidence. Consider an individual's history of experiences with a frequently purchased branded grocery product such as breakfast cereals. Most of us have already tried out multiple offerings in this product category. Promotions and special pricing entice us into trying previously unknown brands, satiation with known brands and the desire for variation may cause periodic switching between brands, and our mother, or spouse, or friend, having invited us for breakfast, may urge us to try a particular brand, either because they like that brand or because they think it is exactly what we need. Ideally, the complete set of experiences with each of the alternatives should be available at each purchase occasion to allow us to make an optimal choice. Time constraints evidently prohibit consideration of all this information, and the processing costs would outweigh the expected benefits. Some of the product knowledge may even be completely irrelevant, for instance, because an alternative may have disappeared from the market. Even a random draw from the pool of currently available alternatives will not be maximally informative: preferences and tastes tend to change with time and aging, and social forces also have an impact on how appropriate certain choices are. In many product categories there is therefore no absolute best choice for a particular person across all purchase occasions. Time and context dictate the best choice. Someone on a diet now would probably like to suppress recall of his or her once favorite Chocolate Sugar Crunch cereal. One may be praised as a beer connoisseur in this country, for ordering Heineken, while the second author's Belgian friends would certainly frown upon this choice.

Within certain constraints, recently acquired or activated information will be most relevant to our current decisions and choices and will be most easily recalled. Products and brands that we can recall now without any effort, for instance when writing down our shopping list, are those that we retrieved from memory, purchased or encountered in the recent past. Those are the ones which best serve our needs, given our current taste, social status, and dietary needs, and given this season's fashion and the current state of technology. (A recent disappointing product trial will also be salient. The product will first be consciously avoided and then gradually lose its salience.)

Activation mechanisms, without inhibition being involved, could produce most, if not all, of these desirable effects. A change in context may, however, make highly active information completely irrelevant for present purposes. The retrieval of recently activated, but now irrelevant, information would not only slow down our performance but could also lead to suboptimal choices. Fortunately, the new set of memory cues that becomes available with a

change in context not only activates a new set of knowledge, but also inhibits possibly competing, but now obsolete, information.

People who regularly spend time in a different country can experience how easily they can recall the different brands of a product that are unavailable in the U.S., given the proper retrieval cues, and how little interference there is from American brands in the same product category that are not distributed in that country. Similarly, current middle-aged shoppers for a television set will not search for one of the many American brands that were available before Japanese electronic companies started dominating the market. Even without conscious learning attempts, our knowledge about market evolutions is constantly updated by the dual mechanisms of activation and inhibition. On the other hand, the features of our first, now almost historic, television set can be retrieved when recollecting personal experiences and anecdotes. Interestingly, our discussion about inhibition also illustrates that recognition may be a less relevant criterion for advertising effectiveness than some authors (e.g., Singh, Rothschild and Churchill 1988) claim. Relying on recognition alone to make a choice would be too time-consuming and overwhelming in today's complex choice environment, and would generate too large a consideration set. So even when all alternatives are visually present, recall (and inhibition of recall) play an important role that is functional in satisfying our needs, with a minimum of cognitive effort.

CONCLUDING COMMENT

There is within human memory a complex interplay of storage and retrieval processes. The pattern of items that are accessible and non-accessible shifts and fluctuates as a consequence of new learning, retrieval practice, and changing contextual cues of multiple types. We have attempted to argue herein that inhibition and competition are as important in the dynamics of such shifting patterns of access as are processes of activation and association.

Consideration of Inhibition as a Mechanism in Decision Processes

Mary Frances Luce, Duke University

ABSTRACT

This paper explores the implications for choice which result from abandoning the capacity model of attention for the selection for action model. Specifically, the likely role of the process of inhibition in choice is discussed. Functions which inhibition may fulfill during choice are proposed. For instance, inhibition may operate upon representations of attractive but nonchosen alternatives, allowing the decision maker to move forward with a minimum of cognitive conflict. Predictions regarding the amount and direction of inhibition during choice are also offered.

The fields of decision theory and marketing have traditionally borrowed from cognitive psychology in order to predict and explain decision making. The capacity model of attention, which has been dominant in cognitive psychology for some time, has often been utilized to explain choice behavior. Criticisms of, as well as alternatives to, the capacity model have recently emerged. The selection for action model, a dominant alternative, stresses the importance of inhibitory processes to cognitive functioning. This paper will consider the choice process within a selection for action framework, concentrating upon inhibition's possible role in choice.

MODELS OF ATTENTION

General capacity or resource views of attention cite a limited supply of cognitive resources as the reason for limitations in cognitive functioning. Several compelling criticisms of the capacity view, which in total leave much doubt as to its viability, have been formulated (e.g., Navon 1984; Neumann 1987). The capacity model is likely unfalsifiable and methods which are purported to test this model have alternative explanations (Navon 1984). Resources defy definition, and methods used to determine resource utilization or availability usually yield conflicting results (e.g., Navon 1984). For instance, it is often proposed that one can deduce resource requirements by measuring interference found between concurrently performed task pairs. However, results in these dual task studies are highly dependent upon the specific structure of each task. These conflicting results led to the suggestion that distinct resource pools exist and that tasks will interfere with each other to the extent that they draw upon identical pool(s). However, even multiple resource views cannot with any degree of parsimony account for both the extremely specific (i.e., based upon task similarity) and the general (i.e., present with any task combination) interference found among dual task combinations (Hasher and Zacks 1988; Neumann 1987). Finally, it is unclear at what stage in information processing the resource "bottleneck" manifests itself, for humans are quite capable of

parallel information processing prior to overt response (e.g., Neill 1989).

An alternative to capacity views, selection for action models generally seem to account for data better than and avoid the many theoretical difficulties of capacity models. These models take a more functional approach, searching for *sources* of attentional limitations. The most obvious source of limitation in information processing results directly from motor limitations. Simply, some mechanism must prevent physically incompatible actions from being attempted, for such attempts would preclude coherent physical or mental activity (e.g., Neumann 1987). A second source of limitation is inferred from the fact that information streams may apparently become confused during processing. For instance, in the Stroop paradigm, subjects required to name the ink color of a word are slowed when the word spells a different color. In other words, multiple, often conflicting representations of stimuli must be narrowed down so that (ideally) only task relevant information is sustained in consciousness (Neill 1989). These motor- and information-based limitations are often discussed separately; however, interference among information streams may result from the fact that such streams often have incompatible implications for action. For instance, in the Stroop paradigm, incompatible tendencies to speak two different color names may arise. Thus, all cognitive limitations may ultimately be traceable to the motor system.

Selection for action authors propose that attention operates to suppress representations which potentially conflict with one's ongoing stream of action (e.g., Neill 1989; Neumann 1987). This is necessary to avoid attempts to complete physically incompatible actions. Of course, physically compatible actions are also frequently prevented. This may happen because the brain operates by a simple blocking mechanism, with one ongoing action or set of actions typically suppressing all others (e.g., Neumann 1987). This apparent inefficiency in attention is likely necessary because there is no "central executive" with sufficient knowledge to ascertain which actions are incompatible. Thus, while capacity models explain most cognitive limitations as resulting from an inadequate resource supply, selection for action models view these same limitations as resulting from active inhibition. This emphasis upon inhibition is likely the most significant departure of the selection for action model from the capacity model. Empirical evidence for active inhibitory processes may be taken as support for the selection for action view; this evidence is reviewed below.

Empirical Demonstrations of Inhibition

There is abundant evidence that inhibition operates in lower level cognitive processes. In selective attention tasks, an ignored stimulus is generally disadvantaged when it is the stimulus to

which the subject must respond on the subsequent trial (e.g., Hasher and Zacks 1988). This indicates that an active inhibitory process acts upon the representations of distractors. For example, if during a Stroop task the ignored word on trial one is identical to the ink color one must name on trial two, response times for the second trial lengthen (e.g., Neill and Westberry 1987). This general pattern of results has been found numerous times using many attention tasks (e.g., Driver and Tipper 1989; Neill, Lissner, and Beck 1990).

More important to my hypotheses concerning the relationship between inhibition and choice, inhibition has been implicated in higher level cognitive processing. Bjork (1989) proposes that a process of retrieval inhibition operates, beyond effects of differential rehearsal, to eliminate access to items which subjects are instructed to forget. Retrieval inhibition may also be inadvertently produced; for example, rehearsal may result in a loss of access to related information (Bjork 1989). Inhibition may operate within comprehension, suppressing words' alternative meanings and irrelevant associations (e.g., Hasher and Zacks 1988; Simpson and Kellas 1989). Simpson and Kellas (1989) find slower responses to a word related to one meaning of an ambiguous prime when the prime has previously been paired with a word related to a different meaning. For example, their subjects are slower to respond to the word "money" after the prime "bank" when they have previously responded to "river" after "bank." This and other empirical work indicates that inhibition is an active, goal directed process which decouples representations from consciousness and/or from action control.

CHOICE

Decision theorists are painfully aware of man's limitations as an information processor. For instance, individuals do not seem capable of trading off or otherwise combining more than a few attributes during decision making (e.g., Shepard 1964). Capacity limits have, at least implicitly, been accepted as the explanation for observed limitations in decision making. Given the compelling criticisms of capacity models, it may be useful to explore alternative causes of these limitations, such as those implied by the selection for action model.

It is not immediately apparent what abandoning the capacity model for the selection for action model implies for choice theories. This new model uniquely predicts that inhibition will play a central role in cognitive functioning, but what understanding or new hypotheses does the process of inhibition add to choice? This question is addressed below.

Inhibition in Choice

Alternatives in choice almost invariably elicit conflicting action tendencies, or the desire to approach (i.e., to buy) more than one alternative simultaneously. It will very likely cause conflict to give up any attractive alternative(s) when one is not absolutely certain that one's choice is optimal. Such

certainty in choice seems unlikely, especially given that people often do not know what attribute levels they do or will prefer (e.g., Shepard 1964). Hence, choice is inherently laden with conflict. Limits apparently exist on the amount of conflicting information one can comfortably sustain in consciousness (e.g., Neill 1989). In choice, individuals may be limited by this inability to sustain cognitive conflict rather than by resource supplies.

Processes which allow a decision maker to deal with conflict in choice have been proposed. Individuals may selectively attend to goal related information, encoding only items which will bolster or protect their current intentions or decisions (Montgomery 1989; Kunda 1990). Montgomery (1989) describes decision making as dominance structuring, or the search for a cognitive representation in which the chosen alternative is best on every relevant attribute. Such a representation may be possible only if the decision maker restricts her attention to a subset of alternatives and attributes, ignoring those which violate dominance (Montgomery 1989).

Inhibition may operate within dominance structuring or other cognitive processes to eliminate conflict in choice. Decisions have been proposed to result from temporary states of mind which allow one alternative to seem best (Shepard 1964). These temporary states of mind may be attained by inhibiting representations of alternatives, attributes, and/or specific alternative/attribute values. Inhibition may operate to decouple all but the chosen alternative from the control of action. The inhibition of problematic attributes may allow choice to proceed without the completion of difficult trade offs. For instance, a car buyer who is unable to decide how much he is willing to pay for an additional "unit" of safety may simply inhibit safety considerations. People may inhibit disadvantages of their chosen alternative and/or advantages of other alternatives. In summary, inhibition may selectively restrict the activation of information, producing a cognitive representation in which one's chosen alternative seems more like a dominating alternative than it is in any objective sense.

P1: Immediately after choice, a individual should display:

- a.) inhibition of items inconsistent with dominance.
- b.) more difficulty retrieving these items than retrieving items consistent with dominance.

The inhibition proposed above, and discussed in several later propositions, would be indicated by a longer latency in responding to (i.e., naming) an item than in responding to a control item.

Long Term Effects of Inhibition. An inhibition framework implies ways in which successive choice outcomes may be related; capacity models, in contrast, do not directly address these relationships. Inhibition may have enduring effects

upon thoughts which an individual has reason to escape. Relatively permanent inhibition may operate upon items such as the disadvantages of one's chosen alternative. Inhibitory pathways analogous to the associative links developed when two thoughts are simultaneously rehearsed may cause one node to automatically *inhibit* another. If so, inhibition during choice should make consideration of a chosen alternative's disadvantages less likely and therefore should correlate negatively with post decisional regret or cognitive dissonance. Further, long term inhibition acting upon nonchosen brands could cause resistance to their reconsideration. This resistance may hold even after preferences and/or product attributes have changed, perhaps making an inhibited brand optimal. This process could operate to create and maintain brand loyalty. Inhibition may also underlie the demonstrated tendency for chosen alternatives to be remembered best (Johnson and Russo 1981) and the low probability of choosing a previously rejected brand even when new information makes that brand more attractive (Biehal and Chakravarti 1983).

Factors Influencing Inhibition

The following sections will focus upon the influence which situational factors and goals may have upon the direction and magnitude of inhibition in choice. Two situational factors are discussed: the overall nature of the evoked set and agenda effects. The discussion of goals focuses upon the effect of effort/accuracy trade-offs upon inhibition. The relationships hypothesized below may not be apparent when using a capacity framework to understand decision making.

Situational Factors. Inhibition seems to operate rather selectively upon representations which have the potential to produce confusion or conflicting response tendencies (e.g., Neill 1989). Therefore, one may be able to predict the target(s) of inhibition by determining the likelihood of conflict. For example, conflict in choice seems more likely to the extent that alternatives are close in expected value. Therefore, when alternatives' values are close, inhibition, especially inhibition of nonchosen alternatives with relatively high expected values, should rise. Attributes on which the chosen alternative is weak may also show increased inhibition in this case.

Inhibition may dampen activation of material that is extraneous to the choice process as well as information causing conflict. The functions of eliminating conflict and of suppressing irrelevant information may have conflicting implications for the inhibition of any one item. Material which is completely irrelevant to choice should not produce conflict, and vice versa. For example, dominated alternatives may produce no conflict, but they may be clearly extraneous to the decision process. Therefore, it is difficult to determine whether a dominated alternative will be inhibited. However, situational factors may allow for such prediction. For instance, it seems that alternatives dominated by the chosen alternative will not be inhibited because they can be

profitably incorporated into a dominance structure, and therefore are not truly irrelevant to choice.

P2: Inhibition should operate upon:

- a.) information which produces cognitive conflict.
- b.) extraneous information activated during choice.

More specific hypotheses are also possible, such as:

P3: As a non-dominated alternative's expected value becomes closer to that of the chosen alternative, inhibition of that alternative becomes more likely.

P4: Dominated alternatives are likely to be inhibited, unless they are dominated by the chosen alternative.

The above analysis is very different than the one which a capacity viewpoint would yield. The selection for action framework uniquely implies that one's ability to simultaneously consider a number of alternatives will vary as a function of the relationship(s) among the alternatives, rather than strictly of available capacity. For instance, this framework implies that a large dominance structure may be more easily maintained in consciousness than a smaller amount of information relating to severely conflicting alternatives. Stated differently, information overload is no longer strictly a function of the difference between available capacity and externally available "bits" of information. Information overload may occur due to incomplete inhibitory processes and may be indicated by sustained activation of extraneous or conflicting information. This break down may be correlated with both the amount and the type of information available.

P5: Information overload is more likely as:

- a.) more information is available.
- b.) pieces of information related to a choice conflict with one another more severely.

Again, it is also possible to develop more specific predictions, for example:

P6: Subjects will be better able to process and to recall a given amount of choice information as that information more closely approximates a dominance structure.

A second situational factor which may affect inhibition is the order in which alternatives or attributes are considered. Inhibition in attention tasks is most likely once an individual focuses upon a candidate for response (Neill 1989). During decision making, a tentative choice is analogous to a candidate

for response. Much of the choice process seems to involve a building up of one's intention toward such a tentative choice (Montgomery 1989). Once one alternative is tentatively accepted, any information which indicates that this alternative is not best will potentially cause competing action tendencies, and so may be inhibited. It seems likely that there is some arbitrariness to which out of an acceptable set of alternatives becomes the tentative choice, given that preferences are not always well defined; thus, inhibition may be subject to agenda effects.

P7: Items which are processed earlier will have a lower probability of becoming inhibited than items which are processed later will have.

Note that this proposition implicitly assumes that the individual is processing by alternative, at least during the earliest stages of choice. The order in which attributes are considered may likewise influence which alternative first becomes the tentative choice, especially during more attribute-based processing (Montgomery 1989).

Goals. The selection for action framework often emphasizes the apparent goal directedness of inhibition (e.g., Hasher and Zacks 1988; Neill 1989). This framework implies that more complete information processing is possible if the decision maker adopts the appropriate goal(s). On the other hand, the capacity framework implies that information processing is simply possible before and impossible after a decision problem reaches some level of demand for capacity. Again, the selection for action model uniquely implies situational variance in individuals' abilities to process information.

If inhibition is goal directed, the decision maker's goals should directly influence the choice process. Inhibition may be driven by the extent to which the goal of minimizing effort (versus maximizing accuracy) is prevalent. Inhibition may act as a substitute for effort during choice, allowing confidence in a decision although all of the appropriate comparisons and trade-offs are not made. Hence, as one's relative emphasis on minimizing effort rises, more inhibition should be observed in choice. Of course, inhibition may also be necessary when an individual has made the most accurate choice possible, for choice will almost always involve both conflicting and extraneous information. Still, if accuracy is foremost, inhibition should be relatively less prevalent, allowing more complete memory search and decision processes.

Further, specific goals have been hypothesized to enhance the accessibility of information consistent with them (Kunda 1990). Perhaps inhibition is the mechanism through which this occurs. For instance, some motivation to buy one brand may initiate inhibition of that brand's most attractive competitors.

P8a: Within a given level of confidence in a given decision, inhibition and effort will be inversely related.

P8b: Goals of accuracy and effort should have inverse effects upon inhibition's magnitude while more specific goals should influence inhibition's direction.

The goal to minimize effort may be somehow "hardwired," or present unless an individual makes considerable effort to overcome it. Effort minimization, and the concomitant inhibition, may have adaptive value in many decision situations. Neumann (1987) discusses the problem of picking a path of escape from a predator. In such cases, unwavering commitment to a course of action is often more important than which alternative course is actually chosen. Inhibition may serve the crucial function of eliminating doubt, therefore allowing the chosen alternative to be executed as quickly and completely as possible. This is also consistent with Shepard's (1964) assertion that the primary goal in choice is to escape the conflict of the decision situation. Situational factors, such as involvement, will likely influence the extent to which the decision maker desires to make a truly accurate choice.

CONCLUSIONS

This paper represents an attempt to develop the implications for choice realized by utilizing an alternative to the capacity framework of attention. In general, it seems that decision researchers would be well served to abandon the computer metaphor for a brain metaphor acknowledging the parallel processing, and the excitation and inhibition, which underlie cognitive functioning (Bjork 1989). Part of this process will likely involve abandoning the capacity model which has been heavily influenced by the computer metaphor (Bjork 1989; Navon 1984). It is hoped that this work provides a small step toward such a paradigm shift.

Investigation of inhibition in choice is important for a broader reason than its impact upon consumer and decision making research. Inhibition has the potential to be a powerful unifying principle in psychology, illuminating topics from perception (McClelland and Rumelhart 1981) to choice. In fact, the principle of inhibition may have the considerable unifying power often attributed to the capacity metaphor. The finding that inhibition operates in choice would be evidence for such unifying power.

Driving Passions: Vehicles and Consumer Culture

Michael R. Solomon, Rutgers University

OBJECTIVE OF THE SESSION

Few consumer researchers would dispute the contention that automobiles and other vehicles have evolved into some of the most significant material objects in popular culture. This special session focuses on some of the relationships between vehicles, consumers, and popular culture from a variety of perspectives.

BACKGROUND

Cars and other vehicles both shape and reflect consumer behavior processes, especially because they often serve as an important extension of the self and as a mediator of self-concept (cf. Belk 1988; Flink 1988; Marsh and Collett 1986; Solomon 1983):

- They have significantly influenced demographic patterns (e.g., by providing the catalyst for suburban development)
- They have affected social relationships (e.g., by facilitating changes in sexual mores via drive-in movies, "lovers lanes," etc.)
- They are connected to expressions of cultural values (e.g., individualism, power, freedom, materialism)
- They are canvases upon which developments in design and esthetics are created (e.g., as representations of modernity)
- They provide props for the enactment of such cultural structures as myths and rituals (e.g., the rite of passage associated with the granting of a driver's license to an adolescent).

Relationship to Prior Work

Recognition of the pivotal role played by vehicles in consumer culture is not new. Indeed, Birdwell's (1964) research comparing the self-concepts of Pontiac and Volkswagen owners was one of the first self-product image congruence studies. Cars also figured prominently in classic motivational research analyses conducted by Ernest Dichter, Pierre Martineau, Sidney Levy, and others. Russell Belk's development of the extended self construct explicitly includes the auto in its discussion of the investment of self in objects (Belk 1988).

Despite the prominence of vehicles and ancillary products in advertising and other aspects of consumer culture, surprisingly little research has focused specifically upon artifacts linked to personal transportation. In recent years, ACR presentations and other consumer behavior literature have witnessed an upsurge of interest in such expressive products as housing and home decoration (e.g., Claiborne and Ozanne 1990; Kron 1983), cosmetics and other forms of body modification (e.g., Schouten 1991), and

clothing (e.g., Solomon 1986). This recognition of the communicative properties of products has not been paralleled by empirical or ethnographic work on consumer vehicles: "living rooms on wheels."

This session aims to redress this omission by providing four different perspectives on consumers' relationships with vehicles. Taking a symbolic/linguistic perspective, Barbara Stern and Michael Solomon approach the vehicle as a medium for interpersonal communication. They present research on car ornamentation, with a specific focus on the messages transmitted by consumers' choices of bumper stickers and other semantic media as they personalize their vehicles. John Schouten and James McAlexander explore in depth the consumption subculture composed of Harley-Davidson motorcycle owners, and also assess the interactions of owners with the company itself. Bruce Vanden Bergh examines literary and cultural influences on advertising creatives, with particular reference to Doyle Dane Bernbach's classic Volkswagen Beetle campaign. Finally, David Banik discusses research done for Amoco gasoline by the DMB&B advertising agency on consumers' relationships with their cars.

OVERVIEW OF SPECIAL SESSION PAPERS

"Have You Kissed Your Professor Today?": Bumper Stickers and Consumer Self-Statements

Barbara B. Stern, Rutgers University
Michael R. Solomon, Rutgers University

We approach the car as a highly visible communications medium that permits consumers to make a wide range of statements about themselves and the world around them. This paper presents research on the rich variety of car ornamentation, with a specific focus on the messages transmitted by consumers via bumper stickers and other semantic media. The research program aims to better understand the dynamics of cars as social or personal canvasses by which expressions of the self are signified within the context of mass culture.

Bumper stickers represent a unique "media" category in that they convey *in words* direct consumer statements -- self-proclamations, affiliation with kinship groups, directives to others, epithets, boasts, and so forth. Furthermore, the choice of these statements (or whether to display any at all) is highly voluntary, thus affording insight into consumers' volition and commitment to the messages. As such, these media afford the opportunity to study consumer communication about the self (personal identity) and about outreach to others (social identity) in terms of verbal artifacts freely chosen. The overt and public nature of these verbal statements renders them particularly accessible to systematic empirical analysis.

Volkswagen as "Little Man"

Bruce G. Vanden Bergh, Michigan State University

This presentation makes the case that the creative approach employed in the well-known Volkswagen Beetle campaign did not come out of the air as suggested by advertising great David Ogilvy, but instead had as its foundation fairly specific cultural and literary origins. The primary strategy of the campaign was to position the Beetle as an automotive "Little Man" who could not (and did not want to) live up to the superficial styling and advertising offered by the major American car manufacturers. Instead, the strategy was to offer the consumer an honest vehicle that could deliver on its rather understated promises.

The use of the little-man persona to criticize social inequities and myths is not entirely new, for it can be traced to the use of the clown in such works as William Shakespeare's *Twelfth Night*. This little-man character, much like a hero, is an archetypical character who is often conjured up to confront forces larger than the individual. And, this approach is often executed in a humorous vein in order to leave the audience hopeful of reconciliation at some future point in time.

The presentation analyzes eleven advertisements from the Volkswagen Beetle campaign to demonstrate how the little-man approach has been executed over time. Finally, the presentation addresses some of the practical considerations that made the campaign a success. These include the uniqueness of the Doyle Dane Bernbach agency, the forthrightness of the client, the influence of *The New Yorker*, and the social context provided by the iconoclasm of the 1960s.

Hog Heaven: The Structure, Ethos, and Market Impact of a Consumption Subculture

John W. Schouten, University of Portland

James H. McAlexander, Oregon State University

Past studies of subcultural consumption patterns have focused on ethnic or other ascribed subcultures, which, despite some general commonalities, often display such diversity of consumer preferences as to limit severely their potential as market segments. This research looks instead to subcultures that self-select on the basis of shared consumption interests (cf. Donnelly and Young 1988).

The study focuses on the behaviors, values, structures, and market importance of one such consumer subculture - namely, Harley-Davidson motorcycle owners. Data are drawn from a wide variety of sources including depth interviews with Harley owners; participant and non-participant observation at such venues as rides, rallies, swap-meets, HOG meetings and other club gatherings; archival sources such as ethnographies of motorcycle gangs, biker fiction and poetry, and biker magazines; and depth interviews with key members of the Harley-Davidson Motor Company in such areas as product design, marketing strategy, advertising, and retail sales.

The presentation discusses the structure and ethos of a complex consumption subculture and its interaction with the Harley-Davidson Motor

Company. It offers fresh perspectives of such traditional marketing themes as brand loyalty, product positioning, opinion leadership, and new-product development. Furthermore, new themes for marketing scholarship emerge from a focus on marketers and subcultural groups as co-creators of product symbolism and subcultural identity.

The All-American Unobtrusive Measure...Or, You Are What You Drive, Even if You're Not From California

Douglas Banik, DMB&B Chicago

Californians wear their cars the way

Midwesterners wear class rings and Easterners wear school ties. Many spend more per month on their car than they do for housing. As one Californian told me, "I can live in my car, but I can't drive my house."

Aberrant behavior? Maybe. But as with much that we associate with the West Coast, attitudes toward cars are simply more obvious, more extreme, and a bit ahead of attitudes in the rest of the country. Just a little bit of historical perspective reveals that in many ways the car defines much of what is American. It is symbolic of our affluence, our technical leadership, our commitment to freedom and individualism. And what is true for our society is largely true for each of us as individual members of that society. We buy cars that fit with our self-image, that say something about us, that say something to us.

As marketers of gasoline, we've had to be very sensitive to the relationship of the motorist and his or her car. For example, many car owners anthropomorphize their cars. They describe them as "sexy, cute, muscular, quick, hot, powerful, macho." Some give their cars names. Others claim they run better after they've been washed. And many tell us their car "knows" whether it's getting the best gasoline. We've built a whole campaign around that one. These motorists wash their cars more frequently, change the oil more often, accessorize and customize their cars, drive more miles, and enjoy their cars more than do other motorists.

Other segments of motorists have quite different relations with their cars. For example, some consumers see their vehicles as functional, precision machines. They're willing to pay for good quality gasoline, but not for octane they don't need. Others are purely utilitarian: They rarely wash their cars, never wax them, and forget to change the oil.

The key point is that for all of these motorists their cars say something about them: about their success and achievement, their intelligence and practicality, or about their preferences for a sedentary lifestyle. This presentation discusses research on these motorist self-statements, and demonstrates how the insights derived from our work for Amoco have been translated into actual advertising executions.

"Have You Kissed Your Professor Today?": Bumper Stickers and Consumer Self-Statements

Barbara B. Stern, Rutgers, The State University of New Jersey
Michael R. Solomon, Rutgers, The State University of New Jersey

Cars and other vehicles both shape and reflect consumer behavior processes, insofar as they often serve as an important extension of the self and as a mediator of self-concept (Belk 1988; Solomon 1983). Their influence on the consumer extends beyond their transportation function, for cars have affected demographic patterns by providing the catalyst for suburban development. Additionally, they have affected social relationships by facilitating changes in sexual mores via drive-in movies, "lovers' lanes," and -- with the popularity of vans -- portable bedrooms. Cars are also powerful symbols that express cultural values such as power, freedom, materialism, success, and individualism.

As expressions of individualism, cars are a canvas for personal statements. In addition to the symbolic statement made by the car itself, consumers can add self-statements by means of bumper stickers and additional symbolic statements by means of other ornamentation, such as objects dangling from mirrors, custom paint jobs, and elaborate stereo equipment. Bumper stickers represent a unique ornamentation category in that they convey direct consumer statements -- self-proclamations, names of kinship groups, messages about the self or directives to others, epithets, boasts (Baker 1991), and so forth -- in words. As such, they afford the opportunity to study consumer communication about the self (personal identity) and about the self in relation to others (social identity) in terms of verbal artifacts that the consumer has chosen. Furthermore, since they are widely available and inexpensive, bumper stickers can be exhibited by consumers of many social strata. The overt and public nature of these verbal statements render them not only highly visible, but also fortuitously accessible for research purposes.

The aim of our overall research project on car ornamentation is to understand the dynamics of cars as social canvases on which expressions of the self are displayed against the background context of mass culture. This paper begins the project by developing a theoretical base for analysis of bumper stickers as a communication medium for consumers and by reporting on the findings of an exploratory study designed to test the theoretical concepts. To initiate the research stream on verbal ornamentation, we address the following questions:

- What kinds of messages are likely to be conveyed?
- How can the universe of messages be described taxonomically?
- What future research issues should be addressed?

BUMPER STICKERS: THE NATURE OF CONSUMER SELF-STATEMENTS

Bumper stickers represent an outlet for consumer creativity (Stern and Zaichkowsky 1991), insofar as selection processes are involved in two choices: first, the choice to use (or not to use) a sticker, and second, which one to use. In terms of use versus non-use, let us note that since the purchase of stickers is voluntary, their absence is a statement as significant as their presence. As expressions of creativity, stickers afford an opportunity for playfulness, humor, statements of feelings and opinions, and announcements of affiliation. These statements can be personal or social, micro-level or macro-level, and self-deprecating or self-enhancing. While often the verbiage is not "original" -- that is, unique to the consumer -- this is not always the case, for catalogs such as Hanover House sell "design your own" customized messages. No matter what the message content, its media "reach" is widespread, for it is a public self-statement observable by all passers-by.

This research relates to studies of other forms of public self-statements that can be considered aspects of the extended self -- notably tee shirt slogans -- but differs in focus. Unlike tee shirts, cars are durable goods, and bumper stickers represent a more permanent part of automotive decor than any single tee shirt in one's wardrobe. Thus, bumper stickers make a more enduring statement insofar as they are not easily changed or discarded, and for that reason may relate to the more stable aspect of the extended self.

Further, their explicitness as self-statements makes them more overt attitudinal comments. In effect, consumers are revealing something about their attitudes directly in words -- a medium not only visible to other drivers and pedestrian passers-by, but also to researchers. The nature of these statements (or lack thereof) is not only visible, but also readily amenable to interpretation as specimens of language with formal dimensions (grammatical and literary) as well as with content dimensions. What consumers say about themselves symbolically through their possessions has been studied in reference to the "extended self" (Belk 1988), with objects viewed as implicit self-statements. We propose that examination of bumper stickers can extend our knowledge of the extended self by affording researchers the opportunity to analyze *explicit* attitudinal comments. In sum, the stability, visibility, and interpretability of bumper stickers make them a meaningful canvas for researchers to examine.

TABLE
The Theme-Referent Matrix

		Referent		
		Self	Collective/ Other(s)	Abstract
Theme	Doing	1	2	3
	Being	4	5	6
	Feeling	7	8	9
	Metonymic	10	11	12
	Other	13		

Note: Numbers in the Table refer to specific theme/referent combinations isolated and discussed in text.

A TAXONOMY FOR BUMPER STICKERS: CONTENT ANALYSIS AND PARSING THE GRAMMAR

Once bumper stickers are identified as worthy of analysis, the next question is, how best can they be analyzed? The theoretical basis was drawn from the trilogy in communication theory -- source, message, and target. "Source" was interpreted as the *car*, and its attributes were defined as number of ornamental items per car, make and model of vehicle, condition, and so forth. "Message" was defined as the *content* or *theme* of the words (the "what"), and "target" was defined as the *referent* -- the person/group/thing that the message is about (the "who").

In order to maximize understanding of both content and form of the messages, we decided to augment the methodology of content analysis with a familiar method for analyzing sentences: grammatical parsing. That is, for each word group on a sticker we set out to identify the parts of speech (noun, verb, pronoun), its grammatical function (subject, verb, object), and the kind of statement (declarative, interrogative, imperative), just as one would do if one were to parse an English sentence. The purpose of this was to expose the linguistic structure of the messages in order to use grammatical form as well as content as a guide to meaning.

Since the universe of messages has not received research attention, a pilot study was conducted to ascertain the formal and content domains in a representative environment. This study was conducted in a northeastern suburb, using student observers to collect data from a sample of cars ($N = 200$) observed over several occasions in the parking lot of a large suburban shopping mall serving a wide trading area. The researchers examined the samples inductively, subjecting them to a content analysis using a researcher-generated typology of meaning similar to "domains" typologies used in exploratory psychological research. The procedure involves sorting the messages into groups based on the dimensions of meaning conveyed by the grammatical entities -- verb ("theme") and the noun or pronoun ("referent"). Further sorting took place when the focus was on content, to identify the areas of expression

(such as hobby/sport/lifestyle or political/environmental/patriotic) and strength of expression (neutral, negative, positive). The outline of the matrix and the thirteen categories will now be discussed (see Table).

Theme

The concept of content or theme in verbal messages has long been used in content analysis (see Kassarjian 1977), and is especially suited to short and unambiguous messages such as those in advertisements (Belk and Pollay 1985), and humorous ones such as those in comic books (Spiggle 1986). Since bumper stickers convey attitudes about the self, the attitude model of affect-cognition-behavior seemed a likely source of thematic dimensions. We hypothesized that the attitude's locus would be expressed in the *verb*, for that is the grammatical indicator of the "what" of meaning. The four theme categories express the "what" of the messages in the universe examined, including the dynamic categories of "feeling-doing-thinking" and the static category of metonymic association.

Feeling messages are about affect, and express a feeling or an emotion. The verbs are likely to be ones indicating action, but "internal" action that occurs within the individual rather than "external" action that occurs on the social stage. An example is, "I love New York." *Doing* messages are about behavior, and are likely to indicate overt or external action. This is generally expressed by active verbs -- those that take objects. An example is, "Rugby players eat their young," in which the subject ("Rugby players") does something ("eat") to the object ("their young"). In contrast, *being* messages, those about a thought, an opinion, or a state of being, are likely to be indicated by verbs of being (to be, to seem, to appear). These are linking verbs that do not have an object, but merely link two entities. An example is, "If you're rich, I'm single," an if-then expression of the state of being of the message source ("I am single") and also of the target ("You are single").

A fourth message category was necessary to categorize those messages that had no verbs, and thus expressed neither action nor inaction. This was called

metonymic (Stern 1992) to indicate that the message cathetically *associates* some person, place, idea, or thing with the car to which it is attached. In this category, the connection of the message with the source is assumed on the basis of cathexis, for just as body parts are in cathectic association with the consumer, so too are bumper stickers with a car. Grammatically, the message is likely to be limited to a noun or noun phrase, for it names something, and in the absence of any verb, the action can only be presumed to be an association of the item named with the consumer. Some examples are, "Power 95" (the name of a radio station), "Rutgers," the name of a university, and "AAA," (the abbreviated name of the American Automobile Association).

Referent

"Referent" refers to the person, group, or thing that the message is about -- that is, its "who." Grammatical concepts of nominal and pronominal reference reflect the tendency of people to make statements about themselves, other people, or ideas. English pronominal structure determined the parsing of statements to distinguish between first-person usage ("I," "we"), second-person usage ("you"), and third-person usage ("he," "she," "it," and "they"). Note that the third-person includes the non-personal "it," and that "they" is an all-purpose plural denoting more than one of anything (personal or abstract). The sticker referents echoed these categories, depending on whether they referred to the personal (self), the other (collective, group), or the non-personal (abstract).

Self messages refer to a comment about the person(s) on whose car the sticker appears. The context is personal, and is indicated grammatically by the first-person singular or plural ("I" or "we"). The sticker makes a statement (a declarative sentence) about the "I" or the "we." An example of the singular self-statement is, "I love New York," and of the plural, "We brake for animals."

Collective/other messages refer to a comment about a collective group of individuals that may or may not include the self. The context is social, and the "other" may be an institution, a religious or ethnic group, an occupational group, a country-of-origin, or any entity that comprises a group of people considered as part of a collective (rather than as individuals). When the grammatical mood is declarative -- a statement of fact -- the message is meant (albeit facetiously) to be read as a true statement. One example is, "Sewer diggers do it deeper," referring to an occupational group in a third-person plural. Another is, "Mother-in-law in trunk," referring to someone other than the self in a third-person elliptical declarative statement, with "is" omitted but understood.

When the grammatical mood is the imperative -- that is, a command to "others" -- the message is in the second-person, for "you" is implied in imperatives. An example is, "Kiss a nurse today," where the "you" is understood ["you should kiss a nurse today"] and the command is given via an active verb ("kiss") to do something to another ("a nurse").

Abstract messages refer to comments about an object, idea, place, or any other non-personal entity. The impersonal subject can be singular or plural ("it," and "they" in reference to things, not people), and tangible (a place) or intangible (an idea). The mood can be a full sentence, as in "It's ugly, but it's paid for," which is a complete comment about an object, or an elliptical sentence, as in "Insured by Smith and Wesson," where "[This car is...]" is implied. Abstract messages can also take the form of commands, such as "Split wood, not atoms." Here, the "you" is understood, and the imperative mood is used to command action ("split").

THE THEME-REFERENT MATRIX

The categories described above are used in the "Theme-Referent Matrix," numbered to facilitate the explanations and illustrative examples that follow.

Doing-Self (1) messages refer to a comment (statement, question, command) about an action performed by the self ("I") singly or as a part of a group of similar individuals ("we"). An example of a singular message is, "I owe, I owe, so off to work I go," in which the self is the doer of the actions ("owe" and "go"). An example of a singular question -- the interrogative -- is, "How's my driving?" Here, the self asks a question about something s/he is doing ("driving").

Doing-Collective (2) messages refer to a comment (statement, question, command) about an action in reference to a group of others (not the self). A declarative statement is, "Rugby players eat their young," and an imperative is, "Respect animals, don't eat them." In the latter, a group of others -- the implicit "you" -- are ordered to do something positive ("respect animals") and to avoid doing something negative ("don't eat them").

Doing-Abstract (3) messages refer to a comment (statement, question, command) about an action in reference to an object, place, idea, and so forth. Examples of commands that include what should be done as well as what should not be done are, "Split wood, not atoms," and "Hugs, not drugs." An example of a declarative statement about general life action is, "S___ happens."

Being-Self (4) messages are declarative statements of a thought, opinion, or state of being of the self. Examples are, "I support Greenpeace," and "I'm a card-carrying member of the ACLU." "Bush for President" is an elliptical statement about a self-opinion, in which "I endorse" is omitted but understood.

Being-Collective (5) messages are statements or questions expressing a thought, opinion, or state of being associated with a collective (group) of others or about one or more other(s). Examples of statements are, "Whoever dies with the most toys, wins," and "Happiness is Being Pakistani." A question about the state of being of a group is, "What's a Pythian?"

Being-Abstract (6) messages refer to a thought, opinion, or state of being associated with a non-personal entity (place, object, idea). An opinion about a place is, "It's better in the Bahamas," and one about an idea is, "It's OK not to drink." More general

comments about abstract states of being are, "Easy does it," and "One day at a time."

Feeling-Self (7) messages express a personal feeling or emotion. An example is, "I love my wife."

Feeling-Collective (8) messages express a feeling or emotion associated with a collective (group) of others. An example is, "Cambridge athletes: You gotta love 'em."

Feeling-Abstract (9) messages express a feeling or emotion associated with a non-personal entity (place, object, idea). An example is, "Vermont is for lovers."

Metonymic-Self (10) messages represent a name associated with the self. One group of messages are stickers such as "Big Mama" or "Proud Grandma." Proper nouns (as opposed to common nouns) are seen in stickers such as "Wendy's Wheels" or "Cindy's Car."

Metonymic-Collective (11) messages represent a name of a group. Examples are "National Rifle Association," "American Association of Retired Persons," and "Patrolmen's Benevolent Association."

Metonymic-Abstract (12) messages represent a name of a non-personal entity. Examples in the travel category (place) are "Howe Caverns" and "Niagara Falls."

Other (13) is a miscellaneous category needed to include exceptions, for while the matrix covers most forms of expression, there are certain unclassifiable types. One is the split-category type, which is unclassifiable because the message presents a statement that falls equally well into two categories. An example is, "I'm pro-choice, and I vote." Here, the first statement ("I'm pro choice") is Being-Self, while the second ("I vote") is Doing-Self. Another unclassifiable type is the ambiguous message, one in which the meaning is open to variant interpretations or is uninterpretable. Insofar as some group of stickers may not readily fit into the twelve-box matrix, the "other" category is needed.

An example of a message with more than one interpretation is "Chocaholic on board." While the message is one of being -- (the implicit verb is "is" and the statement in full would read, "chocaholic is on board), it is not clear whether the referent is the self or someone else. A question exists as to whether we should interpret such a message as a variation of the original being-collective message -- "baby on board" -- or whether we should interpret it as a departure from the original that has mutated into a being-self (3) comment.

FOCUS AND VALENCE OF MESSAGE

The focus of sticker messages and their valence provide further insights into meaning, ones accessible to content analysis. On the basis of domains sorting (see above), nine areas of interest were identified:

- 1: Hobby/Sport/Lifestyle
- 2: Consumption/Product/Service
- 3: Professional/Occupational
- 4: Gender/Family/Sexuality
- 5: Institutional Affiliation
- 6: Political/Environmental/Patriotic

- 7: Experiential/Tourism
- 8: Theological/Spiritual
- 9: Ability/Attribute (Physical, Intellectual)

Additionally, valence or strength of expression was categorized as "neutral," "positive," or "negative."

FUTURE RESEARCH ISSUES

There are four areas planned for future research on car ornamentation and meanings:

- Existential-phenomenological exploration of vehicle/message meanings by means of personal interviews with car owners
- Semiotic analysis of non-verbal symbols to study verbal/visual message interaction
- Quantitative analysis of correlations between message, car, and driver characteristics
- Literary analysis of message content in terms of other dimensions such as humor, sexual content, and word-play

Existential-phenomenological Exploration (E-P)

Since the *gestalt* meaning of a car includes both the vehicle itself and all of the ornamentation, we suggest that the E-P interview (Thompson, Locander, and Pollio 1989) can be used to explore these meanings. These interviews allow respondents to reveal attitudes about all of the aspects of their cars to an interviewer who has been trained to elicit information. When this interview technique was used in prior research on women's attitudes toward shopping, consumption themes emerged that would not otherwise have been obtainable by more structured survey or focus group methods. Insofar as cars express magic/totemic and mnemonic qualities with deep subjective meanings, E-P interviews with owners seem to be a promising way of uncovering these meanings.

Semiotic Analysis of Non-Verbal Objects

We recall that in addition to stickers, car ornamentation also includes objects such as fuzzy dice and visuals such as pictorial ornaments. For this reason, semiotic analysis of iconic, indexical, and symbolic meanings can augment analysis of the verbal messages. One question is the relationship of verbal to non-verbal ornaments in terms of consistency -- are the messages redundant, or are they inconsistent?

Quantitative Analysis of Relationships Between Message, Car, and Driver

The question of message consistency raises the issue of more general relationships between types of messages and car attributes. In this regard, the correspondence of visual and/or verbal ornamentation to car types and driver characteristics needs study. Here, demographic variables such as age, gender, and subculture, and psychographic ones such as self-confidence, role-completeness, and role-stress can be investigated.

Literary Analysis of Messages: Sex and Humor

Many of the bumper stickers are humorous, using word-play such as puns and irony (Stern 1990) to structure the messages. The concept of a car as an outlet for humor requires further research, especially in view of the sexual nature of much of this humor. The sexual expressiveness of messages such as "Sewer diggers do it deeper" ties in with the importance of a car as a sex symbol, but what is interesting here is that the bumper stickers are almost always humorous comments on sex rather than serious ones. Social acceptability may be at work here, in that stickers may represent a way to make a sexual statement in ironic or self-deprecating terms in order to avoid censure. A related matter for future investigation is the tendency of men versus women to make humorous and/or sexually provocative self-statements. Gender differences can be hypothesized on the basis of Lakoff's (1975) analysis of women's tendencies to avoid obscenity and slang expressions as "unladylike." To conclude, the importance of the automobile as one of the most significant material objects in popular culture may better be understood by extending consideration of the vehicle to include that of its owner-attached ornaments. The view of a car as a canvas upon which the consumer can create meaning allows for examination of the extended self by various means -- verbal and pictorial as well as product choice -- to provide a rounded picture of the relationship between vehicles and consumer culture.

Volkswagen as "Little Man" Extended Abstract

Bruce G. Vanden Bergh, Michigan State University

The presentation attempted to explain the origins of the Volkswagen Beetle advertising campaign from both literary and cultural perspectives. It used David Ogilvy's observation that the campaign appeared to have been "created . . . out of air" as an informal null hypothesis against which to demonstrate that advertisements (like art and literature) are influenced by other works of art and literature and the broader cultural context in which they are created (Fox 1984, p. 255).

The analytical framework for the study presented is an integration of interpretative approaches borrowed from literary criticism, anthropological and cultural studies, and depth psychology that converge at the point where the role played by archetypal forms or structures reveals the primal origin of motifs in the arts that might otherwise (as was the case with the Beetle campaign) be considered entirely new. The various approaches tend to focus on the study of religious themes and motifs as the place where both literary and psychological structures will reveal themselves in their most abstract form devoid of confusion from representational or local content (Campbell 1949; Frye 1957; Jacobi 1959; Jung 1959; Levi-Strauss 1963). Similarly, this study tries to discover underlying cultural, literary, and psychological patterns that transcend the context in which the Volkswagen Beetle advertising campaign was created and connect it to more basic structures within these realms.

The purpose of the study, then, was to discover an archetypal structure within the Beetle campaign. The specific archetypal pattern studied was the characterization of the Beetle's personality as that which Welsford (1935) calls the "Fool," Jung (1959) labels the "Trickster", and contemporary scholars of comedy have termed the "Little Man" (Pogel 1987; Yates 1964).

Within this context, the presentation demonstrated that the literary and psychological persona created by William Bernbach and his fellow writers and artists for the Volkswagen Beetle can be found in the "Little Man" character of film, literature, comics and cartoons, and stand-up comedy routines. And, this brand persona and literary archetype has its twentieth-century origins in the works of creative personalities such as Woody Allen, Charlie Chaplin, Robert Benchley, S. J. Perelman, James Thurber, and E. B. White (Blair 1937, 1942; Blair and Hill 1978; Pogel 1987; Welsford 1935; Yates 1964). A modern cultural and historical context was provided that traces the little-man character back to the clown figure in the work of Shakespeare and its slightly earlier roots in the theater of the Italian Renaissance (Welsford 1935).

An analysis of 126 Volkswagen Beetle advertisements was presented in support of the thesis brought forth. Additionally, an in-depth literary critique was performed on eleven of these ads (which

VW of America calls the "philosophical ads") to illustrate how the characteristics of the little-man personality were projected onto the Volkswagen Beetle itself.

The author concluded that the use of the little-man character provides a fundamental purpose to the human psyche. He or she (i.e., the clown) is ultimately an emancipator of us all from "our slaveries" whether they be social or psychological (Welsford 1935, pp. 323-324). And, in the late 1950's such a slavery was America's love affair with the big, gas-guzzling automobile. But, the clown knows the truth because he or she is an outcast and can see the foolishness of society's ways clearly. And, it was through VW's little-man, self-deprecating character that Doyle Dane Bernbach showed us how foolish it was to own a large expensive car when for the same money you could own two Beetles plus a host of other items.

Issues in Consumer Choice With Uncertain Product Outcomes

David E. Hansen, Virginia Polytechnic Institute and State University

In consumer choice, two fundamental kinds of uncertainty have been identified: uncertainty over the importance of attributes (e.g., is performance in a car more important to me than luxury) and uncertainty over product outcomes or the level of attributes (e.g., is gas mileage going to be as good as the EPA sticker claims). This paper focuses on uncertainty over product outcomes or risky choice, a topic that has been studied in other fields but that has received little attention in the consumer literature. In risky choice there are two emerging directions of research. One is normative, in that it focuses on how people should make decisions under ideal risky choice conditions in order to maximize their expected utility (Hauser and Urban 1978). The other is more descriptive, in that it focuses on how people actually do make decisions under ideal conditions, such as the work by Kahneman and Tversky (1979). Another descriptive area involves uncertain choice under less than ideal risky choice conditions such as ambiguous probabilities (Kahn and Sarin 1989; Hansen 1991) and is the area of concern in the present paper.

Under ideal conditions in uncertain choice, each choice alternative (e.g., a car) is described as having different possible outcomes or levels for the same attribute (e.g., time between auto repairs), each outcome with its own explicit probability. These ideal conditions describe what is known as a gamble (e.g., a 20% chance that the repair interval is only one month and an 80% chance that it is six months). Theories of risky choice maintain that individuals evaluate alternatives as if they are forming statistical expectations based on the probability-weighted outcomes of gambles which implies the use of a compensatory choice process. Gambles have become the decision theorist's "fruit fly", since gambles are assumed to be representative of the way people set up risky decisions and because they are easy to work with. However, there is a problem in using gambles to describe consumer choice, since in most consumer choice situations explicit well-defined probabilities rarely exist and are otherwise difficult to formulate (Kahneman, Slovic, and Tversky 1984). Furthermore, people may not even recognize that the variation in the attribute level is due to randomness, although they can identify variation and thus uncertainty in attribute levels (Hogarth 1987). Under the less than ideal conditions found in consumer settings, decisions based on expectations or probabilities may be quite difficult, inviting the use of decision shortcuts or heuristics (Payne 1982).

The main issue here concerns how consumers actually make decisions under uncertainty when probability is not explicitly given, cannot easily be formulated, and thus may be ignored or suppressed. Much of the descriptive research on how people make decisions under uncertainty has found that people are highly concerned with negative information or losses (Einhorn and Hogarth 1981). It has also been found that outcomes are segregated into losses and gains

relative to some neutral reference point and that losses loom larger than gains (Kahneman and Tversky 1979), that probability is often ignored (Einhorn and Hogarth 1981), and that most decisions are made using heuristics (Payne 1982). Because of this, it may be that in decisions without explicit probability consumers with little ability to formulate subjective probabilities use a choice heuristic that focuses on potential losses. By focusing on the worst possible loss of each alternative and minimizing losses, the alternative chosen should have the smallest potential loss of all alternatives. This choice strategy is non-compensatory in that it focuses only on losses as opposed to the compensatory nature of expectations which consider both losses and gains. Statistically naive consumers may actually use such a strategy to suppress uncertainty in the decision, if they do not know how to deal with it otherwise.

This leads us to ask whether individuals who are more experienced in uncertain choice deal with the lack of explicit probabilities differently than the naive consumers. Despite the ambiguity of the less than ideal conditions for consumers, it may be that individuals with statistical training look for ways to deal with the uncertainty rather than trying to suppress it. Hansen (1991) found that when sample statistics were used as choice data, the salience of the displayed data guided the use of a compensatory choice strategy by buyers and managers. Consumers who are not statistically naive may also use a more compensatory strategy in which potential gains and losses are considered, which can produce different decisions than those of the statistically naive consumers. Such a strategy does not make the implicit assumption of the naive consumer that only a loss will occur, since weight is given to both losses and gains. The issue this raises is what difference between naive and experienced consumers could explain the use of such different strategies. One reason may simply be that the trained consumers are able to recognize the existence of randomness and formulate subjective probabilities to help make the decision.

The implication of these proposals, if empirically supported, is that when statistically naive consumers make decisions under uncertainty, they may not be using the same decision formulation or choice strategy assumed by the decision theorist. That is, they may not formulate the decision problem as a gamble, let alone solve it via expectations. They may be using simple choice strategies which focus only on losses, unlike less naive decision makers who may try to use more of the outcome distribution (i.e., losses and gains). This coincides with the notion that the naive consumers may not be using concepts related to probability, either due to lack of recognition of the need to use them or lack of ability to use them. In effect their choice strategy may be a way to suppress uncertainty. It may also be construed as "certaintizing" the decision and is similar to Kahneman and Tversky's observation that very high

or low probabilities are changed to certainties--the certainty effect (1979). However, whether such a choice strategy is used merely to simplify the decision or because naive consumers are unable to recognize randomness or formulate subjective likelihoods is another issue in need of empirical research.

Decision Making Under Risk: Applications to Insurance Purchasing

James Shanteau, Kansas State University

ABSTRACT

The purpose of this paper is to provide an overview of psychological research on decision making under risk, with an emphasis on insurance behavior. This research approach has supplied many insights into how humans react to risk and uncertainty. These insights may help explain why people buy insurance in some circumstances and not others. For instance, decision research has shown that humans:

- have limited cognitive capacity to process low probabilities,
- focus more on loss probability than the magnitude of loss,
- are risk averse for gains but risk seeking for losses,
- misperceive randomness of runs -- the "gambler's fallacy,"
- seek an optimal level of risk, i.e., "risk homeostasis,"
- show wide individual differences in risky decision making,
- are resistant to changing attitudes and beliefs about risks,
- exaggerate their decision making ability -- overconfidence,
- are influenced by subtle shifts in problem wording, and
- cannot conceptualize losses they haven't experienced.

To examine these findings, a small pilot study was conducted which investigated decisions about flood and drought insurance. These and other results imply: (1) expected utility is inadequate to describe insurance decisions, (2) the monetary value of insurance has little relevance to purchasing, (3) insurance is viewed as an investment, instead of protection, (4) people want to "trade dollars" with insurance companies, and (5) there is a risk threshold, which limits desire to buy insurance.

This paper is intended to provide an introduction to research on risky decision making and how it relates to insurance buying behavior. The focus will be on using insights about decisions under uncertainty to account for willingness to purchase insurance.

BACKGROUND

Behavioral decision research began in the 1950's with analyses of how people make choices between gambles (Edwards, 1954). In the 1960's, the emphasis was on investigating probability revision and probability learning (Slovic and Lichtenstein, 1971). The decade of the 1970's produced research on risk heuristics (mental rules of thumb) and biases (Kahneman, Slovic, and Tversky, 1982). The 1980's has seen analyses of framing (context) effects and

comparisons between experts and novices (Shanteau, 1987).

Today, the field of judgment and decision making, or behavioral decision analysis, is rapidly expanding. The Society for Research on Judgment/Decision Making has over 900 members worldwide. There are two journals devoted to the area: *Organizational Behavior and Human Decision Processes* and *Journal of Behavioral Decision Making*, with many other periodicals publishing relevant material. Numerous books have appeared at all levels, ranging from introductory (e.g., Huber, 1980) to intermediate (e.g., Hogarth, 1987) and advanced (Arkes and Hammond, 1986). Although initially dominated by psychologists, decision researchers now represent a variety of disciplines including management, engineering, statistics, political science, medicine, economics, geography, law, and accounting.

This paper is concerned with describing how the findings from decision research can be applied to explain insurance behavior. The description will be divided into four parts. First, some general principles of risk behavior will be outlined. Second, specific findings will be described from a pilot study of decisions about flood and drought insurance. Third, the implications of these and other results for insurance behavior will be discussed. Lastly, the paper ends with some suggestions for the application of behavioral concepts to insurance decision making.

PRINCIPLES OF RISK BEHAVIOR

As noted by Slovic (1984, p. 4), "it is extremely hard (for people) to think about...uncertainty, probability, and risk." Indeed, repeated demonstrations have shown that most people lack an adequate understanding of probability and risk concepts (e.g., Kahneman and Tversky, 1984). A number of principles have been uncovered which describe how people think about probability and risk. A few of these will be described here.

Misperception of Small Probabilities.

Obviously, people can only respond to the risks they perceive. "If their perceptions are faulty, efforts at personal, public, and environmental protection are likely to be misdirected" (Slovic, Fischhoff, and Lichtenstein, 1982, p. 463). One persistently reported misperception is an inability to react logically to low-probability events (Anderson, 1974). People either ignore low probabilities or are unable to make rational decisions involving low probabilities (Schoemaker, 1980).

In part, this misperception arises from a limited capacity people have for processing risk information. Simon's (1957) concept of "bounded rationality" contends that cognitive limitations force people to construct simplified models of the world. According to Simon (1957, p. 198), the decision maker a "behaves rationally with respect to this

model, (but) such behavior is not even approximately optimal with respect to the real world." Thus, people's limited processing capacity restricts attention for rare events.

Focus on Probability of Loss.

People don't like to lose money. This aversion to losing, however, seems focused more on the probability than the amount of loss: "It is not the magnitude of a potential loss that inspires people to buy insurance voluntarily -- it is the frequency with which a loss is likely to occur" (Kunreuther, 1979, p. 2). The criminologist Sir Robert Mark (1976) makes a similar argument, the "best deterrent to...crime is not so much the severity of punishment as the likelihood of being caught."

Focusing on the likelihood of losing, of course, can lead to irrational behavior. In studies of choice behavior, for instance, subjects preferred unfavorable gambles to accepting a sure loss (Hershey and Schoemaker, 1980). Other studies have reported that people choose a sure gain over a gamble, but reverse their preference when the same options are presented as losses. In short, attention is "captured" by the loss probability.

Risk Aversion vs Risk Seeking.

It is commonly assumed a person's propensity to seek or avoid risk is consistent over gains and losses. A risk-averse individual, for instance, would presumably avoid risk of any type. Empirical evidence, however, suggests that most people are risk averse for gains and risk seeking for losses (Kahneman and Tversky, 1979).

"People are often risk seeking when it comes to losses; they are willing to chance a loss even when they can insure against it....Many even decline to buy government-subsidized insurance in which the premiums are so low that buyers are effectively in a 'can't lose' position" (Schwartz and Griffin, 1986, p. 141). This tendency reflects the distaste people have for sure losses.

Gambler's Fallacy.

Many people have a strong, but false, belief that random events are self-correcting. If a couple has a series of girls, then a boy is viewed as likelier (Anderson, et al., 1981). A common example is the belief that a previously hitless batter is somehow "due" to get a hit in a baseball game.

The inability to appreciate the independence of random events also shows up in low probability situations (Hogarth, 1987). If an unlikely event occurs once, people believe that it is less likely to occur again -- "lightning can't strike twice." Thus, the perceived likelihood of future events changes because of prior outcomes.

Risk Homeostasis.

A general principle of behavior is that people want to remain at equilibrium levels, e.g., of motivation. This concept of homeostasis has been extended by Slovic (1984) to risk settings: There is "an optimal level of risk that people are comfortable

in accepting (p. 9)." Efforts to decrease risk, therefore, may be met by riskier behavior.

One example relates to farm machinery. When improved design made tractors more stable, farmers used them on steeper slopes and the accident rate remained constant. This suggests that risk-reduction measures may be offset by riskier subsequent behavior (Slovic, 1984).

Individual Differences.

A common finding is the presence of widespread individual differences in how people respond to risky situations (Slovic and Lichtenstein, 1971). Johnson, et al. (1961) studied over 1,000 midwestern farmers and found a relationship between willingness to accept risk and the types of farm crops grown. High risk takers were in cash crops and stock feeding; those intermediate in accepting risk were in dairy and tobacco farming; the least risk takers were in general farming.

Such behavior can be self-limiting, since unwillingness to accept risks can keep farmers from engaging in more profitable efforts. As Kunreuther and Wright (1979) note, those who practice "safety-first farming" may be trapped by their own risk aversion.

Resistance to Change.

Perceptions of risk are quite stable and resistant to change. Reliance on "personal experience may promote a false sense of security....People's beliefs often change slowly and show extraordinary persistence in the face of contrary evidence" (Slovic, et al. 1982, p. 478).

One of the difficulties is that we seldom receive feedback about the appropriateness, or inappropriateness, of our perceptions of risk. Consequently, people have a tendency to deceive themselves about how well they can handle risk. Through hindsight, for instance, we can "post-dict" almost any outcome (Fischhoff, 1975).

Overconfidence.

Humans often operate under what has been labeled a "certainty illusion" -- a belief in their own infallibility (Fischhoff, et al., 1977). "Even when people are wrong...they are tremendously confident in their opinions....People generally tend to underestimate their own vulnerability to certain sorts of risks" (Slovic, 1984, p. 5).

A related phenomenon is that we tend to view ourselves as invulnerable to hazards (Kunreuther and Slovic, 1978). Most believe they are better than average drivers, more likely to live past 80, and less likely to be harmed by consumer products (Slovic, et al., 1982). Given such expectations, it shouldn't be surprising that many people refuse to take personal actions to reduce risk.

Context Effects.

Psychologists have long been aware of the prevalence of context effects in judgments. One class of such effects has been labeled "framing" by Kahneman and Tversky (1984). They found that

people respond more positively to losses labeled as "cost of protection" than as "uncompensated losses."

Researchers have reported that slight shifts in problem wording can have a pronounced effect on choice behavior: "Subtle differences in how risks are presented can have marked effects on how they are perceived" (Slovic, et al., 1982, p. 483). That means context effects can be used to change (i.e., manipulate) risk perceptions.

Inability to Conceptualize Losses.

A major limitation to our capacity react to low-probability risks is the inability to imagine hazards which have not occurred. "Men on flood plains appear to be very much prisoners of their experience" (Kates, 1962, p. 140). Much of the difficulty in improving flood planning can be attributed to the "inability of individuals to conceptualize floods that have never occurred" (p. 92).

People are influenced, often inappropriately, by prior events (Arkes and Blumer, 1985; Shanteau and Harrison, 1991). They "are strongly conditioned by their immediate past and limit their extrapolation to simplified constructs, seeing the future as a mirror of that past" (Kates, 1962, p. 88).

A PILOT STUDY OF INSURANCE DECISION MAKING

To examine the applicability of some of these concepts, I conducted a small pilot study on hazard risk perception and insurance decision making.

Methods.

A group of 48 undergraduates were told that "a major disastrous event has occurred in the past year." They were asked to judge the likelihood of recurrence in the coming year and to indicate whether they would be willing to pay more for insurance.

Four events were described: drought, natural flood, car theft, and man-caused flood; the former two hazards are "acts of nature" and the latter two are "man-made." The probability for each was described as alternately "1-in-20" years or "1-in-100" years.

Results.

There were four findings of interest: First for natural hazards, there was a uniform trend to estimate the chances of a recurrence as less likely in the coming year. Thus, 75% of the subjects said that a 1 in 100 year drought is less likely to occur again in the coming year. This suggests a belief in the gambler's fallacy -- people believe it improbable that an unlikely event will recur.

Second, the preceding effect is roughly 20% less in the 1-in-20 year condition than in the 1-in-100 condition. For example, 55% of subjects said that a 1 in 20 year drought is less likely in the coming year. The shift, therefore, appears to be more pronounced with lower probabilities.

Third, natural hazards led to about a 10% greater effect than man-made hazards. 83% of subjects said that a 1-in-100 year natural flood is less likely to recur, whereas 73% said that 1-in-100 man-caused flood would recur in the coming year. This suggests a

context effect, by which natural events are viewed differently than man-caused events.

Lastly, the amount of insurance subjects were willing to buy changed little across conditions. Roughly two-thirds of subjects were willing to pay the same premium as before, despite being told they had a major loss. Apparently, their beliefs about insurance rates are unaffected by events in the preceding year.

Discussion.

In all, these findings show that people tend to feel that once a low-probability event happens, they are "inoculated" against a repetition in the coming year. Such an inoculation effect would make it difficult to convince people of the need to reduce risks by buying insurance. This may explain why many residents in flood-prone areas are willing to move back, without insurance, following a major flood (Kunreuther, et al., 1978).

OBSERVATIONS

Let me now offer some comments about insurance-buying behavior. First, it is clear that economic theory is not adequate to account for insurance behavior (Pashigian, Schkade, and Menefee, 1966). "Utility maximization is neither a necessary nor a sufficient condition for deducing who will buy insurance" (Simon, 1987, P. 32). As an alternative, Simon argues "if we wish to understand the insurance-buying behavior, then we must determine... the circumstances that attract the attention of a property owner" (also see Hogarth and Kunreuther, 1985; Kunreuther, 1983).

Second, the monetary value of insurance appears to play little role in whether consumers purchase it. Eisner and Strotz (1961) observed that flight insurance is less attractive economically than life insurance, yet consumers have a stronger desire for the former than the latter. Apparently, the relationship between expected return and premium is unimportant for many insurance decisions (Simon, 1987).

Third, people tend to view insurance as an investment, rather than as protection. A policy is viewed "as an investment aimed at maximizing claim payments in case the hazard should occur" (Schoemaker, 1980, p. 79). Because low-probability events are unlikely to happen, there is in fact little chance of getting a payback. Hence, most people prefer to insure against higher-probability, low-loss hazards (Kunreuther and Slovic, 1978).

Fourth, by viewing insurance as an investment, consumers want to see some return on their premiums. This leads to a desire to "trade dollars with the insurance company even though it is very costly" (Slovic, 1984). Thus, people appear to have distorted ideas about the function of insurance.

Finally, there appears to be a risk threshold, below which people ignore the threat of a loss (Slovic, Fischhoff, and Lichtenstein, 1977). When very low probabilities are involved, the premium amount is viewed as irrelevant. That means people illogically will buy insurance against common hazards

and avoid policies for unlikely catastrophic events (Hogarth, 1987).

CONCLUSIONS

I have three final thoughts: (1) It is likely that efforts to increase protection of the public paradoxically may have the opposite effect. By eliminating minor losses, e.g., resulting from floods, people are denied an opportunity to experience their own vulnerability. Successes in civil engineering are therefore limited by failures in social engineering (Burton, et al., 1978).

(2) By working together, decision researchers and consumer researchers may be able to offer new understandings of insurance behavior (Kunreuther and Slovic, 1978). Although the two disciplines of psychology and marketing often failed to communicate in the past, there is some evidence of breaking down the barriers.

(3) Despite the problems people have in coping with risk, humans are capable of adapting and improving their decision making (Clark, 1977). One suggestion by Kunreuther (1979) is to lengthen the time horizon for risk communication -- a 1 in 100 year flood becomes a "more than 5 to 1 chance of flood damage in 25 years." To get around beliefs in the gambler's fallacy, my suggestion is to educate people about the potential for hazards to repeat themselves -- lightning can strike twice. Finally, policy makers should make a greater effort to understand how consumers think and react to risk and uncertainty.

The Time and Outcome Valuation Model: Implications for Understanding Reactance and Risky Choices in Consumer Decision Making

John C. Mowen, Oklahoma State University

ABSTRACT

The time and outcome valuation (TOV) model (Mowen and Mowen 1991) was described and used as a metatheory to account for the effects of reactance and risk perception on consumers. A key assumption of the model, that negative outcomes are discounted more rapidly than positive outcomes over time, was successfully tested within the context of individuals making choices between risky or conservative bets. Implications of the model for understanding consumer decision making and for future research are identified.

INTRODUCTION

Consumer decision making occurs within a world filled with risk and uncertainty. Researchers generally regard risk perception in terms of an expectancy-valuation model that is based upon two factors: (a) the likelihood that a bad outcome could occur and (b) the degree of negativity of the outcome should it occur (Dowling 1986). Thus, risk perception can be conceptualized as based upon the integration of a probability estimate and a valuation of an outcome in order to form an overall evaluation of risk.

Researchers have begun to investigate risk perception by analyzing separately the factors that influence the estimation of probabilities and the valuation of outcomes (e.g., Kahneman and Tversky 1979). Valuation occurs when an individual assesses the extent of the goodness or badness of a possible or actual outcome, event, or thing. The concept of valuation is central to many mid-range theories used to describe consumer behavior. For example, valuation is a critical element of the many expectancy-value models employed by researchers to describe various consumer processes. In such models the overall evaluation of a course of action is predicted by multiplying the likelihood of each of the various outcomes occurring by the value of each outcome should it occur and then summing across the outcomes. From the compensatory models of choice and attitude formation (e.g., Fishbein and Ajzen 1975), to models of risk perception (Bauer 1960), to subjective expected utility models (e.g., prospect theory, Kahneman and Tversky 1979), one finds valuation as a central element.

Mowen and Mowen (1991) developed a model, that focuses on the role of time on outcome valuation. Called the time and outcome valuation model (the TOV), it proposes that the distance in time between when a decision is made and when potential positive or negative outcomes occur systematically influences the perception of the goodness/badness of the outcomes. Derived from approach-avoidance conflict theory (Miller 1959), prospect theory (Kahneman and Tversky 1979), and discounted utility theory, the TOV acts as a metatheory, which proposes that a family of "time and outcome valuation" phenomena exist. Some of these phenomena include: risk aversion in the present, future optimism, individual traps and fences,

speed-up costs, and delay charge effects. See Mowen and Mowen (1991) for a description of these phenomena.

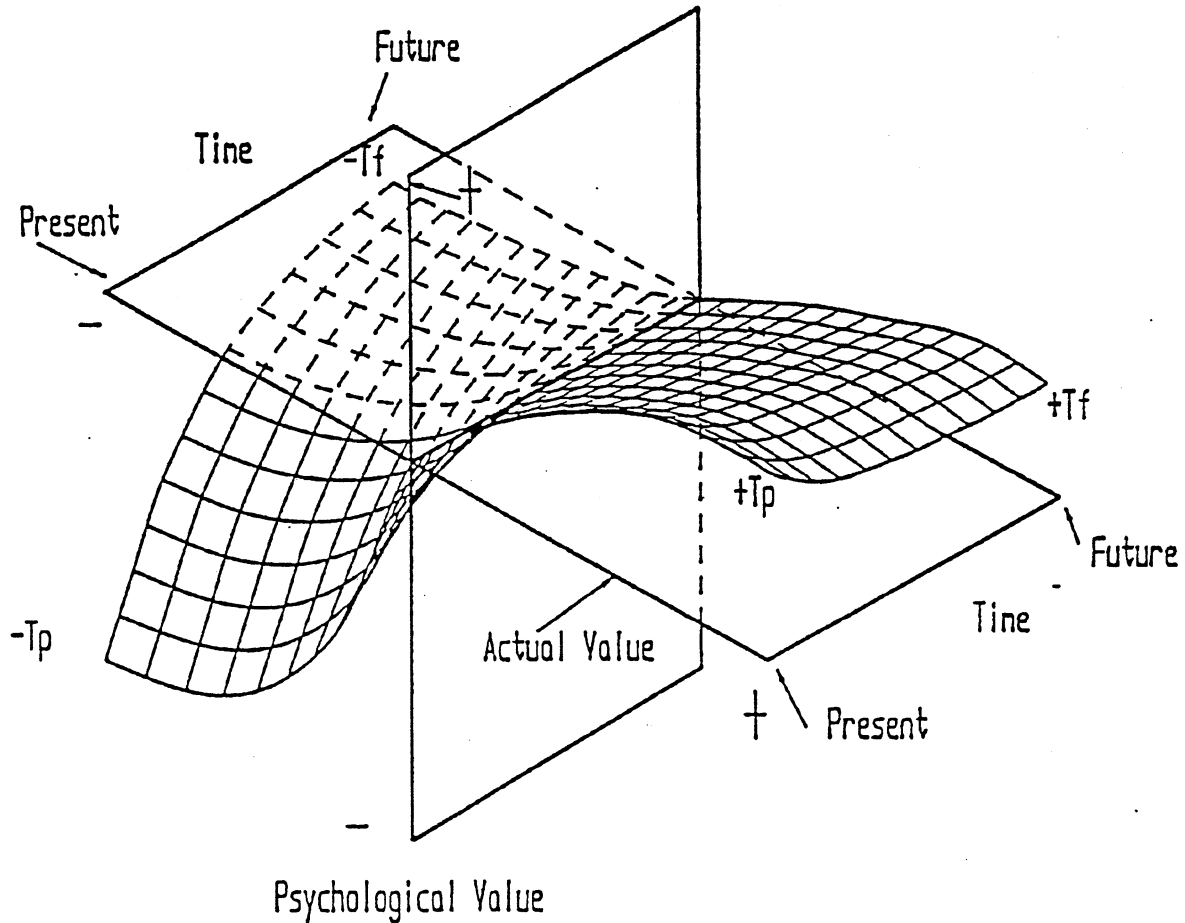

The TOV proposes that depending upon situational circumstances, losses and gains can occur at different points in time relative to when a decision is made. Based upon when in time the losses or gains occur relative to the decision point, divergent decision biases may result. For example, when situational circumstances cause the negative outcomes of a decision to occur in the present and the positive outcomes of a decision to occur in the future, the individual fence (Platt 1973) is predicted to occur. An investment decision is a case in which an individual fence would impact consumer decision making. In an investment decision, the money or time required to make the investment is taken from the consumer's expendable income in the present causing a short-term loss. Only in the long-term will the benefits of the investment be felt. Because losses are overvalued in the present and the future gains are discounted, consumers will have a strong tendency *not* to make long-term investments unless the positive benefits in the long-run are extremely salient.

The TOV model is based upon a series of assumptions, which are summarized below. (See Mowen and Mowen, 1991, for the empirical basis for these assumptions.)

- A1. The psychological reaction to outcomes is described by the decreasing marginal valuation of gains and losses.
- A2. For outcomes that occur in the present, losses are valued relatively more heavily than gains.
- A3. The net valuation of a prospect results from the difference in the valuation of gains and losses.
- A4. Outcomes are discounted in time with losses discounted faster than gains.
- A5. Time and outcome framing exist. The loss or postponement of a gain is framed as a loss. The avoidance or postponement of a loss is framed as a gain.
- A6. Gains and losses may occur at different points in time.

The present paper has three purposes. First, it presents a method of graphing the model in a manner that allows for the derivation of decision phenomena from the TOV. Second, the paper extends the TOV model to account for reactance in consumer settings. Third, the paper presents an empirical study testing a critical assumption of the TOV, that gains are discounted more rapidly than losses.

FIGURE 1
The TOV Model

A GRAPHICAL REPRESENTATION OF THE TOV

Figure 1 presents the graphical representation of the TOV found in Mowen and Mowen (1991). In the three dimensional figure, the x axis represents the actual value of a stimulus and the y axis the psychological value of the stimulus. These axes correspond to those found in prospect theory. The third axis depicts time moving from the present to the future. In the present, the curves match those found in prospect theory resulting in a heavier weighting of losses than gains. Thus, when equivalent gains and

losses occur in the present, risk aversion is predicted to occur. However, as time passes, gains and losses are discounted so that the planes begin to approach the x axis. Because losses are discounted more rapidly than gains, the loss plane more rapidly approaches the x axis. As a result of the differential discounting of gains and losses, gains are weighted more heavily than losses when they occur far into the future. Thus, when evaluations occur long prior to the outcomes occurring, the psychological value of a gain may be greater than the psychological value of a loss of the

FIGURE 2
Two-Dimensional Representation of the TOV Model and the Derivation of Psychological Reactance

Note: Reactance may occur in a situation in which a buyer must choose between two alternative brands. In the example, Option 1 is chosen because it has more value--+110 utiles, as compared to +100 utiles. After the choice, however, Option 2 is foregone and its +100 utiles are lost. Because losses are weighted more heavily than gains in the present, the person experiences negative affect (i.e., line segment O-L is longer than O-G) resulting in a reactance state.

same amount. Mowen and Mowen (1991) called this effect "future optimism."

A problem with the representation of the TOV shown in Figure 1 is that it is relatively difficult to depict the changes in valuation that occur as gains and losses occur at different points in time relative to when the decision is made. Figure 2 portrays in 2-dimensional space the same relationships found in Figure 1. The curve labeled "Outcome in Present" is the classic prospect theory curve of Kahneman and Tversky (1979). The curve labeled "Outcome in Future" is the curve that results for the valuation of

gains and losses when they occur far into the future (e.g., several years away). Note that the differential discounting of gains and losses results in the curve for future value being steeper in the gain domain than in the loss domain. As a result, the overweighting of losses that occurs in the present has been replaced by an overweighting of gains that occur in the future.

Figure 2 can now be used to depict visually the phenomena that can be derived from the TOV. The next section discusses how the phenomenon of reactance can be derived by using Figure 2.

Reactance Theory

Brehm (1969) in his development of reactance theory suggested that people have a need to maintain their behavioral freedom. If their behavioral freedom is violated, they will react against the threat in order to restore that freedom. Thus, if an option or possession is taken from them, a negative affective state is created, and they will reevaluate it so that it becomes relatively more attractive. Clee and Wicklund (1980) identified a number of situations in which reactance theory has implications for consumer behavior.

Reactance theory can be used to explain post-decisional regret (Walster 1964). Post-decisional regret occurs when, after making a choice between two positively valued alternatives, individuals may experience displeasure and reevaluate the alternatives such that the unchosen option is liked more than the chosen alternative. The TOV proposes that the regret is caused by a reactance state in which the buyer gives up all of the positive attributes of the unchosen alternative (i.e., he loses the freedom to obtain these positive qualities) while they accept all of the negatives of the chosen alternative. Mowen (1990) has suggested that what researchers call cognitive dissonance (i.e., the discomfort that may occur after a purchase) results from the cognitive imbalance that occurs from reactance causing the unchosen alternative to be valued more than the chosen alternative.

The TOV proposes that the negative feelings that occur in a reactance state result from the high weighting of losses taken in the present. That is, the loss of behavioral freedom to possess the desired attributes of the unchosen alternative is tantamount to the loss of any resource. According to Assumption 5 of the TOV, the loss of a positive outcome in the present will be framed in the loss domain and will create highly negative feelings.

The effect is diagrammed in Figure 2. Let us assume that Option 1 (the chosen option) is rated originally as having +110 utiles and Option 2 (the unchosen option) as having +100 utiles. Thus, both options are viewed positively, but option 1 was chosen because the overall preference for it was higher. Once the person has been committed to the choice, however, the unchosen option is now framed as a loss of 100 utiles. When the loss is extended down to the curve that represents its psychological value in the present, one finds that the line segment O-L results. Now, consider the chosen alternative--Option 1. When the gain is extended up to obtain its psychological value, one finds that the line segment O-G results. Because of the greater valuation of losses than gains in the present, line segment O-L is longer than O-G. That is, the negative feelings resulting from the loss are stronger than the positive feelings resulting from the gain. As a result, the buyer experiences the overall negative affective state called reactance.

Linder and Crane (1970) performed a study that supports the TOV explanation of reactance theory. These authors asked subjects to rate the attractiveness of two people either of which could interview them for a job. The attractiveness was rated at different points

in time prior to when a final choice had to be made. Linder and Crane (1970) predicted that reactance forces would tend to make the attractiveness of the choices converge as the time approached to make the choice. The results supported the prediction. That is, as the time for the final choice grew closer, the subjects increasingly rated the interviewees as similar in attractiveness.

The TOV accounts for the results of the Linder and Crane (1970) study by virtue of the discounting function for gains and losses. That is, as the outcome draws closer, the effects of gains and losses have increasing psychological value with the losses growing more rapidly. Because the inferior (but still positively evaluated option) is the one that the person is considering for elimination, the loss of its positive elements loom large. As a result, it will tend to increase in attractiveness, because of its potential loss. Thus, the TOV model predicts that the attractiveness of the two options will tend to converge.

In sum, the TOV model accounts nicely for the effects of reactance under the same rubric that handles a variety of other mid-range theories. A critical issue for the model, however, concerns the evidence for Assumption 4, that the discount rates for gains and losses diverge.

On the Differential Discounting of Gains and Losses

A key assumption in the TOV is that the discount rate is greater for losses than gains. Both Wright and Weitz (1977) and Jones and Johnson (1973) found indirect evidence that supports the assumption. In each study, the researchers found that people tended to make conservative decisions when outcomes occurred soon after the decision. This result is consistent with a greater weighting of the negative outcomes in the present. However, when outcomes were to be experienced further into the future (i.e., a week or more), riskier decisions were made. This result is consistent with the derivation that when gains and losses occur in the future, gains may be weighted more heavily than losses. As a result people move from a risk averse state in the present to a risk seeking state in the future.

The assumption that losses are discounted more rapidly than gains is controversial, however. Based upon the results of a carefully conducted study, Benzion, Rapoport and Yagil (1989) concluded that the discount rates "...are smaller for losses than for gains" (p. 282). In the Benzion et al. study, subjects gave an estimate of the amount of money that they would receive or pay in order to make them indifferent between a present and future outcome. For example, in the "postpone receipt" condition, the subjects might expect to receive \$1,000 right now. They would then indicate the amount of money that would make them indifferent between getting the \$1,000 now and getting \$X a year from now. Similarly, in the "postpone payment" condition, they might learn that they must pay \$1,000 now. They would then indicate how much they would pay a year from now that would make them indifferent between paying now or later.

Supporting the previous findings, Benzion et al. (1989) found that the discount rate for "postponing a receipt" was greater than the discount rate for "postponing a payment."

The question is, "Do these results provide evidence for the greater discounting of gains as Benzion et al. suggested?" Their conclusion was derived from the finding that postponing receipts has more psychological impact than postponing payments. Thus, the researchers equated postponing a receipt with a gain and postponing a payment with a loss. This author suggests, however, that in fact subjects frame these situations in a far different way. That is, in accordance with Assumption 5, subjects will frame postponing a receipt as equivalent to taking a loss. (That is, the individual is losing the current use of the money.) Conversely, the postponement of a payment will be framed as a gain. (That is, the individual is gaining the current use of the money.) By recognizing that individuals will frame postponing a receipt as a loss and postponing a payment as a gain, the study provides strong evidence for the assumption that losses are discounted more rapidly than gains.

THE EXPERIMENTS

Study 1: Method.

The goal of each study was to independently manipulate when the potential gains and losses from a decision would occur in time. In each study subjects were asked to rate, on an eight-point scale, their preference for which of two bets they would prefer to play. One bet was conservative with a high likelihood of winning a small amount of money. The other bet was risky with a low likelihood of winning a much larger amount of money. In each study they read:

"On the next several pages, you will find a series of pairs of bets. We would like you to examine each pair of bets and to rate your preference for which you would prefer to play. In the study imagine that you are at a wheel of fortune. Imagine that after you choose each bet, the wheel is spun; and, depending upon where it lands, you will either win or lose based upon the probabilities given in the problem.

Subjects were given a practice problem. They were then asked to look through the entire questionnaire. Any questions that they had were answered. The twenty-five subjects in the study participated either alone or with one other person. They were paid \$10 for participating.

Study 1 employed a 2x3x3x2 mixed, factorial design. The first three independent variables were taken as repeated measures. Thus, each subject made 18 choices. The fourth variable was a between subjects variable--the order of the presentation of the stimuli. One-half of the subjects answered eighteen, randomly ordered bets in forward order, and one-half answered them in reverse order. The independent variables were:

Factor A: Size of bet. *Low*--.80 to win \$5 and .20 to lose \$5 versus .20 to win \$35 and .80 to lose \$5. *High*--.80 to win \$60 and .20 to lose \$16 versus .80 to win \$246 and .20 to lose \$16.

Factor B: When gain occurs--immediately, 12 months, 48 months.

Factor C: When loss occurs--immediately, 12 months, 48 months.

Factor D: Order of receiving the 18 bets. The 18 bets were randomized and one-half of the subjects received them in forward and one-half in reverse order.

An example of a problem is shown below:

.80 to win \$5 in 6 months	1 2 3 4 5 6 7 8	.20 to win \$35 in 6 months
.20 to lose \$5 in 4 years		.80 to lose \$5 in 4 years

The bets on the left side were always the conservative ones, and expected values were held constant between the conservative and risky bets. A second example of a bet is shown below:

.80 to win \$60 in 4 years	1 2 3 4 5 6 7 8	.20 to win \$246 in 4 years
.20 to lose \$16 now		.80 to lose \$16 now

The second example shows the high priced bet. It also shows another combination of when gains and losses could occur. Note that the expected value of the risky bet in this condition was slightly lower (\$40.00) than the conservative bet (44.80.)

Hypotheses. It was hypothesized that preferences for the bets would shift in the following way.

- H1. A main effect for bet size would occur, such that higher cost bets would lead to greater preference for the conservative option.
- H2. As gains moved further away in time, preferences would shift towards the conservative bet.
- H3. As losses moved further away in time, preferences would shift towards the risky bet.
- H4. The shift in preferences across time would be greater for losses than for gains.

Results of Study 1

Supporting H1, the results revealed a significant effect for the size of the bet (F=38.6, p<.0001, mean small bet = 5.5, mean larger bet = 4.8.) Subjects preferred the risky option to a greater

extent when the bet was smaller. Hypothesis 2 was not supported. No effect was found for the manipulation of when gains occurred ($F < 1$). The results did support H3. As expected, when losses occurred further into the future, subjects increasingly preferred the riskier bet ($F = 51.5$, $p < .0001$, mean "now" = 4.4, mean 1 year = 5.3, mean 4 years = 5.7). H4 received indirect support from H2 and H3. That is, if no main effect was found for gains and a main effect was found for losses, then the discount rate for losses must be greater than that for gains.

In order to test H4 directly, the conditions in which gains and losses occurred at the same point in time (i.e., now, 1 year, 4 years) were compared. The means revealed a strong linear pattern in which increased preference for the risky alternative occurred as the outcomes moved farther into the future (mean now = 4.2, mean 1 year = 5.2, mean 4 years = 5.8.). (A priori F tests indicated that each mean was significantly different from the others.) This pattern of results could only occur if losses were discounted more rapidly than gains. In sum, the results strongly supported Assumption 4 of the TOV.

Study 2.

Study 2 replicated the first study while extending it in several respects. First, a sample of adults was obtained. Second, three different bet sizes were employed. Third, four levels of time when outcomes for gains and losses would occur were manipulated. Finally, subjects responded to all the bets twice so that the analysis could be performed on an individual subject basis.

Study 2 employed a $2 \times 3 \times 4 \times 4$ repeated measures, full factorial design. The independent variables were:

Factor A. Replicate in which subjects answered all questions twice.

Factor B. Three levels of bet: *low* = .80 to win \$5 and .20 to lose \$5 versus .20 to win \$35 and .80 to lose \$5; *medium* = .80 to win \$60 and .20 to lose \$16 versus .20 to win \$246 and .80 to lose \$16; and *high* = .80 to win \$3,000 and .20 to lose \$80 versus .20 to win \$12,240 and .80 to lose \$80.

Factor C. Four levels of when in time gains would be received--now, 6 months, 1 year, 2 years.

Factor D. Four levels of when in time losses would be received--now, 6 months, 1 year, 2 years.

The procedure was the same as in Study 1 except that questionnaires were delivered to 34 white collar professional workers in their offices at a university in the Mid-West. Subjects answered the two questionnaires approximately 1 week apart. As in the first study, subjects rated on an 8-point scale which of the two bets they would prefer to play. However, only

30 of the 34 subjects provided responses adequate for analysis.

Study 2 Results

In the first analysis, the replicate was ignored and an overall repeated measures, analysis of variance was run on the responses to the first set of questions. Supporting the results of the first study, main effects were found for the level of the bet ($F = 306.4$, $p < .0001$) and for the time when the loss would occur ($F = 26.4$, $p < .0001$). Means for the bet size variable were: small bet 5.7, medium bet, 4.7, and large bet 3.4). Thus, as the bet increased in size, subjects increasingly preferred the conservative option. Means for the loss variable were: now = 4.2, 6 months = 4.5, 1 year 4.7, and 2 years = 4.9. A priori F tests indicated that a significant difference occurred between each of the conditions except for between the 6 months and 1 year condition. No significant effects were found for the gain variable. These results are consistent with those found in Study 1. Thus, evidence was found for the greater discounting of losses than gains.

In the second study, the replicate was included in order to perform individual analysis on each of the subjects. Because not all subjects completed both questionnaires, the analysis could be run on only 21 of the subjects. The results revealed that for 20 of the 21 subjects the effect for the bet size was significant at $p < .10$ or less. Only 4 of the subjects revealed a significant main effect for the time when gains would be obtained. In contrast, in nine instances a significant effect was found for time when losses would be paid off. Inspection of the means for each of the subjects showed a consistent pattern in which losses were discounted as they occurred further away in time. In contrast, for those revealing a main effect for gains, in some cases discounting was found. In other cases, gains were viewed as *more* valuable when they occurred in the future. The inconsistent pattern of responses for gains explains why no overall main effect was found for gains when the analysis was performed over the group rather than over individuals.

DISCUSSION

The TOV acts as a metatheory that can account for a variety of phenomena that involve the valuation of outcomes at divergent points in time. Previously, Mowen and Mowen (1991) developed the TOV and applied it to individual traps and fences, risk aversion in the present, and future optimism, among other phenomena. This paper extends the model to account for the effects of reactance. From a TOV perspective, reactance can be viewed as occurring when a person believes that a potential gain is about to be or has just been lost. Because people frame the failure to obtain a gain as a loss, a negative affective state is created that has been labeled reactance.

The paper also examined the relationship of the TOV to consumer risk perception. The model suggests that all else equal, when outcomes occur close in time to when the decision is made, risk aversion results. Conversely, the TOV predicts that, all else equal, when outcomes occur far away in time from when the decision is made, increased risk seeking behavior

results. The results of the two experiments supported this prediction.

The results of Study 2 also revealed large individual differences in the subjects' choice of risky and conservative bets when the outcomes occurred at divergent points in time. When aggregated across individuals, the higher discounting of losses than gains is found. At an individual level, most subjects revealed the expected heavy discounting of losses. However, in some instances subjects discounted gains more. Some subjects even exhibited a tendency to inflate gains across time. Like most behavioral theories, the TOV is a model of "everyperson." Not all individuals will reveal the differential discounting of gains and losses predicted by the model. One avenue for future research is to investigate individual differences in the discounting of gains and losses. Potentially, a scale could be developed that would be effective in predicting the discounting tendencies of individuals. For example, those who are willing to make long term investments should exhibit a tendency to discount losses more quickly than gains. In contrast, those who fall for "get rich quick" schemes may be people who overweight gains in the present and then discount them very quickly when they occur in the future. Similarly, those who engage in compulsive consumption (Faber, O'Guinn, and Krych, 1987) may also reveal a pattern in which they overweight gains and underweight losses in the present.

An important question concerns identifying the mechanism that causes the differential weighting of gains and losses. Is it a memory phenomena? Is it "wired" into our affective response system? Does it relate to a differential ability to imagine the feelings obtained from positive or negative outcomes. These ideas suggest that future research should investigate the differential ability of people to recall positive or negative events from their past. It also suggests the possibility that mood states (Gardner 1985) may influence the impact of time on outcome valuation. Perhaps when people are in a good mood, they discount losses more rapidly. Conversely, when people are in a bad mood, perhaps they discount positive outcomes more rapidly.

If the author is right and individuals differentially discount gains and losses, why would this be the case? I would like to suggest the possibility that it would be advantageous from an evolutionary perspective to have such a valuation process wired into our biological system. The overweighting of negatives in the present and underweighting of negative future outcomes creates an impetus to change and to progress. Further, it would seem that creating a mechanism to cause future optimism would improve our outlook on life. While the model predicts that, all else equal, people are somewhat dissatisfied with their present state of affairs, it also suggests hope for the future. As a result, people may have a "wired-in" tendency to take actions to create a better future.

Knowledge and Knowledge of Knowledge: What We Know, What We Think We Know, and Why The Difference Makes a Difference

Lawrence Feick, University of Pittsburgh
C. Whan Park, University of Pittsburgh
David L. Mothersbaugh, University of Pittsburgh¹

ABSTRACT

This paper is a summary of a special session titled, "Knowledge and Knowledge of Knowledge: What We Know, What We Think We Know, and Why the Difference Makes a Difference." The papers presented in the session focus on the constructs of knowledge, self assessments of knowledge, and over and underconfidence. The papers provide empirical results which shed light on these constructs, their interrelationships, and antecedents and consequences of the constructs.

OVERVIEW

There has been much research directed at understanding the effects of knowledge on consumer behaviors such as information search and decision making (see for example, Beatty and Smith 1987, Bettman and Park 1980, Punj and Staelin 1983). Still, there is a lack of agreement and consistency about the definition and operationalization of the knowledge construct. For example, Alba and Hutchinson (1987) define two components of knowledge - familiarity (or experience) and expertise, while Brucks (1985) includes subjective knowledge as part of the knowledge construct. Alternatively, Beatty and Smith (1987) define consumer knowledge as self-assessed knowledge. However, the theoretical and empirical relationships among these constructs have not been fully explicated. For example, many researchers have used self-assessed knowledge as the sole measure of consumer knowledge. However, given the rather modest correlations (.4 to .6) that often have been found between measures of objective and self-assessed knowledge, the use of self-assessed measures of knowledge may obscure our understanding of the effects of objective knowledge on behavior. It may be more useful to consider the two variables as separate but related constructs that have important implications for consumer behavior. Since self-assessed knowledge is the consumer's perception of what or how much he or she knows, self-assessed knowledge may be the more important determinant of behaviors, particularly such behaviors as information search and decision making.

Consumers' perceptions of what or how much they know may be systematically biased. Specifically, consumers may be over or underconfident about how much they know about a given product class. Little research has focused on the determinants of over and underconfidence in knowledge assessment. The existence of over and underconfidence has important implications for consumer behavior researchers since

these inaccuracies could lead to suboptimal consumer behaviors. For example, overconfidence could lead to insufficient information search, while underconfidence might cause consumers to be more susceptible to persuasion attempts. In addition, it is possible that the marketing actions of firms actually contribute to the bias through the amount, and/or type of information given.

The papers in this session focus on questions such as: what are the conceptual and empirical relationships among self assessments of knowledge, objectively measured knowledge, and product experience? What is the basis consumers use to assess their own knowledge? How does the basis they use affect their perceived extent of knowledge? What are the conditions under which consumers (and decision makers more generally) are likely to be over confident? Does overconfidence occur because of the effects of actual knowledge, perceptions of knowledge, or both? Are there ways to reduce overconfidence, i.e., to bring perceptions of knowledge more in line with actual knowledge?

The first paper, by Catherine Cole, Gary Gaeth, Goutam Chakraborty, and Irwin Levin, focuses on the relationship among the constructs of objective knowledge, self assessments of knowledge and product experience. The authors review their own empirical results which illustrate the interrelationship of the constructs across a number of product categories. In addition, they show the relationship of these constructs to other constructs of conceptual and practical importance.

The second paper, by Susan Broniarczyk, Wesley Hutchinson, and Joseph Alba, focuses on overconfidence. In two sets of laboratory experiments they examine the determinants of confidence in knowledge and the impact of types of presentation formats in a learning task on the effect of confidence on judgements.

The third paper, by Jayashree Mahajan, also focuses on confidence and overconfidence. In her paper Mahajan reports on a laboratory study which examines the sources of overconfidence in decision making about marketing strategy. She examines the impact of the type of evaluative feedback and the presence of contradictory evidence on overconfidence.

The final paper, by Park, Feick, and Mothersbaugh, examines the consumer knowledge assessment process. They gather data about the process consumers use to assess their own knowledge about C.D. players and examine the impact of the type of approach used on knowledge assessments.

More detailed abstracts of the papers follow.

Exploring the Relationship Among Self-Reported Knowledge, Objective Knowledge, Product Usage and Consumer Decision Making

*Catherine Cole and Gary Gaeth, University of Iowa
Goutam Chakraborty, Oklahoma State University
Irwin Levin, University of Iowa*

Except for a rather small collection of experiments specifically designed to investigate relationships among different measures of knowledge, most studies operationalize the knowledge concept in whatever happens to be the most convenient fashion. However, partly due to recent theoretical work in the knowledge area, and partly due to indirect evidence emerging from our own work, in this paper we look more closely at these measures and report that there is a disturbing lack of shared variance.

First, we present data from a number of studies that have used a wide variety of product classes where we have measured the following three types of knowledge: *self-reported knowledge* (SK) - based on a response to rating scale measures; *self-reported experience* (SE) - based on reported frequency of use; and, *object knowledge* (OK) - based on a factual test. On average, the correlation is strongest (about .55), between SK and SE, and weakest (about .30), between SK and OK.

Second, we inspect the amount of variance these different measures of knowledge explain in a variety of dependent variables. Our results, again taken across a number of different studies, suggest that SK and SE relate best to dependent variables representing affective reactions. To illustrate, we found that involvement with a product class, (electronic typewriter), is significantly related to SK and SE (.23 and .46), but not related to OK (.02), while high basketball OK showed reduced context effects in assessing free throw proficiency. We speculate that OK may be related to task performance oriented measures (e.g., recall, accuracy, use of simplifying heuristics).

Two conclusions seem appropriate. First, it is risky to depend on only one of these three measures of knowledge. Our results would suggest substantively different conclusions may emerge depending on the measure chosen by the researcher. Second, our inconsistent results suggest prior work relating knowledge to other consumer behavior variables needs to be reconsidered with explicit attention paid to what type of knowledge measure was used.

What Consumers "Really" Know and What They "Think" They Know: Investigations Into the Determinants of Confidence and Performance

Susan Broniarczyk, J. Wesley Hutchinson and Joseph W. Alba, University of Florida

Two important problems for consumer research are (1) identifying the determinants of knowledge confidence and (2) developing interventions that can counteract the negative effects of this confidence when it is misplaced. In this paper, we present results from two sets of experiments that address these issues.

In the first set of studies a concept learning paradigm was used. Subjects took part in an initial learning phase in which they were exposed to two categories of goods within a single product class (e.g., high quality versus low quality stereo speakers). Afterward, a categorization test was administered in which subjects were presented with additional examples of the product class and were asked to determine the category to which each belonged. In addition, scale ratings of confidence for each judgement were taken. The percentage of correct categorization responses measured what subjects "really" knew, and the confidence ratings measured what consumers "thought" they knew. Results showed that our most powerful independent variables affected both measures. However, the manipulations of some factors affected only the objective measure, while others affected only the confidence measure. Interestingly, individual covariates such as gender, subjective knowledge, and objective knowledge primarily affected confidence. One explanation is that confidence is sensitive to salient manipulations and self-perceptions that subjects believe should affect performance but is not sensitive to "subtler" manipulations.

The second set of studies involved a prediction task in which we attempted to instill factual knowledge that was at variance with consumers' general beliefs. Specifically, subjects were presented with quality predictors for stereo speakers. In the learning phase, quality was highly correlated with level of advertising expenditure but was uncorrelated with price. This information was conveyed in one of three different ways: (1) through inspection of 25 fictitious brands and their associated levels of quality, price, and advertising, (2) through summarized central tendency information, i.e., the median prices and advertising expenditures of high quality and low quality brands, (3) through directly informing subjects of the correlations between price and quality and between advertising and quality. Afterward, 15 new brands were presented and subjects were asked to predict quality based on price and advertising levels. Results showed that prior beliefs exerted a strong influence in all cases but varied as a function of learning condition. When allowed to inspect individual brand information, low and nearly equal weights were placed on price and advertising as predictors of quality; that is, subjects were unwilling to rely heavily on either predictor despite the dominance of advertising in the data. When expressed as central tendencies, predictions were based almost exclusively on price. Finally, when expressed as correlations, subjects appropriately placed a high weight on advertising but also placed an equally high weight on price. Thus, even when provided with knowledge in an unambiguous manner, performance can be driven by what consumers think should be true. When prior beliefs are strong, attempts to debias consumers may be difficult.

The Overconfidence Effect In Strategic Marketing Predictions

Jayashree Mahajan, University of Arizona

Estimating the likelihood of future events is a critical aspect of making strategic marketing decisions. An important bias that has emerged consistently in a variety of studies in the area of probability assessment is that of overconfidence (e.g. Fischhoff 1982). Typically, individuals believe they know more than they actually know. These findings have implications for strategic market planning, as predictions of this type tend to be complex as compared to the types of judgment tasks reported in earlier work (Barnes 1984). More importantly, it is highly confident predictions that managers are most likely to act upon and commit resources to without pausing to consider additional information.

This study conceptually and empirically evaluates the sources of overconfidence by examining the psychological context within which strategic marketing predictions are made. Specifically, the processes of how individuals learn from past performance, generate evidence to assess the current situation, and subjectively construe the future are hypothesized to affect overconfidence. The study explores the robustness of the overconfidence bias in the context of predictions commonly made by managers from company and industry data contained in a strategic marketing plan. Three levels of evaluative feedback (Favorable, Neutral, Unfavorable) and two contradictory evidence conditions (Contradictory Evidence, No Contradictory Evidence) were investigated in a 3x2 factorial design. A total of 90 students participated in a study in which data were collected over 3 months.

The results suggest that evaluative feedback has a large impact on overconfidence, primarily through its impact on accuracy rather than through an impact on confidence. In addition, subjects who were required to provide contradictory evidence proved to be less overconfident than subjects who were not so required. There was no interaction between feedback and evidence.

To summarize the findings, overconfidence in strategic marketing predictions tends to be higher when: (a) prior performance is perceived to be superior, (b) no contrary evidence is generated, and (c) events are perceived to be more certain or familiar, or prediction behavior is atypical.

Consumer Knowledge Assessment: How Product Experience and Knowledge of Brands, Attributes, and Features Affects What We Think We Know

C. Whan Park, Lawrence Feick and David L. Mothersbaugh, University of Pittsburgh

Researchers in consumer behavior have studied the effects of knowledge on a variety of consumption-related behaviors. Across studies, researchers often have used either a measure of actual knowledge or a self assessment of knowledge, or both. This paper focuses on the knowledge assessment process.

Results of an exploratory study designed to investigate the knowledge assessment process

indicate that information ranging from specific knowledge about the product (e.g., brand names, attributes, and features), memory for experience events (e.g., ownership, usage, ad search), and involvement with the product category are used in making SAK judgements. The results indicate that of these, experience related information dominates consumers' responses - about 70 percent of the responses involved experience. The experience-based responses also seemed to have a large impact on the level of the respondent's SAK. That is, individuals who mentioned they had experience reported higher levels of SAK than those who didn't mention experience. Similarly, those who mentioned they lacked experience had lower levels of SAK than those who didn't mention experience.

Finally, some results of the study suggest that brand and attribute information was as available to individuals who used that information in their SAK assessment as it was to those who didn't. We discuss the implications of these results for future research.

Consumer Knowledge Assessment: How Product Experience and Knowledge of Brands, Attributes, and Features Affects What We Think We Know

C. Whan Park, University of Pittsburgh
Lawrence Feick, University of Pittsburgh
David L. Mothersbaugh, University of Pittsburgh

ABSTRACT

Results of a study conducted to understand the knowledge assessment process indicate that information ranging from specific knowledge about the product (e.g., brand names, attributes, and features), to memory for experience events (e.g., ownership, usage, and search), to statements about involvement with the product category are used in making knowledge assessment judgements. In addition, experience-related information (ownership, usage, search) was found to dominate consumers' responses in the knowledge assessment process. Finally, tentative results suggest that attribute and brand information may not be used as a cue to infer actual knowledge even when this information is available in memory. Implications of these results for future research in knowledge assessment are discussed.

INTRODUCTION AND BACKGROUND

In consumer behavior, researchers have examined the effects of knowledge on behaviors such as the extent of information search (Brucks 1985; Moore and Lehmann 1980; Punj and Staelin 1983), the efficiency of information search (Brucks 1985; Punj and Staelin 1983), the order of information acquisition (Siminson, Huber, and Payne 1988), the learning of new product information (Johnson and Russo 1984), choice of evaluation strategies (Sujan 1985), and decision processes (Bettman and Park 1980).

However, across studies, there has been little consistency in the definition or operationalization of consumer knowledge. Specifically, while some research has defined and operationalized knowledge as the nature and amount of information about a specific domain that is stored in long-term memory (i.e., actual knowledge (AK)), other research has defined and operationalized knowledge as consumers' perceptions of what or how much they know (i.e., self-assessed knowledge (SAK)).

Despite the apparent multidimensional nature of the consumer knowledge construct (e.g., AK vs. SAK), it is often treated as a unidimensional construct, with results obtained using AK or SAK measures of knowledge interpreted as representing a "knowledge effect." However, research indicates that (1) what people think they know and what they actually know often differ (DeNisi and Shaw 1977; Lichtenstein and Fischhoff 1977; , Fischhoff, Slovic, and Lichtenstein 1977; Schacter 1983; Nelson, Leonesio, Shimamura, and Landwehr 1982; Park 1982), and (2) actual knowledge and self-assessed knowledge may have different effects on consumer search and decision processes (Bransford 1979; Park, Gardner, and Thukral 1988; Rudell 1979).

Actual vs. Self-Assessed Knowledge

The research by DeNisi and Shaw (1977) suggests that at "moderate" levels of actual knowledge, what people know and what they think they know do not correspond well. Research by Lichtenstein and Fischhoff (1977), and Fischhoff, Slovic, and Lichtenstein (1977) had subjects provide answers to dichotomous questions and then judge how certain they were that the answer they gave was the correct answer (i.e., they provided a confidence rating). Results suggest that even when subjects were very confident in their responses (e.g., a 100 percent probability that the chosen answer was the correct one), these responses were only objectively correct 20 to 30 percent of the time (Fischhoff, Slovic, and Lichtenstein 1977).

Further indications that what people know and what people think they know may differ comes from Schacter (1983), Nelson et al. (1982), and others studying the "feeling-of-knowing" phenomenon. Schacter reasoned that people who lacked the information needed to recall an item may still know enough to indicate whether or not they would be able to recognize it if they saw it. This mode of expressing knowledge about unrecalled information is termed the "feeling-of-knowing" effect. Although such feelings appear to predict recognition of formerly unrecalled items at an above chance level, the effect is modest. Specifically, subjects fail to recognize many items which they feel they know (Schacter 1983). Nelson, et al. studied how extent of learning affects the accuracy of feeling of knowing judgements (Extent of learning was operationalized as the number of times an item was recalled after an initial exposure). They found that when learning was low, the correlation between feeling-of-knowing (analogous to SAK) and recognition (analogous to AK) was zero. Even when the extent of learning was high, the correlation was modest ($r=+.31$).

Finally, there is also research in consumer behavior that supports the potential discrepancy between AK and SAK. For example, Park (1982) found that consumers think they know more about their spouses' home preferences than they actually do. Specifically, their perceived knowledge of their spouses' home preferences did not accurately reflect their spouses' actual home preferences in terms of salient features, and preferred levels on these features.

The Differential Effects of AK and SAK

Because AK is an objective measure of factual memory content, and SAK is a perceptual measure of memory content, it seems reasonable to view AK as an ability factor, and SAK as a motivational factor. Specifically, AK may provide raw material for problem

solving, and lead to increased efficiency in search, and, hence, better accuracy in problem solving. Alternatively, SAK may provide the motivation (or lack of motivation) to search for and process task-relevant information. Research support for SAK as a motivational factor is provided by Bransford (1979), Park, Gardner, and Thukral (1988), and Rudell (1979).

Bransford (1979) has suggested that metacognition (or awareness of a deficiency in knowledge needed to complete a task) is one of the most important means to enhance the motivation to learn. Given the close conceptual connection between SAK and metacognition (both require self-assessments of knowledge), it is likely that SAK consists of a motivational component as well. In addition, Park, Gardner and Thukral (1988) found that independent of AK, SAK affected inference generation, and receptivity of subjects towards updating prior information and beliefs based on new information. Specifically, individuals with low SAK generated more inferences and were more receptive to updating prior information based on the new information than those with high SAK. Rudell (1979) found that while higher levels of AK increased subjects ability to use new information, higher levels of SAK increased subjects reliance on internal information or memory (i.e., it appeared to decrease their motivation for external search).

An additional finding on the differential effects of AK and SAK is provided by Brucks (1985). Brucks found that SAK can have an effect on search strategy that is unrelated to AK. Specifically, Brucks found that SAK was negatively related to use of expert advice (dealer evaluations), while AK was not related to the use of these evaluations.

These results have several implications for consumer behavior research. First, given that SAK acts as a motivational factor, it may be important in determining whether or not search is initiated, and the types of information that receive attention and subsequently get processed by a consumer. Second, since SAK is often an inaccurate indicator of AK, this inaccuracy may lead to biased or suboptimal consumer behaviors.

Given the potential importance of SAK in consumer behavior, and the potential for SAK to be a biased indicator of AK, it is important to understand how SAK judgements are made. Understanding this assessment process, and information that is used by consumers in making SAK judgements, will yield a better understanding of the SAK construct. This, in turn, should help researchers understand (1) when and why discrepancies will exist between AK and SAK, and (2) when and why SAK will have effects on behaviors and decision processes that are different from the effects of actual knowledge.

The purpose of this study is to gain a better understanding of the knowledge assessment process and the information that is used by consumers in making these knowledge assessments.

KNOWLEDGE ASSESSMENT

Consumer knowledge assessment can be seen as a judgement task in which contents of internal memory are scanned for information relevant to the

judgement. Specifically, assessing one's own knowledge involves self-perception (Bem 1972) based on internal information, or memory cues.

A wide range of potential memory cues could be used in making an SAK judgement. For example, one set of cues that could be used is specific product-related information (or awareness of the lack of such knowledge) such as brand names that are known, attributes, features, and differences among brands on a given feature or attribute. Specifically, when asked how much they know about a given product, consumers might use the fact that they know many brand names or attributes of the product, and therefore infer that they know quite a bit about the product.

Alternatively, SAK judgements could be made based on memory for events or experiences (or lack of experience) related to that product. For example, memory of past experience with a product in the form of ownership, usage, or information search may be used to make SAK judgements. Specifically, when asked how much they know about a given product, consumers might utilize the fact that they own or use the product or that they have searched for information about the product, and therefore infer that they know quite a bit about the product. In addition, they might distinguish between different sources of information search such as media vs. personal sources. In fact, given that event memory is less likely to decay over time (Carlston 1980), memory of product-related experiences may have an impact on SAK judgements that is largely independent of the amount of product-related information that is available.

Other memory cues that could be used include (1) relative amount of knowledge compared to others (e.g., I know a lot compared to my friends), (2) relative amount of knowledge in one domain as compared to knowledge in another domain (e.g., Compared to my knowledge of Product X, I know very little about Product Y), and (3) level of interest/involvement in the product and product class (e.g., I am very interested in Product X).

METHOD

Overview

In order to understand what information consumers use when making knowledge assessments, we conducted an exploratory study. The product used in this study was CD players, since a pretest indicated that there was sufficient across-individual variation in SAK on CD players to allow for a meaningful study of the knowledge assessment process.

First, participants were asked to indicate how much they felt they knew about compact disc (CD) players. Next we collected cognitive response data by asking participants to write down why they felt they knew as much about CD players as they indicated on the first question. Later in the questionnaire, respondents were asked to recall as many (1) brands, and (2) attributes and features of CD players as they could.

Two questions were of interest in this study. First we were interested in identifying the types and frequency of usage of information or internal memory

cues used in making knowledge assessments. Second we were interested in understanding the effect of the use of various memory cues on knowledge assessments.

Sample

Self-administered questionnaires were completed by a convenience sample of 93 MBA students at The University of Pittsburgh who were paid to participate. The average age in this sample was 26 years, 54 percent of the respondents were male, and 39 percent of the respondents owned a CD player at the time of questioning.

Measurement

Self-Assessed Knowledge - Self-assessed knowledge (SAK) was measured using a 9-point single item question. This question asked "How much do you feel you know about CD players?" Response categories ranged from (1) "very little," to (9) "very much." This SAK measure is a very general type of SAK question. It includes (1) no mention of a comparison standard (e.g., How much do you know about CD players as compared to the average person), and (2) no mention of the dimension on which knowledge assessment should be based (e.g., How much do you know about the features of CD players?, or How much do you know about the brands of CD players?) Although other research on SAK has utilized both comparison standards and/or dimension statements (Brucks 1985; Spreng and Olshavsky 1990), we wanted to impose as little outside structure on the task as possible, and therefore did not utilize these types of structuring statements.

Cognitive Responses - Immediately after responding to the general SAK question, respondents turned the page and were asked "On the lines below, please list the reasons why you felt you knew as much as you indicated in question 1." Coding of the responses was done by two coders, one of whom was not involved in the study design. Interjudge agreement was 85 percent, and disagreements were resolved by discussion. Next, general categories were developed for the analysis presented in this paper.

Table 1 describes these general categories which include: (1) knowledge-based responses such as (a) brand name knowledge (Brands), (b) knowledge of the attributes and features of CD players (Attributes), and (c) knowledge of technology (Technology), (2) experience-based responses such as (a) ownership of a CD player (Ownership), (b) usage of CD players (Usage), and (c) search for CD player information (Search), and (3) responses indicating involvement with CD players (Involvement).

For each of the seven response categories, each respondent was categorized into one of three groups as follows: (1) Positive mention - respondents with one or more positive responses in that category (e.g., I own a CD player), (2) Negative mention - respondents with one or more negative responses in that category (e.g., I don't own a CD player), and (3) No mention - respondents who made no statements that fell within that category. Because of the coding scheme, it was possible for a respondent to be categorized into both

the positive and negative mention groups. In the few cases when this occurred, the respondent was not included in that particular analysis.

As an aside, although previously we suggested that comparisons with other people and comparisons with knowledge in other categories might be used as cues to infer SAK, no statements of this nature were made by the respondents.

Knowledge of CD Brand Names - Knowledge of brands of CD players was measured using a free-recall question that asked respondents to list as many brands of CD player as they could. The total number of brand names listed was used as a measure of the number of brands of CD players available in memory.

Knowledge of CD Attributes - Knowledge of CD attributes and features was measured using a free-recall question that asked respondents to list as many attributes and features of CD players as they could. Examples of attributes and features from other product domains were given to ensure that respondents understood the meaning of these terms. Again, the total number of attributes and features listed was used as a measure of the number of attributes and features of CD players available in memory.

ANALYSIS AND RESULTS

To answer the general questions of interest in this study, we conducted two sets of analyses that utilized the SAK measure and the cognitive response categories shown in Table 1.

The Relative Importance of Different Internal Memory Cues

In the first analysis, we examined the relative importance of each cognitive response category in making knowledge assessments. This analysis was completed by computing the percentage of each participant's total responses that fell into each of the seven categories, and then averaging these across all 93 respondents. These results are shown in Table 1. The results indicate the dominance of experience-based cognitive responses. Almost seventy percent of the cognitive responses were linked to product experience. On the other hand, less than thirty percent of the responses related to knowledge about CD players. The single most frequently mentioned category was ownership (28 percent) and the least frequently mentioned was knowledge of brands (2 percent).

The Effect of Internal Memory Cues on SAK Judgements

In our discussion of knowledge assessment, we proposed that knowledge assessment is a judgment process based on internal memory cues. Therefore, the cues used by a respondent in making a knowledge assessment should affect the level of SAK indicated by the respondent. Specifically, those in the positive mention group (POSM) of a given category should be expected to have higher levels of SAK than those who make no mention (NOM), while those in the negative mention group (NEGM) should have lower levels of SAK than those in the no mention group.

TABLE 1
Description of the Cognitive Response Categories

Response Category	Description	Average Percentage of Total Responses*
<i>1. Experience-based</i>		
•Ownership	• Statements referring to ownership/lack of ownership.	28 %
•Usage	• Statements referring to usage/ lack of usage.	17 %
•Search	• Statements referring to search/ lack of search. Search statements include both general statements, and specific mention of sources such as <i>Hi-Fidelity</i> magazine and word-of-mouth.	23 %
<i>2. Knowledge-based</i>		
•Brands	• Specific listing of CD brand names, or statements referring to a knowledge/lack of knowledge about brands of CD players.	2 %
•Attributes	• Specific listing of CD player attributes, or specific differences between brands of CD player. Also, statements referring to knowledge/lack of knowledge about the attributes and/or features of CD players.	16 %
•Technology	• Statements referring to an understanding/lack of understanding about the underlying technology of CD players, or how CD players work.	10 %
<i>3. Other Responses</i>		
•Involvement	• Statements referring to involvement/lack of involvement with music, stereo equipment, and CD players.	4 %

*Note that irrelevant responses were ignored, and hence total responses represent the sum of responses given in the seven categories listed above.

In order to determine which internal cues had an effect on SAK judgements, we performed a one-way ANOVA for each cue category, using the general SAK measure as the response variable, and group membership (e.g., negative mention, positive mention, and no mention) as the explanatory variable. In addition, Tukey's pairwise comparisons were performed on the groups to determine which groups differed in terms of average SAK. These results are presented in Table 2.

Several results from Table 2 are worth noting. First, with one exception, the means within each cognitive response category exhibit the pattern $NEGM < NOM < POSM$, i.e., those in the positive mention group had higher SAK scores than those in the no mention group, and those in the no mention group had higher SAK scores than those in the negative mention group. Even in the case of the exception (usage), the positive mention group had higher levels of SAK than the negative. Differences were significant in all response categories except the two in which there were very small n's in one cell

(brands and attributes). For all other response categories, SAK was higher in the positive than in the negative mention group.

Table 2 also includes the percentage of respondents who mentioned each of the response categories. The results indicate that more respondents gave experience-based than knowledge-based responses. For example, while brands and attributes were mentioned by 8 and 33 percent of respondents, respectively, ownership, usage, and search were mentioned by 73, 50, and 44 percent of respondents. These results led us to wonder if lack of positive mention of brands and attributes was due to a lack of knowledge of brands and attributes. To check for this possibility, we performed further analyses using the free-recall measures of brand-name and attribute knowledge. In these analyses, we examined the number of brands and attributes listed (free-recall) by whether or not they mentioned brands or attributes as a reason for their SAK.

The number of brands listed by respondents ranged from 0 to 16, with an average of about 6. The

TABLE 2
Self-Assessed Knowledge Scores by Response Category

Response Category	Percentage of Respondents who Mentioned	Mean Self-Assessed Knowledge Score			F-Statistic
		Negative Mention Group	No Mention Group	Positive Mention Group	
<u>Experience-based</u>					
Ownership	73%	3.0 ^a (35)	4.0 ^a (25)	6.0 (32)	25.7*
Usage	50	1.9 (15)	5.2 ^a (45)	4.3 ^a (30)	18.4*
Search	44	1.9 (10)	4.2 (50)	5.5 (30)	15.0*
<u>Knowledge-based</u>					
Brands	8	3.0 ^a (3)	4.3 ^a (86)	6.0 ^a (4)	1.9
Attributes	33	4.0 ^a (3)	4.1 ^a (60)	4.9 ^a (26)	1.4
Technology	32	3.4 ^a (11)	4.1 ^a (63)	5.6 (19)	5.8*
<u>Other Responses</u>					
Involvement	15	2.2 (6)	4.3 (79)	6.3 (8)	7.3*

Notes:(1) * $p < .05$; (2) Numbers in parentheses are the number of respondents in each group; (3) Means with the same letter superscript are not significantly different from each other using Tukey's test ($p = .05$).

number of attributes listed ranged from 0 to 20, with an average of 5.5. Because of the small number of respondents who provided positive mention of brands, the results for brands are likely to be unreliable and therefore no statistical tests were performed. Still, in the no mention group, the average number of brands listed was about 6, while the positive mention group listed 7.

For attributes, the mean number of attributes listed in the no mention group (NOM) was 5.2, while the mean in the positive mention group (POS) was 6.5, and the difference is not significant ($t = 1.5$, $p = .136$). For both brands and attributes, these results suggest that those in the no mention group were as able to list brands and attributes as those in the positive mention group. The results suggest that brand and attribute information was available in memory to these respondents but not used in making knowledge assessments.

DISCUSSION

This study was conducted to better understand the knowledge assessment process, and the kinds of information or internal memory cues used by consumers in making knowledge assessments. Preliminary analyses indicate several interesting results. First, the types of internal memory cues used by consumers in making knowledge assessments range from specific knowledge about the product (e.g., attributes and features), to memory for experience events (e.g., ownership, usage, and search), to statements about involvement with the product category.

Second, experience-based cues were found to dominate consumers' responses in the knowledge assessment process. On average, 68 percent of a participants responses fell into the experience-based category. This is contrasted with only 28 percent in the knowledge-based category.

Third, in addition to being mentioned more frequently, experience-based responses also seemed to have a greater effect on the level of SAK reported by respondents. There were significant differences in SAK across the mention groups for ownership, usage, and search: all of the experience-based responses. On the other hand, of the knowledge-based responses, only technology responses resulted in significant differences in the level of SAK reported by respondents. One implication of these results is that to the extent that there is not a one-to-one correspondence between experience and actual knowledge (Brucks 1985), the use of experience as a heuristic to infer actual knowledge will lead to biased knowledge assessments.

Fourth, although the results are tentative because of small sample problems, the results indicate that the presence of a cue in memory does not necessarily lead to its use in an SAK judgement. Those who did not mention attributes or brands as cues were found to be about as capable of listing attribute and brand information as those who did mention brands or attributes. It appears that memory for experiences is relatively more accessible than memory for specific product knowledge, and therefore is more likely to be used in making knowledge assessments.

Several areas of future research in consumer knowledge need further exploration. First, further research is needed to better understand the interrelationships between experience, actual knowledge, and self-assessed knowledge. Although product experience is likely to result in actual knowledge (Alba and Hutchinson 1987; Brucks 1985), the relative effects of experience and actual knowledge on self-assessed knowledge are less clear.

A second and related issue is the role of actual knowledge and experience in causing over and underconfidence in SAK judgements. Specifically, while much research has examined factors leading to overconfidence, little research has examined factors such as lack of product-related experience that might result in underconfidence in knowledge assessments. Finally, more research is needed to better understand the different effects that actual and self-assessed knowledge may have on consumer search, processing, and decision processes.

Postmodernism, Consumer Culture and the Society of the Spectacle

Alladi Venkatesh, University of California, Irvine

INTRODUCTION

The notions of modernism (or modernity) and postmodernism (or postmodernity) are currently a subject of great debate across many disciplines. Featherstone (1988) lists several fields where this debate has been raging for some years in the Western world: art (including music), fiction, film, and photography, architecture, philosophy and literary criticism. Recently, the debate has entered the social sciences, and in particular into cultural and social anthropology, sociology, political theory and social theory. In the field of consumer behavior specific attention to postmodernism is limited and is quite recent (Firat 1989, Firat and Venkatesh 1992, Sherry 1990, Venkatesh 1989). However, there has been a burgeoning of research in a related area, now known as post-positivism, as represented in the contributions of Belk, Hirschman, Holbrook, Mick, Anderson and Ozanne, O'Guinn, Thompson, Wallendorf, to name an important few.

Postmodernism, unlike postpositivism which it subsumes, represents a more fundamental historical development signifying an emerging cultural condition that stands both as an extension of modernism and as its critique. This paper is an attempt to capture some of the main ideas represented within postmodernism and its relationship to consumer culture.

BACKGROUND

The focus of attention in this paper is postmodernism. The prefix "post" refers to something that comes after something else--in this case, modernism. Similarly, that which came before modernism is called premodernism. For the sake of keeping the analysis a little simple, we might say that these three concepts, premodernism, modernism and postmodernism represent three different periods in the history of the West. In each of these periods, the basic focus is on the "individual" and his/her relationship to the external world. Thus in the premodernist period, the philosophical focus was on the concept of "being," that is, on human existence and the relationship of "being" to God and the Universe. In the modernist period, the focus shifted from "being" to "knowing", or from existence to cognition. In this period, the main concern was to understand the individual as a "knowing (or cognitive)" subject and the external world as a rational social order. In the postmodernist period, there is a further shift from the knowing subject to the "communicative" subject and in the case of the external world from a rational to a symbolic system. The question then is, how has this entity whom we call a human-BEING, who later became a knowing-subject, now become a communicative subject. Similarly, how do we account for the macro shift from a rational to a symbolic system. Using a more technical language, we might say that the individual seems to be moving from a cognitive world (modernism) to a semiotic

world (postmodernism)--the world of knowledge acquisition and production to a world of symbol and sign manipulation. Before we proceed to develop fully the notion of postmodernism, it is important to understand what modernism (or modernity, an equivalent concept) stands for.

Modernity refers to the last three hundred years of Western history during which many of the current ideas were developed. To quote Habermas (1981 p.9), "The project of modernity formulated in the 18th century by the philosophers of the enlightenment consisted in their efforts to develop objective science, universal morality and law, and autonomous art, according to their inner logic. At the same time, this project intended to release the cognitive potentials of each of these domains to set them free from their esoteric forms. The Enlightenment philosophers wanted to utilize this accumulation of specialized culture for the enrichment of everyday life, that is to say, for the rational organization of everyday social life."

Some people argue that there is no single idea (metanarrative) or a universalistic principle that is associated with modernity. We can, however, glean a cluster of closely related ideas in the various descriptions of modernity: the rule of reason and the establishment of rational order; the emergence of the cognitive subject; the gradual secularization of human thought and the decline of religion in the conduct of human affairs, the rise of science and an emphasis on material progress as the goal of the scientific enterprise; realism, representation, and the unity of purpose in art, architecture and science; the emergence of industrial capitalism and the separation of the spheres of production as an institutionally controlled public activity from consumption as a domestically defined private activity.

If one were to describe the central characteristic of modernist narrative, it refers to a period when the individual is defined as a "knowing" subject, an autonomous agent working within a social and economic order which was driven by the power of reason. In the modernist ethos, knowledge serves an instrumental purpose, as a tool for improving the material conditions of human life on this planet. Thus, human life is considered in terms of here and now, and there is little reference to life after we leave this planet, as was the case in the premodernist period. The focus of all knowledge is, herefore, the living life that occurs between birth and death. Improvement necessarily means building on what was available in the past. Thus the progression of knowledge becomes linear, futuristic--and goal oriented--or as philosophers call it teleological. The goal of knowledge in modernism is to make it possible for conditions of material life to improve and to make the linear progression towards better life possible. It also means improving the cognitive capacities of individual minds and enhancing their reasoning skills and abilities so they can make better judgements. The

social system accordingly expects to better prepare its members to apply their knowledge to socially determined goals. Individuals become investments and society rewards them in terms of how well they perform in this rationalist enterprise.

The positive assessment of modernity usually runs as follows: the process of modernity has improved the human condition and led to material progress beyond imagination. It is generally known that, in today's world, modernization is a goal that many traditional societies aspire for and toward which they have committed their national resources. The global shift to industrialization and the easing of economic restrictions in command economies, coupled with the move toward individual growth and privatization, constitute a signal that what is modern is desirable and what is desirable must be attained.

What are the implications of the idea of modernity for consumer research? The hallmark of consumer culture is the creation of products and services which have both use value and exchange value. Marketing practice is based on the knowledge that helps achieve its main goal of creating "marketable products," a term that has come to mean everything from shampoo to religion. Since modernity represents the rise of capitalism which legitimates the exploitation of both nature and culture for the pursuit of wealth accumulation, marketing becomes the consummate instrument in creating the ethos of consumption with which we are all identified.

The question now is, how and why would this modernist model be subject to change, or why do we speak in terms of a new paradigm. Of course, there is no implication here that somehow the period called modernism has suddenly ended, or will soon come to an end. It is just that we see some anomalies, some cues which suggest that perhaps the assumptions and conditions subsumed under modernity need to be scrutinized. So we ask the question what these cues are and what are the postmodernist tendencies that are relevant here.

LATE MODERNISM, CRITIQUE OF MODERNISM AND THE EMERGENCE OF POSTMODERNISM

We shall now briefly discuss some emerging themes in the modernism/postmodernism debate.

The first theme centers around the idea of the post-industrial state as enunciated by Daniel Bell (1973) and his contemporaries in the late sixties and early seventies. Here the essential idea is that the industrial societies are moving toward a new phase in their evolution. This new phase which may be called "post-industrial" differs from "industrial" as industrial was from "pre-industrial." The basic difference between industrial and post-industrial is that the latter is distinguished by the domination of information oriented industries and the centrality of information technology in both production and consumption sectors. Since it is generally acknowledged that we have already entered the so-called information age, this issue, as presented by Bell, is less contested now.

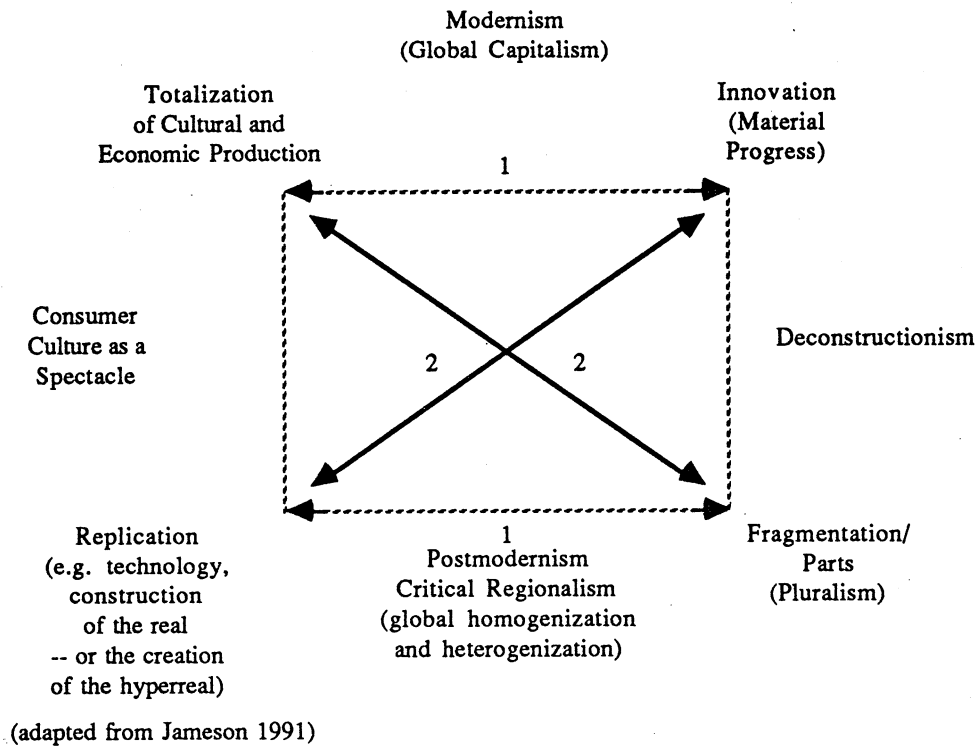

A second theme on modernity is directed towards its paradoxical character. This has to do with

the ideality and reality in modernity. Under conditions of modernity, real becomes hyperreal, representation becomes interpretation, substance becomes form, objects become images, and modernism begins to be consumed in its own images. Modernism, while incorporating uniqueness, produces fragmentation, while emphasizing real produces the imaginary and the hyperreal, while stressing representational fidelity in art and science produces illusions by a clever application of technologies, and while exalting the bourgeois subject into a privileged position alienates him/her and then fragments him/her. Thus the paradox of modernity is the unconnectedness of its ideality to its reality. In this sense modernity is viewed as a myth, or more exactly, its own myth, the myth of modernism. Consequently, the postmodernists would argue that the purpose of their critique is to lay bare the myth of modernity and confront it on its own terms. This is also the celebratory notion of modernity, that is, its liberation from its own constraints. This is also the beginnings of symbolism (as opposed to rationalism) as the basis of human discourse.

A third theme refers to the idea that modernism has run its course, giving way to new forms of representation, new social movements, and an emerging global order in which no single idea dominates, and in which a diversity of forms, however contradictory, can coexist. Jameson (1983) calls this, a pastiche, which signifies a juxtaposition of unrelated ideas, consumer experiences, and historical moments, all packaged and offered to the public. In this scenario, what replaces modernism is not a single postmodernism but several postmodernisms, all competing for attention.

A fourth theme has to do with the scopic regimes of modernity and the accumulation of spectacles as the basis of representation. The notion of representation is fundamental to modernistic thought. The original meaning of representation was the capturing or comprehending of "objective reality" through direct observation, or artistic transformation (eg., painting, photography etc.), or scientific modelling. Representation has also come to mean the construction of the real as conceived by human cognition without reference to objective reality. This means reality intervention is possible either by the application of technology or other forms of human control. The construction of reality therefore suggests that reality is not always treated as a given but subject to manipulation for aesthetic or commercial purposes. Such a notion of representation lies at the heart of the market culture, as witnessed in the design of products, in packaging, in creating spectacular shopping environments and other private and public spaces, and even in the making of the modern human body through various technologies and means of control. These cultural possibilities have prompted different interpretations from contemporary critics. Benjamin's essay on the "Work of Art in the Age of Mechanical Reproduction," Debord's "Society of the Spectacle," and Baudrillard's "Simulations," and "Fatal Strategies" are but a few examples in this direction. All these pertain to the moments of intervention with

FIGURE 1
Greimasian Semiotic Square of Modernism and Postmodernism

the real and the creation of the visual in what Martin Jay (1988) calls the "scopic regime of modernity."

The philosophical basis of the visual can be traced to Cartesian perspectivalism which according to Jay is the essence of the occularcentric culture which characterizes the society of spectacle. As Jonathan Crary (1988) argues about Western visual tradition, "the emergence of photography and cinema in the nineteenth century is a fulfillment of a long unfolding technological and/or ideological development in the West in which the camera obscura evolves into the photographic camera." As he further notes, "the abstraction and exchangeability of visual experience is intimately connected to economic and social transformations." That is to say, modernism has fused cultural forms into industrial/economic spheres of activity. The notion of the visual, a cultural transformation that is integral to the development of the spectacle is basic to the development of consumer culture where the visual imagery and the "reality" collide. The visual field, the argument goes, is commodified by spectacular creations which have become possible due to postindustrial technologies of reproduction, representation and information.

A fifth theme is a direct critique of modernity. Simply put, it states that modernity, in its quest for ethically ordered, rationally constructed, technologically oriented, seemingly progressive, and relentlessly unifying social order, has failed. It failed because it has alienated the individual, totalized human

life by marginalizing the lifeworld, and reduced form and substance into a single category of implosion. This condition of loss has resulted in considerable self-doubt, and has led to pluralistic modes of life through a desperate search for alternatives. This is what Lyotard (1984) calls the postmodern condition, or a condition arising out of a failure of modernity to truly emancipate the individual. Thus as a critique of modernism, postmodernism represents a realization that there is no single truth but multiple realities, all are legitimate and all equally valid; that individuals, societies and economies are not governed solely by instrumental reason but are subject to historical and cultural processes that cannot be explained by reason alone; that the human being is not necessarily the center of the universe; that modernism is itself an egregious male oriented conceptualization of the world and has consistently retarded female participation in human affairs (hence the emergence postmodern feminism); that capitalism is not the only desirable form of economic order; that progress does not mean marching linearly toward a predetermined goal; that the quality of life need not be measured in economic and material terms only; and that in human affairs aesthetic judgement is just as important as economic judgement.

As an extension of modernism (as opposed to a critique), postmodernism represents certain other developments. They relate to the burgeoning of new technologies, the changing nature of the global order,

and the development of new forms of aesthetic consciousness and knowledge structures.

Finally, we propose a Greimasian semiotic square to depict the relationship between modernism and postmodernism (Figure 1). The square also serves to represent the general boundaries of discussion for this debate. Using a system of contraries and contradictories, we argue that modernism and postmodernism stand in opposition to each other in the following way. Modernism, in economic terms, represents global capitalism which in turn is comprised of two key elements, (a) totalization of culture and economic production and (b) "innovation" as its transcendental telos, signifying the modernist imperative of relentless creation of things that are new, in an effort to keep moving ahead constantly, all the time. Postmodernism is represented in the figure in opposition to modernism with emphasis on pluralism (fragmentation) and the principle of replication. Replication stands for the reconstruction of the real, or as Baudrillard calls it the creation of the hyperreal.

To conclude, we quote from Featherstone (1991) as the main problematic of postmodernist debate, "A central intention in this [analysis] is to understand how postmodernism has arisen and become such a powerful and influential cultural image, and how this image has unfolded with such energy in contemporary consumer culture. This is not to assume that postmodernism is merely a deliberate "artificial" construct of disaffected intellectuals out to increase their own power potential. Far from it. Rather it is to raise questions about the production, transmission and dissemination of knowledge and culture. All developments point to the general conclusion that postmodernism has now outlived the duration of a fad, and is emerging as a powerful cultural image. This is a very good reason for social scientists and others to be interested in it. My purpose is to take the experiences and practices designated as postmodernism seriously and seek to investigate and comprehend the range of phenomena associated with this category. Yet, once we focus on actual experiences and practices, it is clear that there are similarities between these alleged postmodern experiences and practices and many of those designated as modern and even premodern. The challenge lies in differentiating between the dichotomies of modern and postmodern."

Fragmentations in the Postmodern

A. Fuat Firat, Arizona State University West

ABSTRACT

This paper (deliberately not fragmented by headings) investigates the different kinds of fragmentations present in contemporary life and their influences upon the consumer, and questions whether, contrary to the postmodernist position that all metanarratives are at an end, we are witnessing the appearance of a new kind of metanarrative.

Postmodernists have alerted us to fragmentations that seem to be all around us. These fragmentations pervade many experiences and take different forms. Philosophically, the more important form of fragmentation involves the discursive formations (Foucault 1972; Jay 1986; Lyotard 1984). This pertains to the inability, or in the case of the postmodernist, the unnecessary, the undesirability, of referring to any unified, consistent, centered field, idea system, or narrative. Thus, the postmodernist call to noncommitment to, or "incredulity with," metanarratives. Postmodernists see, in this fragmentation of and from metanarratives an end to such grand narratives, and some a liberation of discourse, experience, and self from imposed requirements of the unified centered idea system and culture (Lyotard 1986; Wilson 1989) or "regime of truth" (Foucault 1979). It is possible to argue, on the other hand, that the omnipresence of fragmentation in discourse, experience, and self constitutes, in itself, a new metanarrative; a postmodern one, one that is difficult to identify through modern(ist) categories and concepts.

Fragmentations in everyday experience abound. They persist in the media, the most important and dominating mode of exposure to our universe in contemporary society. Fragmentation is in advertisements on television, for example, where we have the thirty-second spots, each further fragmented into many fleeting moments of spectacular visuals which rarely link (as in the case of the *Disney* or *Headline News* commercials) with each other. The purpose of these fleeting scenes and visuals that are exciting to the senses is not to connect to (re)present a centered, unified meaning; thus, the necessity for continuity or complementarity is transcended, allowing the free play of visual images which are only meant to leave the audience with a heightened sense of excitement about the product marketed, an image which is attractive to the emotional existence of the targeted individual. While television is the major medium in contemporary society, it is by no means the only medium of fragmentation. Spoken or printed blurbs on the radio or in newspapers and magazines, highlighted brand names that flash by on billboards constitute primary experiences along with television.

Furthermore, advertising is not the only form which presents fragmentation in the media. News programs on radio and television, news items in magazines and newspapers, situation comedies, soap operas and other programs on television, all exhibit

similar fragmentation. One form of this fragmentation is the partition of the programs, etc., into short, disconnected moments and items, presenting each with great sophistication in technique and style, as a spectacle, to keep the interest, attention, and excitement levels high in the audience, but, then, having to "move along," with pace, onto other spectacles, since the disconnectedness among fragmented moments and items disallow the keeping of attention on the basis of a uniting content. Even the news programs attain the intensity of the commercial ones, playing the spectacle and the spectacular in each item of news, moving from one item to the next, each a spectacle. This is not different from the form of a situation comedy, for example, which moves from one scene to another, one "incident" to another. The trick in all programming for the mass audience seems to be one of allowing the audience to come in or leave the "scene" without feeling awkward, disoriented, or as if something is missing. Each moment, each item, each spectacle has to stand on its own, not necessarily begin and conclude, but (re)present an exciting, spectacular presence.

This requirement and, at the same time, strength of the spectacle is related to the second form of fragmentation. The moments, items, and scenes disconnected to each other are also fragmented from and disjointed to any context. As Gitlin (1989) articulates, each moment, each spectacle is decontextualized. No longer do things belong within a context or a historical process. "Anything can be juxtaposed to anything else. Everything takes place in the present, "here," that is, nowhere in particular" (Gitlin 1989; p. 350). It becomes possible, even preferable, to represent historical events on an even surface, without depth or a sense of the historical process, as a bricolage (Newman 1986; p. 45), in a way which maximizes the spectacle, the excitement, the emotional high. In news programs on television, news items in magazines and other print media, on the radio, and elsewhere, events, scenes, and personalities are often superimposed and juxtaposed onto each other from completely independent and disconnected contexts. In the postmodern, this is not absurd or improper journalism. Rather, the visual sensation of the bricolage is greatly enjoyed.

There is, as a corollary of this continual fragmentation from contexts in our media surrounding and informing us, a fragmentation of our thoughts, desires, and behaviors from our own contexts. Especially the postmodern generation, our youth, sever themselves from the worldly events around them. To the modern(ist) mind this is a state of being uninformed or ignorance. To the postmodern(ist) mentality this is an alternative form of being; one that liberates from the conformities or impositions of a single "regime of truth."

Such postmodern existence is reinforced by another set of fragmentations; that of the signifier

from the signified, the object from the function, and the product from the need. That all signifiers are only arbitrarily linked to the signified (and the referent) has been well recognized by semioticians at least since Saussure (Eco and Sebeok 1983; Santambrogio and Violi 1988). The link is only pragmatic, that is, culturally, linguistically imposed. In the postmodern, the modernist assumption of a natural link is ended and the freedom of the signifier is both declared and celebrated. As in the case of marketing campaigns, the "free-floating" signifiers are playfully and gainfully employed in (re)signification. They are constantly imbued with novel or nostalgic or reinforced meanings to represent a multiplicity of ideas, things, and positions.

As in the case of the fissure between the signifier and the signified, so is there one between the object and its function. All objects, including those specifically produced for a particular function, are, nevertheless, only arbitrarily connected to that function. At the moment of the object's origination is its independence from its culturally signified function. Imagine, for example, the number of different uses a child or even an adult not acculturated to a Western kitchen could find for a mixer. It would be very unlikely that they could correctly guess the use of a mixer in Western civilization. This liberation of the object from its intended use (freedom of objects from their functions) was well recognized by surrealist and other artists, such as Duchamp, Raushcenberg, and Warhol, who turned utilitarian objects (toilet seats, meat grinders, *Coca Cola* bottles) into icons and art pieces in their own right (Varnedoe and Gopnik 1990).

Finally, the product acquired in the market is independent of the need(s) for which the consumer initially sought it and the producer provided it. This, of course, is just an extension of the separation of the object from its original function. In effect, the consumer acquires the product for the image that it represents, and this image is only partially, if at all, constructed on the basis of the need perceived by the consumer. Furthermore, a single product is capable of representing multiple images, as signified by culture and by the marketing effort. Consequently, the disconnectedness of images and products from each other, from their original contents and from their contexts is complete.

The market and marketing practices further emphasize fragmentation of the product. In market exchange and in marketing there is a necessary concentration on the singular product or product group given the competitive conditions. Both in earlier representations of products by artists in catalogues and in more contemporary forms of advertising, the focus is the product which has to be singled out from a crowded background to concentrate attention on it. Such isolation of the product from its context, as in the case of "Just do it" *Nike* advertisements, reinforces the fragmentation that the consumer experiences in consuming the products. Such decontextualization seems to also promote the marketability of an item by making it a spectacle. An example is the sand painting, which originally was part of a medicinal ceremony and was destroyed at the end of that

ceremony. As a commodity, it becomes merely an object of desire, an art object, to be viewed and admired, and bought and sold. This decontextualization is, by no means, original to marketing, however, as evidenced in the sacralization of products through attributing of values and meanings to them independent of their original function or status (Belk, Wallendorf and Sherry 1989).

All such fragmentation certainly reflects upon the everyday life and being of the consumer. Growing influence and part of the market in human life, in terms of an increasing, almost complete, domination of life by the products bought in the market, the consumer's life experiences become also fragmented. In consuming each product, as the consumer eats a frozen dinner, watches television, feeds the cat, washes dirty clothes in the clothes washer, the consumer is involved in an independent, separate task which is only connected in the culture's imaginary, in narratives of purpose regarding a healthy life, a long life, an enjoyable life, etc. But these are indeed narratives that seem to seek a central, unified meaning and purpose for a life that is increasingly fragmented into moments dominated by tasks required by products consumed. In effect, these are modernist narratives, products of the modernist imaginary.

On the other hand, the consumers of postmodernity seem to be transcending these narratives, no longer seeking centered, unified characters, but increasingly seeking to "feel good" in separate, different moments by acquiring self images that make them marketable, likable, and/or desirable in each moment. There is, indeed, a growing disillusionment with committing oneself to long-term consistent goals or characters since there is the feeling that such commitment never delivers the promises of the narrative that required it. As a result, one finds a growing playfulness with the game of simulating and switching images to make the best of each situation the consumer finds oneself in.

Thus occurs the fragmentation of the self. In postmodern culture, the self is not consistent, authentic, or centered. Postmodernists will argue that it never was, in its core, or in tendency, but that in modernity the illusion of such a self was sanctified and, therefore, sought. The postmodern generation has transcended this quest and neither seeks it nor feels a guilt in not seeking it. On the contrary, this ability to switch images and represent different selves, by switching products that represent the images, allowing oneself to lay claim to powerful, successful images is considered as a liberation; freedom from monotony, boredom, and the necessity to conform.

In this fragmenting of self into self-images is also the partitioning of the body into body parts. The media, advertisements, music videos, artistic representations abound with such fragmentation. This reinforces the objectification and commodification of self through signification of self-images to be marketable in different situations. By considering each body part, the lips, the hips, the legs, the chest, etc., separately, each as a means of enhancing a required or desired image, and by (re)shaping or (re)dressing each body part with one's marketability in

mind in each situation, there is both a decontextualization of body parts and their perception as distanced from one's own being. In effect, the distancing is one of one's gaze from one's body. There is, in this process of perceiving each body part as a marketable item (as in the case of models whose hands or feet only are "bought" to be used in advertisements) a standing away from one's body and looking on as the other, testing and scrutinizing oneself from the vantage point of a distanced gaze, the gaze of the other. While this may recall the Cartesian separation of the mind and the body, it is, in fact, quite different. That which is distanced from one's own body is not the *mind* but the *gaze*. Specifically, this is not one's own and independent gaze (as the Cartesian mind is) but the gaze of the *other*. The scrutiny is done from the perspective of the expectations and requirements of the culture to which the body (representing the self-image) will be marketed, for which one's image must be marketable.

In partitioning the body and perceiving each part as an object to be dressed or customized (Moyers 1989) for marketability, the consumer turns to the market, to the products s/he can acquire in the market that represent the same images s/he wants or needs to represent. Not only are products that can be attached to the body purchased in the market but also the customized body parts in terms of plastic surgery, implants, etc. While the general perception is that women get such surgical customization of body parts, the number of men who acquire biceps, calves, etc., is also growing very fast. The separation of categories of gender (feminine-masculine) from categories of sex (female-male), in tune with fragmentations in the signifier-signified relationships, has allowed increasing possibilities for males to express themselves as consumers (Firat 1990 and 1991). These possibilities and the break in the traditional (modern) connections between sex and gender are increasingly represented in advertisements such as those for *Charlie*, the perfume, where women are represented in traditionally masculine roles and men are represented in traditionally feminine roles.

Some students of postmodernity have chosen to call the fragmentations in self representations and the switching of self images the schizophrenic self (Deleuze and Guattari 1983; Jameson 1983). There is a difference, however, in this fragmentation of the self, from the modernist definitions of schizophrenia in terms of an estrangement from oneself and from society (Laing 1969). While there is an estrangement from a self in the postmodern fragmentation of self-images, one cannot really talk of an estrangement from society. The multiple self-images are results of the reading of the society's, the culture's expectations from one. In a culture that does require multiple self-images, not being schizophrenic, in the sense discussed, may come to be categorized as pathological!

In a market exchange economy, all these self-images are, indeed, represented through the products acquired in the market, and, thus, the market becomes the locus of realizing the fragmented self, the fragmented moments of "feeling good." The market

is, itself, fragmented, since it appears to have no central, unified agenda, is construed of many consumers and products, and all relationships in the market are truly momentary; each transaction requiring no deep commitment on the part of the consumer. Indeed, the consumer can do a trial purchase, as long as the buying power is present, and drop the product, or use it momentarily as required in representing an image in one situation, then move to another, with other products. While, thereby, the moments of involvement in the market are fragmented, the consumer's self-images are to be marketable, that is, for the benefit of the market, and these marketable self-images are represented through acquisition of products in the market. In this sense, the market and its fragmentation become the center of all activity and the medium through which all is signified and represented without the appearance of any unified purpose, ideology, or narrative. This may indicate, contrary to the claims of the postmodernists for an end of metanarratives, the existence, at this juncture of the postmodern, of a new metanarrative that is not recognizable with the modernist categories and constructs which historically enabled the perception of existence of a metanarrative. Fragmentation, itself, and its medium, the market, constitute, in fact, this new metanarrative.

What Are You Doing After the Orgy? or Does the Consumer Really Behave ("Well")?

Ahmet Suerdem, University of California, Irvine; Mimar Sinan University, Turkey

"In the middle of the revelries, a man whispers into the woman's ear: What are you doing after the orgy?" (Baudrillard 1990)

In his "Cool Memories" on America, the French writer Jean Baudrillard discusses through his anecdotes some of the problems that contemporary societies of mass consumption are facing: In an endless schema of frustration/gratification, is human desire kidnapped and turned into a hostage without exchange? Aren't we sacrificing something through the model of affluent society in which we are trapped in a vicious cycle of coping up with the others? Isn't our obsession to compare our desires with those of the others reducing the ambivalent character of it to a "natural" and "naked" state so that our only pleasure resides in the act of watching? Isn't this commensurate spectacle leading to the impoverishment of the ambivalent character of human desire? Or better, is ambivalent symbolism itself becoming a parody through the system of signs of social standing as an only way of existing in the society? Are the orgies, feasts, potlatches, in short, ecstatic states of mind where the people could forget their self consciousness and transgress the limits of reason in order to be a part of the other, becoming a simple pornography, a simulacrum, a hyperreality, a reality more real than real? Are our irrational passions continuously captured and programmed into a hyperirrational order? Are we living in a permanent state of surveilled dream?

The first aim of this presentation is to try to investigate the philosophical origins of our obsession to "discover" the human desire and to "colonize" it by turning it into "needs" and "wants". Secondly, I will try to discuss how these "discoveries" and their utilization in their attempt to "educate" people are implicated in the modern societies. Last but not least, I will try to question the "success" of these implications in the process of disciplining the behavior of the consumer and shape the discipline of "consumer behavior". Can we get a "well behaving" function of consumer behavior and does the consumer behave "well" as presupposed by the consumer researchers and mass-media?

PHILOSOPHICAL ORIGINS OF SUBJUGATED DESIRE

The colonization of passion by reason finds its philosophical origins in Socrates and Plato. Pre-Socratic mythological thought is a game of passions, emotions, imaginations, as well as a system of measured reason. Aesthetics and Ethics are not universalized in mythological Pantheon: each of the Gods and demi-Gods represent a part of the excellence and the weakness of human existence trying to find its way through the misty aura of the cosmos. Mythology is a magical dramatization of everyday events, it represents the imaginative appeal of

instantaneous, miraculous and capricious rhythm and harmony of the cosmos (Beckman 1979; Richard 1982).

According to Socrates and his successors, virtue is obedience to reason considered as the right use of the mind. Passion distorts reasoning; it is evil. The mind free from passions is a citadel- a refuge for men who desire. Desire must be subjected to reason:

"Wipe out imagination; check desire; extinguish appetite; keep the ruling faculty in its own power" (Marcus Aurelius in Dawson 1924, pp: 86)

Good man puts himself under the control of intellectual reasoning. The source of all the evil is ignorance. Whoever commits error in the choice of pleasure and pain -that is, good and evil- commits it through the lack of knowledge; knowledge of what eternally exists: science. Science is the basic of ethics because it searches for the divine order of what really exists. The opinions are immoral because they deal with the changing facts, appearances. Facts are not true in themselves, they must be referred to the harmony, which is the mathesis, the order of orders. We can reach scientific knowledge by the education of desire; by the subjugation of desire to the disinterested, and sublimated knowledge in search of eternal truth (Cristaudo 1991).

The real object of science is knowing the necessities which are indexed in the universal order. Logical intelligence is the faculty of thinking the necessities in terms of universal harmony. It is the guide which illuminates our everyday life distorted by passions. The right and duty of the citizens is to know the necessities of every day life, production and consumption, that is, the universal law and order of existence. And one should always keep in mind the "real" necessities during the consumption act (Ostenfeld 1987, Dawson 1924):

"In things that concern the body accept only so far as the bare need -as in food, drink, clothing, habitation, servants (!). But all that makes for glory or luxury thou must utterly proscribe" (Socrates, Encheiridion xxxiii, in Dawson 1924, pp: 64)

In his famous trial, Socrates was accused, by Alcibiades, of being hypocrite by means of an excellent mastering of words in order to justify his passions. Maybe he was right when we consider Socrates' interest in "servants" as a bare need!

Passing through canonical monotheistic religions, subjugation of passion to reason finds its ultimate expression in Cartesian thought. According to Descartes, nature is a pre-set divine order and god gave us the reason as an instrument of understanding it for the general interest of the mankind. Freedom is the

understanding of the divine order of things; the will must follow this order. The more one is inclined toward natural order, the more free he is (Cristaudo 1991).

Nevertheless, man is not only a rationally thinking being; he is an animal machine who lives without the permission of thought. Our passions are generated not from our opinions but from the involuntary movements of human body. They are not good or bad in themselves, but a part of human nature. Hence, desire must be recognized as need in order to be under the control of the reason to promote the general welfare of the mankind.

Another tendency of modern rationalism is represented by Friedrich Hegel (Grumley 1989). According to Hegel, nature itself is a self-realizing consciousness. It is a moment in the accomplishment of the absolute reason- Spirit. In this sense, consciousness of the individual can not realize itself through the knowledge of existing natural facts which themselves are the alienated singular moments of Universal Spirit. Freedom is not only knowing the necessities but also changing them toward the self-realization of the finality of the History.

Hegel (Richard 1980) considers desire as the motivation for passion; the opposite of Spirit. Passion is the particular, multiple, it does not envisage the unity but diversity. Desire ties the man to his body by detouring him from the search of absolute knowledge which should be his real aim. Desire opposes the will to realize the universal reason because it is determined by particular needs. Passion is a "pathos", a sufferance which turns life into destiny instead of driving the subject to the quest of freedom.

THE SOCIAL IMPLICATIONS OF THE RATIONAL MODERNITY

The extension of these two tendencies of modernity in terms of social and economic explanations of human behavior manifests itself in utilitarian (Cartesian) and Marxist (Hegelian) theories. For the first one, human being is a rational being with unlimited needs and wants who has to act in an environment determined by scarce resources. Although needs and wants are unlimited, they are not ambivalent: they are commensurate according to the different levels of utility gained from their satisfaction.

Thus, freedom is full information of what is available; at what cost; and the ability to compare different levels of utility which would be obtained from the satisfaction of wants. Individual has a preference, he knows what he wants; he is capable of consistently ordering his wants from most preferred to less preferred; and he will choose from within this ordering in such a way to maximize his satisfaction (Bohm-Bawerk 1949, McKenzie 1976).

Talcott Parsons (Parsons 1964) extends the utilitarian theory to a social system basis. According to Parsons, the motivation for human behavior is not the pure self-interest. Economic rationality is not a psychological generalization but a value system appropriate to the social system. The goal of the economy is not simply the production of income of an

aggregate of individuals. Besides, the reproduction of the social system as a complex whole of institutionalized value patterns is the essential mechanism of the social system. The first functional imperative of the social system is to maintain the integrity of that value system and its institutionalization. In this sense, households, universities, units of government, churches etc., are in the economy (Parsons 1956).

Freud introduces a new dimension to the concept of desire as a motivating force of human activities: the satisfaction of primary needs such as food, shelter, clothing, etc., is more or less immediate. Desire realizes itself and consumes its realization spontaneously. Nevertheless, this is not true for sexual instinct (libido). Desire stays latent in the unconscious because of the repression of the immediate consumption. This causes a state of frustration and the missing object of desire is replaced by symbolic objects. Desire, which is sexual in nature, transforms itself into a need for these objects. The "pleasure principle" replaces itself with the reality principle: man learns to give up momentary, uncertain, frustrating pleasure for delayed, restrained but "assured" pleasure (Marcuse 1966, Freud 1970).

The discourse on consumption shifts its axis from the principle of "lack" to the principle of "abundance" during the post-second world war period: The organization of the society becomes so complex that the "homo economicus" can no more decide on what is "good" and what is "bad" without the help of educators. This is a dangerous affair however: who would decide about the "realness", "essentiality" of the needs which the consumer is not aware of? There comes our old friend "science" who is accustomed to operate always together with the morality since Socrates. It seems that science and morality are not satisfied by the colonization of the nature outside the "human subject", now they are here for the discovery of what is inside the man. Motivation research was their first galley in their conquest of the dark waters of the non-rational and they are finding more and more complex vehicles. "Conquistodares" continue to colonize the world and their missionary is the mass media.

Of course some old fashioned moralists did not wait to criticize this situation: the motivational analyst and symbol manipulator pooling their talents and millions of dollars at their disposal, were making a fascinating and at times disturbing team. They were shaping the minds by using the occult influences (Packard 1957).

Ernest Dichter comforts: there is nothing to be afraid of. Motivation research is only in the quest of human behavior. Human desire is the raw material it is working with. Human progress is a conquest of the animal within us. The strategy of human desire is the tool of shaping the human factor. No conquest is possible without strategy !

Human behavior can not be explained merely by the rational, conscious acts. Our daily decisions are governed by motivations over which we have no control and of which we are often quite unaware. Modern communication makes the use of emotional

appeals in addition to rational ones in order to sway people. Very few products have purely utilitarian aspects. Motivation research only helps us to achieve a number of deeper psychological goals. Why should we try to repress them? What we need is a new freedom - the freedom to think in new channels. Motivational research is the application of social science techniques to the problems of human motivation (Dichter 1960).

The Hegelian extension of modernity as a socio-economic system manifests itself in Marxism. According to Marxism, classical and neo-classical economic theories reflect an alienated reality. The concepts of utility and exchange value which are taken for granted by these economists are in fact historically determined and socio-economic processes. The scientific method can not restrict itself only to the understanding of the immediate reality but has to operate in order to change it towards the laws of motion of the history.

According to Marxists (Mandel 1969), man is estranged to nature through his act of production. In primitive societies where the division of labor is not developed, men produce use values for their immediate satisfaction. Nevertheless, with the development of division of labor, men begin to produce commodities for exchange. Exchange value becomes a mediator between man and man whereas use value is the mediator between man and nature. This process of objectification turns into a process of alienation; man becomes alienated to the product of his labor.

Total alienation occurs with the generalized commodity production, where the private property of means of production deprives the laborer from his direct labor act. Concrete labor becomes subjugated to the exchange value, the abstract quantity of social labor. This subjugation implies the commodification of labor as labor power. Alienated labor becomes the only mediator for social exchange. Society loses the control of social relations created by itself. Commodity fetishism occults the market relations as a product of human activities and makes people believe that the laws of market are natural laws. During this process of production for pure exchange, the capitalist speculates on creating a new need in another so as to drive him to a fresh sacrifice, to place new independence:

"Subjectively, the extension of products and needs becomes a contriving and overcalculating subservience to inhuman, sophisticated, unnatural and imaginary appetites".(Marx cited in Mandel 1973 pp: 36)

The only possibility of overcoming this distorted reality is the action of historical subject armed with critique.

Criticism has its origins in Post-Socratic philosophy as its cousin positivism. It is the art of explaining the phenomena which are "veiled" by images, appearances. Considered as one of the essential activities of reason, critique opens the way for the rational subject through all spheres of life to make them accessible. In monotheistic religions, it is a way of interpreting the "signs" in order to justify the

supremacy of the "word", "scripture", "the holy book".

In this context, critique is the instrument of reason to reflect on the "objectivity" of the objects of experience. On the other hand, dialectical critique distinguishes itself from the metaphysical critique in the sense that it aims to change the conditions of what is considered to be false or distorted consciousness. It claims to render transparent what had been previously hidden in order to initiate a process of self-reflection to achieve a liberation from the dominations of past constraints.

In its vulgar forms, marxist critique observes the liberation from the alienation in ex-socialist countries (alas !). In these countries working class is not alienated to its labor because the private property of the means of production is abolished. Socialist state takes care of the "essential needs" (i.e. use value) and socialist man does not have "inhuman", "sophisticated", "unnatural", and "imaginary" appetites. Working individual in socialist countries is not alienated to his products; he constructs socialism through his production act: he is a "labor hero", a new man, who realizes his "unalienated desire" in making of history. Each magnificent dam built, each sputnik sent to space, each olympic medal won by an athlete belongs to the victory of the socialism in which each individual is involved as an organic member.

More subtle approaches of critical theory are represented by the Frankfurt School. Adorno and Horkheimer claim the replacement of practical reason by instrumental reason as a result of the developments in culture industry. The alienation caused by the commodity fetishism infiltrates into the consciousness of the working class through the commodification of culture by the leisure market. Since then the self realization of working class through its "praxis", its practice of labor to transform the world becomes a part of instrumental reason. Although the classes exist, there is no more possibility for class consciousness for working class. Public invades private, private invades public. It becomes difficult to make a distinction between the external suggestion and internal desire. The main principle of domination becomes manipulation of desire instead of repression. Hence, instrumental reason forms an impersonal system which becomes independent from all the members of the society, including those in the ruling positions. Either bourgeoisie or working class lose their position as subjects but turn into objects dominated by the technical rationality. Adorno and Horkheimer try to recover rational subject by means of a "negative dialectics", a criticism of commodified objects according to a sublimated art (Bottomore 1984).

Even in this subtle approach of Adorno and Horkheimer, reason as the realization of the universal ideals continues to colonize everyday life. Furthermore, they seem to share the same ideals with the "consumer researchers", in the sense of "educating" and "informing" people about their "true needs". They form a harmonious couple after all, where human boredom needs exigently self-cannibalizing

novelties: critique and interpretation revolutionizes, consumer research rationalizes.

TOWARD A PROGRAMMED SOCIETY?

One of the first resistances to the reason oriented universalist modernity comes from Friedrich Nietzsche. Nietzsche accuses Socrates of reducing philosophy to a discourse which tries to regulate passion for will to live into a unique, universal reality. Philosophy becomes serious, logical, clear and demonstrative with Socrates. Reason analyzes, dissects, systematizes, makes rigid what is hidden in deep. Nevertheless, interior life of man is an act of ambivalent passion rather than being an act of cold objective rationality. Desire is rooted in the life which gives us the will to live. It is the passion to exist. In this sense, it is not possible to rigidize it into the tracks of rationality. To live in harmony with cosmos does not mean to follow the tracks of an assumed universe but to feel the rhythms and pulses of the life. Thus, desire opposes knowledge when it does not accord with life. Desire is pathetic; in the sense of both suffering and sharing. It is the aspiration to deepen the life in our singularity and to be in accord with the flow of the cosmos (Deleuze 1983, Richard 1980).

Georges Bataille (Bataille 1985) pushes further Nietzsche's arguments. Bataille claims that rationalistic realism invades all domains of life with the development of modernity. Endless quest of reason to appropriate external forms into an organized system of words causes the impoverishment of human imagination: words order, but images evoke symbols. What strikes human eyes determines not only the knowledge of relations between various objects, but also a given and decisive state of mind. Therefore, it is not the rational signification of the symbols which make them important for human existence, but their irrational ambivalence.

Following this reasoning, Bataille points out that the rationalization of the human desire as necessities and regulating it in terms of a rational utility frame would be repressing it in order to maintain a certain order which is hypocritical and unjust. How can material utility be the main task of life, Bataille asks, since it is limited to the reproduction and conservation of whatever exists? Man is not only a calculating machine whose goal is to realize benefits, but also an emotional being which realizes itself in the symbolic sacrifice. Sacrifice is a mythical delirium from all selfish calculation and reserve. It signifies an ecstatic exit from the self, a desire to put one's body and mind entirely in a more or less violent state of expulsion. Sacrificial consumption is the elementary form of orgy, which has no other goal than the incorporation of irreducibly heterogeneous elements (Bataille 1985).

Jean Baudrillard (Baudrillard 1970; 1983; 1990) develops similar arguments concerning symbolic exchange. In today's consumption societies symbolic exchange becomes a parody under system of signs of social standing. What we consume in consumption societies is the meaning of the signs. The signs transmitted by the mass media do not

signify a meaning in themselves, but mobilize the collective imaginary to give them a signification. When everybody agrees on the meaning of the sign then it is consumed (consumated). Mass media is an infinite generator of signs without signification. Thus, the main principle of consumer society becomes non-difference through difference, normality through competition.

Mass psychology provokes the people to have what others do not have, but since everybody is doing the same thing, there begins a competition for the "ultimate model". When everybody has it then it is no more "ultimate" but "obsolete". Contrary to the puritan rationalism where the "model" is more or less stable, today's hyperrationalism has to consume its "model" in order to maintain its operation. Planned motivation takes the place of moral responsibility and extends the puritan morality to a hedonistic morality of self-fulfilment. The feeling of guilt after transgression replaces itself with the rationalization: in order to be normal, you have to change- you have to cope with others.

Language of the consumption society is the most impoverished of languages: full of signification and empty of meaning. This empty space is filled by the consumer researchers who always find and operationalize new motivations to replace the obsolete ones. There is no more fixed "human nature" or a referent for marketing. Unlike the modern establishment, there is no more a discourse of reality which serves as a fixed referent in the post-modernity; it is replaced by its simulacra. Social sciences invent new realities when the old ones are obsolete and diffuse them through mass-media: the invented reality becomes real through simulation; a reality more real than real; a hyperreality. In the simulative church where the researchers are the priests and the "deep motives" diffused by the media are the preachings, the masses depend on the mood of the consumer: they do not repress, they do not manipulate, but simply seduce the desire in order to turn it into new tracks of sign.

Thus, the system of consumption society does not reproduce itself according to total order and to the principle of production. Programmed chaos and "catastrophe" becomes the main principle of the system: the system must destroy its order in order to maintain the order. The main principle of this system cannot be power, because power produces the real, it perceives itself as real, immortal, eternal (with the aid of the theories which analyze it, even to criticize it.) Seduction is stronger than power: because it does not need a fixed reference; it is a reversible and mortal process.

Every body is not as pessimist as Baudrillard. According to Michel de Certeau (de Certeau 1984), most of the analyses of the consumer culture are concerned with the representations produced by an ordered system on the one hand, and the modes of consumer behavior adapting to these representations on the other hand. However, these analyses do not take into account what cultural consumer "makes" or "does" during this process of consumption and with the images represented to him/her.

Although de Certeau agrees with the theories of colonization of every aspect of life by systems of production, he goes further and observes a silent, non-violent resistance which survives in the domain of consumption. As the indigenous Indians of South America under Spanish colonizers, who did not resist Christian missionaries but simply adopted the signs of Christianity and subverted them according to their own culture, today's consumers use and transform the meanings of the "products" which are imposed to them. The preachers, educators, popularizers of production may present and diffuse the "technologies" of "how to use" the signs- that is all they can do. They can not control the users since they do not resist and seem to accept these rules. They can act as engineers of the social mind, but this does not necessarily mean that they can fragment and construct it. The masses follow a different way of thinking which is too fugitive and ambivalent to be shaped by the strategies of the managers of the mind (de Certeau 1984).

Michel Maffesoli observes the renaissance of the mythological ecology in the post-modern object. Post-modern ethos does not constitute itself according to a historical project, but in a reappropriated nature, within a shared space, collective participation to the world of objects. We are witnessing a naturalization of culture and culturization of nature through post-modernity. Objects invade spirituality and spirituality invades the world of objects. Our megalopolis become jungles where different objects flow imprevisibly. Post-modern object becomes the "fetish", the "totem" where social body remembers itself. The invasion of the natural and social by the "reified" objects makes any attempt of a planned control by a manipulating subject very difficult. We begin to live in an aura weaved by mystical objects. The world of objects is no more mastered by anybody; post-modern object revenges by returning to ambivalent symbolism. It reenchant the world disenchant by modernity.

Hence, Maffesoli does not observe a programmed system of objects in commodity fetishism. The order of post-modern object is rather like a kaleidoscope which is a programmed uncertainty. It is a diffraction to the infinity. The nature of the post-modern object is not evolutionary, objects revolt against their programmed finality (either in the form of invisible hand or history); they re-evolutionize (in the sense of revolving) their order in order to subvert it. In each order, the "system of objects" has a different logic. It is a nature in a state of permanent creation through its degeneration, instead of an evolutionary nature where the strongest survives.

The masses do not converge toward a "standard package" through consumption but they diverge toward multiplicity. This gives rise to a more complex society which is fragmented and disseminated with a multiplicity of contradictory values instead of homogeneous and linear order of modernity. Post-modernity, like the Baroque, degenerates and regenerates different styles harmoniously through small details (Maffesoli 1990, 1988).

Gilles Lipovetsky (Lipovetsky 1987) criticizes the critiques of consumption society and mass culture and concludes that fashion is not a form of "soft neo-totalitarianism", "repressive tolerance" but on the contrary, the expansion of the public questioning, autonomization of public thought and the agent of individualist dynamic in its divers manifestations. In this sense, fashion is the ultimate phase in today's democratic societies. Lipovetsky also observes a "ruse of reason", a popular wisdom in the crazy orgy of mass culture: collective reason advances by the help of its opposite, the irrational heteronomy of the seduction. As in the rational city of the antiquity whose rationality was formed by a network of egoist passions, autonomous subjectivities develop themselves through seduction and ephemere, critical, realist consciousness develops itself through frivolousness in today's consumption societies.

Hence, with its ambivalent structure, today's individual constitutes and reconstitutes itself in the unordered order of generalized fashion. On the other hand, this unordered does not represent an ideal system, a best of the worlds but a possibility toward a more free, better informed society. Generalized fashion lives in paradoxes: its consciousness favors unconsciousness, its craziness the spirit of tolerance, its mimetism individuality, and its frivolity the respect of human rights.

CONCLUSION

We are living an explosion of the universalist reason and post-modern consumer does not behave totally reasonably. He/she lives in an emotional aura where the borders between the real and imaginary are blurred; maybe in a hyperreality where the ordered reality is replaced by its simulacra. The closed systems of thought which refer to economics, sexuality, politics etc., as the content of reality deconstruct themselves. The referentials come and go like comets in the sky making a general theory of consumer behavior ridiculous. Not only does the consumer behave according to the caprices of fashion; but also its "science". They interactively transform each other towards new fashions in a reversible, baroque cycle of seduction. In the 1950s consumer was "homo economicus"; in the 60s he was "homo sexualis"; in the 70s he was "homo politicus"; in the 80s he was "Rambo"- "homo survivalis" with a manager's suit at the top and naked as a savage at the bottom- with an American Indian mother and a German father. In the 90s there is no reason for not to presuppose that he is becoming a "homo ecologicus". However, these cycles are not "trends". They do not assume a linear development which exclude one another. Rather, each cycle collapses onto and into the other squeezing the other layers to form colorful pieces of quartz.

Last but not least I would like to comment on our position as a social scientist, citizen and consumer in this changing world. Post-modernity gives an end to the dichotomy of order and chaos. We are living in a jungle where order of chaos generates its colorfulness and its peril. It may turn into a joyful spectacle where different species enjoy to share the

same ecosystem or a carnage where the stronger cannibalizes the other. Although we have renounced all "grand responsibilities" implied by a rational puritan morality; we need to develop "little responsibilities", (ability to respond), responsibilities of cohabitation in everyday life depending on ethics of existence, a manner of being which would turn post-modern life into communion rather than cannibalism. Since we are con-damned to live in this jungle; since "we may have come with different boats or canoes, but today we are in the same boat" (Martin Luther King), we have to learn live together.. (After all ?) Hence, what are you doing after the orgy?

Examining the Descriptive Value of "Ritual" in Consumer Behavior: A View From the Field

Douglas B. Holt, Northwestern University

ABSTRACT

The term "ritual" is increasingly used to describe certain types of consumption activities. Ethnographic research examining one such activity -- baseball spectating -- is used to ground a discussion on the accuracy and usefulness of this application of ritual. I argue that three current conceptions of ritual in consumer behavior -- one which examines behavioral traits associated with ritual, one which considers ritual as sacred experience, and one which considers ritual as symbolic action -- do not usefully describe the experience of most baseball spectators. Rather, I speculate that baseball spectating is more aptly described as an experience where the consumer makes profane use of legitimated cultural meanings.

A small group of spectators gather in the bleachers an hour before the game to watch their favorite players take batting practice while they swig beer, eat peanuts, and bake in the sun. Many wear the colors and logo of the home team -- the Chicago Cubs -- on their clothing and some have brought signs to display in front of the TV camera. By 12:45 PM, the bleachers are nearly full while the spectators in the grandstand are just beginning to search for their reserved seats. At 1:05 PM, 15 minutes before game time, an employee of one of the Cubs' corporate sponsors takes the field to throw the ceremonial "first pitch." The Cubs catcher, Joe Girardi, catches or otherwise retrieves the ball, signs it, and returns it to the spectator. Several minutes later, the Deer Plains Community Choir leads the crowd, 35,000 strong, in the singing of the national anthem. As the announcer intones "Now taking the field, are *your* 1991 Chicago Cubs!" the Cubs warm up for several minutes and, at approximately 1:20 P.M., the game begins with the announcer dramatically ordering "Let's [pause] play ball!"

Each play begins more or less the same way: a batter stands beside home plate, the pitcher exchanges signals with the catcher, the ball is thrown, sometimes the batter swings at the ball, and some of these swings connect, leading to some type of play on the field if the ball hasn't gone foul. When the batter hits the ball in fair territory, or accumulates three strikes or four balls, another batter comes to the plate and engages in the same structured activity. When the team at bat accumulates three outs, the teams switch positions and the

sequence of action is repeated. When the team that is losing has had an opportunity to bat nine times, the game is over (excluding tie games). This pattern is repeated during each of 81 games at Wrigley Field over the six-month baseball season, year after year.

In the early innings, most of the spectators pay attention to the game and often respond in unison to the events on the field: as an opposition batter strikes out, they applaud and cheer; when the Cubs' pitcher walks several batters in a row, most spectators boo and some yell comments like "Get him out of there!"; and when a Cubs batter hits a home run, the spectators behave hysterically, standing on their feet, yelling and applauding, pounding each other on the back, waving their hats, fists in the air, "high fives" everywhere.

Occasionally, the spectators will begin a chant, such as "Right fields sucks!" When Andre Dawson makes a nice catch in right field, some spectators bow to him, bending at the waist (a "salome") to show their appreciation. In the middle innings, many spectators become less attentive and discussion moves to problems at work or the various attributes of a nearby member of the opposite sex. After 7 1/2 innings, the spectators rise to their feet and join Harry Caray in singing "Take me out to the Ball Game." Toward the end of the game, if the score is close, attention turns once again back to the game. In dramatic finishes, such as extra-inning or come-from-behind victories, the crowd buzzes with excitement, cheering uproariously when play on the field brings the Cubs closer to victory and grimacing and swearing when they make crucial mistakes. At the end of the game, when the Cubs win, the crowd is jubilant, revelry is in the air; a loss, especially in a close game, brings collective grief as the spectators shake their heads in dismay.

This composite description exemplifies the collective, formalized, repetitive, bracketed (in terms of time and space), dramatic, and emotional qualities that characterize the spectator's experience of attending a professional baseball game, and likely numerous other consumption activities (e.g., other spectator sports, participatory sports, music concerts, theatre, movies, festivals, parades). These attributes are remarkably similar to those associated with the religious or sacred rituals of primitive societies (e.g., Durkheim 1915; Turner 1967). Thus, the term "ritual" has often been used by social scientists, both within consumer behavior (Belk, Wallendorf, and Sherry 1989; Rook 1985) and in other disciplines (Birrell 1981; Cheska 1978; Fiske 1972; Stein 1977; Voigt 1980) to describe such events. In fact, a recently-

¹I would like to acknowledge the constructive comments provided by Sid Levy, Dennis Rook, Helen Schwartzman, and John Sherry on an earlier draft of this paper.

published essay by the past commissioner of baseball (and ex-president of Yale) is devoted to demonstrating the relation between baseball and the sacred (Giamatti 1989).

The purpose of this essay is to examine critically the application of the term "ritual" to describe these consumption activities. Three distinct uses of ritual found in the consumer behavior literature are evaluated in terms of their ability to describe one example of this form -- baseball spectating. None of the three captures the experience of baseball spectators as I have encountered them in my fieldwork. Rather, I speculate that the exigencies of modern/post-modern society lead to a distinct form of group consumption that is profane in character. Ethnographic fieldwork is used to guide these speculations.

THREE APPROACHES TO RITUAL

While the study of ritual originated in the anthropological study of behaviors referencing magico-religious beliefs, within consumer behavior (and elsewhere), the domain of ritual has been extended well past this original conception to include many symbolic actions carried out by individuals, groups, and societies (e.g., attendance at museums, music concerts, and sporting events, making a house a home through decorating, grooming activities, national holidays, collecting). Belk, Sherry, and Wallendorf (1989) generally adopt the traditional view, restricting the domain of these rituals to that which is sacred. Rook (1985), and Tetrault and Kleine (1990) in their modification of Rook's approach, reject this type of limitation on ritual in favor of a definition based on commonly-observed trait characteristics (referred to as the RTK definition). McCracken (1988) adopts a generic definition of ritual as "symbolic action." I will examine the RTK definition first.

Ritual as the Intersection of Behavioral Traits

Definition. RTK define ritual (with slight differences between the two papers) as an analytical class of symbolic-expressive behavior demonstrating certain qualities such as standardization, purposiveness, formality, repetitiveness, drama, bracketing (in time and space), scripted sequences, and group enactment. Through this combination of traits, ritual is differentiated from related types of behavior such as habits, customs, and conventions.

This list of traits provides a useful foundation for understanding ritual but is incomplete. Constructs such as "ritual" are given meaning when they are embedded in a nomological network that describes their antecedents and consequences (Cronbach and Meehl 1955). Except for a brief reference in Tetrault and Kleine (1990, p.33) to the role of ritual in social and/or moral ordering, neither paper attempts to make such nomological connections, leading to a definition that becomes increasingly fuzzy under scrutiny. First, consider that research in both anthropology (Rosaldo 1968) and sociology (Goffman 1967; Wuthnow 1987) has demonstrated that ritual can effectively reinforce social and cultural structures with few if any of these

attributes. Studies on the ritual dimension of the televised Watergate hearings (Alexander 1988) and the television mini-series *Holocaust* (Wuthnow 1987), for example, suggest that ritual need not be repetitive, formal, or enacted in groups. And Goffman's (1968) studies of interaction rituals show how non-dramatic, non-bracketed, mundane behavior acts to maintain the individual's moral order. The trait characteristics aptly noted by RTK serve to enhance the communicative value of ritual (Wuthnow 1987; McCracken 1988), but ritual regularly occurs outside of this domain.

Second, in order to maintain definitional boundaries, RTK attempt to exclude certain behaviors that demonstrate some or all of the listed traits -- habits, customs, conventions -- as non-rituals. Many habits, for example, are formalized, repetitive, dramatic, bracketed and so on. As Wuthnow (1987) argues, attempts at differentiating these actions because of their lack of drama or formality are not convincing, for many supposed "non-rituals" are highly dramatic (consider changing a flat tire on a busy highway) and highly formal (consider the behavior sequences found in riding elevators).

If, following this line of argument, one rejects attempts to limit the domain of ritual through trait characteristics, then a non-religious approach to ritual as pursued by RTK necessarily expands to include all symbolic-expressive action (Leach 1976; Wuthnow 1987). Ritual, in this conception, is not a type of activity that can be isolated, but rather a dimension of all social activity.

Ritual as Symbolic-Expressive Behavior

Definition. As symbolic-expressive behavior, ritual is defined as that dimension of behavior which assists in the communication of socio-cultural meaning. For example, ritual can maintain, transmit, or manipulate meaning (Cheal 1988; McCracken 1988; Wuthnow 1987). McCracken (1988, p.84), following Victor Turner, views ritual as "an opportunity to affirm, evoke, assign, or revise the conventional symbols and meanings of the cultural order." Ritual, then, describes those aspects of symbolic consumer behavior involving action, as distinguished from a focus on the symbolic content of objects.

Baseball Spectating as Symbolic-Expressive Behavior. Baseball spectating certainly qualifies as a ritual according to this definition. Through their actions, spectators develop, maintain, and manipulate many different types of cultural meanings concerning the players, the home team, the baseball park, other spectators, and the game itself.

But while baseball spectating is no-doubt a form of symbolic-expressive behavior, this attribution does not provide much assistance in discriminating this activity from infinite other consumption activities that serve similar communicative functions. If all forms of eating, driving, listening, talking, dancing, wearing, reading, and so on can be considered as rituals based on their symbolic content, the term is of little use in describing any unique qualities of these practices. This definition, then, is too inclusive to usefully

describe baseball spectating relative to other consumption activities.

Ritual As Behavior Referencing The Sacred

Definition. "Ritual" initially emerged as a descriptive term in cultural anthropology to name certain expressive forms of behavior that referenced the cosmological and magical (Malinowski 1954), mystical (Turner 1967), superhuman (Rappaport 1971) and/or sacred (Durkheim 1915). While Rook (1985, p.252) and Tetrault and Kleine (1990, p.31) have criticized the religious version of ritual, viewing it as "myopic" and "jingoistic," these authors seem to aim their criticism toward the traditional definition involving supernatural, mystical entities, rather than toward the broader Durkheimian understanding of religious ritual as behavior that references the sacred. Individuals do not have to invoke cosmological beliefs to engage in sacred ritual, although such beliefs are certainly pervasive. Belk, Wallendorf, and Sherry (1989) use a Durkheimian conception of ritual in their development of the sacred dimension of consumption. They define ritual as those activities that evince sacred properties such as *communitas*, *kratophany*, contamination, ecstasy, and flow. Their definition, too, becomes better specified if expanded to include antecedents and consequences. Here I suggest that the areas of experience that consistently evoke the sacred, treated briefly in the conclusion of Belk, Wallendorf, and Sherry's paper, be appended to their formal definition. (One might also include Turner's concept of liminality or anti-structure in ritual as a creative, generative source of culture and structure (Turner 1969). Space limitations, however, prevent a satisfactory exposition of both of these approaches.)

For "neo-Durkheimians" (e.g., Berger 1967; Douglas 1966, 1970; Geertz 1973; Wuthnow 1987: "neo" in that these theorists focus on order at the cultural rather than the social level), ritual is considered to be a means for managing ontological disorder. Ritual seeks to resolve the tensions that emanate from areas of human life that are difficult to comprehend and incorporate into one's moral order -- that is, one's understanding of "the way things are" and "the way things should be." While most experiences are easily integrated and thus are taken for granted, there are perplexing and troublesome questions that universally arise, arational areas that resist organization through logic or science (e.g., those involving death, nature, goodness, suffering, and social/political order). These areas of ontological disorder -- referred to variously as "chaos" (Berger 1967; Geertz 1973), "dirt" (Douglas 1966), and "social uncertainty" (Wuthnow 1987) -- occur as a universal human condition and are typically managed through culturally-constituted meanings. Humans collectively develop systems of meaning (the "nomos," Berger 1967) that manage the incomprehensible. The nomos joins an individual's values (or ethos) with his or her understanding of existential order (or world-view). This "sacred" system is made up of two components -- a belief system and a system of symbolic action (or ritual) -- that are mutually reinforcing (Geertz 1973). Since the

belief system is culturally created and thus potentially ephemeral, humans must actively validate and empower these sacred concepts. Rituals, then, serve to make concrete and credible the cultural principles and categories that organize the inherently chaotic elements of human life. In addition, sacred rituals are not only a means of comprehending, but also a way of experiencing. Along this line, Belk, Wallendorf, and Sherry (1989) elegantly synthesize the accounts of sacred experience that appear in many of the social science literatures (e.g., Durkheim's "collective effervescence" and Turner's "communitas").

This conception of sacred ritual, in addition to providing a linkage between the variety of metaphysical beliefs found in different societies, also encompasses many of those rituals that often are categorized separately as "secular ritual." For example, rituals reinforce or make concrete ontological organizations regarding the genealogy of animals (food taboos), the social status of the individual in a society (rites of passage), fate or chance (rites of affliction, magic rituals), the boundary between personhood and society (positive rites, national holidays, political coronations), and the structure of interaction in an impersonalized society (conversation openings and closings).

Baseball Spectating as Sacred Ritual. Clues to the sacredness of a symbolic action can be gleaned by looking for indicators of both characteristics of sacred ritual discussed above. As a tool for making sense of ontological disorder, sacred ritual is indicated by the intensity of effort applied to maintain a particular reality in the face of profane threats (Durkheim 1915). And as a way of experiencing the world, sacred ritual is indicated by the achievement of transcendent experience (Turner 1969). In my fieldwork to date, involving interaction with some 300 spectators, I have witnessed only a handful of spectators that may have demonstrated these qualities. (The actual number is somewhat arbitrary since these qualities exist as a continuum, not as a duality, and my demarcation is necessarily subjective.)

One spectator whom I frequently encounter -- Tim -- exemplifies the first indicator in that he demonstrates a profound respect for the set of guidelines that define the proper comportment for a spectator at a game. The rules of baseball, both formal and informal, are treated with the utmost respect. Tim becomes visibly upset when other spectators fail to live up to these rules, often reprimanding them. Tim, and the few others like him, have internalized these rules to the point where they are unquestionable; they are "the way things are," so that any threats to these rules become threats to the self.

While many spectators are just as competent as Tim in their ability to understand and act on these informal rules, very few treat them as Tim does. They do not "live" these rules, but enact them to enhance their consumption experience. Often the rules conflict with other interests and are unhesitantly broken: spectators often stop paying attention by the middle of the game and chat with their friends; they leave in the eighth inning to beat the rush to their car; they refuse to show deference to the Cubs' star players.

Perhaps even more telling, most competent spectators completely accept the inability or unwillingness of other spectators to follow the rules and conventions of baseball. It is my opinion, then, that the vast majority of spectators understand these rules as more-or-less arbitrary conventions that make the game interesting rather than rules that directly connect to their *nomos*. The meanings intrinsic to the game are important only in respect to their ability to enhance the consumption experience; they have little intrinsic value except to the few spectators who, like Tim, use them as concrete reminders/examples of their understanding of the world.

The second indicator -- transcendent experience -- is rare indeed. I have observed several spectators, including Tim above, who appear to lose themselves in the game, who treat the game, its players, and its play with awe, and who evince an intense joyfulness emanating from their interaction with the game. But the vast majority of spectators I have encountered rarely exhibit signs that spectating allows them to achieve transcendence.

There is one potential exception to this statement -- specific situations arise in some games that lead to spectator responses closely matching descriptions of transcendent experience. In fact, it is the presence of these situational emotional responses, in addition to the formality and repetitiveness of the game, that leads many observers to categorize sports spectating as sacred ritual. But these situations are counterintuitive to theories of ritual, and are susceptible to an alternative interpretation. Two types of situations repeatedly evoke sacred-like emotions: dramatic situations and outstanding performances.

Dramatic situations usually occur toward the end of the game when the outcome hangs in the balance. The drama is magnified if the game outcome also has implications for season outcomes. There are certain dramatic structures that tend to evoke transcendent reactions: for instance, come-from-behind victories, games where the lead changes hands frequently, and extra-innings games. For instance, when the Cubs win an extra-inning game on a two-out hit, spectators stand and cheer for several minutes, high-fiving, yelling, shaking their fists, viscerally experiencing the intense feelings of victory channeled through their association with the team.

Spectators also demonstrate these qualities in reaction to exceptional displays of athletic prowess -- for example, when an individual Cubs player makes an unusual play such as a grand-slam home run or has an extended hitting streak. Last season, Ryne Sandberg, who has never been a league-leading home run hitter, challenged for the home run hitting title and finished the year with the highest total. As this side-race progressed and it became clear that Sandberg's home-run hitting performance was truly exceptional, his home runs became events in themselves, and spectators responded to them with an intensity of feeling that they did not express for other players. These emotions were also witnessed when the team accomplished an unusual feat, such as scoring ten runs in one inning without making an out. The spectators

understand that they have witnessed a remarkable performance, and the experience of being close to it, being involved with its happening, gives them a great emotional rush.

While an interesting phenomenon in its own right, the causes of these "sacred" feelings are the opposite of what one would expect if professional baseball spectating were a sacred ritual. As Wuthnow (1987) argues, spectators are most likely to experience a communion with the sacred when the ritual is performed correctly, with all of the participants following the ritual norms. But baseball spectators contradict this expectation in such situations: when action is the most scripted, the spectators are the least involved, but when action is truly unexpected, the spectators may exhibit an emotional reaction that is comparable to sacred experience. Thus, while seemingly comparable to sacred experience, these highly-emotional spectator experiences appear to be of a different type.

Following this argument, baseball spectating may serve as a sacred ritual for a small fraction of those in attendance. But for the rest of the spectators, the concept of sacred ritual as developed above is not an accurate reflection of their experience. Two questions naturally arise from this discussion: If the sacred-like experiences noted above are not sacred, then how can they be described? And, why do so few spectators experience baseball spectating as sacred? The remainder of this essay provides some grounded speculation on these topics.

IF NOT SACRED EXPERIENCE, THEN WHAT?

Rather than sacred experience, the highly emotional situations cited above more closely parallel aesthetic experience (Holbrook and Zirlin 1985). The reason that these situations yield an intense emotional response is that they are so unusual. Spectators have normative expectations for what they think will happen in terms of the ballpark aesthetics, spectator behavior, the level of drama, the performance of the team, and the individual accomplishments of the players. When these expectations are far exceeded, they have experienced something truly out-of-the-ordinary. The spectator is confronted by action that does not conform to conventional expectations, and the spectator's engagement and integration of this action provokes an intense reaction. While it is true that the felt qualities of aesthetic experience are similar to "flow" and thus to sacred experience (Csikszentmihalyi and Robinson 1990; Belk, Wallendorf, and Sherry 1989), I would argue that the two are distinct forms: the aesthetic experience is an encounter within a socially-constructed world of meaning (an "arbitrary code"), while the sacred is an encounter with the chaotic elements of human experience (though this encounter is culturally channeled). Geertz' (1973) distinction between the aesthetic perspective and the religious perspective is relevant here. The aesthetic perspective relies on ignoring everyday experience (the common-sensical perspective) in favor of dwelling upon surfaces, appearances, the contemplation of sensory qualities

without their usual meanings. The religious perspective, on the other hand, moves beyond everyday realities to create a fundamental ordering of the world that "accounts for, and even celebrates, the perceived ambiguities, puzzles, and paradoxes in human experience" (p.108). The next section further develops this distinction.

WHY DO SO FEW SPECTATORS ACHIEVE SACRED EXPERIENCE?

Belk, Wallendorf, and Sherry (1989) observe that the sacred has become increasingly difficult to experience in formal religion and thus is often located in previously profane activity such as consumption. Given the apparent benefits to the individual from participating in these modern forms of sacred experience (Belk, Wallendorf, and Sherry 1989, p.31), it is curious that only a handful of baseball spectators appear to achieve this state. Some speculation is in order. I make use of the distinction between the sacred as developed above (i.e., the individual's moral order or *nomos*) and Berger and Luckmann's conception of "sub-worlds" (Berger and Luckmann 1967, p.138), and borrow from theories of the modern and post-modern to construct a conceptual framework that addresses this query.

While individuals develop a single (though imperfect) *nomos* that organizes and guides their experience, they actually live their lives in many different "worlds." That is, individuals engage in many different interwoven, institutionally-defined experiences. Each of these worlds contains its own internally-coherent system of meaning that, building on the extant *nomos*, helps to organize the reality within the particular institutional framework. For example, a "single" becomes a meaningful event for baseball spectators only through the application of the system of meaning that is the sub-world of baseball. A critical difference between sub-worlds and the *nomos* is that much less subjective inevitability is usually bestowed on the contents of the former (Berger and Luckmann 1967). This is because the individual realizes that participation in sub-worlds is primarily agentic. That is, he or she has (consciously or subconsciously) been socialized and/or chosen to engage in this particular activity as one of many viable alternatives. Participation in this world does not substantiate an objective, external reality, but rather, makes concrete one possible subjective structuring. Based on this difference, one is able to distinguish between objectified reality at the level of *nomos* and the more fragile, constructed reality at the level of the sub-world by observing how the individual reacts to a situation where each type of reality is threatened. In the case of sub-worlds, the individual may lose emotionally satisfying ties, but retains his or her ability to "make sense" of experience. For example, if the game of baseball were banned, most baseball spectators, while perhaps deeply saddened, would still find experience comprehensible and would eventually move on to other activities that would replace baseball. By contrast, the loss of the *nomos* results in the loss of orientation to all experience. Garfinkel's (1967) breaching experiments provide a

poignant example of the anxiety and even terror that occurs when the ontological foundation for social activity is no longer secure. It is this difference between *nomos* and sub-worlds that, I believe, separates that which is sacred from that which is merely desirable, enjoyable, or pleasing. I do not wish, here, to imply that participation in an activity such as baseball spectating cannot become sacred to some individuals, but rather, that such individuals are outliers in that their participation in the game has come to embody their *nomos* when most others understand it to be one of many sub-worlds that are possible within a given *nomos*.

The ability to partake in sacred ritual has declined in the modern era due to a decrease in the potency of the *nomos* and the concurrent proliferation of sub-worlds. A primary characteristic of small, homogeneous, non-market societies is that sub-worlds are virtually non-existent. Knowledge and action are little-specialized so all members view experience through a similar lens. In a "unified life world" such as this, the same integrative symbols permeate all sectors of one's everyday life (Berger, Berger, and Kellner 1974, p.64). Interventions (from other cultures, for instance) that suggest alternative ontologies are incorporated into the current ontological structure (e.g., the cargo cults) or rejected in order to maintain a corporate perspective. Ritual in these societies is necessarily of the sacred form since it serves to directly reinforce the *nomos*.

Alternatively, through the media technologies, mode of education, and cultural mobility associated with post-industrial society, many individuals now learn that their particular moral ordering is one of many that exist in the world. This knowledge leads to a destabilizing relativism where the grounds for believing that "this is the way that things are" become less secure. In addition, the degree of specialization found in modern society -- in activities associated with work, leisure, family, and religion -- has led to a tremendous explosion of ever-finer levels of sub-worlds. The sub-worlds that do exist in small homogeneous societies are easily integrated into the culturally-shared *nomos* as defined by formal religion. Examples of this high level of integration abound in ethnographic work in anthropology. On the other hand, in contemporary Western society, the level at which an institutionally-defined reality is engaged is likely to be many levels below the *nomos* (e.g., *nomos* → leisure → sports → spectator sports → baseball spectating) and is likely one of many alternative sub-worlds that are possible at this level (e.g., football, soccer, hockey, cricket, etc.). Making this array of sub-worlds even more difficult to ontologically manage is the decentering, cluttering, and overlapping of cultural meanings endemic to contemporary Western societies (the "symbolic anarchy" noted in much post-modern thought) that challenges the coherence created within a given sub-world. Thus, at the same time that the modern individual's *nomos* is weakened through relativization, the sub-worlds in which consumption experiences take place have become multitudinous,

ever-distant in their connection to the individual's moral order, and less coherent in their own right.

While numerous sub-worlds are presented to the individual as sacred entities via advertising and elites, it is becoming more and more problematic for the individual to make use of these meanings to form a moral foundation from which to organize experience. One is made aware of their imputed sacred value, but it is increasingly difficult to actually make the leap of faith (i.e., to accept that this is *the* order of things) required to personally experience these realities as sacred. Instead, the individual often ignores this ontological claim, neither believing it nor challenging it, and, instead, makes practical use of its structuring power. This contemporary "strategy" for managing disorder parallels what theorists of the post-modern have referred to as the "aestheticization" of everyday life (Baudrillard 1983; Featherstone 1991). In such a situation, while individuals may treat these sub-worlds *as if* they were sacred, the structure that results is not moral but arbitrary. That is, the structure itself holds little intrinsic meaning for the participant; its value is shaped by its aesthetic and instrumental values (e.g., the pursuit of cultural capital).

Erving Goffman (1959, 1967) provides a complementary line of argument in his recasting of modern secular experiences with the sacred as idolatry (Creelan 1987). He argues that the individualism of modern society leads to a profanation of the sacred where the enactment of a purportedly self-transcending ritual may not be authentic at all. Rather, the ritual serves as cover for self-interested motives (Creelan 1987). The individual performs the sacred rather than engages it:

...individuals are concerned not with the moral issue of realizing these [sacred] standards, but with the amoral issue of engineering a convincing impression that these standards are being realized. Our activity, then, is largely concerned with moral matters, but as performers we do not have a moral concern with them. As performers we are merchants of morality (Goffman 1959, p.251).

Goffman argues that individuals often act as if they are referencing the sacred, but infrequently is this an authentic experience. Rather, the individual manipulates characteristics of the sacred to achieve alternative symbolic-expressive purposes as in a "black mass" (Creelan 1987; Goffman 1967).

An alternative to Goffman's bleak view of the human psyche is to frame the issue in terms of the socio-cultural challenges posed by modernity as outlined above. The existential quest for firm ontological footing has been dealt a severe setback by the pluralism of differentiated, mass-mediated, post-industrial society. The leap of faith required to achieve the sacred requires bounding across an ever-widening chasm. Often, this leap is not possible and one is left "homeless" (Berger et al. 1974).

Examples of this idolatry and/or homelessness are available in the consumer behavior literature.

Contemporary theorists of the sacred have noted that tourist sites, museums, and spectator sporting events are treated as sacred entities (Belk, Wallendorf, and Sherry 1989). However, there is considerable empirical evidence demonstrating that a significant component of the consumption of these vessels of the sacred is not in achieving sacred experience, but, rather, in manipulating these qualities for profane reasons (e.g., status, self-concept). Kelly (1987) observes that a significant category of museum-goers is more interested in documenting their museum attendance through purchases in the museum gift shop than in actually viewing the art that the gifts represent; documentation of tourist experiences (Stewart 1984; Gordon 1986) is so important that sometimes the documentation facilities (photo opportunities, souvenir shops) of a touristed site become more popular than the site itself. And in my own research on baseball spectators, the consumption experience often involves the profane manipulation of the symbolic aspects of a game, a team, a player, or the ballpark. Spectators attend the game to increase their ability to incorporate these qualities into the self (McCracken 1988; Belk 1988), and use documentary techniques (e.g., photos, appearing on television, autographs, stealing vines from the outfield fence) in order to substantiate these claims. I would argue that these modes of possession are typically of the profane form discussed by Belk (1988), rather than of the sacred form as discussed in Belk, Wallendorf, and Sherry (1989).

This essay was motivated by the question: Is it useful to describe baseball spectating as a ritual? I argue that three current conceptions of ritual do not adequately describe the experience of most of the spectators I have encountered. Rather, depending upon one's perspective concerning human nature, these spectators might be viewed in Goffman's terms as engaging in narcissistic and manipulative idolatry, or, alternatively, one could look to Berger's metaphor of "homelessness" to describe their unsuccessful attempts at achieving the sacred in an environment where the sacred is often fragmented and commoditized.

Halloween As A Consumption Experience

Stacey Levinson, Rutgers University

Grace Yeh, Rutgers University

INTRODUCTION

Over the past decade, consumer research has broadened its domain of inquiry to incorporate an increasingly diverse set of consumption phenomena. Included among these more recently investigated topics are cultural festivals such as Christmas, Easter, Thanksgiving and Halloween. Examining cultural festivities as consumption phenomena can provide novel insights into consumer behavior, because such festivals often make manifest the more general values underlying consumption. For example, Belk's (1987, 1989) inquiries into the celebration of Christmas made evident the commercialism and materialism present in aspects of this holiday. An analysis of adult consumers' narratives about the meaning of Christmas detected both sacred and secular consumption themes (Hirschman and LaBarbera 1989). A gift store ethnographic study conducted by Sherry and McGrath (1989) revealed the gift-buying customers associated with the holiday, as well as the enlarged role women play in fulfilling Christmas consumption rituals. Similarly, the consumption rituals and meanings surrounding Thanksgiving have been extensively documented by Wallendorf and Arnould (1991).

Our interest in the present study focuses upon the festival of Halloween. As Belk (1990) notes, Halloween in several respects appears to represent oppositional consumption patterns as compared to Christmas (and Thanksgiving as well). For example, there is no communal family meal, rather children independently go from house to house in search of candy. In contrast to the openness and informality of interactions during Christmas and Thanksgiving, Halloween is characterized by secretiveness and the formal "masking" of personal identity.

In the present inquiry we present an ethnographic account of the Halloween consumption experience. The use of an interpretive method such as ethnography is "intended to provide a rich portrait of the phenomenon so that the reader not only learns inputs and outcomes but also gains an understanding of the texture, activities, and processes occurring (Belk, Sherry, Wallendorf 1988)." It is the hope of the researchers that this inquiry will spur further research on Halloween consumption activities and consumer research on American holidays in general.

The paper is divided into four sections. The first section discusses the history and background of the Halloween festival. Methodological and interpretive issues are addressed within the second section. The third section describes the various ethnographic sites used to construct the interpretation. This section is further divided into retail Halloween stores and actual festival sites visited prior to and during Halloween. Emergent themes are discussed in the fourth section.

The History of Halloween

Few Western holidays have a more paradoxical history than Halloween. Halloween is the eve of one of the most important feasts of the church year--All Hallows Eve--solemnly observed by Roman Catholics, Anglicans, and Lutherans (Hatch 1987). In many countries of Western Europe, such as France, Spain, and Italy, Halloween is observed as an austere religious occasion with extra masses and prayers at the graves of deceased relatives and friends; but in the British Isles and, especially in the United States, Halloween is primarily regarded as a night of merry making, superstitious spells, fortune telling games, and pranks (Hatch 1987). Thus, Halloween is a curious mixture of the religious (sacred) and the secular (Belk, Wallendorf and Sherry 1989; Hirschman 1988).

In the second century B.C., the Celtic order of Druids ended the year on October 31. The Celts believed that on October 31 the Lord of the Dead assembled the souls of all those persons who had died in the previous year; the spirits of the departed were allowed a brief visit to their relatives. The departed souls would play tricks, so the Druids attempted to appease them with sanctices (Hatch 1987). This tradition was continued in medieval Europe, where black cats were sacrificed in ritual acts, in the belief that they were disguised witches.

During the ninth century, Pope Gregory IV placed Halloween on the church calendar, decreeing that the day and vigil be generally observed to honor numerous martyrs and, eventually, saints on a common day (Hatch 1987). By the end of the 15th century, Halloween was believed to be the gathering time of unsanctified spirits. Many believed that witches flew on broomsticks accompanied by their black cats and that the Prince of Darkness mocked the feast of the saints with unholy rites (Hatch 1987). These beliefs continued during the Colonial period in America, culminating in the campaign against witches in Salem, Massachusetts in 1692 (Hatch 1987). Halloween folk customs continued to flourish in Ireland, Scotland, Wales, and parts of England well into the 18th century, where pranks and mischief on October 31 were common in rural areas of the British Isles.

Nevertheless, widespread observance of Halloween appeared relatively late in the United States. Most of the early settlers, the majority of whom were Protestant, did not observe Halloween. In pioneer days, Halloween practices were scattered and regional until the great Irish immigration in the 1840's. The Irish brought with them not only the religious observance of Halloween, but also their folklore remnants of Halloween which included the traditional mischief (Hatch 1987). By the late 1800's, Halloween had become a national observance in the

United States, characterized by games, divinations, parties, and especially the children's custom of going "trick-or-treating" dressed in masks and costumes.

By the 20th century, Americans became less tolerant of pranks, which often descended into vandalism (Hatch 1987). Community Halloween festivals, sponsored by local merchants, civic groups, and schools (especially PTA's) have done much to curtail the formerly widespread vandalism. The folk vitality of witches, divinations, and the black arts have long receded into the past. But the decline in its significance has not affected small children, who still enjoy ringing door bells and shouting "Trick-or-Treat" (Hatch 1987).

The Role of Costumes

Perhaps, the most visible part of Halloween as a consumption festival is the number and variety of costumes worn each year. Costumes, like clothing, are powerful social communicators (McCracken 1988, Solomon 1983). Much consumer research on clothing over the last ten years has centered on the symbolic value and social meaning of clothing (Solomon 1983). It is not our goal here to discuss this literature in depth, but only to advance three concepts that are important to note in the study of Halloween. A costume is a *transformation* device that allows the individual to change his or her own identity (Dichter 1964). The choice of a costume allows the chooser, (who is not always the wearer), a form of *self-expression* and *creativity*. The self-expression enables the chooser to express his or her own individuality to those around him/her. Creativity allows one to strive for *exclusivity* of the costume and therefore establish the individual's unique identity.

METHOD

Our research team consisted of four women and one man. Subsets of two researchers selected various Halloween stores and festival sites to investigate in detail. We adopted a modified version of Sherry and McGrath's "one-researcher-one-site" principle. First, due to time constraints we felt that immersion in separate field sites would generate more detail. Second, we wanted to keep interference with the daily life of the stores at a minimum (Sherry and McGrath 1989). Therefore we triangulated across sites through regular discussions of our observations and interpretations.

In order to gain an in-depth understanding of Halloween as a consumption experience, the researchers had to balance their competing interests as former participants and as researchers when observational settings were chosen. In accordance with the researchers' background, observational settings were selected based on typical Halloween interaction points of middle class, suburban families as well as settings that would provide the research team with a multifaceted view of the Halloween experience. These settings were divided into two categories: retail stores where consumers purchased Halloween paraphernalia in order to participate in the consumption experience and festival sites where the participation occurred.

The stores and sites were patronized mainly by upper-middle class consumers. A smaller representation came from the lower-middle class. The study began in mid-October and ended on October 31, 1990. Unlike other holidays such as Christmas, Halloween does not allow for significant post-holiday investigation (Sherry and McGrath 1989). Stores were observed 3 to 4 times at hour-and-a-half intervals. Festival sites were observed between 1 to 3 hours according to site time constraints. The stores and festival sites are located in suburban communities in the northeastern United States. Collection of data occurred through observation, participation, interviewing, and photography. Data were recorded both in field notes and journals.

Retail Stores

During the course of the study, we visited four retail stores -- Everything Halloween, Party City, McCrory's and Lynn's Hallmark. These are described below:

Everything Halloween

Everything Halloween is one of many stores crowded into a suburban shopping mall. It rents its space temporarily for the Halloween season. After Halloween it is transformed into another seasonal specialty store. As the name implies, Everything Halloween contains different types of accessories to make the holiday complete.

Ambience Upon entering the store the consumer is greeted by a mechanical vampire in a cemetery setting. Eerie howls emanated from the tombstones. One is immediately immersed into the Halloween atmosphere. The 13,000 square feet of selling space overwhelms the customer with merchandise. Items are found hanging from the walls, display cases and centrally located islands. Consumers throughout the store frequently handle the props, as they are easily accessible.

Merchandise Everything Halloween has a wide variety and deep assortment of goods. The merchandise ranges from accessories to fully complete costumes. Packaged items include masks, wigs, make-up, stockings, and colored hairspray. Also available are fake fingernails, swords, pitchforks, and eye patches. Clown, monster and animal costumes are among the few disguises available for children. Adults can choose from jailbirds, vampires, bellydancers, and french maids. Prices range from a few dollars to one hundred dollars.

Party City

Party City is one of five stores located in a strip mall on a state highway in New Town. It exclusively carries items appropriate for a party including streamers, balloons, paper plates, and invitations. As holidays approach, sections of the store are dedicated to specialty merchandise.

Ambience Due to the importance of sales during the Halloween season, Party City dedicated a third of its store to Halloween goods. Merchandise filled the shelves, ceilings and walls. Salespeople helped customers try on costumes. Creaking doors and monster howls were heard throughout the store.

Merchandise Party City had an extremely large assortment of costumes. Instead of displaying the actual costumes, small pictures of the ones available are hung on the walls. Consumers choose a costume from these pictures and a salesperson then retrieves it from the storeroom. In contrast, accessories are openly displayed in large boxes for consumers to choose from, including fake blood, clown shoes, necklaces, and press-on-nails. Prices range from a few dollars for accessories to fifty dollars for a complete costume.

McCrorry's

A third retail site was McCrorry's, a well known discount chain store located in the Caravelle Square Mall. This particular store is approximately the size of a small supermarket, or 26,000 square feet. It sells everything from clothes to housewares to toiletries to candy. As with other retail establishments, McCrorry's has sectioned a large area specifically for Halloween merchandise.

Ambience The store displays several eye catching signs showing passers-by the sales and low prices McCrorry's has to offer. From the window sign, it is obvious that Halloween is approaching. The entrance is filled with candy displays, reminding customers of the advent of trick-or-treaters. From the appearance of the store it is evident that the costumes have been rummaged through repeatedly.

Merchandise For children, costumes consist of a plastic or fabric body cover and a hard plastic mask. These include cartoon characters such as Mickey Mouse and the Ninja Turtles. Adult costumes featuring a Devil and a French Maid, among others, are constructed of flimsy fabric. Accessories, such as costume make-up and colored hair spray, are also offered to complete self-designed costumes.

Lynn's Hallmark

Lynn's Hallmark, which is also located in the Caravelle Square Mall, is a few stores down from McCrorry's. It is a specialty store known for its high standard of quality, featuring exclusive greeting cards and gifts.

Ambience Lynn's Hallmark, gives a feeling typical of any Hallmark store - a comfortable, at home, cozy feeling. Everything in the store from the layout, merchandise, and salespeople notify the customer of its high quality image. When a holiday approaches, it is evident by the specialty decorations and the goods filling the store.

Merchandise There is a wide variety of goods ranging from glittery masquerade masks to baby diaper covers with ghosts on the backside. Consistent with the store's image, much of the merchandise is geared toward party favors in attractive colors and designs. Many items emphasize safety features such as ease of visibility and breathing. The masks are constructed of a soft cushiony material to prevent children from hurting themselves. Other merchandise available emphasizing safety includes glow-in-the-dark necklaces and light sticks.

Halloween Festival Sites

In addition to making observations at retail stores, we also observed the celebration of Halloween at five sites.

Caravelle Square Mall

Halloween Show "Halloween Spooktacular"

At 3:30 pm, October 31, 1990 in the Caravelle Square Mall, thirty costumed children aged 3-6, and their mothers gathered to watch the "Halloween Spooktacular", sponsored by the Caravelle Square Mall store owners. The stage was a haunted house. A magician's assistant in costume appeared for the performance and introduced the show. The magician, dressed in a tuxedo and white face, wearing a bone through his head, did magic tricks for the audience. After about 20 minutes, the magician went backstage. The assistant gave the audience trick-or-treating safety tips, such as: "always go out in groups", "cross streets at the corner" and "never eat candy until your parents check it first". Then the magician did a few more tricks and a costume contest was held. The two winners, who wore a jack-in-the-box and bride costume, received a \$35 and a \$20 gift certificate good at any store in the mall. After the show, the children went trick-or-treating from store to store.

At 7:00 pm there was another show. The format was the same except Everything Yogurt, a frozen yogurt store, gave a free yogurt to each child in costume. At this performance, there was a much larger crowd of about 100 children aged 5-11 and their mothers and fathers. After the show most children ate the provided yogurt; few went trick-or-treating in the mall.

New Bridge Pumpkin Carving Display

Along Route 615 in New Bridge, is a large farm owned by Bob Spinelli. Each year Bob and his family put together what they call the "Nite of the Jack-O-Lantern." His family and friends carve out 800 pumpkins and display them in the field alongside the road. Bob's children dress up in costumes and greet the parents and children who come to see his display. Bob receives pleasure from entertaining neighboring families and putting smiles on children's faces. People are intrigued by the seemingly infinite number of pumpkins. The event has become so popular that police are now required to direct traffic. Bob recently has opened up a stand to sell Halloween paraphernalia in order to subsidize the cost of the presentation.

Trick-or-Treating

To observe trick-or-treating, a female researcher (in costume) accompanied her female cousin and four of the cousin's girlfriends (age 11) on Halloween. The trick-or-treating observed took place after school from 4:00-6:30 pm, in the town of Kent which is located in the central part of the state. Kent, population 21,723 is comprised of upper middle class families predominantly of Jewish ethnicity. This year the town council had imposed a 6:00 pm curfew for children trick-or-treating. If accompanied by an adult over 20 years of age, children were permitted to stay out later. The trick-or-treating observed took place in one of the many housing developments in Kent. In this development, there were approximately 75 trick-or-treaters ranging in age from 5-13 years. Smaller

children were accompanied by adults even in the daylight. Older children (aged 10-13) toured in groups without a chaperone. About half of the houses approached had no one home. Several homes were decorated with some type of Halloween paraphernalia such as pumpkins, pumpkin leaf bags, and Halloween window posters. Two police cars were observed patrolling the development during the course of the evening.

Halloween Parade and Party at St. Peter's School

A male and female researcher observed a class of 19 first graders at a middle class Catholic elementary school in New Town. The principal had previously granted permission to the researchers to observe the class. Halloween was treated as a special day for the children with a parade and party planned. An extra long lunch hour gave the children the opportunity to go home and change into their costumes and allowed the parents time to come home from work and bring their child back to the school. At school, preparation was underway for a Halloween parade through downtown New Town. The children assembled in the street for their short trip through New Town while parents videotaped, took photographs, or watched their progeny from the sidewalk. The children proudly pranced through New Town with a police car, marching band, and color guard leading the way.

Upon their return, the children raced into the school knowing what was waiting in their classroom. While they were gone, parents had decorated the classroom and distributed candy to the desks of each child. On each child's desk was neatly placed a small bag of candy, a juice box, pumpkin napkin and a large Halloween cupcake. As the class ate, the teacher informed them that safety was the most important concern in celebrating Halloween. The teacher read them a list of safety rules and told the children that some of the parents had a surprise, a Halloween game which helped the children with letter recognition. Each child was rewarded with a Halloween mug and a rubber skeleton. The school bell rang and a stampede of Ninja Turtles, princesses, and other assorted characters poured out of the tiny school and onto the streets of New Town. Trick-or-treating started immediately with a flood of children arriving at the residential houses nearest the school.

Brock Farms Garden Center

The Brock Farms Garden Center was observed by a female researcher acting as a passive observer. Brock Farms is a garden center located on Route 6 South in New Town. The premises consist of a building in which fertilizers, tools, and other garden accessories are sold, a greenhouse which contains plants and flowers, and a large outdoor area with shrubs, trees, and lawn ornaments. On the day visited, Brock Farms was decorated with Halloween icons, and a witch and a pumpkin stood next to its outdoor sign. On the roof of the building was a large inflated pumpkin and scarecrow. The front of the building was decorated with pumpkins, scarecrows, and skeletons. A gift section inside the building had been transformed into a Haunted House. To the left was a graveyard with skeletons and tombstones that led to the entrance. Eerie howls and spooky noises played on a

loudspeaker. Upon entering the Haunted House, one is struck with the overabundance of Halloween paraphernalia, featuring devils, skeletons, and vampires; bats flew across the room; smoke wafted through the air. A table carried candles of various types: ghosts, pumpkins, and witches. A mechanical Esmeralda the Fortune Teller with a crystal ball was reduced from \$1299 to \$899. Another table had ceramic pumpkins costing \$9.99-\$16.99.

EMERGENT THEMES

Commercialization

Due to the commercialization of such holidays as Christmas and Easter (Belk 1987, 1989), it was perhaps inevitable that Halloween would follow. Retailers and manufacturers, always searching for novel markets, have discovered that Halloween offers such an opportunity. For example, Sun Hill Inc., a holiday product merchandiser, after twelve years of successful Easter product launches, needed to find expansion opportunities elsewhere. Sun Hill first tried the glutted Christmas market and "got our heads beat in" (Grimm 1990). When brainstorming about possible pumpkin products, the company executives decided, "Nobody is going to put another pumpkin out in their yard unless it's the biggest one they ever saw." Thus, the jack-o'-lantern leaf bags were created. With six million units sold since August, (fifteen million dollars in retail sales) the future of this innovative new Halloween product seems quite promising (Grimm 1990).

In addition to merchandisers that specialize in holiday products, others in the marketing channel are taking advantage of the trend towards the commercialization of Halloween. Halloween merchandise has always been prevalent in such traditional retailing institutions as Hallmark, Spencers and Caldor. With the high degree of marketability of Halloween, these retailers are becoming overshadowed by specialty stores such as Everything Halloween. The store markets itself as a "one-stop Halloween Shopping Center", with convenience its most salient attribute. It has emerged as a dominant competitor within the Halloween industry.

Even seasonal retailers such as Brock Farms Nursery are trying to capitalize on profitable out-of-season opportunities. Brock's haunted house, which contained everything from ceramic pumpkins to ghost candles to mechanized devils, effectively capitalized on consumers' desires to appropriately accessorize their celebration of the festival.

Halloween commercialization is not only evident in the retail sector, but is also present among consumers as well. For example, each year Bob Spinelli and his family organize a pumpkin carving display on their farm. With over eight hundred jack-o'-lanterns, the Spinelli's pumpkin festival attracts huge crowds of parents and children. Adjacent to this altruistic endeavor, the Spinelli family sells Halloween paraphernalia. Even though the Spinelli's create this jack-o'-lantern display for charitable

reasons, they also do so in hope of realizing a financial profit.

Perhaps the most blatant examples of Halloween commercialization are the marketing efforts of some beer manufacturers. Brewers need to generate additional sales in October, traditionally one of their slowest months (King 1989). As a result, brewers have been looking toward the Halloween festival in an effort to boost beer consumption. For instance, Miller Brewing Company now sells its Lite brand with special glow-in-the-dark Halloween labels. This past season Coors was promoted in stores and bars by a character called Count Drakula. Anheuser-Busch spent 1 million dollars on its "Fright Night" campaign and gave away free paper masks to bar patrons (King 1989). As Christine Lubin, a representative of the National Council on Alcoholism, says, "Beer companies try to make drinking a part of the [Halloween] celebration (Farhi 1989)." Thus, from its inception as a sacred festival in Europe, Halloween in North America has evolved into a secular event driven by commercialization.

Enforcement of Gender Roles

A second emergent theme was that of gender roles, which were apparent in many aspects of Halloween consumption. Evidence for this is provided by examining the various costumes available to the different age groups. Each of the party stores visited was found to have the costumes segregated into three basic groupings. The first grouping was pajama costume sleepwear for toddlers two to four years old. Such costumes included Devil, Bunny, Pumpkin, Circus Clown, and Yellow Chicken. These costumes were basically genderless as either sex could wear them. The second grouping was for ages five to eight years and provided gender separation in contrast to the first group. Such costumes included Mouse Girl, Pirate Boy, Devil Boy, Lil' Red Riding Hood, and Child Princess. These costumes were very gender specific and clearly alerted the consumer as to which gender was to wear them. This was evident in the costume titles which included the word "boy" or "girl." For example, there were not just pirate costumes, but rather Pirate Boys. In addition, costume characters were offered that were clearly male or female such as Princess. The last grouping was targeted at pre-teens. For girls this included French Maid, Suzy Starlet, Slave Girl, Cover Girl, and Rock Star. Costumes for boys included GI Soldier, Greaser, Cowboy, Law Enforcer, and Combat Hero. In this age group the genders were segregated not only in their themes but also in their design. The girls' costumes were quite skimpy, even sexy. They featured short skirts, lace, sequins, and bright colors. The girls depicted on the package also wore a lot of makeup. In contrast, the boys' costumes were not skimpy, and the boys in the pictures were fully clothed. Their costumes were mainly in dark colors, such as black and khaki, and the themes were of a male nature, that of the hero type. Overall, it is apparent that as the child's age increases, costumes move from androgynous to gender specific. This pattern was also present in Belk's (1990) Halloween study.

In addition to costumes enforcing gender roles, it is also apparent that both parents and peers socialize children into "appropriate" gender roles. One researcher observed this overtly in the Everything Halloween store. As a mother and daughter were shopping for a Halloween costume, the girl exclaimed, "Mom, I want to be a Ninja Turtle!" The mother responded, "No honey. That's a boy's costume." Often when parents dress up a young son and daughter, they have them dress as the same theme; the son as the male part and the daughter as the female counterpart. For example, one researcher observed a Mickey and Minnie Mouse pair. Another researcher saw a Tarzan and Jane.

Such gender socialization carries into adulthood and even contaminated the researchers. At a costume show in the Caravelle Square Mall, a researcher saw a child dressed in a pink bunny costume. The researcher said to the child's parents, "Your daughter looks so cute." The parents responded, "Thanks, but that's our son." Due to the researcher's socialization, she instinctively assumed that the child in the pink costume was female. From the evidence cited, it can be concluded that the enforcement of traditional gender roles during Halloween is perpetuated by parental preference and further reinforced by costume manufacturers.

Self and Self-Image

As children become older, their costumes, like their clothing, serve as powerful social communicators, especially to other children. Within our observations the age group of 7-12 is where the individualistic experience of Halloween begins. Children in this age group have more of a say as to what they are going to wear, where they are going to go trick-or-treating, and who they are going to go with. We found that children of this age group want to dress in similar costumes and trick-or-treat together. This occurs because children want peers to accept their social selves.

Children also have a strong need for affiliation and belongingness; they desire love and acceptance from their social world. The need for acceptance from peers was evocatively demonstrated by one of the trick-or-treaters we observed. This trick-or-treater was dressed as a member of a professional football team. But, she and her friends were dressed as infant versions of the players similar to "Baby Muppets." The trick-or-treater pulled the researcher aside before she began her quest for candy. She asked, "Do you think people will recognize who we are? Do we look like 'Baby Giants'?" The researcher was not sure, so, she suggested that the girls write the player's name on a piece of paper and tape it on their backs. Therefore, their costume "identities" would be recognized. The trick-or-treaters were concerned with performance risk; the consequences of a product that did not perform, behave, or appear as planned or promised. The performance risk here was that the costumes would not be recognizable (DeVault and String 1989).

Tremendous peer pressure exists at this age to conform to group norms. Children do not want to be stigmatized by association with an unpopular

character. The researcher observed an incident where one girl would not walk down the street. Instead, she walked in the opposite direction. When the researcher asked the girl where she was going, she responded, "I don't like that street. I like the houses down there better." The researcher asked another trick-or-treater why the girl would not walk down the street. She said, "She's afraid of the 'cool kids' will see her, see the 'big shots' are down there". The trick-or-treater defined a 'big shot' as "someone who is older than us and thinks they're cool". The researcher noted that the "big shots" were trick-or-treating without costumes. Eventually, the girl was coaxed to walk down the street with the others. When they encountered the "big shots", she was intimidated. She wrapped herself in a blanket in hope of concealing her costume. Her goal was to disassociate herself from the group she was with. The trick-or-treater justified her actions to the researcher by claiming, "I'm cold."

College and high school students also want to be accepted by their peers and try to accomplish this by dressing in similar costumes. When a group of eight college roommates was asked if they had considered dressing up, they responded, "We want to dress up as a group." They had made a list of themes which included all eight of them. Their choices included Santa Claus' reindeers and Snow White and the seven dwarfs. In the end some of the girls decided not to dress up, so none of them did. A group of high school girls was observed at Everything Halloween saying, "As long as we go as the same thing that will be cool." Performance risk is reduced when a group of people dress together, instead of the individual dressing by himself/herself.

Costumes allow children to express their individuality by allowing them to pick out their own costumes. It also fosters creativity. The child can adopt a variety of identities, utilizing them as an outlet to exhibit self-aspirations or to imitate role models. At St. Peter's grade school, a little girl was overheard saying, "I want to be a cheerleader just like grandma. She was one when she was little." Party store managers also stated that children were buying costumes which represented their aspirations. For example, girls in elementary school were observed buying cheerleading costumes since this was something they aspired to be in high school.

Costumes can also act as a reinforcement of a couple's identity by emphasizing the fact that they are a couple. In Party City, a couple was observed examining costumes which were complements. They selected Napoleon and Josephine, a readily identifiable couple.

Vicarious Consumption and the Extended Self

Belk (1988) suggests that we are what we have, i.e., possessions contribute to our sense of self. This he terms the Extended Self. Consumers learn, define, and remind themselves of what they are by their possessions. We seek to express ourselves through possessions and use material possessions to seek happiness, remind ourselves of experiences, accomplishments, and other people in our lives, and

even to create a sense of immortality after death. In addition to the use of commonly purchased consumer goods as possessions comprising the extended self, Belk considers several frequently used but seldom researched types of possessions: collections, money, other people, pets, and body parts.

Parents' sense of self also is shaped by their possessions. In most Western cultures, children are viewed and treated as possessions by their parents (Belk 1988). Our laws concerning adoption, in vitro fertilization, and divorce all consider the child a possession that should be awarded to some group or person. Children, therefore, as possessions enhance and define the extended self of their parents (Belk, 1988). Children provide parents with a strong vehicle to advance their own happiness, to remind them of their own experiences (nostalgia), and to live on forever (immortality). The manner in which parents do these things is through vicarious consumption.

Veblen (1899) noted that one can vicariously consume through one's dependents, so that their consumption enhances one's own extended self (Belk, 1988). The concept of vicarious consumption in 1899 is not much different than that of today. We gain in self esteem from the ego enhancing consumption of those who are part of our extended selves. If our friend lives in an extravagant house or drives an extravagant car, we feel just a bit more extravagant ourselves. The success of a spouse, who is seen as an extension of the self, raises one's self esteem in much the same way as personal success (Belk, 1988). Similarly, the accolades and attention a child receives for a costume at Halloween raises the parents' self-esteem.

Three sub-themes were constructed from the ethnographic evidence using the concepts of vicarious consumption and extended self. These sub-themes were redundant across sites and researchers.

- (1) Children are viewed as possessions at Halloween time. They are dressed up and displayed for the self-satisfaction of the parents.
- (2) Parents, mainly through costume selection, live vicariously through their children. The parents' views are either directly or indirectly impressed on the child's choice.
- (3) Parents view their children as a reflection of themselves. A child's actions are a direct reflection on the parent.

These three sub-themes exist subtly between parent and child all year round, but, during Halloween, they are more evident and outstanding. Many children are treated like dolls that are to be dressed up and displayed to other doll dressers for their admiration and envy. Some mothers turn Halloween costume contests into Halloween costume competitions, and their desire to win at all costs rivals that of fathers at Little League baseball games. The notion of Halloween being a time for children to innocently disguise themselves to acquire free candy is lost in the heat of the battle for the prize of best costume. This

was vividly evidenced at the Caravelle Square Mall's Halloween Show and Costume Contest.

Annie is seven years old and dressed in an elaborate jack-in-the-box costume. She had a court-jester-like costume beautifully designed and handmade. Around her was the box which, too, had beautiful designs placed on it that matched those of the costume. "My mom made me the costume and she said I had to wear it. I wanted to be something else." Annie looked sad in the costume. When asked to take a picture, Annie's mother sung out a "yes" and boasted that she had spent days making the costume for her little girl.

The only satisfaction that Annie received from her mother's costume was when she won first prize. A hundred people clapped and cheered. Annie had won a \$35 gift certificate, yet she still looked sad. In front of the stage stood Annie's mother beaming for all to see. It was Annie's mother who had won the contest and the gift certificate at the expense of her child's own happiness. Another researcher observed an even more poignant example:

Walking through the Caravelle Square Mall, I noticed a large TV stand on wheels that apparently had a fish tank attached to it, judging from the seaweed on and inside the tank. Curiously, as I approached the tank, I saw something move inside. As I stepped closer, the owners of the tank turned it toward me. A sign read "Our Pet Goldfish." Inside the tank to my surprise was a small child whose movement was restricted by a large goldfish costume. The costume covered the child from head to toe with only his face visible.

These parents had dressed their child up like an animal and were now treating him like one. The child thrashed around in the tank trying to break free from the costume much like a dog does when covered by a blanket. The child screamed and cried. He tried to get out of the tank only to learn that the tank walls were too high for him. After a while, the child was released from his cage, and his parents entertained questions on the design from other interested parents. Asked for a picture by a bystander, the parents quickly dumped the child back into the tank. The child wailed out and sobbed uncontrollably until the mother said, "Be a good boy and let the nice woman take the picture."

At Halloween some parents take the opportunity to live vicariously through their children as a way of reliving their own past. Parents' nostalgia was the driving force behind some of the costumes children were wearing.

Becky was in first grade and was dressed in a 1920's flapper costume. "Mom wanted me to be a flapper because when she was young she was a flapper too." Becky's mom stood beside her playing with and fussing over her costume

while Becky appeared disinterested. (St. Peter's School)

Becky was one of many children, who when quizzed why they chose that particular costume, replied, "Mom wants me to be _____." The children were like puppets through which their parents briefly tried to relive their own youth.

The selection of the costume was the easiest and best way that a parent could live vicariously through a child. Since the parent was paying for the costume, he or she had a lot of say in what was or was not purchased. Parents used two tactics to persuade youngsters to choose the costume the parent wanted: direct intervention and indirect intervention. By way of *direct* intervention, the parent would, through praise, elevate one costume above the rest and point out limitations or faults in the rest of the selection. This tactic did not appear to work too well. Only young children could not see through the parents' attempt to influence choice. Perhaps the ultimate example of *indirect* intervention was when the parent made the costume. Once the costume was made, the child had to wear it. Other parents influenced their children's costume choice indirectly by taking their children to costume stores that had costumes consistent with their own tastes. The price, the selection, and the quality of the costume varied depending on the store. Some elicited the help of salespeople and even the child's own friends to influence the child's choice.

John was eight years old. "I want to be a pirate, mom." It was obvious his mother did not. She called over a salesperson and asked her to show John the popular costumes. After some coaxing from the salesperson, John chose to be Batman. When John's mother went to pay for the costume, John put the pirate's patch on and swung a sword happily before leaving. (Party City)

In line with the extended self, parents see children and their actions as a reflection of themselves. In Asian cultures, children often are used to signify their parents' aspirations. As noted by one of the researchers, who is Asian, children are raised to understand that they represent the parents and that the child's actions speak for them. This traditional Asian concept has started to become more prevalent in the United States. The concept started in the upper class families and has trickled down the United States class structure (Devault and Strong 1989).

Children's Halloween rituals, as well as their costume selection, made manifest the theme of the child as a reflection of the parent. Children were instructed by their parents on proper Halloween etiquette. One rule was not to run up the lawn, but rather to use the sidewalk. The reason given for doing this was because "Daddy doesn't like it when other kids do it, so we shouldn't." Parents fear that other parents will notice their child's actions, and they will be viewed negatively. A child observed at Party City wanted to buy a Michael Jackson mask, but his mother

insisted that he buy something else. The boy's mother did not want the child to be associated with the "feminine, negative" image that many believe Michael Jackson has. Although the child pleaded, his mother chose something else. Her fear was that through the child's choice of a mask, the social values attached to it would be transferred to her (e.g., McCracken 1988).

New Society

For children across the country, Halloween is a significant festival. It is fun, thrilling, and exciting. However, it is also a day of concern for adults, particularly those who are parents. Halloween was once a "free for all" when children were allowed to go trick-or-treating until late at night, wearing virtually any costume they could get away with. In recent years it has become evident that Halloween is a holiday that can not be taken as lightly as it once was (Belk 1990). With the festivities of Halloween comes also a great deal of responsibility to take precautions for the safety of participants.

Two factors appear to serve as the driving forces behind this concern. One is the perceived omnipresence of violence and danger in modern society. The other factor stems from changes in family structure due to dual wage earning families. The growing fear for safety escalated eight years ago, "when the chilling news broke that seven people had died from Tylenol capsules laced with cyanide" (Kleinfield 1989). As a result of the infamous Tylenol scare, Halloween rituals were drastically revised. Some towns outlawed trick-or-treating that year and many parents forbade their children to leave the house. Similarly, with the increasing level of working mothers, the community has taken extra measures in enforcing safety for the children.

The researcher who participated in the trick-or-treating ritual was able to witness the various safety precautions taken, as well as the increase of working mothers in the town of Kent. When passing by each house, an orange sign was seen hanging on the front door which could be seen from a distance. These had been distributed to every house in the community by the Kent Township Police. The signs stated restrictions that were believed to be in the best interests of both the trick-or-treaters and their parents. It noted that children could not participate in trick-or-treating past 6:00 pm unless accompanied by someone 20 years of age or older. This safety measure was enforced by the presence of police cars patrolling the town. In addition, some working mothers took turns accompanying groups of children in order to provide constant supervision.

Halloween has also become a holiday for compromising. As a result of the curfew, children often became frustrated. Many did not want to be chaperoned and found it embarrassing. From this, compromises were born. In one instance, a group of youngsters were observed trick-or-treating although it was completely dark. They appeared to be alone, but following them very slowly was their mother in a car. She remained far enough away, so that they were not

embarrassed by her presence, yet close enough so that she was assured of their safety.

Another illustration of community involvement were efforts to detect tampering with distributed treats. Parents were aware that some people place sharp objects and dangerous chemicals in candy or cookies. As a safeguard, candy screening centers were located in each municipality so that all candy could be checked. In some areas, hospitals offered free x-ray programs to assure the safety of Halloween candy.

Retailers have also responded to parents' concerns about safety. McDonald's coupons have become a popular treat given out on Halloween. This helps McDonald's market itself and also lessens parents' fears. Some retailers carried costumes that were targeted toward working mothers whose safety concerns were heightened; these costumes were designed to maximize the child's safety in the mother's absence. Yet there was a trade-off -- increasing the safety of a costume increases the price.

Ultimately, it is the children who most directly encounter the negative aspects of Halloween. With the increase in working mothers, the percentage of households providing candy has dropped considerably. The researcher trick-or-treating in Kent observed a child's reaction to empty houses. After the third empty house, the researcher said, "They're probably not home". The child responded, "They pretend they're not home." Children are extremely disappointed when they encounter this situation. They feel that they have been let down by the adults. They cannot accept the idea of a dual career household, especially if their own mother does not work. However, there are individuals who understand the importance Halloween plays in a child's life. While accompanying her children trick-or-treating, one mother distributed candy to children passing by. She explained, "I feel bad that I can't be home to give out candy to the kids because I want to take my own kids trick-or-treating." She felt obliged to bring the candy along with her. Thus, the mother was able to satisfy both her safety concerns and the need to participate in the trick-or-treating ritual.

The Halloween Script

Over the years, children develop a Halloween script. This script is learned from older siblings, friends, schoolmates and parents. Before a child leaves the house, the parent often instructs the child on proper Halloween etiquette. The researcher who observed trick-or-treating in Kent was told three rules by the children. First, "never run up the lawn. Instead, walk up the driveway." Second, "do not bang on the door. Ring the doorbell or knock softly." Third, and most importantly, "always say 'thank you,' even if you do not like what you have received." When one of the trick-or-treaters ran up someone's lawn, the rest of the group quickly reprimanded him. Other rules that are understood by trick-or-treaters are to carefully cross streets, to stay in groups, and to walk-not-run from house to house.

While trick-or-treating, children form a comraderie with other groups of trick-or-treaters.

When one group approaches an empty house, they are quick to inform others not to go there. When groups of children meet on the sidewalk they tell each other which houses are "good houses", i.e., those which pass out desirable treats, and which houses are "bad houses", which give out less desirable treats. It is also common for children to trade candy. For example, the researcher in Kent observed several children dumping their bags of candy onto the sidewalk and bartering for more desirable candy. Later in the day, the children would decide which "good houses" to go back to for more of the desirable treats. To ensure that the "good houses" would not recognize them, the children would wait until it got dark to return. Some children even went to the extreme of switching costumes in the bushes.

The Halloween script does not end with the trick-or-treating. When they return home, the children find an open area in their house where they can dump out their candy. The child's parent then examines each piece of candy and throws out any pieces that appear tampered with. The child then sorts out the treats, usually counting how many pieces of candy and how much money was collected. The average amounts we observed collected were 28 cents and sixty-seven pieces of candy. The candy is then proudly displayed on the floor for the family to see. After displaying their collections, the children next decide which pieces of candy they will consume immediately, which are to be saved for later, and which pieces will be discarded (see also Belk 1990).

Materialism

When it comes to candy, size matters. Children rated houses based on the size and quantity of candy received. While trick-or-treating in Kent the researcher noted that the children were thrilled when they received Sips Juice Boxes at one of the houses. The juice box is quite large and heavy when compared to other treats. The children were pleasantly surprised and labeled the house a "good house". "Good houses" supplied children with unique treats such as the juice box, while a "bad house" passed out smaller, more common treats, such as a small lollypop. What emerged was a hierarchy of candy. The trick-or-treaters would dump their candy onto the sidewalk and rate it. After carefully ranking it, the children then determined each candy's trading or bartering value. For example, if a child did not like peanut M&M's, he would trade it to a child who did. In return, he sought to acquire a candy that he liked. Each child's candy ranking scale appeared to be unique.

As in other commercialized holidays, such as Christmas, Halloween teaches children how to receive i.e. "take," but not how to give. At most of the homes, an adult or a child too old to go trick-or-treating passed out the candy, while young children were the recipients. The joy of giving appeared overshadowed by the thrill of receiving something for nothing. In fact, even high school aged teenagers would go out trick-or-treating in order to "take" candy. Although they could not resist the temptation of free candy, the high school trick-or-treaters only

went out at night, so as not to damage their social image.

Overall, the children appeared to seek immediate gratification. While some were satisfied by sweet candy, others were satisfied only by money. With the influx of working parents, money or gift certificates, such as McDonald's gift certificates, are commonly given out instead of candy. This saves parents' time and it is also safer. At St. Peters, Kent, and the Caravelle Square Mall, children went into a fervor over money. At St. Peters, most of the children polled said they preferred money over candy. When one boy in a pirate costume was asked what he wanted to get, he jumped wildly around waving his arms and exclaimed, "MONEY! MONEY! MONEY!" In Kent, the trick-or-treaters enthused over McDonald's gift certificates, and in the mall the children proudly lined up for the costume contest in hopes of winning gift certificates. Children appear to prefer money and gift certificates, because these gifts permit them to choose exactly what they want. In short, they give them buying power, something which is lacking in a piece of candy. The ancient sacred meanings of Halloween appear to now be overshadowed by its secular meanings. The children at St. Peters, for example, thought that they had November 1 off to eat their candy, unaware that it was actually All-Saints-Day.

CONCLUSIONS

The ethnographic examination of consumption festivals such as Christmas, Thanksgiving and Halloween can reveal underlying cultural values and social processes. The present examination of Halloween suggests that a formerly religious festival has evolved into a modern day celebration of material gratification and identity creation/extension. The ritual aspects of the festival appear to be centered upon the purchase of costuming props and the receipt of money and sweet treats. The "masking of self" aspects of the costume rituals were also found to serve parents' needs to reinforce their own social identities through their children. Children were, in some cases, treated as semiotic objects appropriate for communicating their parents' public selves. Costumes were also used to communicate and reinforce what were viewed as appropriate gender roles.

Consumption festivals, because of their vivid and heightened realities, may make manifest values which are hidden in the mundane aspects of everyday consumer behavior. It is hoped that the present inquiry into Halloween has brought to light some of the social currents which run through our culture.

An Exploration of Materialism and Consumption-Related Affect

Marsha L. Richins, University of Massachusetts, Amherst

Kim K. R. McKeage, University of Massachusetts, Amherst

Debbie Najjar, University of Massachusetts, Amherst

ABSTRACT

Consumers high in materialism believe that acquisition and consumption are necessary to their satisfaction in life and that expanded levels of consumption will make them happier. This paper reports two exploratory studies that examine whether consumption increases these desired positive feelings among materialists in the short term. Findings suggest that consumption leads to no more positive feelings among materialists than it does among consumers low in materialism. Furthermore, materialists experience stronger negative feelings after acquisition than do consumers low in materialism. The implications for materialistic behavior are discussed.

INTRODUCTION

Starting with Alexis de Tocqueville (1835), materialism has been identified as a dominant characteristic of American society. In a similar vein, recent writers have characterized the United States as a society in which people engage in an obsessive striving after things and a mindless indulgence in them (Schudson 1984), where consumers use as their primary indicator of success the number and cost of the items they possess (Arensberg and Niehoff 1975), and where young people increasingly value the means to acquire possessions over other goals in life (Green and Astin 1985). Despite a presidential call for a kinder, gentler nation and recent claims that greed has diminished, a study by an influential advertising agency predicts that materialism will be a driving force in American society for at least the next decade (Backer Spielvogel Bates Worldwide 1989).

Descriptions of contemporary American culture are often accompanied by criticisms of materialism and a plea for consumers to reduce the importance they place on acquisition and consumption. Among other negative consequences, critics have described the ecological and environmental costs of excessive consumption, the inability of the earth's resources to meet the consumption demands of all inhabitants (e.g., Leiss 1976), and the personal and interpersonal damage that can result from an overemphasis on acquisition and possession (e.g., Fromm 1976).

To understand materialism, it is necessary to comprehend the attitudes and processes associated with materialistic values. This paper reports two exploratory studies that examine one of these processes--the affect experienced by materialists during consumption.

There are several reasons to suspect that affective processes are implicated in materialism. After reviewing the writings on materialism, Belk (1984, p. 291) summarized the common themes by defining materialism as "the importance a consumer attaches to worldly possessions. At the highest levels of materialism, such possessions assume a central

place in a person's life and are believed to provide the greatest sources of satisfaction and dissatisfaction." The literature abounds with descriptions of materialists as perceiving their happiness to depend on the acquisition of possessions. Fournier and Richins (1991), in a study of popular notions concerning materialism, found that lay people describe materialistic individuals in a similar manner, noting that "they have to have the material things ... in order for them to be happy" and "their happiness is dependent on whether they get what they want." According to theoretical and popular conceptions, materialistic consumers expect the acquisition of possessions to improve their well-being.

Does acquisition make materialists happy? Do they actually experience the positive affect they expect from consumption? Because the motivation for materialists' pursuit of consumption is to improve well-being, it is reasonable to ask whether they in fact obtain more pleasure from consumption than those low in materialism. The exploratory studies reported here address this question.

Does Consumption Lead to Happiness?

Theoreticians, philosophers, and critics have debated for centuries whether acquisition and consumption lead to happiness. Certainly, there are reasons to expect that having more things can improve well-being. Possessions play an important role in defining the self and providing meaning in life (Belk 1988; Csikszentmihalyi and Rochberg-Halton 1981). They also provide functional benefits. Labor-saving devices can make life easier and allow tasks to be completed more quickly so that more time is available for pleasurable activities. Other possessions such as skis, sailboats, or color television sets enhance certain leisure activities and make them more enjoyable. Ownership of possessions such as one's home or expensive jewelry can provide financial security and create a sense of confidence or contentment. For these reasons, the acquisition of possessions is expected to generate positive emotions.

Critics, however, have described materialists' acquisition of products as "mindless" and without purpose. According to many, materialists who expect to achieve happiness through possessions are doomed to discontent and dissatisfaction because acquisition goals rise endlessly (e.g., Veblen 1899; Wachtel 1983) and because the truly important satisfactions in life come not from things but from relationships with others or development of the self (e.g., Fromm 1976).

Empirical tests of the relationship between consumption and happiness are limited, but two types of studies have indirect bearing on the issue. Researchers have looked at the relationship between happiness and income, or the *capacity* to acquire, and within a single culture find positive correlations (e.g.,

Easterlin 1974). Other studies, however, have examined the link between materialism and happiness, and these show a different picture. Belk (1984), Richins (1987), and Richins and Dawson (1991), using different measures of materialism, all found negative relationships between materialism and happiness or life satisfaction. Taken together, these two types of studies suggest that acquisition can improve happiness, but not necessarily for those who most believe their happiness to depend on acquisition.

The studies described above have examined happiness or satisfaction at a global level by asking respondents to stand back, as it were, and make an assessment of their general condition in life. The research reported here assesses happiness by looking at positive and negative emotions associated with a specific event--the purchase and consumption of a product--and examining its relationship with materialism. Two studies were carried out. The first looks at purchases which respondents reported as making them happy. The second looks at a broader range of purchases and assesses the affect associated with them.

STUDY 1

In the first study, respondents described purchases that made them happy and reported on the kind of feelings they experienced during and after the purchase. The responses of those high and low in materialism were compared.

Method

Data were collected using an open-ended survey format. Respondents were told to think back to purchases they had made and then asked if they could think of a particular purchase that had made them happy. Every respondent was able to identify such a purchase. Respondents were then asked to describe the product and purchase circumstances and to describe the feelings they experienced while making the purchase and during the subsequent few weeks. The questionnaire asked them to elaborate on pleasant and unpleasant feelings. The questionnaire concluded with the Richins and Dawson (1991) materialism measure ($\alpha=.87$) and some demographic items.

Data were collected from a convenience sample of 48 adult consumers. About half of these were consumers approached in various public settings, such as at a local shopping mall or while riding the bus. The rest were bank, hospital, and library employees approached at their place of work. Demographic characteristics of the sample are reported in Table 1.

Results

In analyses the sample was first taken as a whole, then divided into low and high materialism segments. To achieve group separation for the subgroup analysis, the 8 respondents closest to the median on the materialism scale were not classified; remaining respondents were classed as low ($n=20$) or high ($n=20$) in materialism if their score was below or above the median, respectively.

Purchases leading to happiness. In the examination of the entire sample, the purchases most

frequently mentioned by respondents as generating happy feelings were of clothing or accessories (mentioned by 29.2% of respondents). A wide range of clothing items was mentioned, from a wedding dress to a pair of shorts. Automobiles were also frequently mentioned (22.9%). The rest of the products mentioned fell into a variety of categories. Most (87.5%) were durable goods (e.g., grand piano, books), but such consumables as ice cream, flowers, and hair conditioner were also mentioned.

When the responses of those low and high materialism were examined, no particular patterns were evident. The largest difference was for the clothing/accessories category: 40.0% of those high in materialism were more likely to mention a clothing purchase as generating happiness while 15.0% of those low in materialism mentioned such a purchase. Because of the small sample size, however, this difference must be viewed with caution.

Emotions associated with the purchase.

Respondents were asked about the feelings they experienced during and after the purchase and were prompted to describe both "pleasant" and "unpleasant" feelings. All respondents reported positive emotions, as expected given the nature of the task (describing a purchase that made them happy). Frequently mentioned emotions are shown in Tables 2 and 3. Of the pleasant emotions, "happiness" or "pleasure" was mentioned most frequently (by 85.4% of respondents), followed by "excitement" (33.3%), and "anticipation" (20.8%). Less expected was the frequency with which negative emotions were mentioned. Half of the respondents mentioned being either "anxious" (37.5%) or "afraid" (12.5%), and other unpleasant emotions were also mentioned. Separate analysis of respondents low and high in materialism found no significant differences, although consumers low in materialism appear to be somewhat more likely to experience excitement and anticipation concerning the purchase than those high in materialism.

Conclusions

All respondents could readily describe purchases that made them happy, but the differences between low and high materialists in the products generating happiness and the types of emotions experienced were very small. The things that make one happy appear to be idiosyncratic and perhaps situation specific.

Failure to find differences by materialism level may have been due in part to the type of purchase situation covered in the questionnaire in that respondents were asked to describe a happy consumption experience. Study 2 was carried out to examine purchases that were not self-selected for the happiness they induced. Instead, in Study 2 respondents were asked to describe an important purchase they had made, and the affect associated with these purchases was examined.

STUDY 2

Method

The questionnaire used for data collection included both open-ended items and items with fixed response alternatives. Respondents were first asked to "think of any important purchases you've made within the last month or so" and described several characteristics of the purchase. If they hadn't made an important purchase in this time period, they were asked to respond for their most recent important purchase.

Respondents were then shown a list of 24 emotions. This set was chosen from the lists provided by those who have assessed the structure of affect (de Rivera 1984; Shaver et al. 1987; Storm and Storm 1987), from other studies of product-related feelings (Gardner and Rook 1988; Schultz, Kleine, and Kernan 1989; Westbrook 1987), and from the emotions

described by respondents in Study 1. Respondents were asked to indicate the extent to which the product made them feel each of the emotions in the first few weeks after purchase using a response scale that ranged from 0 (not at all) to 5 (very much). They then completed the Richins and Dawson (1991) materialism measure ($\alpha = .86$) and demographic items. Three versions of the questionnaire in which the order of the emotion items varied were used.

Data were collected from a convenience sample of 107 adult consumers who were approached in a variety of settings similar to those of Study 1. Demographic characteristics of the sample are shown in Table 1.

Results

As in Study 1, analyses were first carried out for the sample as a whole and then on the low and high materialism subgroups. The 19 respondents closest to

Types of Products for Important Purchases. As might be expected from the marketing literature on product importance (e.g., Bloch and Richins 1983), the kind of purchases described as important by respondents were generally expensive, durable items (e.g., cars, television sets) and socially visible

products (e.g., clothing, furniture). Electronic equipment (television sets, stereos, personal computers) was mentioned most frequently (20.6%), followed by vehicles (18.7%) and clothing (11.2%).

Subsequent analyses compare low and high materialists with respect to the affect experienced following purchase. If the two groups differ in the kinds of products or consumption experiences they are describing, however, any observed differences in affect may be due to the different products involved

^bExcludes unclassified respondents (neither high nor low materialism)

rather than their degree of materialism. An examination of Table 4 reveals that there were no differences between low and high materialism respondents in terms of the type of product involved in the purchase reported. There were also no differences between the two groups in terms of product cost, length of time respondents had wanted the product before purchase, and how recently it had been purchased ($p > .05$).

Purchase-related Emotions. Table 5 shows the percentage of respondents who reported they had experienced each of the 24 emotions with respect to the product (that is, they assigned the emotion a value greater than zero on the response scale). Positive affect predominated, with happiness, excitement, and pleasure experienced most frequently. Negative emotions were less common, with nervousness experienced most frequently (36.4%), followed by guilt (26.1%) and fear (25.2%). The positive and

negative emotions reported concerning the "important" purchases of Study 2 are consistent with those described in Study 1 for happiness-inducing purchases.

When low and high materialists were compared on the frequency of reported affect, there was only one significant difference: high materialists were more likely than low materialists to report envy ($p < .05$). When comparing intensity of affect, however, several significant differences occurred. Those high in materialism reported stronger feelings of anger, disappointment, irritation, fear, nervousness, and envy ($p < .05$). At a borderline level of significance ($p < .10$), they also scored higher on feeling guilty and unfulfilled.

Because of the increase in experiment-wide error rate that accompanies multiple t-tests, a second approach was used to examine affective responses in which the 24 emotion items were subjected to a

principal components analysis. Using the scree test criterion, two factors were retained, together accounting for 46% of the variance in the affect items. Loadings are shown in Table 5. The first factor has high loadings for 14 negatively valenced emotions, the second factor has high loadings for 10 positively valenced emotions. This dimensional representation is consistent with that obtained in several other studies of affect (e.g., Watson and Tellegen 1985; Westbrook 1987; Zevon and Tellegen 1982). Summed scores were created from responses to the 14 negative and to the 10 positive affect items; coefficient alpha for the negative and positive emotion scales were .88 and .87, respectively.

The correlation between materialism and the positive affect scale was .08 ($p > .10$). Because the negative affect scale was highly skewed, a square root transformation was used; the correlation between materialism and negative affect was .31 ($p < .001$; correlation for the untransformed scale was .27, $p < .01$). Rather than experiencing more positive affect than non-materialists, consumers high in materialism seem to experience more negative affect following acquisition.

DISCUSSION

Like earlier studies of cable television and car purchases (Westbrook 1987) and of impulse purchases (Gardner and Rook 1988), the two studies reported here found a wide range of both positive and negative emotional reactions to purchases. Although both of the earlier studies found negative emotions to follow a purchase, we were somewhat surprised at the high incidence of negative affect following purchase events that respondents described as particularly happy. The largest category of negative affect involved anxiety and related states.

The most surprising aspect of the research, however, concerns the relationships between

materialism and consumption-related affect. Materialists expect acquisition to make them happier, and at least in the short run (the first few weeks after purchase), they report experiencing happiness and other positive affect concerning the product. However, the level of positive affect generated by the product is no greater for materialists than for nonTM-materialists.

Where the two types of consumers do differ is with respect to negative affect following purchase. High materialists experienced stronger feelings of anxiety, guilt, and other negative emotions in the weeks after purchase than did those low in materialism. One potential explanation for this finding has to do with the centrality of consumption in materialists' day-to-day existence. Because consumption is so important to them, they may have higher expectations for what a new possession will accomplish in their lives. With higher expectations, the chances for disappointment increase, and indeed disappointment was greater among those high in materialism. In addition, high expectations increase the chances for cognitive dissonance and generalized anxiety about the correctness of product choice. Finally, purchase of an expensive product can ignite feelings of envy among materialists as they scan the marketplace and the possessions of others, realizing perhaps that the television set, furniture, or automobile they can afford is not as well equipped, as luxurious, or of the quality they desire.

These negative feelings have implications for materialists' subsequent behavior. Because they believe that more consumption will make them happier, the way to erase the negative feelings, in their view, is to consume more. This is one possible mechanism for the perpetuation of the vicious cycle of consumption described by many critics of materialism (Brickman and Campbell 1971; Linden 1979; Wachtel 1983).

The research described here is an exploratory attempt to assess the potential value of examining materialism and affective processes. Future research can extend our knowledge by exploring different aspects of the materialism-affect link and by studying affect itself in different ways. In this study, a two dimensional representation of affect was used. Although this is an improvement over early research that treated affect as a single, bipolar dimension, there have been criticisms of the two-dimensional approach as inadequate (e.g., Shaver et al., 1987; Smith and Ellsworth 1985). Future research on materialism and affect should be designed to test more complex representations of emotion.

Future research should also be directed at determining *why* the various kinds of affect, especially negative, occur among materialists. Depth interviews probing the reasons for disappointment, anxiety, and envy in particular instances would provide a more textured picture of the relationships between materialists and their possessions.

Another approach would be to examine the long-run affective relationships materialists have with their possessions. Materialistic people are often perceived to be wasteful, quickly becoming disaffected with their acquisitions and desiring new ones, and studies covering a longer time period can test the validity of this perception and explain the reasons for this disaffection, if it does indeed occur. Does it result

from a decline in positive feelings about the product, for instance, or from an increase in negative affect such as envy and anxiety?

Examination of *pre-purchase* affect would round out the picture of materialists' affective processes in a different direction. Studies that look at anticipatory affect in conjunction with pre-purchase expectations about how one's life will be affected by the acquisition would be an opportunity to link the affective and cognitive processes of materialists.

The research reported here demonstrates that affective processes play a role in materialism. As future research examines these processes in greater detail, we may gain new and valuable clues about the nature of materialism and why it persists.

An Investigation of the Attribute Basis of Emotion and Related Affects in Consumption: Suggestions for a Stage-Specific Satisfaction Framework

Richard L. Oliver, Vanderbilt University¹

ABSTRACT

Emotions having the potential to be evoked in the consumption experience were related to attribute-specific and overall judgments of satisfaction/dissatisfaction in an effort to more fully understand the role of emotion in consumption. Results of a multidimensional scaling analysis of the attribute dimensionality of automobile purchases and a property-fitting of emotions and satisfaction measures revealed two attribute dimensions and meaningful interpretations for the position of satisfaction/dissatisfaction, enjoyment, interest, surprise, and general negative affect on this space. The attribute and emotion solution suggests a consumption-stage interpretation of the evocation of emotions in usage. Propositions consistent with this framework are offered for future work in the area.

Work on the role of emotion in consumption is beginning to intrigue consumer researchers. Prompted by calls for greater emphasis on non-cognitive elements of purchasing and consumption phenomena (e.g., Holbrook and Hirschman 1982), researchers have, of late, begun to investigate this research domain (Havlena and Holbrook 1986; Holbrook 1986; Holbrook et al. 1984; Oliver 1989, 1990; Westbrook 1987; Westbrook and Oliver 1991). The present paper continues this tradition in the following manner. First, it examines the dimensionality of attribute reactions (satisfactions in the present case) in consumption. Second, it relates reported emotional experiences in consumption to the derived dimensions, illustrating the capacity for attributes to evoke emotion. And third, overall satisfaction and dissatisfaction are positioned within the emotion and attribute configuration.

Background

Prior to recent years, few writers had considered responses other than satisfaction/dissatisfaction to the consumption experience. In fact, few had speculated as to whether satisfaction was an emotion or not. One exception is Hunt (1977) who referred to satisfaction as "an evaluation of an emotion." Two streams of research are available to provide insight to this issue. The first, represented by the work of Leavitt (1977), Maddox (1981), and Swan and Combs (1976), relates to the dimensionality of satisfaction attributes. The second, more recently, investigates the emotional correlates of consumption and includes

the works of Holbrook (Havlena and Holbrook 1986; Holbrook et al. 1984) and Westbrook (1987; Westbrook and Oliver 1991) with respect to overall satisfaction with products. Interestingly, the two streams of work do not overlap in that the "attribute basis" of the earlier works is not reflected in the emotional basis of the more recent writings.

In the following discussion, these perspectives are reviewed to properly frame the present study. First, literature on the attribute basis of satisfaction and dissatisfaction is discussed in an effort to explain how others have viewed attribute categorizations. Second, works on emotion in consumption are reviewed in an effort to position satisfaction relative to other emotions and, to some extent, respond to Hunt's (1977) query about whether satisfaction is an emotion or the evaluation of emotional responses in purchasing. Finally, the present effort links attribute satisfaction, overall satisfaction, and emotion in a manner suggestive of an emerging framework. At present, only Oliver's (1989) theoretical framework containing both satisfaction and emotion is available to researchers. This conceptualization does not address the role of product attributes, however.

Prior Works on the Attribute Basis of Satisfaction/Dissatisfaction

Three studies are known which have attempted to propose or test the role of attributes in product satisfaction judgments. In an investigation of responses to newly acquired apparel, Swan and Combs (1976) argued that attributes can be classified into "satisfiers" and "dissatisfiers" based on whether the product features were expressive or instrumental. Instrumental apparel features were defined as physical product attributes such as "wash and wear," while expressive features were non-product characteristics such as a friend's admiration. Using a method wherein subjects recalled satisfying and dissatisfying clothing usage situations and the reasons for their (dis)satisfaction, the authors found that more expressive than instrumental attributes were mentioned in satisfying scenarios, while instrumental attributes tended to be mentioned more frequently in dissatisfying scenarios.

Maddox (1981) replicated this approach on a larger selection of products and found that, if one restricts analysis to personal care items (including clothing), the separate factor interpretation is supported. However, if other products such as durables are considered, the results tend to appear in a direction opposite to that proposed by Swan and Combs (1976). Maddox suggested that the instrumental/expressive breakdown is flawed because the results appear to be product-specific.

In an alternative approach, Leavitt (1977) used the Herzberg (1966; Herzberg, Mausner, and Snyderman 1959) distinction between intrinsic and extrinsic work factors to classify a variety of

¹The author thanks Wayne S. DeSarbo, Graduate School of Business, University of Michigan, for his assistance with the scaling analysis used here, and the Dean's Fund for Faculty Research of the Owen Graduate School of Management of Vanderbilt University for providing partial support for this project.

marketing mix descriptions (product, price, advertising, and place) into intrinsic (product) and extrinsic (price, advertising, and place) categories. When correlated with separate measures of satisfaction and dissatisfaction, Leavitt found virtually identical correlations (neglecting signs) across categories and concluded that the intrinsic/extrinsic hypothesis was not supported.

Thus, current knowledge about the attribute basis for satisfaction/ dissatisfaction is lacking. Neither the instrumental/expressive nor the intrinsic/extrinsic breakdown proposed in prior works has proven fruitful. Because the former has been unsuccessfully replicated and because the latter showed little promise as a classification scheme for consumer products, these perspectives were not pursued here. Rather, an inductive attempt was made to shed light on the attribute satisfaction phenomenon in consumption.

Studies of the Emotional Content of Product Experiences

To date, four published studies have examined the potential emotional basis underlying experiences with products. The first, by Holbrook et al. (1984) examined the Mehrabian and Russell (1974) pleasure-arousal-dominance (PAD) emotional typology in the context of video games. Their results showed that mastery of the game affected pleasure and dominance perceptions, but not arousal. In a comparison of the PAD framework with eight discrete emotions proposed by Plutchik (1980), Havlena and Holbrook (1986) found that the Mehrabian and Russell PAD typology resulted in more attractive psychometric properties (dimensionality, variance explained, etc.) over some 35 hypothetical consumption experiences. However, neither overall nor attribute-specific satisfaction was investigated in either study.

Westbrook (1987), correlated responses to Izard's (1972, 1977) Differential Emotions Scale, consisting of ten discrete emotions (to be discussed), with various satisfaction and dissatisfaction measures regarding automobiles and cable TV and posited that consumers form two summary affect states, one based on the positive affects in consumption and the other on the negative affects. His results showed that the affects of joy and interest loaded on a factor separate from that of anger, disgust, and contempt, and that these factors were relatively uncorrelated. Moreover, both were related to satisfaction in the expected direction although Westbrook concluded that satisfaction was not fully represented by these emotional dimensions.

In the latest paper, Westbrook and Oliver (1991) replicated Izard's (1977) typology on a new sample of automobile ownership, to study further the dimensionality of consumption. Their results modified the earlier Westbrook (1987) findings somewhat in that they found a broader negative dimension which they labeled "hostility," a positive dimension combined with surprise or "pleasant surprise," and an interest dimension. These dimensions explained approximately 40-45% of the variance in various satisfaction measures.

Thus, these prior works suggest that emotion may play a distinct role in postexposure processes including satisfaction/dissatisfaction. However, the evidence to date is not able to suggest a correspondence between specific states of satisfaction/dissatisfaction, the emotions evoked in consumption, and the attribute basis evoking these emotions. In short, the emotion literature speaks to one link in the three-part attribute-emotion-satisfaction scheme, while prior literature on the categorization of attributes reflects a second -- that between attributes and satisfaction. Missing, however, is an integrated analysis of the attribute basis for emotion and of the relation of satisfaction to these variables.

Such an analysis would perform three functions in efforts to understand how emotions operate within the product consumption experience. First, it would suggest the tendency for attribute experiences to evoke specific types of emotions. Second, it would position satisfaction and, perhaps separately, dissatisfaction within the attribute profile, thus suggesting the tendency for attributes to promote either satisfaction or dissatisfaction. Finally, by positioning satisfaction and dissatisfaction within the emotion-on-attribute space, the correspondence of satisfaction/dissatisfaction to specific emotions can be observed. This would permit an emotional interpretation of some common satisfaction and dissatisfaction measures.

Thus, the goals of this paper are to: (a) spatially describe an attribute configuration of attribute satisfactions, (b) fit an emotional typology on this space to suggest the correspondence between attributes and their potential to evoke emotions, and (c) study satisfaction/dissatisfaction as a property of emotional experience *and* attribute experience, particularly with regard to the juxtaposition of satisfaction vis-a-vis the emotions present in consumption experiences.

METHOD

To address these objectives, a methodological approach and research vehicle were needed with the flexibility to accommodate adequate numbers of attributes and emotions within the same design and analysis. Precedent for this problem has been established in the works of Westbrook (1987; Westbrook and Oliver 1991) and Havlena and Holbrook (1986). The Westbrook studies used Izard's (1977) Differential Emotions Scale containing ten fundamental emotions in automobile ownership and consumption. This approach is combined with the Havlena and Holbrook scaling solution to respond to the study objectives.

Sample

The sample consisted of 125 owners of recently purchased automobiles contacted in shopping centers of a major northeastern city. Details of the sampling procedure appear in Westbrook and Oliver (1991).

Measures

Attribute Satisfaction. To achieve a reasonable list of attributes, *Consumer Reports* and focus groups of graduate and adult evening school students were consulted to determine salient automobile features. Consideration of the overlap and redundancy in the frequency of attributes mentioned across sources produced a list of 19 features. The attributes used were acceleration, body integrity (no squeaks, rattles), fuel economy, handling, image, interior features, luggage space, noise, power, price, quality, repair frequency, ride, roominess, safety, service, sound system, styling, and uniqueness.

Because automobile "consumption" is an ongoing process and not a one-time purchase/usage experience, allowance was made for the possibility that the respondents would have observed favorable and unfavorable experiences with the same attribute. For example, although initial fuel economy may have been poor, later improvements may have occurred through servicing and normal "break-in." Thus, consumers could have been both satisfied and dissatisfied with the same attribute. To account for this, subjects were asked to state the degree to which each attribute provided satisfying and dissatisfying experiences on six-point scales ranging from none to a great amount. The attribute satisfaction score used here was the net of the satisfying and dissatisfying scores.

Emotions. Because of its validated properties and the precedent set by Westbrook (1987), Izard's DES II was used in the present study. Specific scale items represent the ten fundamental emotions of interest, enjoyment, surprise, sadness, anger, disgust, contempt, fear, shame, and guilt. This 30-item scale, consisting of three items per emotion, appears in two forms. It can be used as a "state" measure whereby subjects indicate their intensity of emotion and as a "trait" measure whereby subjects indicate the frequency of experiencing the emotion. Whereas Westbrook and Oliver (1991) used the frequency scales, the intensity scales are used here because the present focus studies attribute experience which Westbrook and Oliver did not address. Since some very important attribute experiences may occur only once (e.g., an intensely negative service experience) and still impact satisfaction greatly, it was felt that intensity would be more meaningful in the attribute context. Moreover, the original DES, as well as Westbrook's (1987) study used intensity measures and greater scale validation is available for this version. Izard (1977) reports original test-retest reliabilities for the ten scales ranging from .68 to .87.

Satisfaction. Because separate measures of satisfaction and dissatisfaction were desired, an alternative to the conventional bipolar scale was needed. Thus, a twelve-item Likert scale expanded from Oliver (1980; Oliver and Westbrook 1982) was adapted to the present study. This scale consists of a set of statements reflecting agreement/disagreement with phrases such as "happy with product," "right decision," etc. To provide a measure of satisfaction only, all items were worded in the positive. A separate negative scale was constructed by repeating the twelve

items in the negative (e.g., unhappy with product, wrong decision). Because these are agreement scales, it was not expected that the subjects would simply give complementary answers to the two parallel scales. For example, a subject could conceivably indicate strong agreement with "happy with product," but indicate neutrality as opposed to strong disagreement with unhappiness.

Alpha reliability estimates for the ten emotion intensity scales range from .70 to .94 and are similar to those for the frequency scales in Westbrook and Oliver (1991). Reliabilities for the satisfaction and dissatisfaction scales were very high (.98 and .97 respectively), indicating strong agreement over items in these scales.

Analysis

The two-way matrix of attribute ratings (125 subjects by 19 attributes) was row-standardized to equate subjects' variances and means so that idiosyncratic anchor points were removed and submitted to MDPREF (Carroll 1972), a vector MDS model. Here, subjects are represented as vectors emanating from the origin of the space, and attributes are represented as points. The projection or scalar products of these attribute points onto subject vectors renders a graphical summary of how each subject's level of satisfaction/dissatisfaction derives with respect to each attribute. Since MDPREF produces orthogonal dimensions, one can examine a scree plot of the variance accounted by dimension to select the most parsimonious interpretation.

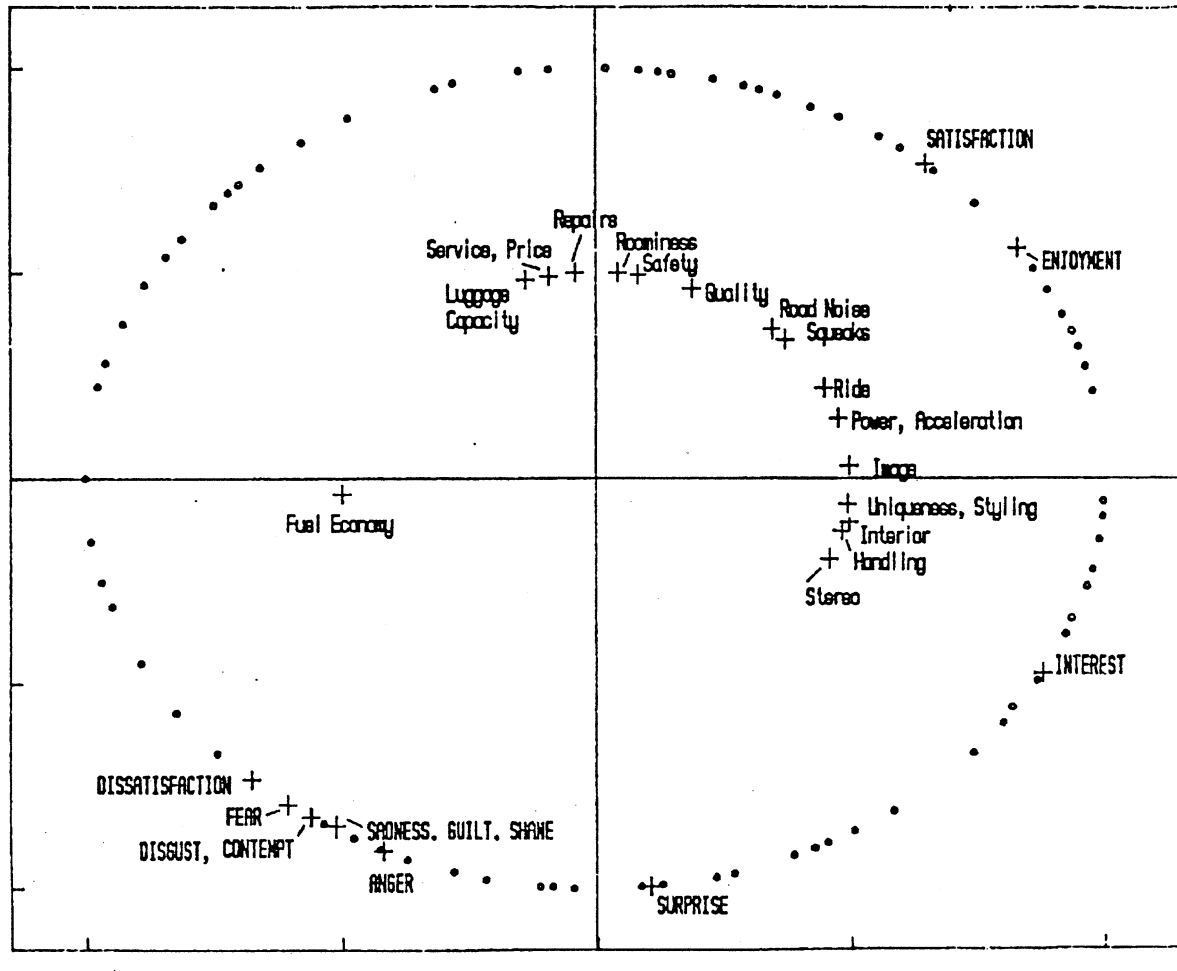

Once the joint space of subject vectors and attribute points is estimated, one can use simple regression procedures to property-fit (cf. Green and Rao 1972) the ten emotions from the DES individually. This would indicate the nature of the relationship between the ten scales and the derived stimulus space. Similarly, one can perform the same property-fitting application with the satisfaction and dissatisfaction scales. The net result, therefore, is a graphical summary of the internal components of attribute satisfaction and how these derived components are related to the various emotions and overall satisfaction/dissatisfaction.

FINDINGS

The MDPREF analysis of the attribute satisfaction scores revealed two orthogonal dimensions explaining 42% and 15% of the variance respectively. Based upon interpretation and scree tests, the remaining dimensions were found to offer no new insight to the analysis. The 57% of variance explained by the first two dimensions is quite good considering the large number of subjects. The Figure presents the two derived dimensions where both the lengths of the attribute points and subject vectors were normalized for convenience. For ease of illustration, the subject and subsequent emotion vectors are not shown. Rather, the end points (termini) are represented as hollow dots for subjects and crosses for the emotions and satisfaction variables.

The horizontal dimension (Dimension 1) consists of satisfaction with instrumental performance

FIGURE
Two-dimensional Joint Space Plot

features (i.e., those which provide ongoing dynamic performance, satisfaction, and pleasure such as ride, acceleration, stereo quality, and styling), while the vertical dimension (Dimension 2) consists of satisfaction with less variable "constants" (e.g., one-time events or factors considered in the initial purchase decision such as price, safety, quality, and size). Note that these dimensions do not fit either the notion of "satisfiers" or "dissatisfiers," or of instrumental/expressive or intrinsic/extrinsic attribute classifications as described earlier. The data reveal, further, that all attributes are essentially satisfying in this sample in that they are positively situated on the dimensions with the exception of fuel economy. Apparently, satisfaction with fuel economy is at odds with satisfaction with the other attributes on Dimension 1. This is easily explained, however, as satisfaction with features such as acceleration and power on this dimension can only come at the expense of fuel economy.

The outer circle of subject vector termini represents the subjects' respective positions vis-a-vis

their net satisfaction with specific attributes.

Generally, the sample appears quite diverse with regard to individuals' satisfaction and dissatisfaction with the attribute dimensions of the car. For example, subjects scoring positively on Dimension 1 apparently derive satisfaction from the performance characteristics of the car at the expense of fuel economy while those scoring negatively on this dimension derive satisfaction from high fuel economy at the expense of performance.

Correlations between the derived attribute dimensions and the emotion intensity ratings are shown in the Table. The ten emotions are shown at the vector termini on the outer normalized radius circle. This mapping reveals four distinct sets of emotional profiles, namely interest, enjoyment, surprise, and general negative affect. Interestingly, the attributes tend to group on two of these, as the following discussion describes.

Enjoyment appears to represent more of the attributes than any other dimension profile although, interestingly, only satisfaction with (the absence of)

TABLE
Correlations Between the Attribute Dimensions and the Consumption Responses

Response	Dimension 1	Dimension 2
Interest	.316	-.171
Enjoyment	.418	.284
Surprise	.030	-.282
Sadness	-.302	-.447
Anger	-.192	-.416
Disgust	-.290	-.419
Contempt	-.274	-.391
Fear	-.200	-.263
Shame	-.186	-.283
Guilt	-.212	-.318
Satisfaction	.491	.481
Dissatisfaction	-.448	-.427

noise and squeaks appear directly related to this dimension. Generally, enjoyment correlates more highly with the attributes on Dimension 1 (dynamic performance) than on Dimension 2.

Interest also appears to be evoked primarily by the Dimension 1 variables and displays a modestly negative correlation with Dimension 2. Apparently, the subjects in this study derived interest from the ongoing performance characteristics of their cars, perhaps because these are capable of maintaining interest. Surprise, in contrast, is captured only by Dimension 2 where satisfaction levels of the attributes are associated with a *lack* of surprise. Thus, unsurprising levels of price, repairs, service, and roominess, for example, tend to characterize this perspective. Finally, all of the negative affects including fear, sadness, disgust, contempt, and anger group together. Somewhat more representative of Dimension 2, these affects do not appear 180 degrees apart from enjoyment, a purer form of positive affect. Anger, in particular, is oriented more closely with Dimension 2.

When satisfaction and dissatisfaction were fit in this same space, satisfaction is shown in the Figure to share more in common with enjoyment than with interest. It also appears that satisfaction is more representative of the attribute satisfactions than is enjoyment. Alternatively, dissatisfaction is more moderately positioned than are the negative affects, correlating almost equally with Dimensions 1 and 2.

DISCUSSION

The discussion proceeds in three sections. First, the attribute satisfaction space as it relates to the solution found here is discussed. Second, the relation between these attributes and the ten discrete emotions are elaborated. Third, satisfaction is discussed, both with regard to its relation to the attributes and to the emotions. At each stage in this process, research issues are proposed to stimulate further work in the area.

Attribute Dimensions

The data suggest two groups of attributes, those which relate to satisfaction with the continuing performance of the product such as acceleration, ride, fuel economy, etc. and those which are one-time (e.g., price), infrequently accessed (e.g., service), or unchanging characteristics (e.g., safety, quality). This dynamic/static description of attribute satisfaction was evident in this study due to the nature of the product. Unlike one-time or short-life products (e.g., foods, entertainment, disposables), automobiles have the capacity to display both "purchase phase" and "usage phase" qualities which have the capacity to evoke a wider range of emotions. Conceivably, there exist other dimensions of performance based on the temporality or emergence of different performance stages.

For example, an initial stage of acquisition attributes (e.g., price, terms) is proposed which includes the known attributes of the product (e.g., size). This is followed by certain "unknowns" which manifest themselves very shortly (e.g., initial defects). The next stage (if appropriate to the product) is a longer period of "steady-state" performance whereby the variable performance dimensions are observed to change and subjective attributes (e.g., image) are reinterpreted. Thus, the following proposition is offered:

Proposition 1. Satisfaction from consumption and, hence, satisfaction with attribute performance may be viewed in stages, each of which has the potential for evoking diverse emotions and further cognition. The first is the acquisition and known characteristics stage where various properties of the product are known with certainty (e.g., size, color). This may be followed by the initial discovery of unknowns as in the number of factory defects and service experiences with the dealer. Finally, there may exist longer term consumption experiences where basically

known elements of the product are monitored for change.

Note that the framework suggested by the present data does not correspond to separate-factor theories as previously discussed. Rather than "satisfiers" or "dissatisfiers," consumption-stage attributes capable of producing either satisfaction or dissatisfaction appear evident. Nor do the expressive/instrumental categories, operationalized as product and non-product benefits, correspond to the present findings. It appears, instead, that product features and external features exist together on both dimensions (e.g., power and image on Dimension 1, roominess and service on Dimension 2). This does not suggest that the prior conceptualizations are incorrect, as a different methodology was used here. Rather, it suggests that alternative interpretations are plausible.

Emotions

The location of the emotions on the attribute satisfaction space can be viewed as consistent with the attribute interpretation above. Whereas Westbrook and Oliver (1991) found dimensions of hostility, pleasant surprise, and interest, an alternative analysis of intensity ratings from the same data set shows that the emotions of enjoyment, interest, surprise, and negative affect appear to operate as responses to underlying attribute dimensions. Thus, these findings differ from those of the Westbrook and Oliver frequency data in that enjoyment and surprise may initially be separate responses in consumption that become additive over time (as consumption experiences become more frequent -- i.e., accumulate) to produce the pleasant surprise dimension.

Of greater interest is the correspondence of the emotions to the attribute space. Specifically, enjoyment was fairly moderately situated among the attributes although it was more highly related to Dimension 1. Interest, however, was clearly aligned with the first dimension, representing dynamic performance and suggesting that continued interest in a product relates to satisfactions with ongoing performance. In contrast, surprise appears to relate solely to Dimension 2 where less (or no) surprise is related to satisfaction with the one-time or static aspects of the product. Finally, general negative affect appears to reflect the negative dimension of enjoyment although these extremes are not 180 degrees apart. Rather, the group of negative affects is approximately 155 degrees from enjoyment. Anger, more so than the other negative emotions, is a Dimension 2 affect, suggesting that dissatisfaction on the Dimension 2 attributes is capable of provoking anger. Alternatively, dissatisfaction on the Dimension 1 attributes is somewhat more likely to evoke the more general negative affects.

The implications of these findings are rather interesting for it appears that the nature of the attributes or, more accurately, the relevance of an attribute to a consumption stage, may evoke certain emotions characteristic of that stage. For example, the data suggest the possibility that dissatisfaction with known attributes may provoke anger while

dissatisfaction with unknown but subsequently observed attributes may produce surprise or anger and surprise. Alternatively, dissatisfaction with the more dynamic attributes possibly may generate less specific forms of negative affect. Based on these observations, the following proposition is offered:

Proposition 2. There may exist consumption-stage-specific affects which are evoked by the attributes unique to or observed in these stages. Initial stage consumption, consisting of observation of previously known and soon to be observed attributes, produces, in the dissatisfying case, short duration but fairly intense emotions such as surprise and anger. Attribute satisfaction in this initial stage may produce similar types of positive emotions of the "surprisingly good" variety such as delight and excitement. Alternatively, later consumption stages may produce emotions capable of being sustained along with the dynamic nature of the later stage attributes. Such emotions in the satisfaction case appear to be interest and enjoyment. Parallel emotions in the dissatisfaction case may be described in general terms such as sadness or resignation.

Satisfaction/Dissatisfaction

Two issues are relevant to the role of satisfaction/dissatisfaction in the present framework. The first concerns the relation between attribute satisfaction and overall satisfaction while the second concerns the underlying emotional basis for perceptions of satisfaction. The data suggest that overall satisfaction includes a fairly global summary judgment of attribute satisfaction. This perspective is suggested by the very central position of the satisfaction vectors among the attribute satisfactions. Thus, it appears that satisfaction is a summary attribute phenomenon, at least in part.

Finally, the results suggest that satisfaction shares commonalities with, but differs from enjoyment (pleasure). This is consistent with Oliver's (1989) position that pleasure is but one of perhaps five satisfaction prototypes. Interest and surprise, other somewhat distinct affects found here, are not well represented on the satisfaction vector. This suggests the possibility that other consumption emotions, and perhaps cognition, coexist with satisfaction/dissatisfaction and have separate, but equally important effects on later purchase behavior. These observations suggest the following:

Proposition 3. Satisfaction and dissatisfaction reflect the general affective tone of the consumption experience, appearing to equally represent static and dynamic purchase elements. However, other purchase emotions (e.g., surprise) may coexist with satisfaction so that a fuller range of postpurchase psychological responses is needed to properly describe the cognitive and affective reactions to consumption.

Limitations

Given the early stages of this research stream, limitations encountered here exist which will serve to alert future researchers to potential pitfalls. One such pitfall is the restriction imposed by a limited sample of respondents and a single product. Automobiles are known to be a high involvement product category which has the capacity to evoke greater levels of both affect and cognition. Low involvement products would not be expected to elicit high levels of processing and may result in the "contentment mode" of satisfaction as proposed by Oliver (1989). As a result, the findings here may not replicate on frequently purchased, everyday products.

A second limitation is the necessity for a greater sampling of emotions. The ten "fundamental" emotions from Izard (1977) were selected because of the precedent set by Westbrook (1987). One problem with this scale, observed in retrospect, is that, although the subjects were largely pleased with their cars, seven of the ten affects in the Izard scale are negative in character. Thus, other typologies, consisting of other sets of emotions need to be studied, perhaps in conjunction with those of Izard. Plutchik's (1980) framework as used by Havlena and Holbrook (1986) is one such example.

Another limitation concerns the methodology and analysis, specifically with regard to the use of the property-fitting procedures in MDPREF. For example, the vector model representation could reflect a misspecification error if an ideal point model were the true underlying structural form. Thus, the suggested research propositions are both data-dependent and specific to the methodology and analysis used here and are not theory-driven. Until more work is done in this area, however, early representations such as that found here will hopefully serve to stimulate future efforts.

CONCLUSION

Drawing on the precedent set by other works in the satisfaction and emotion areas, an effort was made to provide early insights into the role played by emotion in the consumption experience with particular emphasis on attribute and overall satisfaction. The data suggested attribute dimensions differing on a usage stage basis and a mapping of emotion suggestive of early stage and later stage experiences. Satisfaction/dissatisfaction was found to mimic a general affect, more representative of enjoyment than of interest or surprise. Propositions are offered, suggesting a framework for the future study of emotions deriving from consumption and its stages.

Interpreting Perceiver Reactions to Emotional Stimuli

Jeremy D. R. Pincus, University of Connecticut

ABSTRACT

The expressive reactions of perceivers to emotionally expressive stimuli have been considered to be mediated emotionally and unemotionally. In order to demonstrate emotional mediation, a distinction is proposed between supplementary and complementary emotional responses. The emotional releasing function of emotionally expressive stimuli is considered from a psychobiological perspective in terms of effects on attention and attitude formation and change. Implications for ad testing are discussed.

INTRODUCTION

Some theorists have presumed the expressive reactions of perceivers to emotionally expressive stimuli to be mediated emotionally, whereas others have viewed these responses as essentially imitative. This paper attempts to resolve the affect-imitation issue by distinguishing between complementary and supplementary emotional reactions, and using this distinction as a framework for the interpretation of relevant studies. The relative contributions and validities of facial electromyography and other measures of emotion are considered. The implications of automatic affect elicitation are also considered in terms of attitude formation and change.

A major assumption of advertisers and consumer researchers has been that perceivers react emotionally to the emotional expressions of others. Emotion, here, is defined as an internal state which manifests itself through three basic output channels—physiological responses, expressive behavior, and subjective experience (Buck 1988). Accordingly, in the consumer behavior literature, the response of perceivers to emotional stimuli has been characterized as "activation" (Kroeber-Riel 1979) and an "over-time flow of feelings" (Friestad and Thorson 1986), which correspond to the concepts of physiological arousal and subjective experience of emotion, respectively. The Cohen and Areni (1991) model of affective consumer response shares this general orientation, incorporating expressive behavior in their conceptualization of the "first phase affective response". The assumption of affective perceiver reactions to emotional stimuli is clearly evident in the application of their model to the perception of a Michelin tire ad:

"The happy babies in the commercial should elicit an immediate, almost automatic, affective response. Viewers may even find themselves smiling. This 'primitive' affective response occurs without consideration of the meaning of any element of the ad. It may be more related to the facial pattern of the smiling baby's face, or the happy baby may have virtually become an 'unconditioned stimulus' for the generation of affect" (Cohen & Areni 1991, p. 232).

The idea that the emotional expressions of conspecifics cause automatic emotional reactions in observers has appeared in works as early as those of Darwin (1872) and McDougall (1908). More recently, the concept has appeared in Izard's (1977) principle of emotion contagion, and in the work of several empathy researchers (e.g. Stotland, Sherman, & Shaver 1971).

The dominant explanation of the emotion contagion process has employed the ethological concept of the innate releasing mechanism, a phylogenetically pre-programmed system for the instigation of specific motivational/emotional/behavioral patterns. Innate releasing mechanisms are triggered by a set of stimuli known as releasers; a particular category of releaser includes the phylogenetically-based social signals of others which comprise emotional expressions. According to the ethological view, then, the emotional expressions of others act as releasers of internal emotional states in perceivers. In the words of ethologist Eibl-Eibesfeldt, "if we perceive someone smiling, cerebrochemical processes are presumably activated, these inducing a friendly mood and smiling in response" (1989, p.73). Support for this notion has come largely from studies (reviewed below) finding reliable changes in the nonverbal behaviors of perceivers upon exposure to emotional expressions (e.g. Davidson & Fox 1982; Dimberg 1988; Sackett 1966).

An alternative explanation suggests that perceiver reactions to emotionally expressive stimuli may be instances of non-emotional mimesis. Such non-emotional imitation of nonverbal behavior has itself been conceptualized as the product of an innate releasing mechanism (Masters 1979). Others have considered imitative display to serve a social communication function which may or may not be mediated by emotion (Bavelas, Black, Lemery, & Mullett 1986).

IMITATION VS. EMOTIONAL MEDIATION: RESEARCH FINDINGS

The findings of a variety of studies shed light on the imitation-emotion issue. The results of the first group of studies illustrate the ambiguity of interpretation encountered when sender and receiver both exhibit the same nonverbal display; in such cases, expressive behavior may be interpreted as either the result of emotional mediation or non-emotional imitation. These ambiguous cases will conservatively be considered supportive of the mimetic interpretation. In these studies, facial EMG is employed as a measure of emotional response, the merits and limitations of which are detailed below.

Support for Imitation

Vaughan and Lanzetta (1980) in a study of vicarious emotional conditioning, employed expressions of pain as unconditioned stimuli and collected facial EMG and skin conductance measures.

Results indicated that exposure to expressions of pain, even in videotape format, can elicit congruent physiological arousal and facial patterning in the observer. The authors concluded that observers responded emotionally to the model's expressions and that the observation of emotional expressiveness is necessary for the acquisition and maintenance of vicarious conditioning. These results, however, likewise may be interpreted as an instance of imitative responding; that is, the pained expressions of the stimulus person may simply have been mimicked by observers.

McHugo, Lanzetta, Sullivan, Masters, and Englis (1985) exposed American subjects to televised emotionally expressive displays of Ronald Reagan, and compared their physiological and self-reported emotional responses. Although prior attitude significantly influenced self-reported emotion, subjects displayed similar physiological patterns of emotional expression regardless of prior attitude. Across all subjects, facial EMG responses indicated subjects smiling during displays of happiness and frowning during fear and, especially, anger displays. Skin conductance responses indicated least relaxation during anger displays, intermediate activity during fear displays, and most relaxation during happiness displays. Heart rate decelerated most during fear and anger displays. The authors concluded that emotionally expressive displays have a direct emotional impact on viewers, however, they explicitly accepted the possibility that the EMG activity may have resulted from imitation: It was suggested that the finding of "parallel" responses in sender and receiver may be interpreted in two ways, either as expressive displays mediated by internal affective state or as "motor reflexes due to the contagion of the communicator's display" (McHugo et al. 1985, p. 1527).

Dimberg (1982) demonstrated that specific patterns of facial EMG activity are spontaneously produced when subjects are presented with "positive" and "negative" facial expressions of emotion. It was found that slides of happy and angry faces elicited increased zygomatic (happy) and corrugator (negative) facial muscle activity, respectively.

Inference Based on EMG Data. Dimberg (1982) has taken these findings as evidence that facial reactions to facial expressions are emotional outputs stemming from the observer's internal state. Nonetheless, the possibility that these results are due to imitative responding cannot be ruled out. While EMG may be used to differentiate generally "positive" and "negative" reactions, further differentiation among specific "negative" emotions (i.e. anger and fear) is not easily accomplished (Ekman 1982). Therefore, when a "negative" EMG site (e.g. corrugator) is activated in response to an angry face, it is impossible to know from this information alone whether the activity is part of an anger or fear response (or sadness, disgust, or contempt, for that matter). Thus, the use of EMG to distinguish simple "positive-negative" responses to facial expressions does not permit one to unequivocally conclude that EMG responses stem from emotion.

Facial EMG remains a valuable indicator of emotional response, offering on-line, moment-by-moment tracking of changes in the activity of the facial muscles associated with emotional expression. EMG is also largely immune to subject response tendencies and biases, while being able to detect changes in muscle tone invisible to the naked eye. However, as the above analysis has shown, facial EMG results are multi-determined, both emotionally and unemotionally. A particular muscle contraction may have been caused by imitation or emotion, and if by emotion, more than one may be involved.

If the researcher is concerned only with the "positive-negative" distinction of emotion (though this conceptualization has been criticized as simplistic and confounded with evaluation; Batra and Ray 1986), facial EMG may be sufficient as a dependent measure, presuming that imitation or other confounds are not a problem. However, if the research requires a complete description of the emotional response (linked to underlying theory of emotion), it becomes necessary to employ self-reported measures and, possibly, measures of physiological response. Thus, a combination of theoretically grounded self-reported and physiological measures with facial EMG should permit reasonably valid interpretation of the emotionality of reactions.

Support for Emotional Mediation

Studies which demonstrate emotional responses to emotional expressions do so in a variety of ways. These studies have employed measures such as behavioral observation (approach/avoidance; behavior checklists), electroencephalography (EEG), and facial EMG combined with self-report.

Dimberg (1988) replicated his earlier finding of increased zygomatic and corrugator activity in response to happy and angry facial stimuli, respectively, with the additional finding of corresponding self-reports of feelings of happiness in response to happy faces and feelings of fear in response to angry faces. As indicated above, this additional employment of self-report allows greater confidence in inferring that the facial responses were mediated by emotion.

Perhaps the strongest evidence of emotional responses to emotional expressions comes from Sackett (1966), who presented slides of various social and non-social stimuli to eight isolation-raised rhesus monkeys repeatedly at different points in their development beginning at 2-weeks of age and continuing up to 9 months, recording their behavior during each slide presentation. Slides of adult male monkeys displaying threat were accompanied by disturbance behavior and gaze aversion, which have been described as fear responses, while non-threatening monkey pictures were not met with these behaviors. Sackett concluded that these findings constituted evidence of an innate recognition and releasing mechanism for social communication.

Schwartz, Izard, and Ansul (1985), using a paired-comparison novelty discrimination test, presented 5-month-old infants with photos of adult women displaying anger, fear, and sadness in one

condition and anger, joy, and interest in another. They found that fear and sadness were discriminated successfully; infants looked at the novel stimulus longer than at the familiar stimulus. When the anger expression served as the novel stimulus, however, discrimination could not be assessed as there was a "marked tendency for infants to look away from, or to look less at, anger" (p. 71). The authors concluded that the novelty of expressions determined visual responses less than the inherent aversiveness or social significance of the anger expression.

Davidson and Fox (1982) measured the affective responses of ten-month-old infants to videotaped presentations of happy and sad facial expressions. The authors (measuring EEG activity elicited) found greater left frontal region activity in response to happy than to sad expressions. The authors consider the results to support the existence of a fundamental affective distinction between the hemispheres with regard to approach and avoidance tendencies. This asymmetrical frontal activity may reflect the ability of these facial expressions to elicit approach or avoidance behavior.

Further evidence of the impact of facial expressions on the behavior of infants is provided by Sorce, Emde, Campos, and Klinnert (1985). In this experiment, 12-month-olds were placed in a "visual cliff" situation, a steep grade ending in a four-foot cliff covered by hard, clear plexiglass. Infants were placed on the shallow side of the grade and their mothers produced facial expressions from the cliff side. Mothers smiled at their infants until they reached the edge of the cliff and then changed their expressions. When mothers changed to broader smiles or displayed interest, approximately 75% of the infants crossed the visual cliff toward their mothers. However, when mothers displayed sadness, 33% crossed, during anger, 11% crossed, and during fear expressions none crossed.

Conclusion

Based on the studies reviewed, it seems reasonable to conclude that perceiver reactions to emotionally expressive stimuli are indeed mediated emotionally. Supportive evidence has come primarily from studies of the behavioral reactions of infants and primates, while the results of adult studies have been equivocal due to the lack of clear criteria for the discrimination of emotional and imitative responding. Work in our laboratory is currently in progress which attempts to demonstrate the emotionality of reactions in adult perceivers, employing self-reported and facial response measures. This work employs the additional criterion of response complementarity in inferring emotional mediation.

SUPPLEMENTARITY AND COMPLEMENTARITY

With regard to social communications, the interface of emotions displayed by the sender and receiver may be said to be supplementarily or complementarily related.

Supplementarity

A supplementary emotional reaction is one which is equivalent in type to the emotional expression perceived. Such congruence of emotional quality between model and perceiver has been proposed to form the basis of empathy (Wispé 1986). An example of supplementarity is the well-documented reciprocation of the social smile (Kraut & Johnson 1979). Similarly, empathic responses to expressions of fear (e.g. reactions to horror films), sadness (e.g. reactions to "tear-jerker" films), and pain (e.g. Vaughan & Lanzetta 1980) may be viewed as supplementary.

Complementarity

Complementary interactions are those in which the adaptive emotional response differs from the emotional expression perceived. The prototypical complementary relationship is that of anger and fear. Commentary on this relationship has been surveyed by Plutchik (1980):

"...McDougall (1921) wrote that 'the fear-impulse is the most opposed in tendency to the pugnacious.' Tolman (1923) wrote: 'fear operates by leading away from [and anger] by leading towards and destroying.'...Carr (1929) added (1929) that 'Anger is correlated with an aggressive attack against obstacles, while fear is associated with the opposite type of behavior.'...Cannon (1939) has written about the 'fight or flight' opposition..." (p. 136).

Other potentially complementary relationships between emotions include reactions to disgust and contempt, which along with anger form Izard's (1977) "hostility triad". For example, disgust has been conceptualized as an emotion of fundamental rejection (Tomkins 1982) which, directed socially, is likely to elicit either sadness or anger depending upon the particular relationship in question. Examples of higher-level social affects which are complementary include instances of sadism (*schadenfreude*) which involves a "perceiver's" joy at another's distress, and envy which involves malice toward another's joy.

Similar Distinctions

The above distinction between complementarity and supplementarity has been made in clinical psychology in describing different modes of psychological "projection" of traits and emotional states. Complementary projection occurs "when an individual projects a trait that is different from his own (and) the projected trait is the complement of his own trait" (Holmes 1968, p. 250). Supplementary projection occurs when "the individual projects onto other people characteristics which are identical to his own..." (Holmes 1968, p. 253).

Similar distinctions have also been proposed by Heider (1958) and by empathy researchers Stotland, Sherman, and Shaver (1971). Stotland et al. (1971) designated instances in which the emotions of the perceiver and the perceived are highly similar as "simple empathy", and instances wherein the dyad

experience qualitatively different emotions as "contrast empathy". Heider (1958), in his theory of interpersonal relations, distinguished between "concordant" and "discordant" emotional reactions which are equivalent to simple and contrast empathy, respectively.

Inferring Emotion from Complementarity

A potential means to ascertain whether reactions to expressions of emotion are imitative or emotional would involve the comparison of subject facial reactions with regard to the nature of their correspondence with eliciting stimuli, using complementarily related emotions. As previously indicated, the findings of studies using supplementarily related emotions are inconclusive because such reactions may appear to be the result of either imitation or emotional mediation.

Demonstration of perceiver response complementarity can afford the inference of emotional mediation primarily because such a response is not imitative, by definition. To verify that emotion rather than imitation is the mediator, the response must be found reliably over time, across contexts, and across individuals.

For the response to be labeled emotional it must also meet the following requirements. First, the facial response must conform to the patterns of facial expressions of emotion which are cross-culturally recognized as representative of specific emotions and shown when experiencing the same emotion (unless cultural display rules preclude their exhibition; Ekman and Oster 1982). Second, the response should be adaptive; that is, the response should be a true "complement" to the stimulus expression in terms of its expression of action tendencies (Plutchik 1980). Finally, the response should be validated using multiple methods (i.e. psychophysiological measures, self-reports, and coding of expressive behavior).

EMOTIONAL RELEASERS AND PERSUASION

The finding that emotional expressions can serve as elicitors of specific affective reactions is of fundamental importance to an understanding of the effects of advertising, which now incorporates more emotional expression than ever before (Holman 1986). The psychobiological approach to emotion (Buck 1988; Kroeber-Riel 1979) is an appropriate framework for conceptualizing the eliciting effects of emotional expressions. According to the psychobiological model, the perceptual systems of individuals are biologically "attuned" for the reception of certain classes of stimuli which are important for adaptation (i.e. releasers) and for changing patterns of stimulation. Using these recognition rules, stimuli are "filtered" preconsciously, drawing attention toward biologically important stimuli and away from unimportant or repetitive stimuli. Thus, this model predicts that attention will be drawn toward the emotional expressions of others, a position supported by Kroeber-Riel's (1984) finding of increased frequency of eye fixations with ads containing "emotional pictorial elements", and Lang's (1990)

finding that "even a small amount of emotion in a message increases attention to that message" (p. 296). Intimately involved in the operation of the innate releasing mechanism are the attention/activation system (ascending reticular activating system; ARAS) and the subcortical emotional centers (limbic system). There is evidence that the ARAS and limbic structures receive direct inputs from sensory systems, and that these inputs are received before those leading to the neocortex, perhaps establishing a level of arousal and an emotional context for subsequent analytic cognition. The outputs of the attention/activation and emotional systems are communicated to the perceiver as immediate, wholistic sensory experience (syncretic cognition; Tucker 1981) which has been associated with right hemisphere functioning. An implication of the psychobiological model is that automatic operations of the attentional and emotional systems determine to some extent the inputs to analytic cognitive processing and the nature of that processing.

The psychobiological model suggests an important implication for persuasion strategy. Receivers of communications containing emotional releasers are likely to focus on these affective elements, resulting in the elicitation of emotional reactions. The corresponding emotional response (supplementary or complementary) should be experienced before any analytic evaluation, creating a specific emotional context within which to process a neutral stimulus.

A Comparison of Models of Attitude Formation and Change

The features of releaser-based persuasion may be explicated by differentiating such persuasion from the related persuasion mechanisms of peripheral-route processes and direct affect transfer (as in classical conditioning). Whereas the peripheral-route denotes an absence of argument scrutiny, the perception of releasers should increase attention to all message elements, particularly those which are integrated with the releaser through content or other associations (Kroeber-Riel 1979), and should shape interpretation by providing an emotional context. Furthermore, the elicitation of emotion by releasers does not preclude "central" analytic elaboration, which may proceed within the biasing context of the elicited emotion. Thus, releaser-based persuasion is not equivalent to the reliance upon an affective cue under conditions of low elaboration likelihood (cf. Petty, Cacioppo, Sedikides, & Strahman 1988).

Releaser-based persuasion may also be distinguished from the affect transfer of classical conditioning. First, emotional releasers elicit true emotions due to the significance of the information they transmit for the well being of the perceiver. Hence, releasers are not processed in the manner of usual unconditioned stimuli, such as odors and sounds, which produce pleasant or unpleasant sensory experiences. Second, the genuine emotion elicited by releasers should determine the emotional tone of the perceiver's thoughts toward other elements of the communication, providing an emotional grounding

for the development of attitudes. As classical conditioning involves the meaningless association of sensations with neutral stimuli, attitudes formed through conditioning are without emotional grounding, possibly resulting in weaker attitude development. Third, the formation of attitudes through exposure to releasers should not necessitate the repeated pairings required for conditioning because of the emotionality experienced at the first exposure (cf. Seligman 1970). This is not to say, however, that repeated pairings would not strengthen the association. The capacity of the association to be strengthened may be particularly relevant in cases wherein an otherwise neutral stimulus can acquire the characteristics of a releasing stimulus, as in package designs featuring releasers (e.g. the smiling Gerber baby, Quaker Oats man, and Aunt Jemima). Finally, while a major concern with classical conditioning is the question of subject awareness of the UCS-CS contingency, whether or not perceivers are aware of the intent behind the use of releasers should not matter, as the process is essentially automatic.

FUTURE RESEARCH

A practical implication of the psychobiological theory discussed herein concerns the methodology of ad testing. As previously indicated, the process of direction of attention may be seen as strongly influenced by subcortical emotional systems. Based on this notion, it is suggested that the elements of ads which are attended to by perceivers will tend to be those which elicit emotion.

While measures of attention such as eye-tracking techniques and recall tests give the researcher a record of the ad information picked-up by perceivers, the motivation behind the direction of attention is untapped. A greatly enriched picture of ad effects would likely emerge with the addition of converging emotional response measures, assessing changes in physiological arousal, expressive behavior, and subjective experience. While arousal may be measured as changes in skin conductance, an economical alternative may be the measurement of eye fixation frequency (Kroeber-Riel 1984). The most promising candidate for the measurement of subtle expressive behavior is facial EMG, which has been demonstrated to differentiate positive and negative reactions (Bagozzi 1991). The insertion of questions regarding the subjective emotional experience of the respondent into post-exposure interviews would serve to complete the measurement of emotional output. Combining these measures would afford the researcher knowledge of which elements were attended to, the valence and quality of perceivers' reactions to those elements, and the intensity of those reactions.

Incorporating Consideration Sets Into Models of Brand Choice

Prakash Nedungadi, University of Toronto

Vinay Kanetkar, University of Toronto

There has been a recent resurgence of interest in the notion of the consideration set and its precise role within the brand choice process. Behavioral researchers have examined the process of consideration set formation and use (Alba, Hutchinson & Lynch 1991; Baker, Hutchinson, Moore & Nedungadi 1986; Nedungadi 1990). A few quantitative models of consideration set formation have also been developed (e.g., Hauser & Wernerfelt 1990; Roberts & Lattin 1990). In this paper, we propose a model of brand consideration and choice, and examine the implications of incorporating consideration into brand choice models.

CONSIDERATION SETS

In order to incorporate consideration sets into the choice process, we view choice in two stages -- brand consideration and brand selection (see Nedungadi 1990). In the first stage, internally and externally generated retrieval cues lead to a situation-specific consideration set being brought to mind. In the second stage, the brands in this set are compared and one brand is selected for purchase. This separate focus on the consideration and selection stages is useful for a number of reasons. First, it highlights the fact that the processes that lead to brand consideration may be quite different from those that result in choice from the consideration set. While researchers have often alluded to two-stage choice processes, they have essentially treated consideration as an extended version of choice. Thus, brand preferences are often believed to drive both consideration set formation and choice. However, Nedungadi (1990) presents evidence that factors other than brand preference, such as brand accessibility and external retrieval cues may drive consideration set formation during choice.

A separate focus on brand consideration also allows for a more dynamic conceptualization of consideration sets. Thus, consumers need not "have" consideration sets that they carry to each purchase occasion, instead, the consideration set could be "brought to mind" spontaneously, as a first step in choice. Finally, a separation between consideration and selection stages also facilitates a distinction between the effects of marketing variables at each stage.

MODEL

We propose a simple logit model to capture the first, consideration stage of the choice process. Although logit models have been used extensively in the choice context, they have not been applied to brand consideration. Let $c_h \in U$ be the set of brands considered by individual h , and U be the universe of all brands in the product class. We assume that c_h contains at least one brand for all individuals. In addition, consistent with Hauser & Wernerfelt (1990) and Roberts & Lattin (1990), we assume that the

probability of considering each brand is independent. Let $A_{ih} = 1$ if brand i is contained in the consideration set of individual h , c_h , 0 otherwise. Then, the probability of considering brand i is expressed as:

$$Prob(A_{ih}=1) = \frac{1}{1 + \exp(-w_{ih})}$$

where w_{ih} is the consideration "value" of brand i for individual h . If there are M explanatory variables, then consideration value may be written as a linear function of these explanatory variables.

Functionally, we expect that $w_{ih} = \sum_{m=1}^M \gamma_{mi} Z_{mih}$ where Z_{mih} is the value of the m^{th} explanatory variable and γ_{mi} is the parameter associated with that variable for alternative i and is to be estimated empirically. Further, the value of γ_{mi} is indicative of the effect of the explanatory variable on likelihood of considering the brand.

Further, let $y_{ih} = 1$ if brand i is chosen by individual h , 0 otherwise. Then the probability of choosing brand i from consideration set c_h could be expressed as:

$$Prob(y_{ih}=1|c_h) = \frac{\exp(v_{ih})}{\sum_{j \in c_h} \exp(v_{jh})}$$

where v_{ih} and v_{jh} are brand utilities for brands i and j respectively, for individual h . This simple two-stage choice model is different from the traditional multinomial logit model where probability of choice is directly expressed as:

$$Prob(y_{ih}=1) = \frac{\exp(v_{ih})}{\sum_{j \in U} \exp(v_{jh})}$$

In this traditional model, brand choice probabilities are determined by relative utilities alone.

Thus, we propose a simple, two-stage choice model that incorporates both subprocesses of brand consideration and brand selection. The probability of brand consideration is expressed as a function of consideration value, while the probability of selection is expressed as a function of relative preference for brands in the consideration set. We test this model on a set of experimental data that includes measures of brand accessibility, consideration, choice and preference. Nedungadi (1987) collected data on choices of fast-food outlets. PC/LIMDEP (Greene 1988) was used to estimate the consideration choice model on this experimental data and compare it to the traditional choice model, both in terms of prediction and diagnostic insights. While details of the test are

provided in Nedungadi & Kanetkar (1991), our test led to the following conclusions:

1. Brand accessibility and acceptability have a greater influence on the brand consideration stage of choice and a lesser influence on the brand selection stage. As a result, marketing influences (e.g., reminder advertising) that increase accessibility are most important at this stage of the choice process.
2. While brand preferences are important during brand consideration, their chief role is in the brand selection stage when brands are compared for choice. Again, marketing influences that affect brand utilities (e.g., price discounts) are most likely to act at this stage, once brands have entered the consideration set.
3. Incorporation of the brand consideration stage greatly improves the predictive power of brand choice models.

An Empirical Investigation of Consideration Set Formation

John S. Hulland, University of Western Ontario

Consideration has been demonstrated to be an important component in consumer judgement and choice (e.g. Campbell 1969; Hauser and Wernerfelt 1990; Nedungadi 1990). For example, if a product is unable to obtain consideration from a reasonably high proportion of the consumers in a product market, it may be incapable of attaining sufficient market share to ensure long run viability. However, little attention has been paid to the processes underlying consideration set formation (see Roberts 1989 for a recent exception). The current research examines the impact that variations in the accessibility of prior information and the number of previous choices have on the size and composition of subjects' consideration sets.

Consideration set alternatives are likely to be more accessible in memory than unconsidered alternatives, and are therefore likely to guide subsequent search (and choice) behavior (e.g. Biehal and Chakravarti 1986; Lynch et al. 1988). However, when these existing consideration set alternatives are no longer attractive due to a new set of task conditions, externally available brands are more likely to receive serious consideration.

Increasing the number of previous choices should also lead to an increase in the variability of alternatives included in individuals' final consideration sets, for three main reasons. First, previous selections made from subsets of alternatives may include alternatives satisfactory only relative to the other alternatives included in those subsets. Second, previous "errors" in selection are likely to carry over to subsequent choices. Finally, task factors may change from one choice occasion to the next, resulting in more varied alternative selections over time.

An experimental method, closely related to the one used by Biehal and Chakravarti (1983, 1986), was employed to test these suppositions. Subjects were randomly assigned to one of four initial information processing goal conditions, requiring them to make a choice, form overall evaluations, or memorize attribute information. An initial set of product information described a subset of four alternatives on four attributes. When this information was removed, information for a new subset of three alternatives was presented, and subjects were asked to make a choice from all seven alternatives previously encountered. Information for an eighth brand was then presented using the same four attributes as before, along with information for a new, fifth attribute presented for all eight brands. This final attribute was manipulated to be either extremely important or not at all important, after the original attribute information had been removed and was therefore available (if at all) only in memory. Subjects made a final choice from all eight brands, and were then asked to identify their consideration sets.

The results of the current study can be summarized in terms of three major findings. Subjects

with high accessibility for previously encountered brand information were significantly more likely both to include these brands in their consideration sets when they became subsequently more attractive, and to have consideration sets more varied in composition. For example, "brand A" became a very attractive choice alternative when the size attribute was identified as important, but became only moderately attractive when size was unimportant. Because brand A information was encountered with the original subset of product information, it was available subsequently only in memory. As shown in the Figure, subjects asked to memorize this original information were more likely to include brand A in their consideration sets when the size attribute was important. In contrast, subjects asked to evaluate or choose from the original subset of alternatives did not alter their consideration of brand A, regardless of the importance of the size attribute.

A second observation drawn from the current research is that, as the number of previous choices made by subjects increased, the number of previously selected alternatives included in their consideration sets grew, while the sizes of their sets did not change. Finally, the composition of subjects' consideration sets grew significantly more varied as the number of previous choices increased.

The results of this study have a number of practical implications. First, they suggest that, given enough prior choices, many consumers may eventually include only previously selected alternatives in their consideration sets. From a manufacturer's perspective, as consumers' experiences with brands in a product category grow, it becomes more and more difficult for new brands to achieve consideration. Conversely, early entrant brands can expect to achieve high levels of success if they can develop and sustain early consumer consideration. Second, the results of this study suggest that consumers' initial processing goals can strongly influence the particular set of brands that they will seriously consider. In many cases, it appears that consumers will be unwilling or unable to re-evaluate previously rejected alternatives, and that marketers essentially have only a single chance to obtain consumer consideration -- when the brand is first encountered.

Categorization Research and Brand Extensions

Laurette Dubé, Université de Montréal
Bernd H. Schmitt, Columbia University
Sheri Bridges, Wake Forest University

SESSION OVERVIEW

At a time of escalating marketing costs and an increasing number of new product failures, marketers have turned their attention to brand extensions to reduce the expenses and risks associated with new product introductions. To explain how associations and evaluations of the original brand name can transfer to a brand extension, researchers have found categorization models to be a useful framework. According to the categorization approach, consumers evaluate a brand extension on the basis of the fit between the original brand and the product category to which the brand has been extended. This assumes that the existing brand and the extension product category exist in consumers' minds as relatively stable concepts.

How are brands and product categories cognitively organized? How do consumers mentally represent brands and product classes? Based on Rosch and Mervis's (1975) classic work in cognitive psychology, it has been suggested that consumers form relatively stable, hierarchical representations of product classes (e.g., cars), product types (e.g., sports cars) and brands (e.g., Corvette) in long-term memory. These categories are cognitively represented as collections of features (e.g., product or brand characteristics) which are organized around a central tendency, the prototype. It is further assumed that category exemplars vary in terms of their typicality or similarity to the category prototype and that similarity or "fit" with the category is based on a feature matching process.

Such a feature-based conceptualization, however, cannot account for the elaborative and interactive processes by which consumers perceive and evaluate brand extensions--processes that include the formation of cognitive structures related to the brand, to the existing products in the brand line, the extension product category, and the existing brands in the extension product category.

Recent research in psychology and consumer behavior suggests that the categorization process involved in the perception and the evaluation of brand extensions may be more flexible and context dependent than previously thought (Aaker and Keller 1990; Barsalou 1985; Boush and Loken 1991; Park, Milberg and Lawson 1991). For example, individuals may not use one organizing principle, such as similarity to a prototype, to assess typicality. Instead they may derive a category on the basis of functional goals (Barsalou 1985). Therefore brand extensions, too, may show a large degree of flexibility. Moreover, typicality itself seems to depend on the context in which an object is judged (Roth and Shoben 1983). As a consequence, the relationship between the original brand and the extension may also be mediated by contextual factors. In addition, the influence and affect transfer which occurs in brand

extensions may not be unidirectional. That is, perceptions of the core brand may be altered by the way an extension is perceived and categorized.

The session summarized here focused on these recent developments in categorization research on brand extensions providing evidence for the dynamic nature of the link between the original brand and the extension. Farquhar and Herr demonstrated the separate effects of the strength of the category-to-brand association (the dominance) and strength of the brand-to-category association (the typicality) in delineating the limits of using brand equity for brand extensions. MacInnis, Nakamoto and Mani investigated contextual factors that mediate the salience of knowledge domains to be used in consumers' judgments about product categories, and more specifically, in brand extensions. Manipulating the salience of common and distinctive features of brand extensions and existing branded products, Boush reported asymmetry effects as they occur in similarity judgments involved in consumers' perceptions of brand extensions. Based on work by Murphy and Medin demonstrating the role of theories in conceptual coherence (Murphy and Medin 1985), Bridges proposed a process model of brand extension evaluations, suggesting that the existence of explanatory links between the extension and the brand determines both the type of evaluation process that consumers engage in and the valence of their evaluation. Building on Bridges's model, Milberg and Park showed that the existence of explanatory links among existing products and extensions (product-level linkages) and the degree of consistency between brand extensions and the brand image (image-level linkages) affect the beliefs and attitudes toward the original brand and its current offerings. As additional evidence of the reciprocal impact of brand extensions on the original brand, Loken and Roedder-John showed that the degree of typicality of the individual product offerings to the brand category influences the dilution of the overall brand image.

In light of the evidence for contextual variability and sensitivity to context in consumers' perception of brand extension, the present session introduced a constructivist approach to categorization. Barsalou, who recently suggested that mental frames rather than feature lists may be the most appropriate representations of human cognition (Barsalou 1991), presented, in the introductory paper of the session, the basic tenets of frame theory. According to Barsalou, to capture all the information in natural knowledge, a mental representation must include mental structures for multivalued attributes, conceptual relations, and frame recursion. Such mental structures form the core of frame-like representations but are nonexistent in feature list representations. Viewing brand extensions as conceptual combinations, Schmitt and Dubé followed up on Barsalou's recent work and

demonstrated that a constructivist approach may be required to account for the emergence of highly contextualized and unique features of brand extensions.

RECENT THEORETICAL DEVELOPMENTS IN CATEGORIZATION RESEARCH: THE VALUE OF FRAME THEORY

Lawrence Barsalou, University of Chicago

According to a common view in categorization research, categories possess the property of graded structure. This paper discusses the various determinants of graded structure for different types of categories (e.g., common taxonomic categories and goal-derived categories) and reviews recent psychological evidence for the instability of graded structure. Moreover, studies are cited which suggest that categories may not be represented as independent feature lists but as attribute-value sets. For example, when individuals think about a particular car, abstract attributes will adopt specific values, such as "Liz" for "driver," "gasoline" for "fuel", "four-cylinder" for engine, and so on. In addition, the cognitive representation of categories may include relations and constraints (e.g., "driver" buys fuel, "fuel" flows to "engine"). In light of the evidence for contextual variability and against feature lists, frames rather than independent feature lists may provide the fundamental representation of knowledge in human cognition. Frames contain attribute-value sets, and the relations

of a frame connect attributes into a pattern of systematicity. Therefore, from a categorization perspective, frame theory may offer the most comprehensive theoretical model for the study of brand extensions.

BRAND EXTENSIONS AS CONCEPTUAL COMBINATIONS

*Bernd Schmitt, Columbia University
Laurette Dubé, Université de Montréal*

Following recent developments in cognitive psychology and linguistic research, we propose to view brand extensions (e.g. McDonald's Theme Park) as conceptual combinations. In conceptual combinations (e.g. "apartment dog") the former noun ("apartment") is seen as a modifier that contextualizes the attributes of the latter noun ("dog") called the "header." In this process, individuals make extensive use of their world knowledge and attributes may be evoked that are not typical of either constituent concept (e.g., the attribute "neurotic" for "apartment dog"). Similarly, in brand extensions the original brand or company name (e.g. McDonald's) may act on the "head concept" of the extension category (e.g. theme parks) as a "modifier." Using a variety of fictitious extensions, we show that brand extensions exhibit the same degree of flexibility and sensitivity to context as conceptual combinations. Moreover, preliminary evidence suggests that the contextual and relational structure of brand extensions may be best explained by dynamic frame-like structures rather than relatively static feature list representations.

DOMINANCE AND TYPICALITY IN BRAND EXTENSIONS

*Peter H. Farquhar, Carnegie Mellon University
Peter M. Herr, University of Colorado, Boulder*

This paper explores the effects of dominance and typicality on extending a brand across product categories. We begin by defining "dominance" as the strength of the category-to-brand association, and "typicality" as the strength of the brand-to-category association for a consumer. We compare these definitions with others used in categorization research and then examine several operational measures of dominance and typicality.

This paper considers previous research by Herr, Farquhar, and Fazio (1990) that shows how learning associations for a new brand extension depends upon the brand's dominance in the parent category and on the relatedness of the parent and target categories. Since dominance and typicality are correlated for many brands, the present research measures their separate effects on brand extendability. These results on typicality are compared with other findings recently reported in the consumer research literature.

This paper then separates the effects of dominance and typicality in determining the boundaries of a brand franchise. When the same brand has been extended to a variety of target categories, we show how the brand's dominance in the parent category is unaffected, but typicality is diminished. We examine the vulnerability of such a brand against

competitive strategies for product and brand positioning.

CONTEXTUAL VARIATIONS IN PRODUCT CATEGORY COMPARISONS

*Deborah J. MacInnis, University of Arizona
Kent Nakamoto, University of Arizona
Guyathri Mani, University of Arizona*

Considerable research in the brand extension domain has indicated that similarity between an original and extension product category is a critical predictor of consumers' evaluations of a brand extension (Aaker and Keller 1990; Boush et al 1987; MacInnis and Nakamoto 1991). However, many questions arise about how such similarity judgments are made. First, what are the knowledge domains consumers use to judge comparability or similarity across products? Products may not only share physical attributes, but also benefits, usage occasions, usage locations, users, etc.

Second, are certain knowledge domains consistently more salient (i.e. more strongly tied to the product category than others)? For example, across comparison contexts, are the physical attributes which two product categories share more likely to come to mind than similarities in other domains? Attribute similarities may in fact be more salient due to their physical observability (Paivio 1971) and their role in defining category membership.

Third, what factors moderate the salience or activation of knowledge domains? Consumers' knowledge about individual product categories, context effects created by the specific product categories being compared, the task (similarity, choice, evaluation), and other information inherent in the task context may influence the extent to which certain bases are salient (Chakravari and Lynch 1983). Understanding the moderators of salience is important from a marketing context since marketers are often in a position of communicating attribute similarities or differences between two product categories that may not have been immediately obvious (salient) to consumers.

Fourth, to what extent will the activation of similarities between product categories in a certain knowledge domain also affect perceived differences among product categories. Will, for example, comparisons of the similarities between two product categories on a goal derived category also cue consumers to differences between product categories on goal-derived categories? The salience of specific bases may not only be a function of knowledge structure and the task (as indicated above) but also of a spreading activation effect achieved through elaboration (Collins and Loftus 1975).

Finally, to what extent will articulated similarities and differences between two product categories in specific knowledge domains map onto global perceptions of similarity. Will articulated dimensions only partially reflect overall similarity judgments?

We report an exploratory study designed to address these issues. We examine the nature of consumers' knowledge structure for a product category,

and its influence on the comparison of disparate products. We also examine the factors which affect the salience of various domains of knowledge in comparing products. We investigate the role that articulated similarities have on articulating differences among product categories. These results have both theoretical and methodological implications for research which studies product category comparisons.

A SCHEMA UNIFICATION MODEL OF BRAND EXTENSIONS

Sheri Bridges, Wake Forest University

This research proposes a model of the process by which consumers judge brand extensions, then uses the model to identify variables that affect the evaluative outcomes of the judgment process. Underlying the model is the idea that the perceived fit between the extension and brand expectations determines both the type of evaluation process consumers will engage in and the valence of their evaluations.

Based on work in the categorization literature by Murphy and Medin (1985), the key notion of an explanatory link is developed to explain how consumers make sense of the relationship between the extension and the brand. By forming explanatory links at the product or image level, consumers are able to understand how products in the brand line fit together and, consequently, are able to maintain a cohesive, unified brand schema.

Two experiments support hypotheses concerning variables that affect consumers' ability to find explanatory links and, thereby, affect perceived fit. These variables are type of brand schema, type of relationship between the brand and the extension, and type of extension information provided to consumers. Type of brand schema depends on the dominant type of associations consumers have for the brand: concrete/product-related, abstract/product-related, or image-related. The relationship between the brand and the extension is characterized as being of two types: shared physical product attributes (e.g. a watch and a kitchen timer) or no product-level relationship (e.g. a watch and a handbag). The type of information provided to consumers about the extension may be designed to raise the salience of the explanatory link, or to raise the salience plus relevance (i.e. importance) of the explanatory link.

Specifically, when the brand and the extension share physical product attributes, evaluations are higher if the brand's schema is image-related than if it is product-related. The effects of this interaction between schema type and brand-to-extension relationship are moderated by information provided about the explanatory link between the extension and the brand.

Predictions regarding the process model itself also are supported in an experiment in which thought protocols are elicited from participants. Subjects engage in holistic, category-based processing when the extension clearly fits or clearly does not fit with brand expectations. Perceived fit also affects the incidence of nullifying and supporting argumentation

in the evaluation process and, ultimately, the valence of the evaluations.

THE RECIPROCAL RELATIONSHIP BETWEEN BRAND AND EXTENSION

Sandra J. Milberg, *Georgetown University*
C. Whan Park, *University of Pittsburgh*

This paper examines situations in which brand extensions have either a positive or negative impact on the beliefs and attitudes toward the originating brand and its existing products. In particular, this research explores the role played by perceived category coherence (when the grouping of objects makes sense to the perceiver) in understanding when extensions dilute brand associations, fortify and enhance existing beliefs associated with the originating brand, or systematically modify and expand brand associations to adapt to changing markets.

According to ideas introduced by Murphy and Medin (1985) and applied to brand extension research by Bridges (1990), perceptions of category coherence are based on consumers' ability to recognize explanatory links among existing products and extensions (product-level linkages) and perceptions of how consistent products are with consumers' understanding of the brand image (image-image linkages).

When an extension is inconsistent with the brand image it can weaken existing brand beliefs, causing confusion and negative affect. When there are weak product-level linkages, associations with specific products and their related qualities can be diluted. This can also create confusion as to the definition of the business the firm is pursuing. On the other hand, when consumers perceive sensible product-level linkages and consistency between brand extensions and the brand image, extensions should serve to fortify and enhance existing brand beliefs. Conditions under which existing brand beliefs are systematically modified by the introduction of brand extensions, producing positive outcomes, are also explored.

ASYMMETRICAL INFLUENCE BETWEEN BRAND AND EXTENSION

David M. Boush, *University of Oregon*

The recently-voiced perspective that brands can be viewed as categories (Boush and Loken 1991) stresses both the importance of graded structure (a typicality gradient from the most to the least

representative products that share a given brand name) and the flexible, constructive nature of brands as "ad hoc" categories (Barsalou 1983, 1985). Further, the transfer of attitude from a brand's existing products to a new product does not occur in an "all or nothing" fashion. Rather, it is a linear function of the degree to which a product is perceived to represent the brand. The notion of brand attitude transfer based on a typicality gradient suggests that the key to understanding brand extension effects is to understand the structure of brands as categories and the way marketers can influence that structure.

According to Tversky's (1977) contrast model, consumers consider both matching and distinctive features when making similarity judgments (e.g. judgments about the similarity between a potential brand extension and existing branded products.) Perhaps the most significant implication of the contrast model is that it predicts asymmetries in similarity judgments (i.e. the variant is more similar to the prototype than vice versa). Family branded products are frequently (if not usually) characterized by extension from relatively representative (prototypical) products to less representative variants. For example, Hallmark has extended from greeting cards to other products involved with "social expression" such as gift wrap and paper party goods. Asymmetry in similarity judgments implies both that some products might be considerably better than others if you want to enter a new category, and that the flow of attitude from existing products to extensions might be stronger or weaker than reciprocal flow. The contrast model has been demonstrated for consumer products (Johnson 1986) but not in a brand extension context. Data will be reported concerning: (1) the existence of predicted asymmetries in similarity judgments; (2) effects of brand names (including secondary brand names) on similarity judgments; and (3) effects of brand names on asymmetries in product similarity judgments.

THE NEGATIVE IMPACT OF EXTENSIONS ON THE BRAND

Barbara Loken, *University of Minnesota*
Deborah Roedder John, *University of Minnesota*

Researchers are increasingly relying on categorization theories to attempt to understand the manner in which the original product category structure impacts judgments about brand extensions (Boush and Loken 1991; MacInnis and Nakamoto 1990; Park et al 1989). The present research identifies situations in which brand extensions may be more or less likely to "dilute" brand equity associated with the brand's current product offerings. We define brand equity associated with the overall brand image in terms

of the attribute associations that consumers have learned to associate with a brand name and that underlie favorable impressions of the brand. Brand equity dilution is, therefore, a decrease in the strength of these beliefs about the originating brand resulting from brand extensions.

However, brand equity dilution may also be seen as having effects on belief about the brand's current individual product offerings. It seems likely that products closely associated with the originating brand name and considered to be more typical exemplars of the originating brand's product offerings would be most affected by situations that dilute overall brand image. Atypical instances are more likely to be disassociated from the category and less likely, therefore, to be influenced by overall category judgments. Thus, we anticipate that the greater the typicality of individual products marketed under the originating brand name, the greater will be the dilution of beliefs about those individual products.

In sum, our research identifies situations that influence dilution of the overall brand image and examines the parallels between these effects and the effects on dilution associated with the brand's current individual product offerings. These latter effects are examined as a function of the degree of typicality of the individual product offering to the brand category.

Cognitive Associations and Product Category Comparisons: The Role of Knowledge Structure and Context

Deborah J. MacInnis, University of Arizona

Kent Nakamoto, University of Arizona

Gayathri Mani, University of Arizona

ABSTRACT

Research in such domains as choice among noncomparable alternatives and brand extension strategies is rooted in the cognitive associations consumers make among product categories. This paper describes an exploratory study aimed at identifying the domains of consumer knowledge regarding product categories, and the contextual variables that influence the salience of these knowledge domains. The results have both theoretical and methodological implications for research on product category comparisons.

INTRODUCTION

Consumer researchers are increasingly interested in understanding the cognitive processes involved when consumers make comparisons among two or more product categories. Two relevant research domains in which knowledge in this area is central are (1) consumer choice and decision making and (2) brand extension strategies.

Choice among product categories (i.e., noncomparable alternatives) is thought to occur by comparisons of abstract attributes which the two product categories share (Johnson 1984). For example, even though fur coats and stereos are not comparable on any physical attributes, they may be compared (i.e., are similar) in terms of the level of status each communicates. Johnson (1984) proposes that this abstraction process occurs because the two product categories belong to a similar superordinate level category, while Bettman and Sujan (1987) propose that this abstraction process occurs because the product categories achieve similar goals, and are hence members of the same goal-derived category (Barsalou 1985). Because relatively little is known about the structure of consumer knowledge regarding product categories, and the various conditions that make certain kinds of knowledge more or less salient, the nature of the abstraction process operating in a given consumption context is unclear.

The second domain in which knowledge of product category comparisons is relevant is that of category extensions. A category extension occurs when a brand in an established product category (Woolite) is extended to a novel category (rug cleaners). Although it has been suggested that consumers' evaluations of an extended brand depend on attribute similarity between the established and extended product categories (Aaker and Keller 1990), little is known about the knowledge domains consumers use to judge similarity among product categories.

RESEARCH ISSUES

The emergent findings in these two research areas raise several questions about the structure and use of consumer knowledge. First, what are the knowledge domains consumers use to judge comparability or similarity across products? Although Johnson (1984) uses the term "attribute" as a knowledge domain, the term is vague and obscures the potentially rich domains that may comprise knowledge of product categories. Products may share not only physical attributes, but also benefits, usage occasions, usage locations, users, etc.

Second, are certain knowledge domains consistently more salient (i.e., more strongly tied to the product category) than others? For example, across comparison contexts, are the physical attributes which two product categories share more likely to come to mind than similarities in other domains? Attribute similarities may in fact be more salient due to their physical observability (Paivio 1971) and their role in defining category membership. On the other hand, Barsalou (1982) shows that beyond a core of defining features, attribute salience is a function of the context--notably the composition of the comparison set and the associated judgment task.

Third, the salience of specific bases may be a function not only of knowledge structure and the task (as indicated above), but also of a spreading activation effect achieved through elaboration (Collins and Loftus 1975). To what extent, then, will the activation of similarities between product categories in a certain knowledge domain also affect perceived differences among product categories? Will, for example, consideration of the similarities between two product categories in a knowledge domain also cue consumers to differences between the product categories in that domain? Or will the goal-directed salience of consistent attributes inhibit activation of these differences (Fiske and Taylor 1984)?

Finally, what factors moderate the salience or activation of knowledge domains? Context effects created by the specific product categories being compared, the task (similarity, choice, evaluation), and other information inherent in the task context may influence the extent to which certain bases are salient (Chakravarti and Lynch 1983). Understanding the moderators of salience is important from a marketing standpoint since marketers are often in a position to communicate attribute similarities or differences between two product categories that may not be immediately obvious (salient) to consumers.

We report an exploratory study designed to address these issues. Using a thought-listing task, we examine what aspects of a consumer's knowledge structure for a product category become salient in comparing categories. We also investigate the role that articulated similarities have on articulated

TABLE 1
Referent and Comparison Product Categories

Referent Categories	Tomato Sauce	Ballpoint Pens	Dogfood	Ice Cream	Cornflakes
1	Tomato Paste	Mechanical Pencils	Puppy Food	Ice Cream Bars	Bran Cereal
2	Tomato Puree	Markers	Catfood	Butter	Oatmeal
3	Apple Juice	Disposable Razors	Canned Tuna	Frozen Dinners	Birdseed
4	Dill Pickles	Staples	Flea Collars	Chocolate Syrup	Bread
5	White Wine	Auto Parts	Shoes	Canned Peaches	Beer

differences among product categories. We consider two primary methodological questions as well--first, the extent to which articulated similarities and differences predict overall similarity between product categories, and second, the impact of the thought-listing task itself on global similarity judgments.

Most importantly, we examine the influence of three contextual factors on the salience of various domains of knowledge. One context factor is the "base" or "referent" product category. More specifically, product categories are likely to differ in the extent and domains of knowledge available to be used in a comparison judgment. A second context factor is the comparison product category. By manipulating the comparison category we are likely to vary the amount and types of knowledge regarding the referent category that will be relevant to the comparison. A final context variable concerns the more general knowledge bases that may be cued from the situation. Via experimental instructions, we attempt to cue particular functional bases for relating the categories being compared. We show that these contextual variables are all critical to understanding the category comparison process and its informational antecedents.

METHOD

Subjects, Design, Procedures

One hundred thirty-eight undergraduate and graduate students participated in this study. Each subject completed a two-part questionnaire. Instructions at the beginning of the questionnaire told students that their task was to examine product category pairs and to judge the extent to which they were similar. The instructions also contained a cueing manipulation. The cue was designed to prime specific knowledge structures relating the two categories. One

third of the students were simply told to assume that the products were sold by the same company. The second group of students was told to assume that a company that produces the first named product decides to manufacture and market the second product (a brand extension). The third group of students was given the brand extension instructions, and in addition was told that in many cases factors such as manufacturing and marketing synergies are important in extending brands. The three cues were designed to provide progressively stronger priming of potential marketing and manufacturing-related similarities and differences between the two products.

In part 1 of the questionnaire, subjects evaluated the overall similarity between a given (referent) product category and five different comparison product categories.¹ The referent and comparison categories are shown in Table 1. For example, one group of subjects evaluated the similarity of tomato sauce to tomato paste, tomato puree, apple juice, dill pickles, and white wine. Subjects were asked to rate each of the five product category pairs on a 1 to 9 similarity scale (1= not at all similar; 9= very similar).

¹The five variants were selected as part of a pretest designed to identify products that represented a slight variant on the existing product (control), or had high vs. low similarity on naturally salient features and high vs. low similarity on nonsalient features. Subsequent analyses indicated that this manipulation was not successful. Only two broad classes tended to emerge--those comparison categories that had obvious high levels of feature overlap with the referent category and those for which the overlap, if it did exist, went largely unnoticed.

TABLE 2
Salience and Importance of Bases Used to Judge Similarities among Product Categories

Basis	Number of Similarities Noted	Average Importance Rating	Number of Differences Noted	Average Importance Rating
Product Attributes	1.39	5.77	1.33	5.98
Usage	0.41	6.74	0.46	6.42
Usage Occasion	0.28	6.12	0.19	5.78
Benefits	0.16	5.67	0.15	5.19

Packaging	0.16	4.65	0.13	4.75
Users	0.10	5.74	0.13	6.03
Targets	0.08	6.72	0.06	6.60
Production	0.07	6.21	0.05	5.81
Marketing	0.03	4.75	0.02	5.00
Purchase Situation	0.01	4.85	0.009	4.55

Part 2 of the questionnaire followed immediately. As in part 1, each subject was shown a referent category and five comparison categories drawn from those shown in Table 1. The pairings of base categories in parts 1 and 2 were counterbalanced across subjects. Thus, different product categories always served as referents in the two parts of the questionnaire. In addition, presentation order of the comparison products was randomized within groups in both parts 1 and 2.

In part 2, for each referent-comparison product combination, subjects were asked to articulate the ways in which the product categories were similar and different. Following this thought-listing task, consumers were asked to rate the overall similarity of the two product categories, again on a 1-9 point similarity scale. They were then asked to rate on a 1-9 point importance scale the extent to which each articulated similarity and difference influenced their overall similarity judgment.

Dependent Variables

A content analysis of the thought-listing data was conducted to identify the knowledge domains tapped when comparing product categories. This analysis identified 11 general categories which are presented in Table 2. The number of similarities and differences represented for each knowledge domain, and the average weight of the items from each domain were used as dependent variables in the analysis. In addition, the similarities and differences were used to

predict the overall similarity rating, by multiplying the average weight of the items listed for a domain by the number of items listed from that domain. These weighted scores for similarities and differences were then used in a regression analysis to predict the overall similarity rating.

RESULTS

Product Knowledge Salience in Category Comparison

The number of items identified as similarities and differences between product categories for each of the identified knowledge domains was tabulated, with the average importance value attached to the items in each domain (Table 2). These data allow us to analyze the structure of product category knowledge and the salience of knowledge domains. The mean number of similarities and differences articulated for each of the eleven domains indicated that some domains were consistently more salient than others. That is, some domains were consistently used to discuss ways in which the products were similar and different. The most common domain for judging both similarities and differences concerned physical product attributes. A mean of 1.39 statements reflected physical similarities between the product categories while 1.33 statements reflected differences between the attributes of the product categories. Thus, physical similarities and differences among product categories appear to be salient in the context of category comparisons.

A second general domain of consumer knowledge for product categories concerned consumers' self-orientation (e.g., usage) with the product. This general self vs. product domain contained several sub-domains. Consumers' considered similarities and differences in how products are used ($\bar{X} = .41$ and $.46$ similarities and differences, respectively), when the products are used ($\bar{X} = .28$ and $.19$), why the products are used (their benefits) ($\bar{X} = .16$ and $.15$), and who uses the products ($\bar{X} = .10$ and $.13$, respectively).

Less salient to consumers, though still articulated, were thoughts regarding the similarities and differences between products in terms of their marketing or production aspects. Noted similarities and differences between products in their packaging ($\bar{X} = .16$ and $.13$, respectively), their distribution ($\bar{X} = .16$ and $.04$), their production ($\bar{X} = .07$ and $.05$), and their marketing tactics ($\bar{X} = .03$ and $.02$) were not very common. The finding that consumers rarely consider marketing and manufacturing synergies between two products when judging overall similarity has obvious implications for brand extension research. Although product category extensions are often based on marketing or manufacturing synergies that the established and extended product categories share, consumers may not consider such synergies when they judge the value of an extended product.

It is likely that many of the thoughts expressed arise from an elaborative spreading-activation process. The question was raised earlier as to whether domains accessed as sources of similarity would also cue differences from the same domain. The number of items in each domain expressed as similarities and differences are notably symmetric, i.e., the more similarities noted in a domain, the more differences were likely to be expressed as well. While this symmetry may be related to the structure of the thought-listing task, it is suggestive that, at least in the context of category comparison, domain-specific priming rather than item-type (similarity vs. difference) priming appears to be operating.

The other measure taken with respect to these items was their subjective importance to overall similarity judgment (see Table 2). While there are meaningful differences among these ratings which will be considered later, it is notable at this point that subjects generally perceived the self-orientation domains to be most important. Thus, even though product attribute associations were more numerous, they were not perceived to be the most central in judging overall similarity. However, the variation in weights is not large; in other words, given that an item in a domain was identified, it was perceived to be at least moderately important to overall judgment.

These results indicate that the subjective importance of a knowledge domain and the extent of salient knowledge in that domain are separate constructs. The number of items expressed likely reflects a broad range of salient product knowledge, while the importance weights are likely to provide a link to the specific judgment task. Thus, it is likely that both aspects are required in examining the

relationship between salient product knowledge and global judgments.

Articulated Features and Global Category Similarity

In order to examine the mapping of expressed knowledge and global judgments, the articulated similarities and differences were used to predict overall similarity of the referent and comparison categories. The number of items from each similarity and difference domain was weighted by the average importance rating of those items. These indices were used as independent variables in a regression analysis of the overall rated similarity of the two categories. The overall model was highly significant ($p < .001$), with the variables in the equation accounting for approximately 43% of the variance in overall similarity scores. A similar regression using only the number of items (unweighted by subjective importance) accounted for only 32% of the variance in overall similarity ratings, again indicating the need to consider the importance weights.

As would be expected, the parameter estimates for each knowledge domain indicate that all similarities between the referent and comparison product category are positively related to overall similarity judgments (except marketing, which has a nonsignificant negative coefficient), while all differences between the referent and the comparison product category are negatively related to overall similarity judgments. Moreover, the coefficient estimates suggest that bases which are most important (i.e., self-related bases) have the strongest influence on overall similarity assessment. Thus, similarities in product usage and users have strong positive effects on similarity assessment ($b = .22$, $b = .20$, respectively), while differences in product usage and users have strong negative effects on similarity assessments ($b = -.13$ and $-.17$, respectively). These findings suggest that the number of items identified and the importance weights attached to articulated items are relatively good predictors of perceived similarity.²

CONTEXT EFFECTS

Referent Product Category Knowledge and Associated Context Effects

ANOVA's on the total number of similarities and differences and the number of similarities and differences regarding each of the eleven bases and their respective importance weights (see Table 3) revealed several interesting findings. First, the total

²The regression results also suggest that the respondents' subjective importance weights underweight important knowledge domains. In other words, the subjective weights are the respondent's estimates of the coefficients in this model. Were they accurate, the model coefficients would all have been equal. In fact, they add even more weight to the domains perceived by respondents to be important.

number of similarities and differences revealed significant referent product category effects ($p < .001$, $p < .001$ for total similarities and differences respectively). The mean number of similarities and differences for each product category reveal that consumers articulate significantly more similarities and differences for some products (i.e., cereals, ice-cream, pens) than for others (tomato sauce, dogfood). These results suggest that the knowledge structure of some product categories is more elaborate than the knowledge structure of others, leading to the identification of more similarities and differences with the comparison product category.

Some product categories, therefore, may be more easily compared to seemingly unrelated product categories than others. Consumers' knowledge structures for some categories may be sufficiently elaborate to allow the use of a broader range of both similarities and differences as bases for category comparisons (cf. Beattie 1981). As a result, some

product categories may be more or less extendable than others. How these perceptions map onto consumer acceptance of an extended brand remains to be examined.

Second, significant referent product category effects were found for many knowledge domains. For example, consumers articulated fewer attribute similarities and differences among product categories when the referent product category was dogfood ($\bar{X} = .928$ and $.741$ for similarities and differences, respectively) than when the referent product category was ice cream ($\bar{X} = 1.83$ and 1.42). Thoughts regarding similarities and differences in product usage were most common with pens ($\bar{X} = .66$ and $.76$) and least common for dogfood ($\bar{X} = .18$ and $.20$). Similarities and differences regarding product benefits were most evident when the referent product category was cereal ($\bar{X} = .27$ and $.27$) and least evident when the referent product category was pens ($\bar{X} = .06$ and $.08$).

Knowledge of the multiple uses to which cereal can be put and knowledge of its multiple benefits (nutrition, taste, satisfying hunger) suggest that this domain of knowledge for cereals is highly elaborated, while for pens it is not. These findings suggest that product specific knowledge in effect frames or provides a context for the nature of the comparison by identifying the bases on which the comparison can be made.

Context Effects Associated with the Comparison Product

Significant main effects for comparison product category and interactions between referent and comparison product were found across many of the knowledge domains (see Table 3). Although the complexity of the data preclude complete reporting of the nature of these interactions, their presence illustrates a different context effect from the referent category knowledge effect noted above. The knowledge domains tapped in judging similarity of product categories is influenced by the context in which the referent product category is evaluated (i.e., the comparison product)(see Tversky 1977). Comparing products to different product categories means that different bases will be salient. In effect, this finding confirms Barsalou's (1982) notion that associations that are likely to be salient for a product depend on the context in which the product is embedded.

A central problem in the study of multiple distinctive categories is the identification of some a priori basis for characterizing the relationship among the categories. The effects of referent and comparison category found here suggest that the explicit elicitation of shared and unique features may provide a fruitful approach to this problem.

Context Effects Associated with the Cueing Manipulation

The study also revealed that the number of similarities and differences noted within each domain was influenced by the presence of an explicit cue. Specifically, the cueing manipulation appeared to influence which aspects of product categories were selected for processing (see Chakravarti and Lynch 1983). Although the cueing manipulation was generally weak, and did not affect the total number of similarities and differences consumers noted between two product categories, it did have the effect of reducing the number of similarities consumers saw between two products in terms of their attributes ($p < .01$). It also increased the number of similarities consumers saw between the purchase locations of products (i.e., distribution; $p < .01$) and the number of similarities regarding the purchase situation ($p < .01$) (see Table 3).

Thus, it is possible to alter via cueing the nature of associations consumers make between two product categories. Moreover, marketing managers may have control over the type of associations that are made. Through marketing communications, marketers can cue for consumers similarities and differences on attributes that may not be immediately

salient to them. This effect is important both for enhancing consumers' perceptions of the viability of an extended brand and in altering the nature of their comparisons between seemingly noncomparable products.

Limitations of the Thought-Listing Method

An obvious issue regarding the methodology applied in the present study is that the thought-listing task may lead to self-fulfilling overall judgments. In order to assess the magnitude of this problem, we compared the overall ratings taken in part 2 of the study with those provided in part 1. In part 1, no thought-listing task was imposed on judgment. However, the cueing manipulation was present for both parts.

The impact of thought-listing was examined in an ANOVA on the global similarity judgments using referent category and cue as between-subject factors, and comparison product and presence or absence of thought-listing as within-subject factors. As expected, thought-listing had a significant effect on judgments ($F_{1,89} = 106.91$, $p < .001$), an effect that was moderated by a significant interaction with cueing condition ($F_{2,89} = 3.96$, $p < .05$). In addition, the type of comparison product affected the impact of thought-listing ($F_{4,356} = 8.42$, $p < .001$).

The mean global similarity ratings are shown in Table 4. In general terms, thought listing increased the global similarity rating between categories. However, the impact of this elaboration diminished as the comparison product category was perceived to be less similar to the base category. Thus, in elaborating, subjects appeared to search for more bases for similarity, an exercise that was more successful when there was obvious consistent feature overlap between categories (comparison categories 1 and 2) than when there was less obvious feature overlap between the categories (comparison categories 3, 4, and 5). In addition, the cue alerting the subjects to the possible importance of marketing and manufacturing synergies also decreased the impact of elaboration. The types of thoughts elicited shed further insight on this finding; this cue increased the number of purchase location similarities but decreased the number of physical feature similarities. This is again consistent with the notion that the increase in global similarity from elaboration was based on elaboration of obvious consistent feature overlap.

SUMMARY AND IMPLICATIONS

In this study, we have examined featural bases underlying judgments of the similarity of categories. Our first results provide insight on the domains of knowledge applied to this comparison task. These results indicate that consumer knowledge about products spans several knowledge domains: knowledge about physical product attributes, benefits, usage, users, and marketing-related attributes. In making judgments about category relationships, salience and importance of a knowledge domain are different: concrete elements such as physical attributes tend to be highly salient, but self-related elements associated with product consumption tend to

TABLE 4
Comparisons of Overall Similarity Assessments Given the Presence or Absence of Thought-Listing

	3	1.28	1.93	.65

¹ Comparison category numbers refer to those in Table 1.

be most important. In general, while marketing-related elements lack salience, they are moderately important once elicited. In addition, elaboration does not seem to distinguish between similarities and differences; rather, salience appears to derive from the knowledge domain.

From a methodological perspective, articulated knowledge bases and importance weights strongly predict overall similarity assessments, suggesting that these information elements are linked to the similarity judgment task. Our initial concern was the thought-listing task itself would severely distort the judgment process. However, our results suggest that while thought listing magnifies the knowledge effects (most likely because of the extended effort at memory elaboration), it does not appear to change the basic patterns of judgment. It should be noted, however, that our results must be interpreted in light of the specific similarity judgment tasks assigned.

We view the referent category, comparison category, and instructional cues as defining a judgment context. With respect to referent category, we found that product category knowledge varies in its level of elaboration, thus influencing the number of similarities and differences consumers can perceive between the referent and comparison brand. Moreover, the elaboration is domain-specific, and the domains elaborated vary across referent categories. In combination, these findings suggest that the referent category, to a significant extent, defines the "rules" of comparison. The comparison category appears to moderate this referent category effect, emphasizing as critical bases for comparison overlapping and unique

features within the relevant domains. The impact of the cue further suggests that external stimuli can affect the salience and importance of specific knowledge domains, and thus the featural bases used in the judgment process.

While speculative, these results are suggestive of the types of abstractions likely to emerge from the processes advanced by Bettman and Sujan (1987) and Johnson (1984). From the standpoint of the design of new products, the present results suggest factors critical to understanding consumer evaluations of brand extensions. Consideration of physical attribute similarities and economic efficiencies alone may well be insufficient to predict consumer response. More importantly, the present study begins to examine the informational determinants of category comparisons. While this task is clearly different from choice or evaluation tasks, to the extent that comparison processes are integral to consumer evaluation of brand extensions, the present results begin to develop a basis for predicting the likely consumer response to such new products.

Thoughts on the Importance of Psycholinguistics to the Understanding of Effective Advertising Communication

Larry Percy, Lintas:USA

There can be no doubt about the importance of words and how one uses them to the effectiveness of any communication. And while there is certainly no shortage of words in advertising, there is certainly a shortage of research on the impact of semantic content and syntax upon communication effectiveness in advertising. The efforts reported by the researchers in this session are most welcome.

INFERENCE

Weiner and Mehrabian (1968) have done a good job of discussing the often subtle effects of language, and especially that what appears to be the same thing said with different words can be the basis for inferring quite different responses from the communication. Rickheit, Schnotz, and Strohner (1985) have offered the following definition of inference in discourse comprehension: "An inference is the generation of new semantic information from old semantic information in a given context." They go on to point out three areas that must be dealt with in considering the effect of inference:

- (1) the psychological representation of old information and the new information resulting from the inference
- (2) the process of inferring the new information from the old information, and
- (3) the notion of content and its effect upon inferring

A number of concerns are evident for each of these points, and while a thorough discussion of these issues is certainly beyond the scope of these comments, it will perhaps pay us to at least take a brief look at some of the problems outlined by Rickheit et al. The idea of mental representation and inference is tied up in theories of just how people structure internally the meaning of text, what the units of this structure are, and how these units are combined to make a meaningful whole. Secondly, text processing is only a partially automatic process, and unfortunately problem solving processes such as inference, in most cases, do not reach a conscious level. Finally, they point out that although there is no doubt context is essential for making inference, the concept of context is generally left undefined in most current studies of language use. It would certainly seem that we have our work cut out for us.

In trying to determine the circumstances or variables that might lead people to draw misleading inferences from otherwise truthful claims one must necessarily address each of these points. Looking at such things as prior knowledge and expertise and their effect upon processing advertising messages and any subsequent inferences drawn from them cannot be simply addressed, but such pre-existing cognitive structure will surely be instrumental in the manner in which inferences are formed relative to the

information processed. Kehret-Ward has begun to deal with this question in her work.

SYNTAX

Syntax, of course, is the term given over to the composition or grammatical arrangement of words. Psycholinguists study syntax and deconstruct rules or hypotheses of just how all of these arrangements influence the way we learn and understand a language. But understanding syntax is anything but easy. As Akmajian and Henry (1975) remind us, linguistic activity is so much a part of being human that we are not at all conscious of it. People simply use language with no conscious awareness of the complex interactions stimulated by the ways in which they string words together. And while it would be fair to say that on the whole we tend to understand one another, there can nevertheless be unwanted communication consequences of language, simply as a function of the way in which a sentence is composed.

Lowrey (1991) quite rightly laments the paucity of research in the area of syntax and advertising. Percy (1982) and Percy and Rossiter (1980) summarize a great deal of psychology and psycholinguistic literature that bears upon syntactic issues; and, in fact, report several studies that attempt to deal with the issue (c.f. Percy, 1988; Percy and Rossiter, 1983). For example, in one of the studies reported by Percy and Rossiter (1983), subjects were asked to imagine a new calorie-controlled food that is advertised as:

Condition 1: "It's food *that* tastes good in your mouth and looks good on you"

Condition 2: "It's food *which* tastes good in your mouth and looks good on you"

Condition 3: "It's good tasting food *that* looks good on you"

Condition 4: "It's good tasting food *which* looks good on you"

The purpose here was to explore the use of a relative vs. demonstrative pronoun. The results tended to support the contention of Hakes and Cairns (1970) and Hakes and Foss (1970) that relative pronouns facilitate comprehension of self-embedded sentences (here both right branching). A measure of affect summed from four bi-polar scales (good-bad, inferior-superior, unpleasant-pleasant, and interesting-boring) and an intention-to-try measure (using a zero-to-ten scale) were used, with the following result:

Pronoun	Mean Summated Product Affect	Mean Intention
That	3.30	7.11
Which	4.52	8.34

As these results suggest, overall affect and intention do seem to be greater with the use of a relative pronoun (although results were not necessarily significant).

In some additional work dealing with syntax, Percy (1988) found that learning, recall, and comprehension of an advertising slogan all varied, and often significantly, as a function of the slogan's syntax. In one of the studies reported, subjects were asked whether taste or calories was most important to the product described in one of four ways (manipulating placement of negative subordinate clauses within self-embedded sentences). The correct inference in each case was intended to be "taste", and as the results below indicate, most people did indeed infer taste.

Sentence	Incorrect Calorie Inference	Correct Taste Inference
1. It's not just the calories that count, it's the taste	11	89
2. It's the taste that counts, not just the calories	23	77
3. It's the taste, not just the calories, that count	13	87
4. It's not just the calories, it's the taste that counts	15	85

However, those subjects exposed to slogan 2, "It's the taste that counts, not just the calories," were significantly more likely to make an incorrect inference. Slogan 2 happens to embed the negative clause in a right-branching fashion, and there is evidence that suggests right-branching clauses, whether negative or not, are more difficult to process if the right-branching clause is subordinate.

We were reminded of these two studies in reviewing the work of Saliba (1991) and Lowrey (1991), as well as Kehret-Ward's (1991) work on inference. Each of these studies attempts to deal with some aspect of this intriguing yet complex issue of psycholinguistics and its obvious application to advertising. One also senses in their work the frustration of being able to significantly isolate effects; a frustration keenly felt in our own work. None-the-less, work in this area has the potential for meaningful contributions to better understanding advertising message comprehension. An advertisement is a complex communication vehicle, full of verbal and visual interactions. Yet, small efficiencies can lead to better communication; and research into the psycholinguistics of advertising copy will aid in uncovering just such efficiencies.

The Relation Between Syntactic Complexity and Advertising Persuasiveness

Tina M. Lowrey, University of Illinois, Urbana-Champaign

ABSTRACT

Verbal aspects of advertising have long been of obvious interest and importance in marketing research. However, a psycholinguistic approach has rarely been used to study verbal representations. Two important aspects of psycholinguistic theory are useful in the study of advertising effects: semantics and syntax. At the simplest level, semantics involves the study of meaning while syntax involves the study of sentence structure.

Most of the past advertising research using psycholinguistic theory has focused on semantic components of advertising messages, such as word meanings and inference-making. There has been very little empirical work on the effect of syntactic structure on the persuasiveness of advertising.

A pilot study was conducted to investigate these issues. Using the Elaboration Likelihood Model as a framework, advertisements were created that differed in level of syntactic complexity and argument strength. It was hypothesized that attitudes toward the product advertised would differ most greatly for simple versions depending on argument strength, due to elaborative thinking (i.e., bolstering for strong versions and counter-arguing for weak versions). It was also hypothesized that attitudes toward the product advertised would not differ as greatly for complex versions across levels of argument strength. Results upheld these predictions.

INTRODUCTION

Verbal aspects of advertising, although important in marketing research, have rarely been studied utilizing a psycholinguistic approach. Most of the past advertising research using psycholinguistic theory has focused on semantic components of advertising messages, such as word meanings and inference-making. For example, concrete words have been found to be better than abstract words in producing visual imagery (Rossiter & Percy, 1980). In addition, copy that invites readers to make inferences has been found to be particularly misleading (Harris, 1977; Harris, Dubitsky & Bruno, 1983).

Psycholinguistic research which focuses on syntax has shown that complex sentence structures are less easily comprehended than simple sentence structures. In addition, complex sentences are less likely to be recalled than simple sentences. Specific structures that have been shown to reduce the comprehensibility of text include passive construction, negation, and left-branching sentences.

For example, fewer errors are made when recalling affirmative and active sentences than when recalling negative and passive sentences (Mehler, 1963; Miller, 1962). Similarly, when subjects are asked to verify the truth or falsity of a sentence that describes a pictorial stimulus, response latencies are faster for affirmative and active sentences than for

negative and passive sentences (Clark & Chase, 1972; Gough, 1965, 1966; Just & Carpenter, 1971; Slobin, 1966; Trabasso, Rollins, & Shaughnessy, 1971; Wason, 1959, 1965).

Left-branching structures can cause processing difficulties by overloading working memory, particularly in children and older adults. Even for adults with normal capacity, however, such structures can impede comprehension when combined with other factors that place demands on short-term memory (for a thorough discussion of these issues, see Anderson & Davison, 1988).

Syntactic aspects of advertising have been addressed in studies of the miscomprehension of corrective advertising (Jacoby, Nelson & Hoyer, 1982) and in suggested copywriting guidelines (Percy, 1982; Rogers, 1988). Research in corrective advertising has replicated previous findings (Gough, 1965, 1966; Miller, 1962; Slobin, 1966) that affirmations are better comprehended than negations.

The copywriting guidelines which have been outlined look to general psycholinguistic theories of syntax effects for their framework, but to date little empirical evidence exists to support such guidelines in the context of advertising. These guidelines advise copywriters to write short headlines, and to avoid negations (e.g., "7-Up does not contain caffeine") and passive constructions (e.g., "Advil is recommended by more doctors"). However, the relation between syntactic complexity and persuasion has not been investigated. Indeed, the nature of the relation between syntactic complexity and comprehension is unclear. It would be particularly useful for researchers to show empirically that syntax has direct implications for predicting the persuasiveness of message content. A psycholinguistic approach could contribute a great deal to our understanding of how verbal aspects of advertising influence persuasion.

There are several ways in which complexity can be manipulated in the context of advertising. Affirmative statements vs. negations are one way of varying the level of complexity. For example, "Trident gum is sugarless" is syntactically less complex than "Trident gum does not contain sugar." Active vs. passive structures are another way of manipulating complexity. According to existing theory, "More people prefer the taste of Pepsi" is easier to process than "The taste of Pepsi is preferred by more people." Left-branching sentence structures can also contribute to complexity. For example, "Because you care about your health, you should try Healthy Choice entrees" requires more memory capacity than "You should try Healthy Choice entrees because you care about your health."

Psycholinguistic research has shed light on comprehension processes utilizing methods that do not attempt to measure persuasion. Persuasion is not an essential outcome in most reading situations, which are the situations of primary interest to

psycholinguists. However, persuasion is a very important outcome in the study of advertising. In this study, attitudes were measured, in addition to memory and comprehension, in an effort to investigate the interaction between syntax, comprehension, and persuasion in advertising.

There are two persuasion models that have implications for predicting the effect of syntactic complexity on persuasion. The first of these is the traditional information-processing approach to persuasion. Information-processing theory (IPT) considered message comprehension and retention to be important antecedents of persuasion (Hovland, Janis & Kelley, 1953; McGuire, 1966; 1969). It was hypothesized that enduring attitude change could not occur without comprehension and retention of the persuasive message. In fact, IPT would predict that as the complexity of a message increases, comprehensibility is reduced, leading to reduced persuasiveness as well. The second model that has implications for predicting the effect of syntactic complexity on persuasion is the Elaboration Likelihood Model (ELM - Petty & Cacioppo, 1986). The ELM takes into account several variables that affect both the *ability* and *motivation* to process incoming information.

Ability factors include, but are not limited to, distraction, message repetition, and message complexity-comprehensibility. For example, if one is distracted from attending to the message, it becomes difficult to process the information. This is also true if one cannot *comprehend* the message.

The ELM also considers motivation to process to be a key factor in the persuasion process. Factors that affect level of motivation include, but are not limited to, personal relevance, responsibility and message sources. For example, the more personally relevant a particular advertisement is (e.g., relevant to future decisions one anticipates making), the more one may be motivated to pay attention to it and elaborate on it. Both ability to process and motivation to process are important determinants of the amount of elaboration that is likely to occur when exposed to a message.

The ELM would predict that as the complexity of a message increases, comprehensibility is reduced. However, the predictions of each theory about the effects of complexity on persuasion would differ as a function of message strength. As stated previously, IPT would predict that as a message becomes less comprehensible it should become less persuasive, regardless of the message content. The ELM's predictions would be identical to those of IPT *only* for strong messages (e.g., messages with compelling arguments). That is, if ability to process a strong message is impaired, persuasiveness should be reduced due to the reduction in support arguments that would normally be elicited. However, if the message is weak (e.g., contains arguments which are not compelling), the ELM would predict the opposite effect. As ability to process a weak message is impaired, persuasiveness should be enhanced due to the reduction in counterarguments that would normally be elicited.

Although the ELM and IPT differ with respect to their predictions of the effects of message complexity on persuasiveness, both models agree that extreme levels of complexity should overload working memory which, in turn, should impair the ability to process the message, even if motivation to process is high. In the context of advertising, however, it is important to address the role that lesser degrees of complexity may have in the persuasion process. Advertising is designed to be comprehensible to the majority of adults with average language skills. Advertisements may be differentiated, then, in terms of the *amount of effort* required to reach comprehension, not in terms of absolute comprehensibility.

Because complexity requires greater processing effort, motivation to process the message should be a key determinant of the effect of complexity on persuasion. Under situations of moderate personal relevance (moderate involvement), complex syntax may serve to decrease one's motivation to process a message even if the ability to process exists. If one is not highly involved when a complex message is encountered, one might not bother to read the message. If so, syntactic complexity may have a direct effect on the persuasiveness of the message. According to ELM, if message arguments are strong, complexity should serve to decrease message persuasiveness. If message arguments are weak, complexity should serve to increase message persuasiveness.

The pilot study reported herein was designed specifically to address this issue with special attention paid to the levels of complexity and exposure conditions frequently encountered in advertising contexts, as a simple demonstration of the main effect of syntactic complexity on advertising persuasiveness, holding motivation to process constant.

METHOD

IPT and ELM offer two conflicting sets of predictions regarding the relation between message comprehension and persuasiveness. The main purpose of this study was to demonstrate the relevance of the ELM in predicting the effect of syntactic complexity on the persuasiveness of advertising messages. This study focused on the effects of low and moderate levels of complexity on advertising persuasiveness under situations of moderate personal relevance (moderate involvement). Four advertisements for a product (a breakfast cereal) were created that differed in their syntactic complexity and their argument quality (a 2 X 2 factorial design), as follows:

- 1) Simple syntax - strong advertising claims
- 2) Simple syntax - weak advertising claims
- 3) Complex syntax - strong advertising claims
- 4) Complex syntax - weak advertising claims

HYPOTHESES

IPT would predict that, regardless of message strength, simple messages would be more persuasive than complex messages. The ELM would predict that,

in a moderate involvement situation, subjects should be more likely to engage in elaborative processing when processing simple vs. complex versions. Thus, syntactic complexity may serve to increase persuasion by reducing the number of counterarguments normally elicited by a weak message and to decrease persuasion by reducing the number of support arguments normally elicited by a strong message. This study was designed to assist in determining which model is likely to predict effects at moderate levels of complexity.

For all subjects, it was hypothesized that simple versions would produce greater levels of recall and recognition of advertising content than would complex versions, as consistent with predictions of both IPT and ELM. More importantly, it was hypothesized that the effect of syntactic complexity on *persuasion* would depend on message strength. For simple (easy to process) ads, product evaluations should be less favorable for weak argument versions than for strong argument versions. For complex (hard to process) ads, product evaluations should not differ as greatly across levels of argument strength.

SAMPLE

57 students from the introductory advertising class at the University of Illinois participated in this study. The data from one foreign subject and three subjects who failed to follow instructions were eliminated.

PROCEDURE

All subjects received a booklet containing several advertisements. The target ad was embedded within this booklet. In an effort to hold involvement constant at a moderate level, the product chosen for the target ad (a breakfast cereal) is one that is not generally considered a high involvement product.

The strong and weak versions of the ad were created by pre-testing strong and weak arguments for the product chosen. Examples of strong arguments include that it tastes good, is low-fat, and has crispy flakes. Examples of weak arguments include that it has light-weight packaging, comes in a small box that is easy to store, and is available at many stores.

The syntactically simple versions of the claims were written in the affirmative, active voice with right-branching structure. Complex versions were created by transforming the simple versions into negations and left-branching, passive structures. In addition, pre-tests using the Cloze procedure (Taylor, 1953) were conducted to ensure that the versions were differentiated in terms of comprehensibility. The Cloze procedure involves replacing every *n*th (e.g., fifth, tenth, etc.) word from a passage of text with a blank. Pre-test subjects are asked to fill in the blanks. Readability scores are then computed by summing the number of correctly replaced words within the passage of text.

After reading through the advertisement booklet, subjects received the measurement booklet. Attitude toward the target product was assessed first, followed by a measurement of purchase intention. These measures were followed by a free recall task of the target ad content, wherein subjects were asked to

list any information about the target product they could remember. Subjects were then presented with a standard thought-listing measure in order to assess cognitive responses toward the target product (Cacioppo & Petty, 1981). This was followed by an aided recognition task where subjects were asked specific questions about the target product (based on statements that appeared in the ad). Finally, subjects responded to manipulation check items, including rating the comprehensibility of the target ad (Wang, 1970).

RESULTS

Only the results from the recall task and attitude measure are reported here. The average numbers of claims recalled by subjects are shown in Table 1. Although the pattern reflects the predictions, the main effect of syntactic complexity was only marginally significant ($F(1, 51)=3.344$; $p<.08$).

Subjects responded to a 9-point scale to assess their attitude toward the breakfast cereal (1=very negative; 9=very positive). Mean attitude scores along this 9-point scale are shown in Table 2. The pattern of means reflected the predictions, and the argument strength X syntactic complexity interaction was statistically significant ($F(1, 51)=4.633$; $p<.04$). Specifically, subjects who read the easy, yet weak version of the advertisement had more negative attitudes than did the subjects who read the easy and strong version. The attitudes of subjects who read the hard version of the advertisement did not differ as greatly across levels of argument strength.

DISCUSSION

This pilot study demonstrated that syntactic complexity can serve either to increase or decrease persuasion, independently of its effects on comprehension. Thus, this study showed that syntactic complexity can have direct implications for the persuasiveness of advertising messages.

Specifically, it was hypothesized that easy versions of ads would produce greater levels of recall than hard versions, regardless of argument strength. This pattern held true.

More importantly, it was hypothesized that, for easy ads, product attitudes would be less favorable for weak argument versions than for strong argument versions. For hard ads, product attitudes were not expected to differ as greatly across levels of argument strength. The argument strength X syntactic complexity interaction was statistically significant, thus upholding these predictions as well.

In addition to the results reported here, analyses of other measures included in this study have yet to be conducted, including purchase intention, aided recognition, and cognitive responses. It is hoped that these additional analyses will yield similar results.

Future research should also address alternative explanations of these results. One interpretation of such results is that the motivation to process the ad is reduced when extra effort is required. However, this study did not determine whether syntactic complexity is reducing motivation to process the message or

TABLE 1
Average Number of Claims Recalled by Level of Syntactic Complexity

<u>Easy</u>	<u>Hard</u>
3.48 (27)	3.19 (26)

Note: The main effect of syntactic complexity was marginally significant ($F(1,51)=3.344, p<.08$).

TABLE 2
Mean Attitude Scores by Argument Strength and Syntactic Complexity

	<u>Easy</u>	<u>Hard</u>
<u>Strong</u>	4.86 (14)	4.54 (13)
<u>Weak</u>	3.08 (12)	4.64 (14)

NOTE: Subjects responded to a 9-pt. attitude scale (1=very negative; 9=very positive) with a mid-point of 5 (neither negative nor positive).

NOTE: The interaction between argument strength and syntactic complexity was statistically significant ($F(1,51)=4.633, p<.04$).

impairing ability to process the message. The same results might be obtained if subjects weren't able to process the complex version. It could be true that the complex syntax overloads processing space. A study designed to investigate this issue is planned.

This study, in conjunction with proposed future studies, lays a groundwork for exploring the diverse ways in which syntactic complexity may increase or decrease the persuasiveness of advertising. Research in these areas should contribute to our understanding of how message complexity impacts the persuasion process in the context of advertising.

Using Syntax to Direct Processing Resources

Slimen Saliba, Andrews University

ABSTRACT

The purpose of this study is to examine how syntax can direct the processing of messages to discover whether individuals can utilize this process information in making decisions. A promising approach to these issues is offered by the "given-new" theory espoused in psycho-linguistics. This theory suggests that language syntax directs the processing of information. Certain sentence structures can direct attention to what is new information for the hearer and imply, by their syntax, that critical attention need not be paid to old information. As such, the hearer's attention can be automatically directed to processing message meaning.

To examine these ideas, four experiments were conducted. Attention was limited by having subjects read an externally-paced message. By using a pseudo-cleft sentence in experiments one and two, attention was directed to specific parts of the message. Subjects gave evaluative responses based on the advertised product. These evaluations were made when rehearsal was suppressed or after it was motivated.

It was observed that when limited attention was directed and rehearsal suppressed, subjects evaluated favorably. However, when rehearsal was motivated, evaluation was less favorable.

In experiments three and four the limiting and directing effects were replicated. These experiments also explored unmarked information. The outcomes showed that in the unmarked condition evaluation was more favorable under motivated thought rehearsal but the results were not always significant.

The experiments showed that people can process meaning automatically. This information can be recalled and utilized when thought rehearsal is motivated. That ability to recall automatically-processed information can be hindered or enhanced by marking message information.

Comment on Factors Affecting Evaluations

Richard F. Yalch, University of Washington

The conference co-chairs helped my integration task by recognizing a common element, a concern with influences on consumer judgments, in grouping three apparently unrelated studies. Another major element is that the papers assess the influence of new information presented to consumers relative to information consumers previously stored about a particular brand or product. Thus, apparently disparate factors such as context, brand familiarity, self-referencing, and explicit recognition of missing product information similarly affect consumer judgments by altering the importance of message information relative to previously stored information. After reviewing the major findings and some methodological issues, I will present an information processing model elaborating on this perspective.

MAJOR FINDINGS OF PAPERS

The three sets of authors are to be congratulated for identifying important limitations in the literature and designing studies to address overlooked issues. Two papers question whether previously reported levels of association between variables are artificially inflated. Machleit and Sahni (1992) insightfully identify that research relating attitude toward the ad and attitude toward the brand used a context in which the two concepts were measured in close proximity and therefore should tend to appear related. Further, they observed that many studies using familiar brands reported low and insignificant correlations and offered brand familiarity as another important moderator of the attitude toward the ad and attitude toward the brand relationship. Their study verified the moderating roles of context and brand familiarity.

Sirdeshmukh and Unnava (1992) review past research showing that missing information causes consumers to report more negative attitudes toward a product, but express concern that these findings may inflate the importance of missing information because respondents were made aware explicitly that important product information was missing. They hypothesize that without such awareness consumers would be less affected by the missing information. Again, their study validates their suspicions.

Romeo and Debevec (1992) also raise a methodological issue in concluding that past research on the self-reference effect considers self-referencing to be a cognitive process and did not measure affective reactions. Their study includes affective measures and validates that they are affected by self-referencing.

SOME METHODOLOGICAL CONCERNS

Before developing a model synthesizing these results, brief comments are provided on the methods employed by the authors. Although the studies are well-carried out, a few suggestions are offered to aid future research.

Machleit & Sahni (1992) used television ads for two familiar brands (Coke and Michelob) and

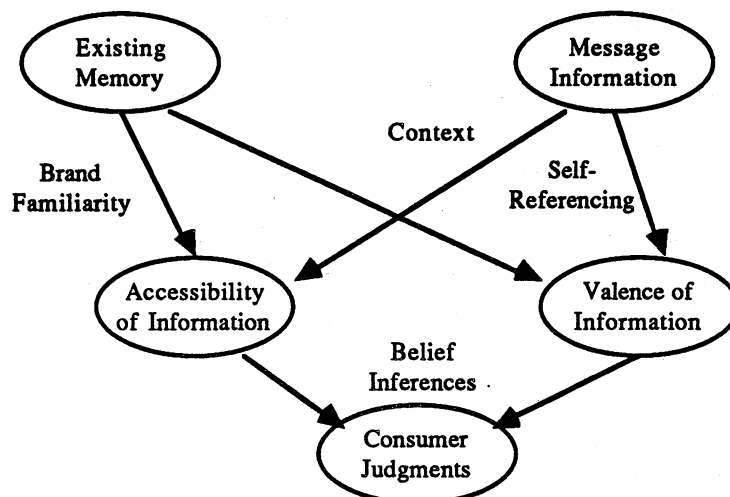

unfamiliar brand (Mug and Kronenbourg). In reading the descriptions, I noticed that the familiar brands used musical themes whereas the unfamiliar brands used humor. Thus, there is a confound between familiarity and advertising approach. I do not know that the literature speaks clearly why correlations should be higher between attitudes toward humorous ads and brand attitudes than for attitudes toward musical ads and brand attitudes. However, humor may be more affect stimulating and memorable than music, providing a rival explanation for the results.

Sirdeshmukh and Unnava's (1992) asked subjects to evaluate hypothetical product given only the information available. Not surprisingly, they did so. Only in the explicit condition (i.e., when clearly more information could have been provided), and only when provided with less than half the information (four out of ten characteristics), did the subjects evaluate the product significantly less favorably than in the full information conditions. Interestingly, this occurred although subjects perceived that the information was not sufficient in most conditions (four attributes - implicit presentation, four, six and eight attributes in the explicit condition). Thus, rather than conclude that consumers react unfavorably when important product information is missing, one could conclude that they are surprisingly indifferent to missing information.

Some questions arose regarding Romeo and Debevec's (1992) analysis rather than their design. In the design, the level of self-referencing was varied by having subjects read copy with pronouns focusing their attention on themselves, another person or the product. However, in the analysis, the authors used the reported level of self-referencing not the assigned level. This amounts to self-assignment to treatments and may undermine internal validity. For example, it risks confounding self-referencing with other factors such as agreeableness or involvement. That is, highly involved or cooperative individuals might be expected to report high self-referencing, positive attitudes toward the ad and favorable product evaluations.

Another concern is the construct validity of the affective and cognitive scales for measuring attitude toward the ad. For example, Romeo and Debevec (1992) use exciting and interesting as cognitive evaluations. However, they relate their results to Edell & Burke (1987) who used excited and interested as measures of upbeat feelings. In addition, Romeo and Debevec (1992) claim that relevant, interesting, exciting and entertaining measure the content whereas believable, realistic and informative measure the of the ad. To me, interesting seems more a quality measure and informative more a measure of content. It would be desirable to validate the scale labels.

FIGURE
Factors Affecting the Influence of Existing Memory and Message Information on Consumer Judgments

A MODEL OF THE JUDGMENT PROCESS

Methodological concerns aside, what do these studies have in common? All three support a model of memory that maintains that consumers base their judgments on the information available to them and that the amount used in making judgments is typically much less than their total product knowledge. Available information includes their experiences, exposures to advertising and other marketing stimuli, as well as the information presented to them in the laboratory. As shown in the figure, consumer judgments are based on two sources of information. One is information retrieved from long-term memory and the other is information recently acquired from an advertisement (e.g., Machleit And Sahni 1992; Romeo and Debevec 1992) or product description (e.g., Sirdeshmukh and Unnava 1992). The extent to which one or the other influences judgments depends on its likelihood of retrieval. Retrieval, in turn, depends on factors such as recency (usually the shorter the time between exposure and judgment the more likely information will be used in the judgment task) and elaboration (the more associations to a specific bit of information the more likely it will be used in the judgment task). Note that thoughts can be favorable, unfavorable or neutral and either cognitive or affective (emotional). Let's apply this model to the three studies.

For Machleit And Sahni (1992), it should be obvious that consumer thoughts should be more elaborate for familiar brands like Coke and Michelob than for unfamiliar brands like Mug and Kronenbourg. For familiar brands, consumers can easily retrieve prior thoughts and attitudes and use them when making product judgments. This is especially likely when filler questions are used to reduce the accessibility of attitudes toward the ad (their context effect). However,

having consumers respond to attitude toward the advertisement questions immediately before making product evaluations might make these thoughts sufficiently salient that they will influence the product judgments resulting in significant correlations. This was true for Michelob but not for Coke. This might be explained by Coke's being such a familiar brand that prior thoughts are extremely accessible and thus not easily ignored. It also might be attributed to the fact that the particular ad used did not present any new information (emotional or cognitive) about Coke.

For unfamiliar brands, attitudes toward a recently viewed ad will tend to dominate prior thoughts. This results in relatively high correlations between attitude toward the ad and attitudes toward the brand. The dominance of advertising-related thoughts will be maintained even when product judgments are separated from advertising judgments by filler questions. However, one should expect some attenuation as Machleit and Sahni (1992) found (see their Table 1). This raises the important question of how much predictive power attitudes toward the ad will have when measures are greatly separated. For example, do attitudes toward the ad in a copy test predict purchase behavior?

For Romeo And Debevec (1992), self-referencing serves as the device for altering the accessibility and valence of message information. The authors believe that having subjects elaborate on message information by relating it to their personal experiences enhances message learning and makes message information more accessible when product judgments are rendered. In addition, Romeo And Debevec (1992) offer the idea that there may be an emotional component to self-referencing such that self thoughts tend to be positive (we think well of ourselves) and this will further encourage favorable evaluations of the advertised product. The results of

their study support these conjectures. However, these results may not always be obtained. For example, research by Brian Sternthal and me (in review) shows that self-referencing has less effect on learning advertising messages than isolated nouns and adjectives. Advertising is connected discourse and hence stimulates a moderate level of elaboration. Further, self-referencing requires that consumers be able to relate the advertised product to themselves. If consumers cannot easily see themselves as users, self-referencing may undermine learning. This occurred in one of Lord's (1980) condition in which individuals found it easier to visualize others using an object than themselves.

Even if it enhances message learning, self-referencing might not produce favorable affective reactions. In Yalch and Sternthal (in review), when individuals had access to personal experiences indicating that a product was not of high quality, individuals using high self-referencing were less favorable toward the products than individuals using only a moderate amount of self-referencing.

In Sirdeshmukh and Unnava (1992), the issue is whether consumers resort to inferences when a message does not provide enough information to make a valid judgment. The researchers' messages consisted of product ratings on a series of characteristics. Subjects received information on four, six, eight or ten characteristics and were either made aware that the product could be evaluated on ten characteristics (explicit condition) or not made aware of this (implicit condition). In the implicit condition, attitudes did not vary with the amount of information provided, whereas attitudes became more favorable when more information was provided in the explicit condition. However, the major difference between implicit and explicit conditions occurred only when four characteristics were described. In this case, subjects provided substantially more negative product evaluations. It is not clear why this occurred except that subjects may have become suspicious why less than half the possible information was available. Their negative evaluations may have been based less on inferences drawn from the information provided and more on attributions regarding the manufacturer's integrity.

Note, that once evaluative information for six characteristics were provided or when subjects were not informed that important information was withheld, their product evaluations tended to be similar. This occurred although subjects acknowledged that the information was not sufficient (e.g., sufficiency rating was less than three on a seven-point scale when information was provided for six attributes in the explicit condition - see Table in Sirdeshmukh and Unnava 1992).

Why are evaluations largely unaffected by missing information? An explanation is that judgments tend to be based only on a limited amount of information even when much information is provided. That is, when making judgments, individuals rarely access and process all pertinent information as they might in a recall task. Instead, they bring a limited amount into short-term memory

(four to five bits) and they reach a judgment. It is possible that Sirdeshmukh and Unnava (1992) are observing the effect of consumer suspicions about why the additional information is not provided. This might include concerns about the quality of the testing agency or the manufacturer's reluctance to cooperate with the testing agency. It would be an interesting follow-up to redo the study and offer different explanations for the missing information. Attitudes should vary depending on whether it was preventable and who is the cause.

In conclusion, the three studies provide confirmation for an integrative view of memory and judgments. They show that the relative effect of product information acquired externally versus information retrieved from long term memory is predictable by the relative accessibility of each. Having individuals rehearse message information by asking them to evaluate the message immediately before making product judgments, by instructing them to self-reference it, or by listing it on the same sheet of paper as the product evaluations enhances the influence of the message information. On the other hand, including a time delay between advertising evaluations and product evaluations, using familiar products, not having individuals self-reference the material, or providing more or less information than needed will minimize the influence of message information.

The Impact of Measurement Context on the Relationship Between Attitude Toward the Ad and Brand Attitude for Familiar Brands

Karen A. Machleit, University of Cincinnati
Arti Sahni, University of Cincinnati

ABSTRACT

This study investigates the possibility that measurement context (the material which precedes a question on a questionnaire) can affect the observed relationships between Aad and brand attitude. The data illustrate that for familiar brands in particular, the magnitude of the Aad/brand attitude relationship can be affected by measurement context. This study demonstrates the need for careful questionnaire construction to reduce concerns regarding the internal validity of experiments measuring both Aad and brand attitude.

INTRODUCTION

The primary focus of the literature addressing attitude toward the ad (Aad) has been on determining the effects of Aad on brand attitude (Ab); the empirical evidence strongly supports a positive relationship between the constructs (e.g., Batra and Ray 1985; Gardner 1985; MacKenzie, Lutz and Belch 1986; Mitchell and Olson 1981). Recently, there has been some interest in studying the moderating impact of brand familiarity on this relationship. The findings regarding this issue, however, have been somewhat inconsistent. For example, Gresham and Shimp (1985) found a significant effect of Aad on Ab for only six of fifteen familiar brands. Edell and Burke (1986) report that for highly familiar brands, the effect of prior Ab on Ab was greater than the effect of Aad on Ab. In addition, the effect of Aad on Ab was weaker for the highly familiar brands than for brands with low familiarity. Phelps and Thorson (1991) report a similar finding; that the effect of Aad on Ab was stronger for unfamiliar brands than for familiar brands when prior brand attitude was controlled. Yet, Machleit and Wilson (1988) found no relationship between Aad and Ab for two familiar brands after controlling for prior Ab. Similarly, Machleit, Madden, and Allen (1990) report nonsignificant effects of Aad and positive affect on brand attitude for two familiar brands. This study is designed to address the inconsistent Aad/Ab findings for familiar brands by investigating the degree to which measurement procedures might impact the relationship. It has been demonstrated that item context (the material which precedes an item in the questionnaire) can have an impact on the responses subjects provide to that item (cf. Bradburn 1982; Schuman and Presser 1981; Tourangeau and Rasinski 1988). More specifically, correlations between constructs can be increased when they are measured contiguously (Feldman and Lynch 1988). Indeed, this is a problem which researchers have recognized in the Aad context (e.g., Edell and Burke 1986; Mitchell 1986). Edell and Burke (1984) caution that "(a)t a minimum, the Aad and Ab measures should be separated in space and time" (p. 648) to insure that method variance can be eliminated as a possible explanation for the Aad/Ab relationship.

Unfortunately, by reviewing the method section of many Aad studies, one can find that such precautions are rarely undertaken. Thus, the purpose of this study is to demonstrate that context effects in measurement can increase the Aad/Ab association for familiar brands and may offer a potential explanation for the inconsistent findings regarding Aad's impact on Ab. We begin with a brief review of the relevant literature before proceeding with the hypotheses.

BACKGROUND

Moderating Effects of Brand Familiarity

The literature offers many studies demonstrating Aad's impact on brand attitude for unfamiliar and fictitious/hypothetical brands. The theoretical justification typically offered for this relationship involves a classical conditioning and/or direct affect transfer explanation (e.g., Gardner 1985; Gresham and Shimp 1985, Machleit and Wilson 1988; MacKenzie, Lutz, and Belch 1986; Mitchell and Olson 1981). However, this theory does not support predictions of an Aad/Ab effect for familiar brands.

McSweeney and Bierley (1984) review classical conditioning procedures and their implications for consumer behavior. They note that "it will be easier to classically condition behaviors to new products (CSs) than to products with which people have had previous experience" (p. 624). Their conclusion is based on a conditioning principle called "latent inhibition" which contends that little conditioning will occur when the CS (in this case, the brand) is presented several times without the US (in this case, the ad and resulting affective responses). Thus, when consumers already have some sort of knowledge and/or experience with a familiar brand and they are subsequently exposed to an ad for that brand, little conditioning/affect transfer should occur. This principle has been demonstrated empirically by Shimp, Stuart, and Engle (1991) who, in a series of experiments, found that for highly familiar brands of cola, little conditioning effects were observed in brand attitude. Indeed, this finding is not surprising given that attitudes for familiar, experienced individuals are difficult to change (Fazio and Zanna 1981; Wu and Shaffer 1987). One would expect that it would take more than just one or two exposures to affect-producing ads to change such a well-formed attitude.

The Impact of Context Effects

The process of measurement and the context of questioning have been demonstrated to impact the correlations among constructs by shaping the computational and retrieval processes that individuals use to generate answers to survey questions. Feldman and Lynch (1988) present an "Accessibility-Diagnosticity" model that can contribute to our understanding of the effects of measurement context.

According to their model, the likelihood that a person's response to a question will be used as a basis for a response to a second question depends upon the accessibility of the first input in memory, the accessibility of alternative inputs in memory, and the perceived diagnosticity or relevance of the input and alternative inputs (Lynch, Marmorstein, Weigold 1988).

It is not uncommon for respondents in a data collection situation to have a relatively low interest in the survey task, as well as to feel some time pressure to complete the questionnaire. As a result, the response process performed by the individual is likely to be carried out superficially, and respondents will often base their opinions on easily accessed situational cues from the immediate context rather than retrieving the appropriate information from memory (Tourangeau and Rasinski 1988). Even without time pressure or low involvement of the part of the respondent, the measurement process may direct the respondent's attention to subsets of their prior knowledge structure. Through output interference, "cognitions activated in the process of making the first judgment may suppress the retrieval of cognitions that would have influenced the second judgment or behavior in the absence of prior measurement" (Feldman and Lynch 1988, p. 422). Further, multiple measures of a construct (necessary for increased measurement reliability) will magnify this problem since they provide increased rehearsal and thus increased memory accessibility (Feldman and Lynch 1988). Tourangeau and Rasinski (1988) note that the retrieval process will reflect what is most accessible to the respondent rather than what is most important. This problem "is likely to be heightened in attitude measurement settings, in which few respondents have either the motive or the opportunity to reflect carefully on their answers. . . what is most readily retrieved from memory does not necessarily reflect either reality or the contents of memory" (p. 301).

HYPOTHESES

Expanding on the "accessibility" portion of their model, Feldman and Lynch (1988) note that separating two mildly similar responses (e.g., responses about Aad and brand attitude) on a questionnaire can reduce the likelihood that the respondent will retrieve the first response as direct input to the second. When making a judgment, subjects begin by searching working memory; the search concludes when a sufficient basis for making the judgment is retrieved. By including "filler" or intervening items between the two measures, it is less likely that the response to the first question will still be in working memory when the second question is encountered. The respondent must then rely on long-term memory (Feldman and Lynch 1988).

However, for the unfamiliar brand, the *only* information that the respondent has about the brand comes from the ad to which s/he was exposed. This is the only information which the respondent has available for use in forming a judgment or attitude about the brand. Thus, this limited information should

be relevant in forming brand attitude regardless of whether it was made salient and in working memory through contiguous measurement or whether the brand attitude was taken after some "filler" questions. Given this limited information, we anticipate that measurement context effects induced by measuring Aad and Ab contiguously in a questionnaire will have minimal effects for the unfamiliar brand. Thus, we hypothesize:

Hypothesis 1: For unfamiliar brands, Aad will significantly impact brand attitude regardless of measurement context.

For the familiar brand, respondents should already have an attitude in long-term memory that will serve as the basis for attitude questioning. However, Tourangeau and Rasinski (1988) report that "(e)ven when the underlying attitude structure is stable, the response process need not be very reliable" (p. 301). This unreliability in the retrieval process will be reflective of the ease in accessing information for generating a response. When Aad and Ab questions are presented contiguously, working memory provides convenient Aad cues for basing responses of brand attitude; when the questions are presented noncontiguously, subjects will be more likely to engage in the more involved and effortful search of long-term memory (Tourangeau and Rasinski 1988). As a result of processing ease, we hypothesize that, for familiar brands, measurement context effects will produce a significant correlation between Aad and Ab when the measurements are taken contiguously; however, with noncontiguous measures, we hypothesize that the Aad/Ab relationship will be, consistent with theory, nonsignificant.

Hypothesis 2: For familiar brands, Aad will significantly impact brand attitude only when the measures are taken contiguously.

METHODOLOGY

Experimental Design

A 2x2 between subjects design (familiar vs. unfamiliar brands x contiguous vs. noncontiguous measures) was conducted. Data were collected within this design for two different product categories relevant to student subjects (soft drinks and beer) to enable a replication of the findings. Product category was not a factor in the design since we simply wanted to insure and demonstrate that the results would be replicable in different product category conditions.

Stimuli

Four commercials were selected as the test stimuli. For soft drinks, ads for Coca-Cola Classic and Mug root beer were selected; for beer, the ads were for Michelob and Kronenbourg brands. The Coke commercial was a 1950s style song and dance production, the Michelob ad included singing artist Steve Winwood, the Mug ad was a humorous animated

sketch, and the Kronenbourg ad was a humorous discussion of the European brand. These ads were selected for their ability to generate some type of affective response from the subjects, and they fit nicely into the familiar (Coke and Michelob) and unfamiliar (Mug and Kronenbourg) factor necessary in the experimental design. Recognizing the limitations inherent in using "real" ads, we concluded that they would produce responses more natural than what would have been elicited through mock commercials (Mitchell 1986).

The test ads were embedded in a ten minute segment of a game show to mimic a more natural viewing environment. The first commercial break included three non-affective "filler" ads. During the second commercial break, subjects were exposed to either the two ads for the familiar brands, or the two ads for the unfamiliar brands. These test ads were then followed by a filler ad.

Subjects and Procedure

Student subjects were processed during undergraduate marketing courses. One of the two videotapes was shown to the students and they were told that they would be asked some questions when the tape concluded. Unknown to the students, questionnaires including either the contiguous or noncontiguous measures were randomly ordered and distributed. A total of 88 subjects participated: 29 in the familiar-contiguous condition, 21 in the familiar-noncontiguous condition, 20 in the unfamiliar-contiguous condition, and 18 in the unfamiliar-noncontiguous condition. A manipulation check indicated the success of the brand familiarity manipulation; on a 1-7 semantic differential scale, Coke and Michelob were rated as familiar (mean values of 6.7 and 5.3, respectively) and Mug and Kronenbourg were rated as unfamiliar (mean values of 1.8 and 2.1, respectively).

Questionnaire Design and Measures

The questionnaire began with the measures of positive affect and Aad validated by Madden, Allen, and Twible (1988). Positive affect was measured by asking subjects reflect how they felt during the ad and respond to five adjectives such as "cheerful" and "pleased" on a six point scale (with endpoints "very much so" to "not at all"). Aad was then measured with a seven-point semantic differential format. The scale items included: unpleasant/pleasant, likeable/unlikeable, interesting/boring, good/bad, tasteful/tasteless, artless/artful.

In the contiguous condition, the Aad measure was followed by the brand attitude measure. Brand attitude was measured with the items good/bad, unfavorable/favorable, and like/dislike with a seven-point semantic differential format. Three pages of "filler" questions then followed. In the noncontiguous condition, the "filler" questions followed the Aad measure, then the brand attitude measure was taken. The "filler" questions (asked with several different scale formats) included a variety of questions regarding the subjects' television viewing preferences and habits.

Coefficient alpha values were high for the positive affect, Aad, and brand attitude measures for each of the four brands. They ranged from .84 to .97 and demonstrate the reliability of the measures.

RESULTS AND DISCUSSION

Table 1 presents the correlations between Aad and brand attitude for the familiar and unfamiliar brands in both the contiguous and noncontiguous conditions. Hypothesis 1 predicted significant Aad/Ab correlations regardless of measurement context for the unfamiliar brands. This hypothesis is supported; the correlations for Mug and Kronenbourg are highly significant in both the contiguous and noncontiguous conditions.

These data were further examined to determine whether the correlations in the contiguous condition were significantly higher than those in the noncontiguous condition (Snedecor and Cochran 1980). For Mug, the correlations are not significantly different (.71 vs. .63). For Kronenbourg, however, the difference (.89 vs. .65) approaches significance ($p=.0524$). We argued earlier that Aad should affect Ab regardless of measurement context since these were affective ads and the ad provided the only basis from which to form a brand attitude. However, in the Kronenbourg ad, the brand was compared to Heineken beer. Thus, in the noncontiguous measure condition, the respondent may have accessed information regarding Heineken from long-term memory, using this information as input into brand attitude and thereby reducing the Aad effect.

Hypothesis 2 predicted significant Aad/Ab correlations for the familiar brands only when the measures are taken contiguously. The data for Michelob support this hypothesis. The high correlation ($r=.65$) in the contiguous condition does not occur in the noncontiguous condition ($r=.07$); these correlations are significantly different at $p < .05$.

It has been suggested that the significant effects of Aad on Ab for familiar brands could simply be spurious and due to the fact that prior brand attitude may act as a common antecedent to both Aad and Ab (Machleit and Wilson 1988). To determine that the effect for Michelob in the contiguous condition was likely due to measurement context rather than a lack of control for prior brand attitude, brand attitude was regressed on both Aad and prior brand attitude (this measure was included with questions for an unrelated experiment one week earlier). The results indicate that while prior brand attitude significantly impacts brand attitude ($\beta=.52$, $p<.0001$), the impact of Aad on brand attitude ($\beta=.62$, $p<.0001$) was not mediated by prior Ab. We therefore conclude that measuring Aad and brand attitude contiguously can inappropriately result in a significant correlation between the constructs.

For Coke, however, the results were not as anticipated. The Aad/Ab correlations were nonsignificant regardless of the measurement context (see Table 1). In an effort to post hoc explain this finding, we began by looking for differences between the two familiar brands, Coke and Michelob. Brand

TABLE 1
Aad/Ab Correlations

	Unfamiliar Brands		Familiar Brands	
	Mug	Kronenbourg	Coke	Michelob
Contiguous	.71 p=.000	.89 p=.000	.10 p=.308	.65 p=.000
Noncontiguous	.63 p=.002	.65 p=.002	.11 p=.323	.07 p=.382

TABLE 2
Positive Affect/Ab Correlations

	Unfamiliar Brands		Familiar Brands	
	Mug	Kronenbourg	Coke	Michelob
Contiguous	.52 p=.010	.42 p=.032	-.02 p=.453	.48 p=.004
Noncontiguous	.51 p=.015	.20 p=.214	.09 p=.340	.29 p=.100

familiarity was measured on a semantic differential scale (7=highly familiar) for both brands. ANOVA results indicate that the respondents were significantly less familiar ($p<.0001$) with Michelob than with Coke (mean values: Michelob=5.3, Coke=6.7). Tourangeau and Rasinski (1988) note that "with *highly familiar* issues, an attitude structure may be activated automatically when the issue is confronted" (p. 309, emphasis ours), and context effects may be eliminated. Further, issue expertise may reduce susceptibility to context effects (Fiske and Kinder 1981); such "experts" are likely to have thorough retrieval processes and, as a result, are less likely to be affected by measurement context. Given that the mean familiarity value for Coke was virtually at the extreme end of the scale, we conclude that this very high level of familiarity and expertise beyond that of Michelob is the reason that different effects were observed for the two familiar brands.

Since the Aad and Ab measures contained similar scale formats, we wished to consider whether method variance played a role in the study. Feldman and Lynch (1988) indicate that shared method variance, like context effects, can be minimized by increasing the amount of unrelated material separating the questions. However, we hoped to discount the method variance explanation in favor of the context effect explanation by evaluating whether context effects were also present for a different type of scale format. The positive affect measure was taken along

with the Aad measure although it was *not* measured with the similar semantic differential scale format. Table 2 presents the correlations between positive affect and brand attitude for the four brands by question context. Note that while these correlations as a whole are lower in magnitude (as we would anticipate since positive affect may precede Aad in a causal chain leading to brand attitude (e.g., Batra and Ray 1986; Edell and Burke 1987; Machleit and Wilson 1988)), the pattern of results is similar to the Aad results. In particular, for the moderately familiar brand Michelob, the correlation in the contiguous condition is highly significant while the correlation in the noncontiguous condition is not. Thus, the data in Table 2 also demonstrate the impact of measurement context.

CONCLUSION

This study underscores the importance of questionnaire design and contextual factors when researching associations among constructs. This issue should be an important concern for those who attempt to understand how affect-producing ads can impact brand attitude. In particular, we demonstrate that when researching familiar brands, measurement context has the potential to seriously inflate the magnitude of the relationship between Aad (or positive affect) and brand attitude. Researchers measuring the Aad/Ab relation for familiar brands should take care that these measures are separated by

filler questions to reduce concerns regarding the internal validity of their experiment.

The Effects of Missing Information on Consumer Product Evaluations

Deepak Sirdeshmukh, Ohio State University

H. Rao Unnava, Ohio State University

Previous research on the effects of missing information on consumer evaluation tended to present attribute dimensions to consumers and then inform them that the information on those dimensions is missing. We argue that the mere presentation of an attribute dimension is sufficient to induce inferences that might otherwise not have been made by subjects. The results of an experiment where subjects were presented only those attributes on which information was available show that missing information has little effect on consumer evaluations. Implications for research on missing information are discussed.

INTRODUCTION

Early models of consumer choice assumed that consumers use only explicitly available information in making choices (e.g., multi-attribute models). However, recent studies have shown that the inferences consumers make upon exposure to advertising information play an important role in consumer decision making (Kardes, 1988). Because consumers are more likely to make inferences when product attribute information is missing, much attention has been directed toward understanding how consumers' product evaluations are affected by missing attribute information (Meyer 1981, 1982; Yamagishi and Hill 1983; Dick, Chakravarti, and Biehal 1990; Huber and McCann 1982). Several recent studies have shown that consumers use different strategies to impute values for attributes about which information is not provided, when arriving at an overall evaluation for a product (Jaccard and Wood 1988; Johnson and Levin 1985).

Some recent research, however, has questioned the validity of the findings reported in the missing attribute literature. For example, Lim, Olshavsky and Kim (1988) and Ford and Smith (1987) suggested that the methodology used in most of the research on missing attributes may have produced effects which overstate the presence and amount of inference making. This criticism rests on the common practice in missing information research of asking subjects to first impute a value for the attribute on which information is missing prior to making an overall evaluation. Such procedures would force subjects into making inferences that they might not have made otherwise.

The present study represents a further attempt to examine the effects of stimulus presentation format and instructions on an individual's tendency to infer. Specifically, past studies, including those by Ford and Smith (1987) and Lim, et al. (1988), have examined the effect of missing attributes on product evaluation by presenting subjects with the description of a brand along a few attributes. The information on one or two attributes is left missing. Product evaluations in the missing attribute condition are then compared with the evaluations in the control condition where subjects have access to all information about the product.

We believe that the very presentation of an attribute or evaluative dimension, regardless of instructions to infer the value, may result in inference making. That is, the mere presence of an attribute name, even without any accompanying information, is sufficient to induce inferences. Therefore, even in studies that have attempted to measure inference making 'unobtrusively', the presentation of an attribute might have been sufficient to cause subjects to make inferences that they would normally not have made. Further, from a practical point of view, an advertiser is not likely to mention an attribute and then not provide any information about the product on that attribute. The objective of this research, therefore, is to examine the effect of missing information on consumer evaluations when consumers are not explicitly made aware of the attributes on which product information is missing.

A second issue concerns the number of dimensions on which information is missing. Most studies that have examined the effects of missing information have typically provided subjects with information on two or three attributes at most. In the missing information condition, subjects are deprived of information on one or two of those attributes so that subjects have information on only one product attribute (e.g., Johnson and Levin 1985; Huber and McCann 1982). Subjects' evaluations are then collected in these relatively information impoverished conditions. The likelihood of inference-making should be artificially enhanced under these conditions because information available for making an informed judgment is limited. This research attempts to examine the effect of missing information on consumer evaluations as a function of the amount of available information.

LITERATURE REVIEW AND HYPOTHESES

Several studies that have examined the effect of missing information on consumer evaluations have concluded that consumers rate products less favorably when confronted with partially described alternatives (Huber and McCann 1982; Jaccard and Wood 1988; Johnson and Levin 1985; Lim, et al. 1988). This negative reaction is attributed to consumers' tendency to discount the imputed value of the missing attribute. For example, Huber and McCann (1982) examined the extent and impact of inference making, and the implications of inferences for cognitive algebra. Subjects were asked to evaluate products on several dimensions, and information on some dimensions was missing. Inference making was either explicitly prompted or was implicit. Subjects in the explicit condition were instructed to generate a value for the missing information and then come up with overall evaluations. In the implicit condition, subjects were presented with identical stimuli and only asked to provide overall evaluations. The results showed that

missing information affected purchase likelihood. When information was missing, subjects expressed lower likelihood of purchasing the target brand. Further, subjects' inferences had a significant impact on purchase likelihood with or without explicit instructions to infer a value for the missing attribute.

More recently, Ford and Smith (1987) examined the effect of explicitly prompting inferences. The authors suggested that studies examining inference making by asking subjects to provide a value for the dimension on which information is missing may be subject to demand artifacts. In their study, some subjects were directly prompted to infer the missing value (explicit condition) while others were given no such instructions (implicit condition). However, both groups of subjects were given identical stimuli where the value of the missing attribute was indicated with a question-mark. Results showed that the two tasks provided conflicting results. Prompting an inference produced results that differed in magnitude compared to those produced without such prompting. The authors discussed the inflationary effects of prompting inferences which call into question the effect sizes obtained in previous literature. Consistent with Ford and Smith (1987), another recent study by Lim, et al. (1988) reported the absence of any effects of missing information when subjects processed product attribute information under conditions that mimicked the implicit condition of Ford and Smith (1987) and Huber and McCann (1982).

In sum, while prior studies have reported significant effects of missing information on consumers' evaluations of products, recent research suggests that most such effects are exaggerated by the methods employed. The most serious criticism that has been leveled against prior research is focused on the practice of explicitly having subjects infer the value of a missing attribute before providing their evaluations. Under such conditions, it is argued, the obtained effects may be more due to the experimental task that requires subjects to make inferences rather than to the tendency in subjects to make spontaneous inferences before evaluating a product (Ford and Smith 1987).

Interestingly, even studies that have attempted to examine inference making without first asking subjects to impute a value to the missing attribute may have generated inferences due to the methods employed. This is because in all those studies (e.g., Lim et al. 1988) subjects are presented with an alternative where the dimension on which information is missing is also listed. Therefore, even in cases where subjects are not explicitly prompted to infer the value of the missing attribute, the very presence of the dimension, could generate some amount of inference making. A more unobtrusive strategy to examine the issue of inference making, therefore, would be to provide subjects with incompletely described alternatives where the attributes on which information is missing will not even be mentioned.

The procedure of omitting the attributes themselves, and not just the information about the attributes, should provide a truly unobtrusive

examination of consumer inferences. If consumers are prone to infer the value of missing attributes, they should do so even when the attributes are not listed. On the other hand, differences in the pattern of evaluations between this condition and a condition where the attributes are listed without providing values would suggest that the methodology that has been adopted in more recent research (e.g., Lim et al. 1988) is inducing inferences that would not normally occur or inflating effect sizes.

A second issue concerns the number of dimensions on which information is available when subjects make judgments. As discussed earlier, past studies have measured the effects of missing information under conditions where the available information was unrealistically scarce. For example, in the Lim, et al. (1988) and Huber and McCann (1982) studies, subjects were presented information on only one attribute, with information on the other attribute missing. We believe that having subjects judge a product on the basis of only one attribute would greatly exaggerate the effect of missing information. Subjects should be more motivated to make inferences because they have very little information to make judgments. Thus, by providing little information on the experimental products, past studies might have inadvertently inflated the effects of missing information.

The research reported in this paper addresses the two aforementioned concerns with the existing research on missing information. First, we provide information to subjects on only those attributes for which attribute values are available. Subjects are not made aware of the other attributes on which information is missing (implicit condition). This condition is contrasted with the condition where subjects are made aware of the attributes on which information is missing (explicit condition). Subjects, however, are not asked to impute values to the missing attributes before providing product evaluations. Thus, the explicit condition in this study is similar to the implicit condition in some of the past research (e.g., Ford and Smith 1987). Second, the amount of information available to subjects is systematically varied so that subjects have information on a minimum of four attributes and a maximum of ten attributes before a judgment is rendered. It is expected that missing information affects product evaluations more strongly in the explicit condition than in the implicit condition. Further, it is expected that the effect of missing information on evaluations would decrease as the amount of available information increases.

METHOD

The effects of information presentation format and the amount of available information on subjects' evaluations were investigated in a 2 (explicit vs. implicit presentation) X 4 (information available on ten, eight, six or four attributes) between-subjects design. 192 subjects recruited from an undergraduate marketing class participated in the study for bonus points in their coursework. All subjects were randomly assigned to the treatment conditions.

STIMULUS MATERIALS

Color television sets were used as the target product in this study. This product was chosen because it was relevant to the student population and the task of evaluating televisions was not novel for them. Further, a product like television is normally evaluated on several attributes before a choice is made. Therefore, the presentation of information on several attributes is neither unusual nor unexpected for the student subjects.

The attributes on which information was presented in the final study were derived from a pretest. Forty six students from the same subject population were asked to list the most important attributes that they would be seeking information on while choosing a television set for themselves. The ten most frequently listed attributes by these subjects were selected for the final study. The attributes generated from the pretest are listed below in order of their importance as defined by the number of times an attribute was mentioned.

1. Screen Sizes Available
2. Sound Quality
3. Remote Control Quality
4. Color Quality
5. Picture Quality
6. Warranty
7. Cable Ready
8. Style and Appearance
9. Service Facilities
10. Hook-up to VCR, etc.

Although price was one of the most frequently mentioned attributes, it was not included in the study because price could have either an allocative role or could be a proxy indicator for quality (e.g., Lim et al. 1988). It is also possible that price could overwhelm the other attributes in affecting quality ratings which would affect the results of this study.

PROCEDURE

Subjects were given a printed questionnaire which contained instructions, manipulations and dependent measures (see appendix). The amount of information available and the explicitness of missing information was manipulated through the presentation of the consumer agency ratings. For example, the appendix displays the questionnaire used in the explicit presentation condition, with information available on 6 attributes. In the implicit presentation condition, with information available on 6 attributes, the names of the 4 missing attributes were not included in the questionnaire. Other conditions were manipulated accordingly. Subjects' overall evaluation of the television brand was measured by two seven-point scales (7= very good, very desirable; 1= very bad, very undesirable). Subjects' perception of the adequacy and sufficiency of the presented information was also collected. Two seven-point scales (very adequate, very sufficient vs. very inadequate, very insufficient) were used for this purpose. This measure was incorporated to check the missing information manipulation. If missing attributes were stated

explicitly, thus drawing subjects' attention to those attributes, then subjects in the explicit condition should perceive greater inadequacy of information in the explicit than in the implicit condition. After completing this measure, subjects were debriefed and dismissed.

RESULTS

Attitudes

The two items constituting the attitude scale were averaged to form the mean attitude score for each subject. The cell means are reported in the Table. An overall ANOVA on the attitude score with presentation explicitness and information availability as the independent variables revealed a significant main effect of presentation explicitness ($F=31.3$, $p < 0.0001$). Missing information negatively affected subjects' evaluations more under the explicit condition ($M= 4.49$) than under the implicit condition ($M= 5.29$). This finding supported our expectation that the very presence of an attribute name enhances the effect of missing information on subjects' evaluations.

The effect of information availability was not significant ($p < 0.15$). However, the interaction between presentation explicitness and information availability was significant ($p < 0.001$). Subjects evaluations were affected more by presentation explicitness when the amount of available information was only four attributes ($M_s=5.5$ vs. 3.7) than when it was more than four attributes ($M_s = 5.21$ vs 4.73). This finding offers preliminary support to our expectation that the effect of missing information is exaggerated when the available information is limited.

A series of a priori contrasts were then conducted to examine the attitude effects in more detail. The contrasts revealed that missing information had no effect on subjects' evaluations (all p -values > 0.25) when they were not specifically told that the information on several attributes was missing (implicit condition). That is, subjects' evaluations of the target product remained unchanged whether they had information on four, six, eight, or ten attributes.

The results, however, were different when subjects were exposed to the names of the attribute dimensions on which information was missing. Subjects' evaluation of the target product was significantly less positive when information was available on only four attributes versus when information was available on six, eight, or ten attributes (all p -values < 0.05). Interestingly, even under explicit presentation conditions, subjects' evaluations remained unaffected by missing information when the amount of available information was at least six attributes (all p -values > 0.1). The absence of effects of missing information on product evaluations even under explicit presentation conditions, when the amount of available information is sufficiently large, suggests that previous studies might have reported inflated effects of missing information when they provided information on only one or two attributes.

TABLE
Cell Means and Results of Contrasts

Dependent Measure	Implicit Presentation Information available on				Explicit Presentation Information available on			
	4 att.	6 att.	8 att.	10 att.	4 att.	6 att.	8 att.	10 att.
Attitude	5.54 ^a	5.39 ^a	5.07 ^a	5.20 ^a	3.77 ^b	4.61 ^c	4.58 ^c	4.98 ^c
Perceived Sufficiency	3.24 ^a	4.43 ^b	4.89 ^b	4.98 ^b	1.79 ^a	2.76 ^b	3.77 ^c	4.74 ^d
n	(23)	(23)	(27)	(23)	(24)	(23)	(24)	(25)

Note: Means with different superscripts, within each presentation condition, are significantly ($p < 0.05$) different from each other.

Information sufficiency

Subjects' perceived sufficiency of the available information in making their evaluations was measured using two seven-point scales. These two measures were averaged to form a mean perceived sufficiency score for each subject. It was expected that subjects' perceptions of information insufficiency would be greater when the stimulus material explicitly states that attribute information is missing than when the stimulus material does not.

As expected, the overall ANOVA on the perceived sufficiency score with presentation explicitness and information availability as the independent variables showed a significant main effect for presentation explicitness ($F=26.33$, $p < 0.0001$). Missing information negatively affected subjects' perceived sufficiency of information to a greater extent in the explicit condition ($M=3.29$) than in the implicit condition ($M=4.41$). Further, a significant main effect of information availability was observed ($F=22.12$, $p < 0.0001$) suggesting that subjects' perceived sufficiency of information systematically decreased as the amount of available information was reduced ($M_s = 4.85, 4.36, 3.60, 2.50$ for ten, eight, six and four attributes respectively). Thus, while all subjects were sensitive to the variation in the amount of information available to them in making their evaluations, the amount of information manipulation exerted stronger effects in the explicit condition than in the implicit condition.

DISCUSSION

Much of the past research on missing information and inference-making has adopted the common procedure of presenting subjects with the product attributes on which information is missing, along with the attributes on which information is available, and then measuring subjects' evaluations of the product. The results of this past research suggest that consumers have less favorable evaluations of products when attribute information is missing than when it is available. Theories of how consumers treat missing information when arriving at an overall

evaluation have been developed based on these findings.

In our research, we contended that the very presence of a missing attribute name in the information set presented to a subject is sufficient to induce inferences about that attribute. It was our belief that when subjects are not cued to a particular attribute, the probability of inference-making about that attribute is reduced greatly. The reason for the curtailment of inference-making is the reduced probability of a consumer dredging the attribute from memory, discovering that information on that attribute is missing, and then imputing a value for that attribute.

The results of our experiment were supportive of our expectations. Consumer evaluations of a television brand were virtually unaffected when consumers were presented missing attribute information implicitly (missing attribute names not presented along with the attributes on which information is available). On the other hand, explicit presentation of missing attributes (missing attribute names presented along with the attributes on which information is available) caused subjects' evaluations to be more negative when compared to the full information condition. This seems to suggest that individuals either simply chose to ignore the missing information, or, even if an inference procedure was at work, it differed markedly from the one used when the dimensions were listed and values were missing.

The effect of missing information was also found to depend on the amount of information that was available to the subjects when they made their evaluations. When subjects had information on only four attributes, with information on six attributes missing, their evaluations were significantly less positive than when subjects had information on six, eight or ten attributes. This effect, however, was limited to the explicit presentation condition.

The finding that missing information did not affect subjects' evaluations when subjects were not explicitly told that the information was missing is important because it casts doubts on the robustness of the findings reported in previous research.

APPENDIX

We would like to obtain your evaluations of a *new television brand* that should be available in your market very soon. The manufacturer of this television preferred not to reveal the company's name or price of the television, because, consumers' evaluations of products are sometimes biased by brand names and prices. Therefore, we disguised the brand name of the new product and have called it Brand K.

The information that is available on Brand K is based on several tests that have been conducted by an independent consumer product testing agency. The testing agency has employed a five-point scale in rating each feature as described below:

Excellent	=	5	Brand K outperformed the entire competition on that feature
Good	=	4	Brand K outperformed most of the competition on that feature
Average	=	3	Brand K outperformed about half the competition on that feature, but was outperformed by the other half of the competition
Fair	=	2	Brand K was outperformed by most of the competition on that feature
Poor	=	1	Brand K was outperformed by the entire competition on that feature

Listed below are the ratings given by the testing agency for Brand K.

<u>Feature/Attribute</u>	<u>Agency Rating</u>
Screen Sizes Available	Unavailable
Sound Quality	Unavailable
Remote Control	Unavailable
Color Quality	Unavailable
Picture Quality	4
Warranty	2
Cable Ready	5
Style and Appearance	4
Service Facilities	4
Hook-Up to VCR, etc.	5

Now, please answer the following questions by circling the number that corresponds most closely with how *you personally feel*.

Brand K television is:

Very Good	1	2	3	4	5	6	7	Very Bad
Very Undesirable	1	2	3	4	5	6	7	Very Desirable

The information provided on Brand K is:

Sufficient	1	2	3	4	5	6	7	Insufficient
Adequate	1	2	3	4	5	6	7	Inadequate

Specifically, it suggests that unless subjects are actually told that information is missing on an attribute, they do not seem to be affected by it.

One possible alternative explanation for this insensitivity of subjects to missing information might be their lower level of task involvement. Stated simply, given the task environment, subjects may not have bothered to think of the information that was required to make an evaluation and therefore exhibited no sensitivity to missing information (e.g., Kardes 1988). However, this argument is not supported by the finding that both in the implicit and explicit conditions, subjects' ratings of the adequacy and sufficiency of the information presented to them was affected by the experimental manipulation of missing

information. It thus appears that subjects were aware of the fact that the information given them was not complete. Their evaluations, however, were affected only when they were cued with the attribute names on which information was missing.

Another possible explanation for the results may be the "recall inhibition" effect (Alba and Chattopadhyay 1986). The recall inhibition explanation would suggest that the presence of the available attributes may have interfered with the retrieval of other attributes. Consequently, given this inability to recall, subjects may not have been sensitive to the missing attributes. Such a possibility may bear further examination.

We would also like to note here that previous research on missing information has employed experimental manipulations and subject pools (students) similar to those used in our study. Hence we are comfortable comparing results of our study with those found in the studies reviewed earlier.

Our findings also question the practice of employing stimuli that typically provide information on only one attribute with information on the other attribute missing. As argued earlier, the potential for artificially inducing inferences is very high under these conditions. The finding, in this research, that subjects are relatively sensitive to missing information when they are provided information on only four attributes, but not when they have information on six or more attributes, demonstrates that the effects of missing information are conditioned on the amount of available information. The findings reported in several earlier studies on missing information, then, have to be interpreted with caution in light of our findings.

Much of the past research on the effects of missing information on consumer evaluations has concluded that consumers evaluate products less positively when information is missing. Some recent research has questioned the methodology adopted in this literature and has cast doubts on the robustness of the findings reported in this literature. Our research extends this criticism by showing the relative insensitivity that consumers seem to exhibit toward missing information, in arriving at product evaluations, when the missing attribute information is not explicitly stated. Future research should examine the conditions under which consumer evaluations exhibit sensitivity to missing information.

An Investigation of Self-Referencing's Influence on Affective Evaluations

Jean B. Romeo, Boston College

Kathleen Debevec, University of Massachusetts

ABSTRACT

Self-referencing has been described as a cognitive process in which individuals associate self-relevant incoming information with information previously stored in memory. Studies have found that individuals who are high in self-referencing have more positive attitudes toward the ad and product. It has been suggested that self-referencing may also have an affective component in addition to the cognitive component. This study investigated the causal influence pattern of the self-referencing construct. The results suggest that self-referencing may influence cognitive reactions to the ad and product as well as both positive and negative affective reactions to the ad and product.

The self-referencing phenomenon is an important one for marketers since research has found that individuals who self-reference information are more likely to remember that information (because it becomes meaningful to them) and more likely to respond in a favorable way. Self-referencing has been described in the cognitive psychology literature as the interaction between one's previous experience and new information such that the new input can be interpreted and coded (Rogers, Kuiper, and Kirker 1977). It has been suggested, however, that the self-referencing process also has an affective quality (Rogers 1981). If self-referencing has an affective as well as a cognitive dimension, it is likely that it will influence cognitive and affective reactions to the ad and product. If self-referencing only occurs on a cognitive level, it may have little influence on affective reactions. Past research has not examined the causal influence pattern of the self-referencing construct. The purpose of this study is to investigate whether self-referencing induces two separate reactions toward the ad and product -- one affective and the other cognitive. A model is developed and tested to provide insight into self-referencing's influence pattern.

BACKGROUND

Self-Referencing

Self-referencing has been described as a cognitive process whereby individuals associate self-relevant incoming information with information previously stored in memory in order to give the new information meaning (Bellezza 1981, Kuiper and Rogers 1979, Markus 1977, 1980, Rogers 1981). Individuals who self-reference information are better able to learn and recall the information than people who do not (e.g., Bellezza 1981, 1984, Kendzierski 1980, Kuiper and Rogers 1979). Marketers should be interested in viewers' ability to self-reference advertising since self-referencing has been found to influence evaluations of an ad and subsequently evaluations of the product featured in the ad. For

instance, one study found that individuals who are high in self-referencing have more positive attitudes toward the ad and product and thus more favorable purchase intentions than individuals who are low in self-referencing (Debevec and Romeo forthcoming).

Researchers who have investigated self-referencing have focused their attention on its cognitive component. Most studies have induced self-referencing by instructing subjects to relate stimulus information to themselves (Bellezza 1984, Lord 1980), to think of personal experiences which relate to a stimulus (Bower and Gilligan 1979), or to picture themselves relative to stimulus information (Shavitt and Brock 1986, Yalch and Sternthal 1985).

In addition to the self's cognitive component, Rogers (1981) suggests that the self also has an evaluative or affective component which plays a role in the encoding of personal information. He feels that the self-referencing process has an emotional quality which the cognitive model overlooks and attributes enhanced memory of self-referenced information to both the cognitive and affective components of the self.

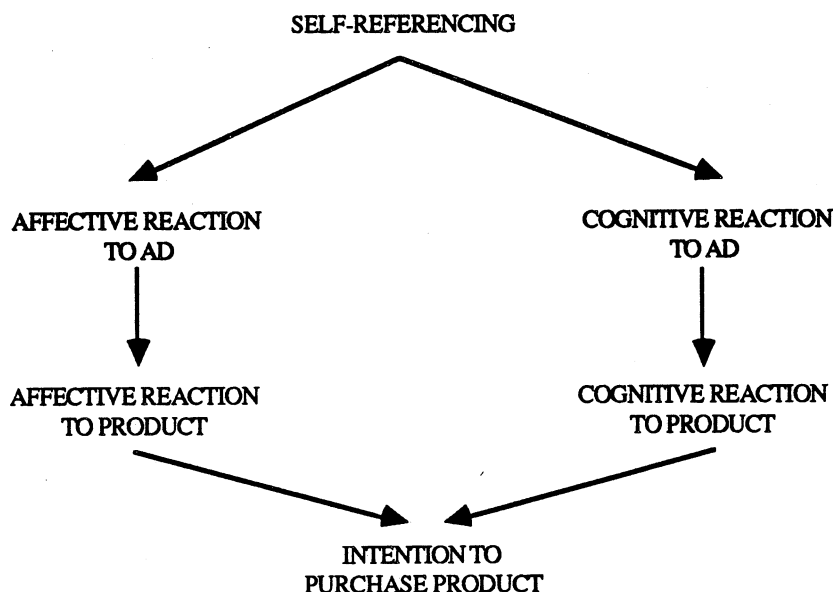

The Affective Component of Self-Referencing

The early buyer behavior models in consumer behavior emphasized the cognitive processing of information. The consumer was viewed as a rational decision maker, and thus economic motives were driving the purchase decision. Research studies focused on the cognitive reaction to persuasive communication and the subsequent effects on beliefs and attitudes toward the ad. More recent research in consumer behavior has given more attention to affective responses (feelings, emotions) to persuasive communications. Batra and Ray (1986) found that determinants of attitude toward the ad are not entirely cognitive-based; affective responses (ARs), related to moods, emotions, and feelings, mediate the acceptance of advertising. They proposed the following model:

ARs ---> Attitude_{ad} ---> Attitude_{brand} --->
Purchase Intention

Holbrook and Batra (1987) were also concerned with the role of emotions in mediating the effects of advertising. They noted that affective responses have been treated as a unidimensional construct (positive/negative) by past researchers and suggest that future studies should emphasize the multidimensional properties of this construct (e.g., include emotional responses such as fear, love, hate, sadness, etc.). Holbrook and Batra concluded that emotional responses to an ad mediate attitude toward the ad and attitude toward the brand. Edell and Burke (1987) found that both semantic judgments and feelings mediate attitudes toward the ad and brand.

FIGURE 1
Initial Self-Referencing Model

They noted that positive and negative feelings can exist at the same time.

As stated previously, much of the research in self-referencing has focused on cognitive reactions and could be summarized by the following model:

Yet, advertising research has shown that there are two processes guiding the responses to persuasive communications -- affective and cognitive. Thus, self-referencing may mediate purchase intention through two separate responses -- one affective and one cognitive. This model, which is outlined in Figure 1, is investigated here.

STUDY

Print ads for a fictitious soft drink, TWIST, were used as the stimuli in this study. Two visual treatments were developed. One ad featured a can of the soft drink beside a glass of the beverage, and the other was a scene of students playing tennis with a small insert in the lower right-hand corner showing students studying. Three verbal copy strategies were examined which were designed to encourage varying levels of self-referencing. The copy strategies were similar in content with the exception of pronoun variations which should have led to the reader to focus on themselves, similar others, or the product. For a more specific description of the copy in the ads, see

Debevec and Romeo (forthcoming). While subjects were expected to self-reference some of the ads more than others, past research suggests that self-referencing often occurs spontaneously (Shavitt and Brock 1986). Thus, in this study, the degree to which individuals actually self-referenced the ad they viewed was important, and not the composite reactions to individual ads.

Participants were 158 undergraduate junior and senior business students (100 female and 58 male) who were given partial course credit in an introductory marketing course for their participation. Students participated in the study by signing up for one of several sessions held outside of class time. Subjects were told that they would be evaluating a sample of articles and ads for a new magazine designed to appeal to college students. Each participant was given a packet which contained an article followed by the experimental ad described above, and a second article and ad. A series of questions followed each article and ad, but only those following the experimental ad are of interest here.

Dependent Measures

Self-referencing has been conceptualized and induced in prior research by instructing the subjects to relate the stimulus information to themselves (Bellezza 1984, Lord 1980), to think of personal experiences which relate to a stimulus (Bower and Gilligan 1979), or picture themselves relative to the stimulus information (Shavitt and Brock 1984, Yalch and Sternthal 1985). Two measures were used to assess the degree to which subjects self-referenced the ad and the product. One measure asked respondents as they were viewing the ad, whether they could picture

TABLE 1
LISREL Estimates of Lambda X

Variable	Initial Model	Affective Response to Ad	
		Positive Dimension	Negative Dimension
Good	1.445	1.414	
Happy	1.266	1.238	
Cheerful	1.405	1.381	
Pleasing	1.467	1.449	
Insulted	.928		1.704
Angry	.597		1.288
Irrational	.785		1.571
Repulsed	.606		1.202

Variable	Initial Model	Cognitive Response to Ad	
		Content Dimension	Quality Dimension
Relevant	1.329	1.318	
Interesting	1.597	1.586	
Exciting	1.353	1.338	
Entertaining	1.281	1.269	
Believable	.846		1.332
Realistic	.926		1.198
Informative	.735		1.011

themselves trying the product and the other measure asked whether they could picture themselves serving the product to a friend. Subjects responded to these questions on 7-point scales (1=not at all, 7=very much so).

Affective reactions to the ad were measured by giving subjects a list of words describing different kinds of feelings (good, happy, cheerful, pleasing, insulted, angry, irrational, and repulsed) and having them indicate on 7-point scales how characteristic each word was of how they felt while viewing the ad. The feeling scales were similar to the ones used by Holbrook and Batra (1987). Cognitive reactions to the ad were measured by asking subjects to rate the ad on 7-point semantic differential scales (relevant/irrelevant; interesting/uninteresting; exciting/boring; believable/unbelievable; realistic/unrealistic; informative/uninformative).

In order to determine affective reactions to the product, subjects were given a list of different kinds of feelings (special, happy, important, concerned) and asked to respond on a 7-point scale how they think the product would make them feel. Cognitive reactions to the product were measured by having subjects rate the product on 7-point semantic differential scales

(superior/inferior; useful/useless; beneficial/not beneficial).

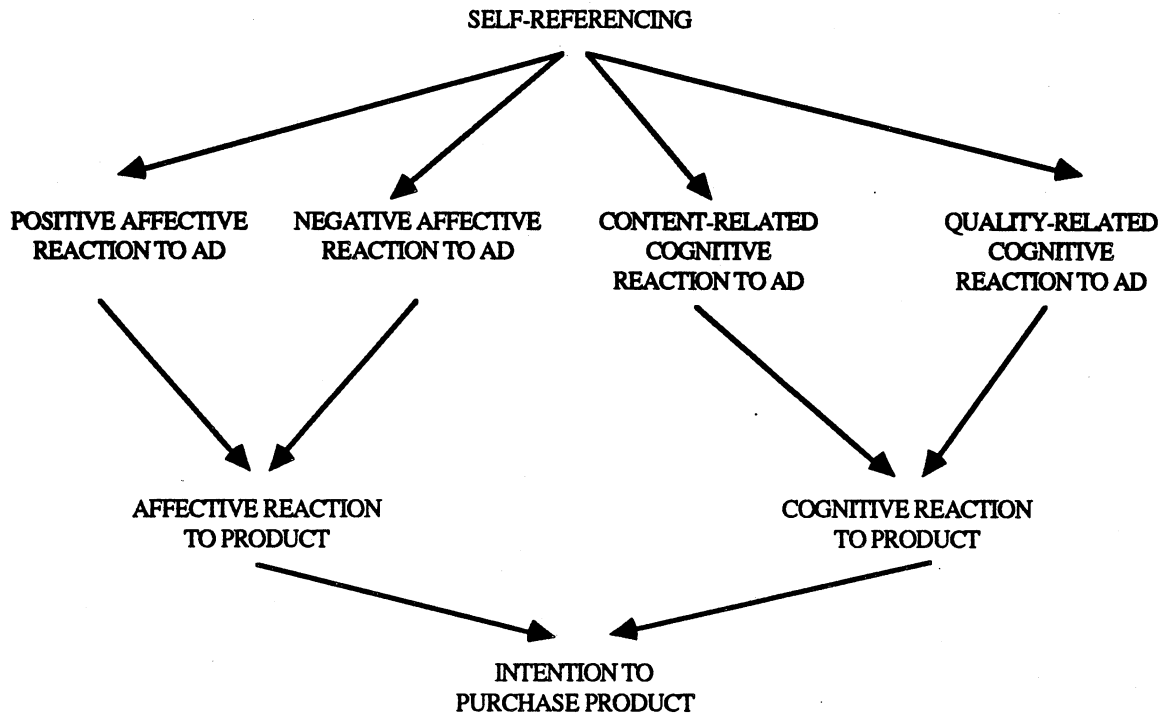

Finally, intention to purchase the product was measured by asking respondents if the product were available locally, how likely they would be to: 1) try the product, 2) purchase the product in a retail store, and 3) purchase the product in a bar or restaurant.

RESULTS

The model proposed in Figure 1 was investigated by performing a Confirmatory Factor Analysis using LISREL VI. In order to find the best fitting model, one modification was made. For both models, 158 cases were processed.

The first model investigated is outlined in Figure 1. The model's adjusted goodness of fit was rather low at .595 (Chi Square (df=293) =978.59), although it did show a significant improvement over a model which did not account for affective responses. An investigation of the LISREL estimates (maximum likelihood) of Lambda X indicated that two separate constructs might be present for the affective reaction to the ad and the cognitive reaction to the ad (see Table 1). For the affective reaction to the ad, the variables good, happy, cheerful, and pleasing appear to represent a positive dimension of feelings. The

FIGURE 2
Modified Self-Referencing Model

variables insulted, angry, irrational, and repulsed appear to represent a negative dimension. This finding is consistent with Edell and Burke's (1987) conclusion that positive and negative feelings can co-exist.

For the ksi variable cognitive reaction to the ad, the adjective pairs personally relevant, interesting, exciting, and entertaining seem to represent characteristics of the ad's content and the adjectives believable, realistic, and informative seem to represent characteristics of the ad's quality. Thus, it seems there should really be eight, not six, ksi variables which alters the original model to the modified model represented in Figure 2.

The increase in the adjusted goodness of fit for the modified model was .804 and significant at $p < .001$ (Chi Square $(df=271) = 379.53$). In addition, the LISREL estimates of Lambda X (see Table 1) that were low in the first model show considerable improvement. Thus, the addition of the two ksi variables in the modified model seems justified.

A check was also made to determine whether self-referencing does mediate purchase intention. Subjects were divided into two groups -- one high in self-referencing and one low in self-referencing. This was done by averaging the two self-referencing measures (coefficient alpha=.90). Subjects scoring greater than 4 on the scale were classified as high in self-referencing, while those scoring less than four were considered low in self-referencing. Then, each of the dependent measures was combined into a

composite measure and subjects who were low in self-referencing were compared to those who were high in self-referencing.

The results in Table 2 provide further support that self-referencing influences affective as well as cognitive evaluations of the ad and product. Respondents who were high in self-referencing had significantly more favorable cognitive and affective attitudes toward the ad and product than those who were low in self-referencing. These results suggest that in a persuasion context, self-referencing is a desirable outcome.

DISCUSSION

Since self-referencing has been shown to have a favorable impact on persuasion, it is important for marketers to have an understanding of the self-referencing phenomenon. This study has provided some insight into the causal influence pattern of the self-referencing construct.

The model developed suggests that self-referencing influences both cognitive and affective evaluations of the ad and product. Self-referencing does not appear to encourage individuals to only evaluate the stimulus ads on a cognitive level as much as the literature suggests. Instead, the results indicated that self-referencing may influence both a positive and negative affective response to the ad, which, in turn, influences affective responses to the product. Thus, as Rogers (1981) has suggested, the enhanced memory of self-referenced information may be due to

TABLE 2
Mean Responses to Dependent Measure for Low versus High Self-Referencing Subjects

Dependent Measure	Coefficient Alpha	Low S-R (n=89)	High S-R (n=69)	p value
Negative affective reaction to ad	.901	2.78	1.46	<.001
Positive affective reaction to ad	.894	5.22	6.52	<.001
Content-related cognitive reaction to ad	.867	2.89	4.90	<.001
Quality-related cognitive reaction to ad	.775	4.00	5.23	<.001
Cognitive reaction to product	.895	2.07	2.89	.003
Affective reaction to product	.855	3.49	5.24	<.001
Purchase Intention	.850	2.49	5.02	<.001

both the cognitive and affective components of the self.

Additional research is needed to provide more insight into the dimensions underlying the self-referencing construct and how self-referencing may be measured in order to understand more fully its role in persuasion. A simple measure (based on how self-referencing has been induced in prior research) was utilized in the present study. Yet, it is likely that self-referencing in a communications context is multidimensional since individuals may self-reference more than one component of a stimulus ad. For instance, viewers may relate to a product and its benefits, to a spokesperson featured, to characters portrayed in an ad, to a scene depicted, or to music or voices (in the case of a radio or television commercial). Thus, there are visual, verbal, and auditory stimuli which may or may not encourage a favorable self-reference response. Scaled measures could be developed to tap into self-relevant responding to a variety of ad dimensions.

The self-referencing construct and its measurement may also be further refined through the thought listing procedure (Greenwald 1968). Respondents' reactions to an ad can be gathered after exposure, and self-relevant thoughts may be identified and coded according to their focus (whether toward the product, ad, spokesperson, etc.), valence, and as either affective or cognitive (if possible). Scaled measures might then be developed to assess the extent to which

self-referencing occurred and the merit of the present model could once again be evaluated.

Past research has not attempted to directly measure self-referencing, but instead has offered methods to encourage it with the assumption that subsequent group differences are a reflection that self-referencing has occurred. Thus, it is a challenge to develop a scale to measure the construct, particularly in a communications context where individuals may be responding to a variety of stimuli.

This study provided initial support for identifying the causal role of self-referencing in persuasion. Broad generalizations from the data reported here cannot be made given the previous discussion and limitations in the methodology (i.e., a student sample was used, data was collected in an experimental setting, only one product class, soda, was investigated). Future research is needed to determine if self-referencing influences affective evaluations of the ad and product across a more diverse range of product categories. It may be possible that for certain product categories where the risk of making a wrong decision is high and many technical features need to be considered (e.g., personal computer, television set), self-referencing will only have an influence on cognitive reactions.

What You See Is Not Necessarily What You Get: The Effects of Pictures and Words on Consumers' Inferences

Ruth Ann Smith, Virginia Polytechnic Institute and State University

For some time, consumer researchers have demonstrated a strong interest in the inferences people form when processing advertisements. Inferences are defined here as conclusions derived from a set of premises using a rule relating the premises to a conclusion in a subjectively logical fashion (Hastie 1983). Consumers' inferences tend to follow everyday, rather than formal, rules of logic and they therefore have the potential to result in incorrect beliefs about product attributes (Harris 1977; Harris et al 1980).

Moreover, inferences may occur automatically when an advertisement is processed and they are integrated with explicit claims in a single representation (Bransford and Franks 1971; Hayes-Roth 1977). Thus, consumers are unlikely to be able to discriminate inferences from explicit product claims with the result that the (possibly) misleading inferences will exert a material effect on purchase decisions. Concern about this problem is exacerbated by advertisers' growing reliance on abstract product claims that do not require substantiation, but which may be subject to several interpretations (Shimp 1979).

PAST RESEARCH ON CONSUMERS' INFERENCES

As I have noted elsewhere (Smith 1991), the large majority of research on consumers' inferences focuses on the influence of the verbal claims in advertisements (cf Ford and Smith 1987; Huber and McCann 1982; Johnson and Levin 1985; Meyer 1981). Minimal effort has been directed toward examining the effects of nonverbal ad components, or the combined effects of verbal and nonverbal elements, despite the fact that advertising relies heavily on pictures, music, nonverbal sounds, color, and even odors (scratch and sniff magazine inserts, for example) in addition to copy.

In a study designed to begin to remedy this gap in the literature, I examined the effects of both pictures and words on consumers' inferences. The results indicated that consumers do form inferences based on pictorial product claims, and that these visually-based inferences tend to follow rules of covariation in a manner similar to verbally-based inferences. Moreover, I found that when pictures and words in an ad convey information about different product attributes, the picture claim tends to dominate inference formation (Smith 1991).

There are at least three important reasons to further investigate picture-based inferences. The first of these reflects a public policy concern. That is, even if the verbal claims in an advertisement are absolutely correct, the pictures may still be misleading. This possibility became very real to me several years ago when I saw a television commercial for a sweepstakes associated with some product (which I can't recall). The grand prize was \$1,000 per month for life and the voiceover was completely unambiguous in making

this claim. The visuals, however, depicted a fabulously wealthy couple living it up on the Riviera. I found myself fantasizing about the great life I would have if I were the winner, until I suddenly realized that \$1,000 per month is actually a very modest amount.

Second, when pictures and words are combined in a single stimulus, the pictures tend to be relatively more salient, and therefore attract a disproportionate amount of processing capacity (Taylor and Thompson 1982). This would imply that pictures would also be disproportionately influential on the meaning (including inferences) extracted from an ad. My finding that pictures drive inferences when they convey an attribute different from the copy is consistent with this proposition (Smith 1991).

Third, inasmuch as all media except radio have the potential to combine pictures and words in a single stimulus, it is artificial to restrict attention to the effect on inferences of verbal claims alone. (And even radio can incorporate some nonverbal elements such as music and nonverbal sounds.) It seems intuitively plausible that consumers' inferences are influenced by the gestalt of all the ad components, not just the copy. For all these reasons, ignoring pictures when studying consumers' inferential processes will result in an incomplete understanding of how consumers derive meaning from advertisements.

Research investigating the impact of pictures alone, however, is likely to suffer from the same limitations as that considering only copy-based inferences. As noted above, it seems plausible to suppose that an advertisement is processed as a unit composed of a variety of verbal and nonverbal components. Thus, the appropriate direction for future research on consumers' inferences would be to examine the total effect of pictures and words on the meaning consumers extract from advertisements. Some thorny measurement issues must be resolved, however, in order to pursue investigations of this type.

MEASURING INFERENCES

Much past research on inferences, both visually- and verbally-based, has employed dependent measures that are potentially reactive. That is, consumers' inferences about product characteristics may be formed spontaneously when an ad is initially processed or they may be prompted later by the dependent measures themselves. Inferences of the latter type are derived deductively from knowledge of the product category and do not necessarily indicate the influence of a particular advertisement on brand beliefs. It is clear that consumers draw this type of inference in natural settings, and therefore research on the processes leading to their formation is valuable. Because product category knowledge includes information from various sources, however, such research would not permit one to evaluate the specific brand inferences a consumer forms on the basis of a particular advertisement. If this is the researcher's

interest, it is critical to use dependent measures that do not prompt inferences after exposure to the ad.

Kardes (1988) has developed such a procedure for evaluating verbally-based inferences. His approach involves presenting subjects with pairs of product claims of the form "A implies B," and "B implies C." A conclusion of the form "A implies C" is also included with some of the claims pairs, but excluded for others. A recognition task is used to determine whether or not the conclusion is inferred when not explicitly stated in the stimulus.

That is, a "hit," or a correct recognition of a previously presented conclusion can be attributed to a simple retrieval process. "False alarms," however, or incorrect recognitions of conclusions that were not presented, would be indicative of inferences derived from the explicit claims. Kardes (1988) reported that inferences about missing conclusions (measured as subjects' recognition confidence for false alarms) were strongest when consumers were knowledgeable about the advertised product, and when the conclusion was logically related to the explicit claims.

Kardes' (1988) approach employs verbal dependent measures to assess the inferences that consumers derive from verbal claims. The feasibility and appropriateness of using this procedure to evaluate inferences derived from pictures, or a combination of pictures and words, poses some problems. With respect to feasibility, developing pictures that unambiguously convey claims of the type "A implies B" may be quite difficult. Even very simple pictures (black and white line drawings, for example) are subject to multiple interpretations. Any researcher who has suffered through the pretesting of visual stimuli designed to communicate a discrete concept (e.g. fast pizza delivery) can attest to the varied meanings that viewers extract from pictures. My own attempts to develop pictures that would clearly communicate the concepts in Kardes' belief statement sets without benefit of verbal labels have been noteworthy only for their lack of success.

Second, some concepts are simply not amenable to pictorial representation. For example, the statement, "Intestinal disorders often cause a loss of appetite," which was included in one of Kardes' belief statement sets, seems to defy pictorial representation. While I can easily imagine my negative reaction to food when my stomach is upset, I cannot imagine a picture that would convey that feeling.

Third, people have a remarkable ability to recognize pictures. Shepard's (1967) findings clearly demonstrate that accurate discriminations between new and old pictures can be made after lengthy intervals of time and for very large stimulus sets. Because their surface structure is so enduring in memory, the incidence of false alarms for pictorial claims would probably be very small compared to that for verbal claims. It would be impossible to determine, however, if this were due to the absence of inferences or superior memory for the specific pictures that constituted the claim set.

Assuming these difficulties could be overcome, the issue of appropriateness must be addressed.

Specifically, the question arises as to whether or not verbal recognition items should be used to assess picture-based inferences. As noted above, the persistence of the surface structure of pictures in memory would seem to argue against using visual recognition test items to assess visually-based inferences. In addition, there is no compelling reason to expect that either the form of processing (imagery of discursive) or nature of the mental representation of information (verbal or visual) is dependent upon or dictated by the form of the original stimulus. MacInnis and Price (1987) argue that "The well-substantiated ability to move from words to pictures and pictures to words suggests that there is a representation in memory that encompasses both" (p. 474).

This perspective seems consistent with the earlier suggestion that the components of advertisements are processed as a unit, rather in isolation from one another, and that the overall meaning is stored in a unitized representation. If so, these meanings should be equally accessible regardless of the form of the recognition items. Moreover, given that the proper focus of inference research is the total impact of all ad components on the meanings consumers derive, the particular form of the dependent measure (visual or verbal) should be of little concern as long as the measures tap the stored meaning of the ad. In view of the problems posed by the persistence in memory of the surface structure of pictures, however, verbal measures would seem to be the preferable alternative.

EVALUATING THE EFFECT OF PICTURES AND WORDS ON INFERENCES

I have argued that future research on consumers' inferences should properly focus on the combined impact of visual and verbal ad claims, rather than assessing the effect of either in isolation. Moreover, I have advocated adapting nonreactive measures, modeled after that developed by Kardes (1988), in such investigations. How specifically might these prescriptions be put into practice?

First, suppose that subjects were presented with the following verbal propositions (Kardes 1988):

- (1) Stresstabs contain B vitamins. (A implies B)
- (2) B vitamins give energy. (B implies C)

The conclusion, which could either be explicitly stated or omitted from this stimulus, is that:

- (3) Stresstabs give you energy. (A implies C)

Given only this verbal information, subjects are likely to incorrectly recognize (3) when it is not explicitly stated. The recognition confidence for the conclusion when only verbal information is presented could serve as a benchmark for evaluating the effect of combining these verbal claims with pictures.

For example, now suppose that claims (1) and (2) were presented together with a background

photograph of people engaged in an active sport, such as a volleyball game on a beach. By itself, such a picture would be likely to elicit a variety of interpretations about the product's characteristics, one of which might be that it gives you energy. When combined with the verbal claims, however, it seems plausible to hypothesize that the recognition confidence of the omitted conclusion, (3), would exceed that of consumers exposed to the verbal claims without the picture inasmuch as the picture reinforces the conclusion. That is, the combination of the pictures and the copy is likely to result in stronger brand beliefs than either by itself. This hypothesis could easily be investigated using Kardes' (1988) measurement procedure with the recognition test items presented in verbal form.

Even more interesting would be to examine the effect of verbal claims and unrelated pictures on inferences. For example, assume that claims (1) and (2) were presented along with a picture of a muscular man and a slender, fit woman. The verbal claims logically imply the conclusion (3), but the picture suggests a different product benefit--physical fitness--that is not logically implied by the verbal claims, and in fact may be untrue. Given the relatively greater salience of pictures compared to words when the two are combined in a single stimulus, it would be hypothesized that recognition confidence for conclusion (3) would be weaker than for the incorrect conclusion and also weaker compared to the other two conditions described. Once again, verbal recognition test items would seem to be appropriate to evaluate this prediction.

CONCLUSION

Despite some formidable measurement problems, research on the effects of verbal and visual advertising claims on consumers' inferences has progressed. To date, however, this research has been limited by its focus on evaluating the isolated effects of either copy or pictures, while failing to consider the overall impact of the two on consumers' inferential processes. It is argued that this shortcoming can be remedied by adapting Kardes' (1988) nonreactive measure of verbally-based inferences to assess the inferences derived from the combination of pictures and words.

Consumer Stereotyping: The Cognitive Bases of the Social Symbolism of Products

Eva M. Hyatt, Appalachian State University

ABSTRACT

This paper provides a framework for the investigation of the cognitive processes underlying the formation of judgments regarding products typically owned by members of different social groups, termed consumer stereotyping. It is an attempt to extend the cognitive perspective to the social realm of consumption. Based on the well-established notion that products provide symbolic, social meaning about their owners, principles from the social cognition literature are extended to explain how and why such consumer stereotypes are formed. This proposed line of research provides a way to empirically test many of the theoretical concepts that have been developed regarding product symbolism.

INTRODUCTION

Most of the growing number of studies taking the cognitive perspective in consumer research deal with the various cognitive processes (attention, encoding, storage, retrieval and inference-making) as they apply to advertising or product information (e.g., Burke and Srull 1988; Johnson and Fornell 1987; Sujan and Bettman 1989), and not to information about consumers themselves. That is, the cognitive processes driving the formation of social judgments regarding product ownership by consumers have not yet been investigated. This paper brings together findings from various areas of cognitive psychology, social cognition, and consumer behavior to provide a framework for a new line of research termed consumer stereotyping which addresses these issues.

The process of consumer stereotyping may be defined as the formation of generalizations about consumption objects possessed or used by members of a particular social category. More specifically, it is based on the well-established idea that people associate ownership of certain products with membership in a certain social group. Such products take on symbolic qualities associated with the group and become descriptive of the group members. From this perspective, the consumption objects owned and used by consumers are viewed as social traits and behaviors. These consumer traits become organized in memory so as to affect later processing of related information. This viewpoint has been neglected in the field to date by consumer researchers utilizing cognitive theory and methods. Instead, they view the products people consume as inanimate objects or bundles of attributes with little concern for their symbolic significance. This is an attempt to extend the cognitive perspective to the social realm; i.e., to try to understand some of the mental processes driving the social symbolism of products.

BACKGROUND LITERATURE

Before developing the concept of consumer stereotyping in more detail, a distinction needs to be made between it and the well-known concept of

segmentation. Segmentation is the process of dividing a market into consumer groups who merit separate marketing mixes based on some similar characteristic(s). This is similar to consumer stereotyping in that both concepts involve the categorization of consumers into homogeneous groups according to some descriptor variable(s). However, segmentation is a managerial function aimed at gaining competitive advantage, whereas consumer stereotyping is a natural process people engage in due to cognitive limitations. The investigation of consumer stereotyping focuses on the *cognitive processes underlying* the association of products with various social groups and the biases in information processing that result.

The following literature review brings together findings from various areas of research that are integral to the conceptualization of consumer stereotyping that follows.

Product Symbolism

There is an established notion in the marketing and consumer literatures that products provide symbolic meaning to and about their owners above and beyond their functional uses (Levy 1959; McCracken 1988; Mick 1986; Solomon 1983). This symbolic meaning is often social in nature. In this sense goods and services are a type of social tool that serve as a means of communication between people (Grubb and Grathwohl 1967). The essence of a product, then, becomes not the physical product itself, but the relation between the product, its owner, and the rest of society. This is especially true of socially visible products that are more central in the process of social interaction among people.

These arguments support a fundamental assumption of the notion of consumer stereotyping-- that the products people own comprise items of social information about them. That is, a product is a socially perceivable trait or an identifiable unit of social information about its owner. Hence, consumers have product-ownership "traits" in addition to personality traits. Product-ownership traits represent the "extended self" (Belk 1988). Belk's conceptualization of the extended self posits that consumption objects actually become part of the self, much like personality traits. The extended self research deals with how people encode who they are into external expressions (i.e., product ownership), while consumer stereotyping research is concerned with how observers decode external product ownership information into meaningful impressions of the consumers of those products.

Product ownership, then, can be studied using social perception methods. The study of consumer stereotyping in particular is concerned with investigating the social perception of products that are typically associated with membership in various groups. At this aggregate level, perceived patterns of

product usage by members of various social groups can be ascertained and investigated in much the same manner as are the perceived personality and behavior patterns of such groups studied by social stereotyping researchers.

Categorization and Schema Theory

The organization of social information into categories provides the basis for giving it meaning and plays a central role in social perception. Rather than hold each discrete piece of information separately, people make their social world manageable by categorizing (Ostrum, Pryor, and Simpson 1981). People do not see others simply as individuals who perform isolated behaviors, but as group members exhibiting patterns of behaviors. This simplification of a complex world is the major task of category systems: to provide the maximum amount of information with as little cognitive effort as possible (Rosch 1978).

Rosch has posited a model of categorization based on schema theory. Her research involves the semantic meaning of concrete objects, but can shed light on social categorization as well. This model pictures categories as organized around salient prototypes (Rosch 1975). That is, the internal structure of a category is composed of a central meaning or prototype based on the clearest instances of that category, surrounded by other less representative members. This results in varying degrees of membership in every category, with members being somewhat good or bad representatives of the category according to their degree of deviation from the prototype. The prototype itself, which may or may not exist in reality, represents the mean or central tendency of all attributes relevant to category membership, with more salient attributes contributing more to this average. Thus, a network of attributes is formed, with fuzzy edges of categories overlapping with each other and the more prototypical core remaining distinct. Semantically, this implies that the prototype has more associative links to the category label than less representative members (Rosch and Mervis 1975).

Social categories, or groups of people based on some descriptor variable such as gender, race, or social class, are more heterogeneous than are natural object categories. That is, the underlying internal structures and the formation and inference-making processes characterizing social categories are much more wide-ranging (Lingle, Altom, and Medin 1984). Social categories often form overlapping classes which may include some of the same individuals as members in several different categories. Any one person can be categorized into a large number of groups, and any one attribute of that person, such as ownership of a particular product, can be associated with many different groups.

An attribute which is used to assign an individual to a particular category is known as a membership attribute. So when someone performs some behavior or exhibits some trait that is very typical of belonging to a particular group, he or she is quickly compared to the stereotype representing that

category and, if the similarity between attributes is high enough, is assigned to that group. Inferences are then made about the likelihood of other associated attributes being present. These are known as inference attributes, and are ascribed on the basis of category membership. Both processes occur in consumer stereotyping.

A category, as described by the prototype model, is a type of schema. Schemas lead to expectations about the structure and content of incoming information (Hastie 1981; Fiske and Taylor 1984). Schema theories deal with the differences between actual incoming stimulus information and its abstract mental representation. Incoming information is interpreted in light of what it should look like according to the schema that is invoked; i.e., a schema is a normative structure against which incoming data are matched (Taylor and Crocker 1981).

Such information is then encoded and stored along with category labels according to this schematic organization. During retrieval, other information in the same schema or in closely related schemas is easily confused with the original information, so that as time goes by, the original facts and details become blurred with schema-generated associations and inferences, and incorrect generalizations or biases can result (Hamilton 1981). This is especially the case when a particular descriptor or category label dominates the processing of information about someone, which seems to be the case with information regarding strangers or unfamiliar persons (Ostrum, Pryor and Simpson 1981). Less congruent or typical characteristics of that person may become less accessible in memory, thus forming the basis for stereotyping. For example, if I see a man wearing a sweat suit and running shoes (membership attributes), my schema for "athletic," along with my stereotype for "jock," may be invoked. Later, when recalling information about this incident, I may incorrectly remember that he was also carrying a gym bag and may forget the color of his hair. I may also infer that he was in good physical condition (inference attribute). Any specific piece of information can be evaluated, then, as either incongruent, congruent, or irrelevant with reference to the schema, and will be differentially recalled accordingly (Hastie 1981).

Stereotyping

The concept of a stereotype was originally conceived of as a "picture in our head" of a typical member of some social group that has been handed down to us by our culture and used to rationalize and defend our social position, as well as to simplify the confusion of the outer world (Lippmann 1922). More recently, it has been established that the normal cognitive processes discussed thus far are adequate for explaining the existence of stereotypes. No motivational construct is needed to explain the biases that exist in social information processing (Taylor, Fiske, Etcoff and Ruderman 1978; Taylor and Crocker 1981). They occur simply because people take shortcuts (due to processing limitations) in the interest of cognitive efficiency, and use only the most readily available, consistent, and salient information when

making judgments. Incoming social information is inevitably selected, simplified, and categorized according to certain invoked descriptor variables. This labeling produces biases in memory that lead to biased perceptions of various social groups (Allport 1954). A stereotype is, then, simply the social equivalent of the prototype, possessing all the attributes most typically associated with a particular group (Brewer, Dull, and Lui 1981; Fiske and Taylor 1984).

When processing incoming information about a particular group member, that particular descriptor variable or category label dominates the encoding, organization, and retrieval of information about that person as well as the inference-making process, so that certain characteristics of that person may become less accessible in memory, or may even be ignored altogether in the encoding process (Ostrum, Pryor and Simpson 1981). Social information becomes organized around the stereotype of the descriptor category, and the unique features of each group member are ignored. Different members of the same group are treated as equivalent through the use of shared labels, then, and cognitive energy and capacity is thus conserved (Cantor and Mischel 1979); however, this is at the cost of lost information and oftentimes incorrect generalizations (Taylor and Crocker 1981). When discrepant information is present, stereotype beliefs are much more likely to be broadened or new subtypes to be added to the network than they are to be thrown out or changed (Weber and Crocker 1983); i.e., stereotypes are very resistant to change.

CONSUMER STEREOTYPING

Each of the background topics just reviewed focuses on a different aspect of consumer stereotyping, but all are essential for a complete understanding. More specifically, product symbolism theory stresses the socially descriptive nature of products and their relationship to consumers. Categorization theory is concerned with the cognitive organization of information into categories around distinct prototypes. Seeing stereotypes as prototypes reflects the focus on the organization of information and points to the need to investigate what information about category members is accessible, to what degree, and why. Schema theory adds the idea that the mental representation of information within a category or schema is often different from the original incoming stimulus information due to biases in encoding. This is in turn reflected in the biased retrieval of information and in biased inferences made based on such information. Finally, the stereotyping literature looks at the heuristic nature of the stereotyping process, in which a salient descriptor variable dominates the processing of information in order to conserve limited cognitive space. All together we get a well-rounded picture of the cognitive view of the consumer stereotyping process. The major difference between the cognitive investigation of stereotyping in general and that of consumer stereotyping is that the attributes organized around the social stereotype are products or consumption objects owned/consumed by (or inferred to be owned/consumed by) group

members rather than personality traits or other behaviors. Thus, the goal in this proposed line of research is to ascertain whether people have product ownership stereotypes of consumers belonging to various social groups and, if so, how the cognitive processes resulting in such stereotypes operate.

Each consumer stereotyping incident involves the following cognitive processes. It begins with *exposure* to a member or members of a social group. For example, an observer might be waiting in line at the post office and overhear several men in front of him or her that appear to be friends. They are talking about an upcoming turkey shoot and one man is describing his new Winchester shotgun. As they leave they agree to meet Friday night at a local country saloon. The observer deduces that these are typical rednecks, and watches them leave the post office. He or she pays selective *attention* to traits/behaviors that might further confirm his or her deduction. One man climbs into a Ford pick-up as he reaches into his Levi shirt pocket for a dip of snuff. The other two men get into a Volvo and one man opens a bottle of Coke as his friend lights up a Marlboro cigarette.

Certain behaviors are ignored altogether, while others are *encoded* into internal representations and *stored* into long-term memory. All these processes are affected by a pre-existing stereotype of rednecks as a social category. If the observer later attempts to *retrieve* the stimulus information, certain biases in recall are likely to result, which in turn can affect *inferences* or further deductions made about the three men. A feedback loop is possible, in which the original stereotype can be affected and modified to better explain the situation.

The study of consumer stereotyping involves the investigation of expected findings regarding the major cognitive processes involved in group stereotyping: encoding of incoming information, storage or organization of information in long-term memory, and inference-making based on this information; i.e., it makes predictions regarding what kinds of biases are likely to occur in a stereotyping incident like the one just described.

Encoding

The encoding of information is the transformation of external stimuli into internal representations; i.e., the interpretation of incoming stimuli that are attended to. In a stereotyping incident more attention is paid to information that is either congruent or incongruent with the group stereotype. Less cognitive energy is required to encode information that is consistent with prior expectations since it readily fits into the existing cognitive structure, while more is required to encode and make sense of inconsistent information. For example, if I see a yuppie wearing a Polo shirt I can quickly assimilate this fact, whereas if he is drinking Busch beer I might have to think about what circumstances may have led to this atypical event. As a result, both pieces of information will be more accessible in long-term memory than will information that is irrelevant to group membership (e.g., he was also reading a copy of *TV Guide*).

One issue relevant to the encoding process is whether people engage in category-based (overall comparison with group stereotype) or piecemeal-based (attribute-by-attribute) processing. Category-based processing is more likely as the salience of the category label, the match between incoming product ownership information and category-based expectations, and the degree of short-term memory load increase (Fiske and Pavelchak 1986). Memory is much stronger and faster for category-based processed information. Thus, by presenting experimental subjects with group membership and product ownership information about a consumer, while varying such factors as salience of social group membership, congruence of product ownership profile with pretested expectations, and/or memory load task, and then measuring recall of congruent, incongruent, and irrelevant products, one could better understand the encoding processes underlying the social symbolism of products.

Organization

This involves the notion that information is organized into social categories centered around stereotypes. Since typical traits are closer to the stereotypical core, there are more links to them in the long-term memory network and thus should be relied on more heavily when new information is being stored (Cantor and Mischel 1979). For example, I have a node close to the center of my yuppie stereotype for BMW. Closely attached to this node may be places that the typical yuppie might drive to in his BMW, such as the country club to play golf or the symphony. Also close to this node might be the kinds of clothes that the typical yuppie might sport around town in. More typical products should also be retrieved easier, faster, and earlier. By measuring and comparing recall levels, reaction times, and order of recall for products of varying degrees of typicality, as well as collecting cognitive responses regarding which products helped subjects remember other products, some light should be shed on the internal structure of category representations concerning social consumption behavior.

Inference-Making

The process of gathering together information, interpreting that information, and making some judgment or inferring additional information is heavily influenced by preexistent expectations (Fiske and Taylor 1984). By knowing the category membership of an individual, people are able to draw inferences about unobservable attributes that may aid in the social judgment task at hand. For example, if I know someone is a yuppie (or categorize him as one), I may confuse information in my yuppie stereotype as being something I know about this fellow in particular so that I have a more complete picture of him. This can be studied by asking experimental subjects to infer additional products owned by profiled group members. Certain stereotyped patterns should emerge. Other types of inferences that are likely (depending on congruence of group membership and product ownership information) include intrusions of

stereotype-congruent products in recall measures, generalizations about product ownership from one group member to another, and certain affective responses.

CONCLUSION

The effects of consumer stereotyping have been proposed to be wide-ranging and diverse. By studying the cognitive processing of product ownership information about group members as has been suggested, a rigorous empirical investigation of the social symbolism of products is possible. This is especially needed in the field of consumer research at present in order to provide a balance with the heavy use of qualitative methods in symbolic research. Understanding the specific cognitive processes driving the social symbolism of product ownership would help to illuminate the valuable descriptive work that has already been done in this area.

A Model of the Scripting of Consumer Lovemaps: The Consumer Sexual Behavior Sequence

Stephen J. Gould, Rutgers, The State University of New Jersey

ABSTRACT

In order to more systematically explore the relationship of sexuality and consumption as linked in consumer lovemaps, this paper considers the issue of how such lovemaps are scripted. In so doing, it adapts a model developed in the field of sex research, the Sexual Behavior Sequence (Fisher 1986), and develops the "Consumer Sexual Behavior Sequence." The stages of the model are outlined in terms of various forms of sexually-related consumer behavior, and finally implications for a research agenda are discussed.

Now after a girl ...has manifested her love to him by the various outward signs..., the man should make every effort to gain her over. When the intentions of the girl are known..., the man should begin to make use of her money, an interchange of clothes, rings, and flowers should be made...And finally at the time of giving her some betel nut, or receiving the same from her, or at the time of making an exchange of flowers, he should touch and press her private parts, thus bringing his efforts to a satisfactory conclusion (*The Kama Sutra* 1966, p.160).

Much as the above quote illustrates, not only is it apparent that "Our everyday world abounds with symbols of affection," as Ernest Dichter (1964, p.155) once observed, but also that the whole lovemaking process is pervaded by acts of consumption. In fact Dichter's name is often associated with sexuality in relation to his practice of "motivation research" in which he studied the basic underlying and often hidden motivations of consumers, including the sexual among others. For example, he noted the 'earning' virility of men who give more expensive furs to women (1960) and explored the sexual implications of various forms of fashion for both men and women (1989). Moreover, as long ago as the 1930's, the sociologist, Paul Lazerfeld, had noted in similar fashion the erotic impact of female shoe salespeople upon male buyers (Fullerton 1990). Yet, although sexuality seems to have implications of mythic proportions for informing both consumer research and behavior, relatively little academic research has explored the sexual-consumption relationship in a systematic or theoretical manner (Gould 1991). This paper aims to remedy the problem by first exploring and formulating the theoretical links between sexuality and consumer behavior and then to set a research agenda for empirically investigating these links.

CONSUMER LOVEMAPS

The central theoretical construct of the sexuality and consumption relationship is the consumer lovemap (Gould 1991), derived from the more general construct of sexual lovemaps. A

lovemap has been defined by Money (1986a, p.290) as:

A developmental representation or template in the mind and in the brain depicting the idealized lover and the idealized program of sexueroetic activity projected in imagery or actually engaged in with that lover.

In general, a consumer lovemap of whatever type may be defined to include as a subset those aspects of the more general lovemap (Gould 1991) which involve the imaging, purchase and use of product-objects directly used in engaging in lovemaking or attracting a sexual partner (e.g. sexual toys, sexy clothes), forming a loving relationship, engaging in person service sexual exchange (e.g. prostitution), or consuming sexual ideas (e.g. reading sex manuals or watching videotapes to learn new sexual practices). However, much of sex research deals with pathological or paraphilic lovemaps (Money 1986a). In contrast to paraphilia, normophilia represents erotosexuality in conformity with a society's standards (Money 1986a). However, we should not think of paraphilia-normophilia as merely categorical opposites but rather as composing the poles of a continuum. In this regard, Simon (1989) notes that one of the greatest although neglected contributions of Freud was his emphasis on the continuities between what is viewed as normal and abnormal. In summary, the lovemap view leads us to consider two things in the present context: (1) consumption objects can become part of one's lovemap in that one desires and seeks them in engaging in the lovemaking process, and (2) insight regarding the paraphilic use of goods may spill over regarding normophilic use and vice versa. Thus, while much of our focus here will be on normophilic behavior, consumer behavior can be seen to be inclusive of pathological paraphilia as well as normophilia, although as consumer researchers we need not be rigidly restricted to these normative views.

PROCESSES UNDERLYING THE SCRIPTING OF THE CONSUMER LOVEMAP

The macrolevel forces of evolution and sociocultural patterning may be seen as the larger forces underlying an individual's sexual behavior and lovemaps (Fisher 1986). Such behavior may be viewed in terms of both unconditioned motivation, largely determined by biological evolution, and conditioned (acquired) motivation, largely determined by sociocultural factors (Fisher 1986). In this context, much of consumer behavior may involve the conditioned and scripted use of products (e.g. attractive clothing; erotica) to obtain and/or enhance what we might call the 'relatively' unconditioned

erotic stimulation provided by sexual arousal and intercourse, i.e. goods play into and help shape the ways our biological desires come to manifest and express themselves. Moreover, classical conditioning which pairs an object with an unconditioned erotic stimulus can make that object into a conditioned erotic object (Fisher 1986). Sexual scripts involving these pairings develop in terms of sexual involvement rooted in the psychological magnification of intense sexual experiences and come to comprise automatic rules of perception and behavior (Mosher 1988). Thus the consumer is led to consider a sexual stimulus, such as an erotic movie or type of clothing, in terms of a goodness-of-fit between it and his or her script. Thus, products which fit a script through conditioning or suggest aspects of one are more likely to be used than are others, particularly where sexuality is salient. Mosher using the example of pornography notes that these scripts become very specific so that market-signals conveying specific pornographic products are used to reach consumers (e.g. "water sports," "AC/DC") and some scripts are also sex-negative in leading to avoidance behavior. However, as Mosher further notes, scripts are incomplete and conditional and thus are subject to change. In this regard, marketing may be seen to influence sexual scripts, especially to the extent that it persuades consumers to inject marketed products into the lovemap. For example, advertising which has classical conditioning properties (Gorn 1982) may be especially effective in this regard and thus should be viewed as creating conditioned erotic objects or fetishes when it pairs 'relatively' unconditioned sexy spokespeople with products.

THE SEXUAL BEHAVIOR SEQUENCE AS A CONSUMER BEHAVIOR SCRIPT

This section takes a basic model, the Sexual Behavior Sequence, which has been used in Western social psychology and sex research and develops it into a model for sexually-related consumer behavior. In general, sexual interaction has been viewed in various approaches as occurring in stages or steps which compose a basic sexual script and each stage of which may be seen to possess its own script. The most basic approach involves three stages: (1) proceptivity as the interplay between male and female in preparation for the sex act, (2) acceptivity as the actual process in which two individuals accept each other in the sex act, and (3) conception which may or may not occur and represents both a sequel to lovemaking as well as a component (Money 1986b). Relatedly and more complexly, the Sexual Behavior Sequence models sexual behavior in terms of erotic stimuli which lead to arousal, affective, cognitive and imaginative response dispositions, which in turn lead to evaluative and expectational processes, preparatory sexual behavior, eventual sexual behavior and outcomes as feedback (Fisher 1986). This model also may be viewed as capturing the dynamics of any single sex act as well as defining the parameters of an individual's sexual development over time. Eroticism aroused in the marketplace, such as through sexy ads or movies, may be seen as informing the whole

behavior sequence, especially in terms of imaginative and expectational processes, as well as standing as distinct 'sexual events', themselves.

The Sexual Behavior Sequence model will be used as the basis for a model shown in the Figure of what can be called the Consumer Sexual Behavior Sequence. The model also reflects the stages of the sexual act outlined by Money (1986b) as well as the three proceptive steps noted by Freund and Blanchard (1986), i.e. (1) location of a sexual partner, (2) pretactile interaction (e.g. looking) and (3) tactile interaction. The proceptive stage should also be viewed as including an even more preliminary step, prior to locating a partner, i.e. setting the stage and preparing oneself for a potential partner in terms of such things as selecting methods of birth control and making oneself sexually attractive (Fisher 1986).

Erotic Stimuli

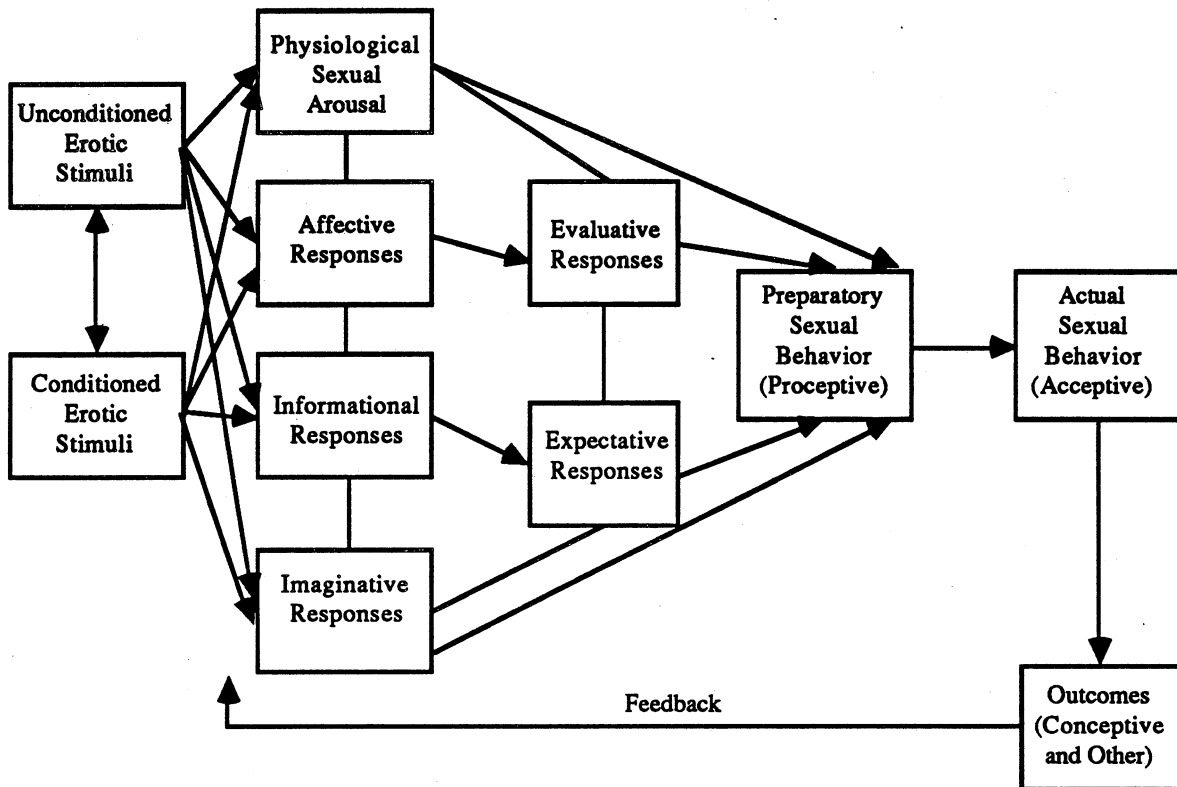

As noted above there are two types of erotic stimuli: unconditioned and conditioned. According to Fisher (1986), unconditioned erotic stimuli cues lead to unlearned sexual physiological responses. These stimuli involve tactile stimulation of erogenous zones and also possibly the effects of pheromones, chemical secretions which act as sexual attractants. Conditioned erotic stimuli seemingly can involve just about anything which gets paired with unconditioned stimuli (Fisher 1986). Consumer activity serves both as a major erotic conditioning force and paired conditioned stimulus in peoples' lives. For example, if one sees a sexy commercial for a product and becomes sexually aroused, it is likely that the advertised product will become marked with sensual feelings, perhaps as a function of the number of times it is seen. Advertising along with film, books, and other representations of sexual behavior and/or sexual-like behavior, including pornography, may also be seen as providing vicarious sexual experiences (Kelley, Dawson and Musialowski 1989) which may stand by themselves as erotic experiences or lead to various erotic experiences later on. This culturally produced sexual conditioning is experienced in our postmodern era "as a marketplace of expectations" in which different versions of the sexual are encountered by different versions of the self (Simon 1989).

Response Dispositions

The Sexual Behavior Sequence model suggests that certain response dispositions mediate the effects of sexual stimulation on sexual behavior (Fisher 1986; Fisher et al. 1988). As discussed in the following sections, these include physiological sexual arousal, affective, and informational (beliefs and expectancies)/fantasy or imaginal responses.

Physiological Sexual Arousal. Physiological sexual arousal occurs in response to both conditioned and unconditioned stimuli (Fisher 1986). Consumer behavior activities can be seen to produce and/or interact with physiological sexual arousal in terms of the following: (1) consumer terms: intentional (e.g. the use of pornography in which consumers deliberately seek to manipulate their own sexual

FIGURE
The Consumer Sexual Behavior Sequence

- ↔ Indicates strong joint effect on other variables
- Indicates primary relationship
- - - Indicates secondary relationship

arousal) or unintentionally and/or incidentally where individuals become aroused in the course of consumer activity (e.g. being aroused by a salesperson where the customer lacked any motivating thought prior to the sales encounter of seeking to be aroused), (2) marketer activity: deliberately induced (e.g. 'relatively' unconditioned attractive models in an ad are paired with conditioned product stimuli to produce both arousal and desire for the product) or unintentionally induced (e.g. a consumer uses a product in the context of a sexually arousing encounter and the product enters his or her lovemap as a conditioned arousal stimulus without any intention or motivation at all on the part of the marketer).

Affective-Evaluative Responses. In the Sexual Behavior Sequence, positive or negative affect mediate evaluative approach/avoidance responses to preparatory sexual behavior. Here we will consider two normophilic traits or styles related to affect: (1) erotophilia-erotophobia and (2) lovestyles.

(1) **Erotophobia-Erotophilia.** Fisher (1986) focused on the trait of erotophilia-erotophobia as being particularly important in affective-evaluative responses to potential sex acts. As the terms suggest, erotophobia represents an aversive view of sexual behavior and erotophilia represents a positive view. This trait has been operationalized as the "Sexual Opinion Survey," (e.g. "Erotica (sexually explicit books, movies etc.) is obviously filthy and people should not try to describe it as anything else") (Fisher et al. 1988). Research assessing erotophobia-erotophilia has found among other findings that erotophobic individuals were less likely to learn contraceptive information, to engage in breast self-examination, to engage in preventive behaviors with respect to sexually transmitted diseases, to use contraceptives regularly, to respond positively to erotic films, and to anticipate sexual behavior (Fisher et al. 1988).

(2) **Lovestyle.** Lovemap research has traditionally taken place within the field of clinical

sexual research with a heavy though not exclusive emphasis on biological factors (e.g. Money 1986 a,b). However, love, as studied in social psychology especially as expressed in terms of lovestyles or approaches to love and based on individual differences (Lee 1973), is related to sexuality and thus should be recognized as an aspect of lovemaps. Perhaps, the most well-researched and compelling theory of love centers on Lee's (1973) typology of six types of love. Within Lee's typology, Eros represents romantic, passionate love. The other types of love styles are: Ludus (game playing love with diverse partners), Storge (friendship love), Mania (possessive, dependent love), Pragma (pragmatic, or shopping list love - love shopping) and Agape (nondemanding, selfless love). In terms of implications for consumer behavior, Woll (1989, p. 499) reports that the erotic lover (as indicated by a high score on the Eros dimension of the Love Attitudes Questionnaire) was likely to agree with the statement, "I like the idea of having the same kinds of clothes, hats, plants, bicycles, cars, etc., as my lover does." This clearly has implications for consumer behavior in terms of lovers' lovemap congruence, product portfolios and self-concepts, although according to Woll it is not clear whether this characteristic of the erotic lover is central to or incidental to this love style. As another example, the Pragma lover was cited by Hendrick and Hendrick (1986) as being the one who uses criteria matching and who is likely to be a "computer mating" person. Thus, the Bernard and Adelman's (1990) consumer research study of an introduction service probably largely involved Pragma consumers although they did not frame their study in this way.

Information-Imaginative-Expectancy Response Effects. The Sexual Behavior Sequence model suggests that people learn cognitive processing responses to erotic stimuli which take the form of information, imagination and expectations (Fisher 1986). One may acquire information about sexuality from a variety of sources such as sex education, sex manuals, pornography, and direct experience. Sexual fantasy in the form of internal sexual imagery is thought to possess motivating properties and is linked directly to preparatory sexual behavior, according to Fisher. Both also lead to the formation of expectations about sexual activity which govern how one conceives the sex act and prepares for it.

Preparatory Sexual Behavior (Proception)

Preparatory sexual behavior involves actions which prepare and set the stage for the actual sex act, including such things as pretactile and tactile behavior, using birth control devices, establishing the setting for the sexual act, and attracting, seeking or maintaining relations with a sexual partner in terms of the stages outlined above (Fisher 1986). Often these behaviors may involve aspects of consumption such as choosing, purchasing and using a form of birth control; purchasing furniture, lights, art, music or even a home etc. for the proper setting for lovemaking; going to a bar, dating service, or other less overt partner-seeking place (e.g. activity groups such as running clubs) to find a sexual partner;

exploring and defining a sexual/love relationship through gift giving (Belk and Coon 1991); and if one already has a partner, sharing in and evolving a daily consumption pattern of mutual benefit. For example, dancing may be seen in some cases as moving beyond the attraction phase to 'test-driving' the dance partner as a potential sex partner in that it allows for a trial intimacy which approximates the sex act but without all its final attendant consequences. In fact, it has become for many a proxy act for the total physical intimacy due to AIDS. For ongoing relationships, dancing serves as foreplay for the ensuing sex act as well as embodying it in a different form.

It is important here to make a distinction between what is directly tied into one's lovemap and what is more indirectly tied. For instance, one person may think of the purchase of a piece of furniture as directly tied into attracting a sexual partner or sustaining a sexual relationship while another might only see a connection if it is pointed out to him or her. Yet another person might not consciously ascribe a sexual or love motive to such a purchase but might feel one unconsciously. Still another person might neither see such a connection nor even 'experience' one unconsciously. The degree of connection between consumption objects and one's sexuality is likely to depend in large part on the degree of erotophilia the individual experiences. The erotophilic individual is likely to view more various acts of consumption in terms of sexuality than the erotophobic one. This may be framed as an example of category width (Pettigrew 1956) with the erotophilic individual being seen as a broad categorizer with respect to the sexuality present in their consumption and the erotophobic individual being seen as a narrow categorizer. Another frame is one's lovestyle - individuals are likely to view consumer goods in terms of their own sexual/lovestyle.

Actual Behavior Involved in the Sex Act (Acception)

Sexual expression in the form of actual or acceptive sexual behavior is likely to parallel preceptive-preparatory sexual behavior in that the attitudes and values reflected in various erotic versus non-erotic-orientations are likely to carry over and determine one's sexual behavior with respect to goods use in similar ways although the goods used will differ. Therefore, consumers perform many consumption acts related to lovemaking (including fore and after play) which involve products and/or ideas concerning sexual methods and ideologies which they are consuming. Thus, for example, the use of sexual toys, music, incense, certain types of bedsheets, beds, couches and hot tubs as locations for the sex act, or the proverbial smoking of a cigarette after sex, etc. are forms of consumption which pervade the actual sex act. Some of them such as various sexual toys may be used as substitutes for sex with another person (Morris 1971). Moreover, the very act of intercourse, itself, has been compared to a form or act of possession (Dworkin 1987, p. 63).

Outcomes (Conceptive and Other)

The final part of the Consumer Sexual Behavior Sequence involves the outcomes of the sexual act carried out (Fisher 1986). These outcomes may take the form of conception, relationship maintenance and dissolution, sexual experience and feedback to the future performance of the sex act, as well as its various antecedents, and sexual satisfaction. Conceptive outcomes are marked by a 'love child' and much sexual energy may as result of this outcome be sublimated and/or manifest in consumption related to that child. Other outcomes which are more overtly sexual in nature are dependent on expectations and fantasy which to some degree are fueled by consumer activities, such as the reading of sexual magazines or watching pornography. However, paradoxically these may often lead to dissatisfaction as one fails to meet one's own expectations or those of others, or one feels that others may be experiencing more sexual satisfaction than oneself (Fisher 1986).

Sexual outcomes also have a great bearing on interpersonal relationships in terms of their (dis)continuance and nature. A key element is the fact that as relationships continue, sexual habituation and also loss of libido are key elements which lovers must confront. To this end, lover-consumers may seek to engage in various processes of variety-novelty seeking within the relationship in order to refresh or restimulate its sexual as well other aspects. We argue here that one prime motivating force driving much of adult consumer behavior is this need to reinvigorate one's sexual-love relationship and that much of this is commodified and tangibilized in the form of consumption activities (cf. Belk and Wallendorf 1990). Consumers take stock of their sexual outcomes and the status of their relationships and often look to external activities and objects for help as props in staging these processes - everything from vacation getaways to new lingerie to couples' renting of pornographic movies to fat-reducing diets may be seen in terms of rejuvenating one's relationship as well as oneself. Thus consumers in engaging in the responses described above through the course of a relationship constantly rescript and reritualize their sexual lives. As Davidson (1990, p. 16) observes:

If your romantic script is as predictable as a summer-rerun maybe it's time to get a new script. The elements of a romantic script are time, place and manner. A new time for a romance (maybe the afternoon), or a new place (a resort hotel weekend) can turn just another tryst into a memorable and romantic rendezvous. But for my husband and me,... we have found that we can create an exotic experience at home... with... adult games... The target audience: couples who have been together long enough to be set in their romantic ways...Adult games make it easy to change your routine and alter the style of your evening.

DISCUSSION AND IMPLICATIONS FOR A RESEARCH AGENDA

The magnitude of consumption's role in consumers' sexual scripts and the degree to which it can effect the outcome of a sexual encounter, as well as the degree to which it itself is altered by the encounter, are crucial matters for researchers to explore in terms of understanding the relationship of sexuality and consumption. The following points should be addressed:

1. The Consumer Sexual Behavior Sequence model suggests that sexually-related products should be considered in light of the various stages of the developing and changing sexual relationship since their role differs both qualitatively and quantitatively throughout. Thus future research needs to focus on how product use might vary across the stages of the model (i.e. products used to attract a lover may not necessarily play a similar role in maintaining a relationship), and also to compare and relate this model to other consumer behavior models.
2. The presence of individual differences, such as those based on biological sex, stage of the lifecycle, and personality traits (e.g. erotophilia-erotophobia), as well as cultural differences, indicate that researchers need to investigate how consumption may take different forms, play different roles, embody different meanings, and allow different behavioral enactments or sexual roles for various individuals through the stages of the Consumer Sexual Behavior Sequence.
3. Mosher (1988) suggests that certain sexual experiences are psychologically magnified so that for a product to be used in conjunction with a lovemap there must be a specific goodness-of-fit between the product and the script. We need to investigate how these goodnesses-of-fits are produced, how they operate and how they influence consumer choice and product use at various stages of the Consumer Sexual Behavior Sequence.
4. Consumer and marketing exchange processes should be considered for the their sexual content, especially in terms of sexual relationships. We have no knowledge, for instance as to how couples develop joint preferences for sexual-related products during the development of their relationship as it follows the stages of the Consumer Sexual Behavior Sequence, although it has been suggested that affection and intimacy play important roles in family decision making in general (Park, Tansuhaj and Koloe 1991). Thus,

exploration of relationships in terms of intimate feelings and love styles would be useful in understanding sexual influence vis-a-vis other personal influence variables (e.g. need for companionship).

5. The consumer's economy of desire plays itself out in self and others' demands of consumption, sexuality, work, leisure, and various relationships. Future research should investigate how consumers distribute their resources of personal energy, effort, and vitality, time, money, relationship capital etc. to meet their sexual and other needs and desires. Moreover, since this distribution of personal resources may vary in focus across various stages of the Consumer Sexual Behavior Sequence, we need to investigate these phenomena as likely changing dynamically as one's relationships and sexual life unfold.

CONCLUSION

This paper has shown how sexuality's purportedly pervasive effect on consumer behavior has a potentially powerful theoretical base which is rooted in previously ignored developments in the field of sex research and related areas. Indeed, it would appear that exploring the Consumer Sexual Behavior Sequence has the possibility of engaging consumer researchers of all methodological stripes.

The Effects of Product Symbolism on Consumer Self-Concept
Newell D. Wright, Virginia Polytechnic Institute and State University

M. Joseph Sirgy, Virginia Polytechnic Institute and State University¹

ABSTRACT

Using the perspective of self-congruity theory as an organizing nomological framework, this paper develops an integrated model of the effects of product symbolism on consumer self-concept. The model specifies predictors of recognition or learning of product symbolism. It identifies the mediating process in which consumers use product symbolism to define themselves in the context of a specific situation. The model also asserts that the outcomes of product/self-perceptions across a constellation of products, across situations and over time serve to establish an extended self.

INTRODUCTION

The literature in symbolic consumption, product symbolism, and self-concept is rich and varied. Consumer researchers have studied many factors which influence the formation and change of product symbolism (or product value-expressiveness): product-related factors (Belk 1981; Sirgy, Johar, and Wood 1986; Varvoglis and Sirgy 1984), individual difference factors (Belk 1978; Belk, Mayer, and Bahn 1981; Belk, Bahn, and Mayer 1982; Hamid 1969; Munson and Spivey 1981; Solomon 1983; Sommers 1964), and social system factors (Hirschman 1985; McCracken 1988a). Consumer researchers have also explored possible mechanisms through which product symbolism contributes to the formation and change of the consumer's self-concept (Belk 1988; Sirgy 1982; Solomon 1983).

This paper attempts to integrate the concepts and findings of many studies in symbolic consumption, product symbolism, and self-concept. The goal is to develop a conceptual foundation for an integrative model that (1) specifies factors which predict or determine a tendency in consumers to recognize and learn about product symbolism, (2) identifies the process which mediates consumers' use of product symbolism to define themselves in specific situations (product/self-perception), and (3) shows how product/self-perceptions across a constellation of products, across situations, and over time establish an extended self. The integrative model is developed using self-congruity theory (Sirgy 1986) as the guiding (though not only) theoretical perspective, which explains and organizes the relationships.

**SELF-CONGRUITY THEORY,
PRODUCT SYMBOLISM AND
CONSUMER SELF-CONCEPT
RESEARCH**

Self-congruity theory is a conceptual framework developed by Sirgy (1986) to explain such self-concept processes as self-evaluation, self-perception, self-concept change, self-concept differentiation, self-concept generalization, decision making, information search, self-monitoring, and is the fundamental process all these self-concept processes have in common. Self-congruity, the match between a perceived self-image outcome and a self-expectancy, is information about the self that is put into the cybernetic system. (A cybernetic system is a comparator process in which input signal is compared with a reference value. Deviations from the reference value produce output designed to impact the environment for the purpose of bringing about homeostatic balance, a state in which the input signal is least discrepant from the reference value). Self-expectancy is the reference value retrieved from memory that serves as a standard of comparison for the perceived self-image outcome. Sirgy argues that the self-congruity process coexists with the aforementioned self-concept processes but is guided by different self-concept motives (needs for self-esteem, self-consistency, and self-knowledge). For example, self-evaluation involves a comparison between a perceived self-image outcome and a self-expectancy; however, the objective is an *evaluation* of the relative "goodness" of the perceived self-image outcome, and this process is mostly guided by the need for self-esteem. More specifically, given that the self-image outcome is better than expected, the outcome is said to have a self-enhancing effect. Conversely, if the self-image outcome is worse than expected, the outcome has a self-debilitating effect. Thus, if a consumer expects to conform to the norms and standards of high society but finds s/he has bought a car that has a working class image, s/he may evaluate him/herself negatively for having purchased that car because the self-image outcome of the purchase deviates from his/her upscale self-expectancy. Sirgy argues that a negative correlation between the self-image outcome of a purchase and self-expectancy decreases the consumer's self-esteem. Self-perception also involves a comparison between a self-image outcome and self-expectancy; however, the objective here is to *interpret* the perceived self-image outcome in relation to a self-expectancy, and this process, Sirgy says, is guided by the need for self-consistency, the need to maintain consonance between self-images and behaviors ascribed to the self. Since a review of the entire subject of self-congruity theory is beyond the scope of this paper, we will only focus on self-perception and self-concept generalization, ideas

¹The authors would like to thank Val Larsen for his critical review and comments on this paper.

borrowed from self-congruity theory that are central to the integrative model developed in this paper.

According to self-congruity theory, self-perception is a process in which information about an event is ascribed to the self. More specifically, the perceived self-image outcome is matched with a particular self-expectancy. For example, a woman consumer is complimented on her good taste in wearing fashionable clothes. How does she make sense of this message? If she thinks of herself as being a fashionable dresser, then she will ascribe the message to her fashionableness, assimilating the message into her self-schema. Hence, her self-perception is explained as a self-congruity process in which a message or event confirms a particular self-expectancy. This self-congruity process is mostly guided by the need for self-consistency, i.e., the motivational tendency to accept information about the self that is consistent with one's established view.

According to self-congruity theory, self-perception is moderated by the strength of the perceived self-image outcome and the strength of the self-expectancy. That is, given weak perceptions of self-image outcome and/or weak self-expectancies, the strength of self-perception is also weak. Thus, if the woman consumer is not certain that she "heard the compliment" or is uncertain about her fashionableness, the change in self-perception resulting from the compliment may also be weak, for she may feel *uncertain* about her interpretation of the message concerning her fashionable dress.

If, on the other hand, incoming information is congruent with the established self-image, that self-image is strengthened, for high self congruity increases self-concept generalization, whereas low self congruity decreases it. For example, suppose a woman wearing a fashionable outfit at work is told that she looks fashionable with that outfit. If this message matches her assessment of herself, it will consolidate her image of herself as a fashionable person. Thus, the image (self-expectancy) increases in salience or connectedness. An increase in the generalization of a specific self-expectancy, according to self-congruity theory, reflects an increase in the salience of this self-expectancy in an overall hierarchy of self-expectancies. This means that the self-assessment becomes more central in the person's belief system and is likely to play a greater role in the person's life, a fact which is important for consumer research that focuses on the extended self.

TOWARD AN INTEGRATED MODEL OF PRODUCT SYMBOLISM AND ITS EFFECTS ON CONSUMER SELF-CONCEPT

The proposed integrated model is shown in Figure 1. This model shows that qualities of the product and consumer influence the recognition/learning of product symbolism. In turn, the consumer's recognition/learning of product symbolism and his/her self-image moderate the relationship between product use/ownership and product self-perception. Then, over time and across product-related situations, those product/self-

perceptions contribute to the formation and change of the consumer's self-concept (the extended self).

Finally, the consumer's materialism and recognition of the product constellation play a moderating role in the formation and change of his/her extended self.

Before we start addressing the conceptual relationships shown in the figure, let us first define the central variables of the proposed integrated model. These are recognition/learning of product symbolism, product/self-perception, and the extended self. *Recognition/learning of product symbolism* refers to the degree to which a consumer is aware of associations between symbols and a given product. For example, a sports car is associated with a kind of person who is sexy, attractive, young, and socially outgoing. These idealized people associated with the sports car are traditionally referred to as product symbols (Sirgy 1982; Solomon 1983). This construct is also traditionally referred to as "strength of product user image" and "product value-expressiveness" in the consumer self-concept literature. In self-congruity theory, recognition/learning of product symbolism can be construed as the strength of the product image, the perceived self-image outcome of using a particular product.

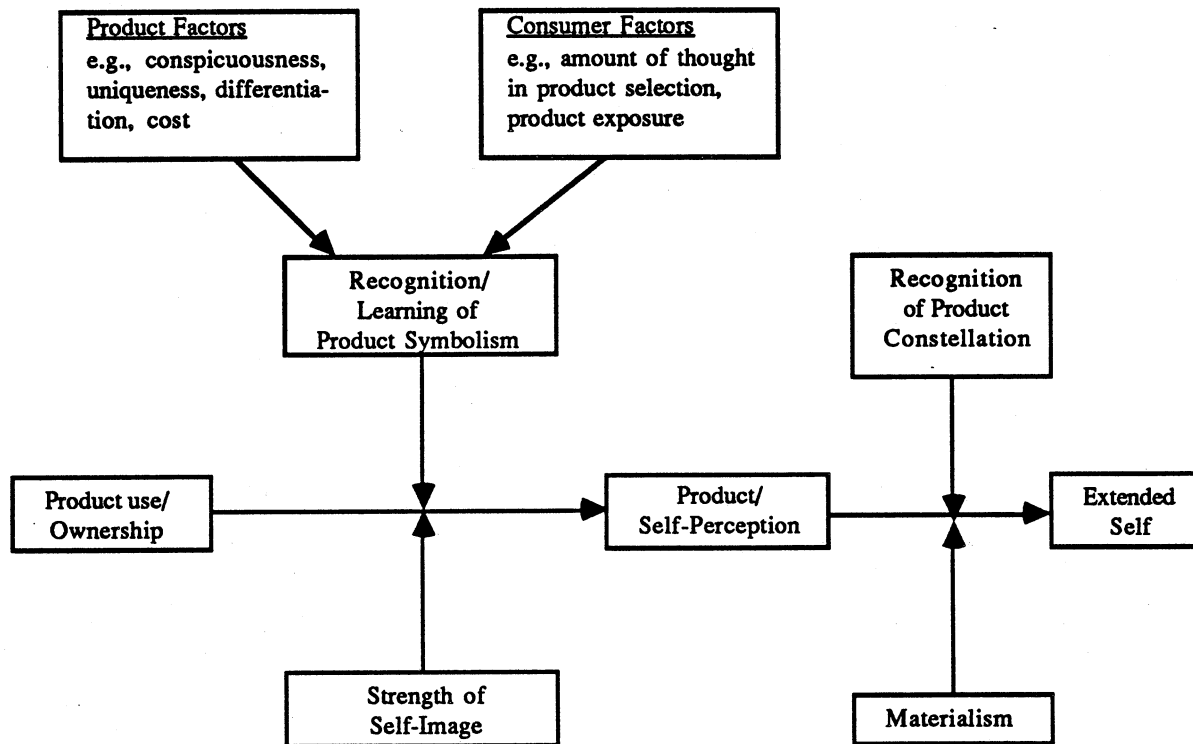

Product/self-perception refers to the formation and/or change of beliefs about the self as a consequence of the use or ownership of a product or service. For example, if a woman consumer who often patronizes an upscale clothing boutique infers that she is an affluent person because she patronizes the store, she is said to have made a product/self-perception. She formed an image of herself based on her patronage of the clothing boutique. This self-perception is product and context-specific. That is, she may only perceive herself as being upscale in the context of purchasing and wearing clothes. The situation-specificity of product/self-perception is important, since the *extended self* is defined just like product/self-perception except that the self-related beliefs are more cross-situational, i.e., *not* situation specific. That is, the extended-self refers to the extent to which people view themselves as being a certain kind of individual because they use or own certain product/service constellations. Using self-congruity theory, product/self-perception can be construed in terms of self-perception, whereas the extended self can be thought of as the outcome of self-concept generalization.

Predictors of Recognition/Learning of Product Symbolism

As previously mentioned, recognition/learning of product symbolism refers to the extent of awareness of associations between symbols and a given product. Figure 1 shows that product and consumer factors influence recognition/learning of product symbolism.

Product Factors: Belk (1981) argued that product uniqueness, variety of choices available, cost of the product, product visibility or conspicuousness, product complexity, and rate of stylistic change associated with the product all influence a user's impression of a product. The greater the uniqueness, variety, cost, social visibility, complexity, and rate

FIGURE 1
An Integrated Model of Product/Consumption Symbolism and Consumer Self-Concept

of stylistic changes associated with the product, the greater the likelihood that consumers will draw inferences from product cues about the image of the product user. However, only the relationship between cost and the tendency to draw inference about personality and social class was supported by Belk's study.

Sirgy, Johar, and Wood (1986) studied the effects of product conspicuousness, product differentiation, and product uniqueness on product value-expressiveness. As expected, their results showed that conspicuousness, differentiation, and uniqueness are positively related to value-expressiveness. So, Belk and Sirgy et al.'s studies suggest that product conspicuousness, uniqueness, differentiation, and cost are directly related to product value-expressiveness or recognition/learning of product symbolism.

Proposition 1: Conspicuous, unique, differentiated, and high cost products are more likely to generate recognition and learning of product symbols than inconspicuous, common, nondifferentiated, and low-cost products.

The theoretical justification for this proposition is as follows. Products that are publicly visible (i.e., socially consumed) are more likely to be associated with these personal characteristics of their users than products which are privately consumed. The social visibility of the product facilitates learning and helps establish *consensual* beliefs regarding the stereotypic image of the product user (Belk 1981; Sirgy et al. 1986). Attribution theory also justifies this proposition (Kelley 1973), arguing as follows: people weigh unique or uncommon events and characteristics heavily when making casual attributions, whereas they discount the social significance of common characteristics. Accordingly, when watching consumers use products directed to the select few (product unique usage), consumer observers can make attributions about the personal characteristics of the product user (Sirgy et al. 1986). These observers can easily draw the inference that the user of a highly differentiated product prefers the differentiated attributes that brand provides (Sirgy et al. 1986). Belk (1981) argued that people attribute different stereotypic images to cosmetic users because many brands are available. He also argued that the cost of the consumption item facilitates inferences about the social status of the product user. The more costly the product, the more it may be perceived as belonging to a person with a higher social status.

Consumer Factors: Belk (1981) also argued that the amount of time and thought that goes into product selection contributes to the learning of product symbolism. That is, the more consumers think about the product, the more likely they will make inferences about the stereotypic image of the generalized user. The results of the study supported this hypothesis, and, accordingly, proposition 2 comes from Belk (1981).

Proposition 2: Consumers who expend more time and thought in selecting a product are more likely to recognize and learn of product symbols than consumers who expend less time and thought.

Hirschman (1985) and McCracken (1988a) refer to specific symbolic content being encoded by product designers and media creative people. Greater exposure to the messages leads to greater ability to decode and recognize the intended symbolism. McCracken and Hirschman both point out the importance of advertising in transferring symbolic meaning to consumer goods. The advertising system transfers meaning to products by linking consumer goods and culturally constituted symbolic meanings in an advertisement.

One component of Hirschman's cultural production system is the communication subsystem, which includes advertising and other communications efforts, such as product rating services. This subsystem provides consumers with information about products and facilitates the transfer of symbolic meaning to products. McCracken identified the fashion system as a method for transferring meaning from the culturally constituted world to consumer goods. As used by McCracken, fashion applies to all goods, not just clothing, that can become culturally obsolete, "out of fashion," before they are functionally useless. Like advertising, the fashion system transfers meanings by linking goods with established cultural categories and principles. The fashion system also invents and transfers meaning through elevated opinion leaders, usually in the upper classes of society, who establish and pass on meaning to others who imitate them. Regardless of the level of symbolism, one may argue that product exposure through advertising and the fashion system facilitates the recognition of product symbolism.

McCracken also recognized that products can be deliberately exploited by consumers for symbolic purposes. He used the example of the feminist movement away from traditional female work attire to the more authoritative style that follows men's fashion (i.e., the female "business suit"). Using product symbolism, these women revealed how they wished to be viewed in the work place. Claiborne and Ozanne (1990) discussed how symbolism was purposefully created in custom made homes, and why these dwellings had special meaning for their owners who had participated in their creation. O'Guinn and Belk (1989) have shown that profane items (e.g., enticing perfume, sexy lingerie) can become symbols

of marital fidelity to deeply religious consumers by encouraging husbands to remain faithful to their wives.

McCracken (1986, 1988b) also recognized that product symbolism can be created through consumption rituals. Ritual has only recently been recognized in consumer research (Rook 1984, 1985; Rook and Levy 1983; Tetreault and Kleine 1990), but it is a powerful way to create product symbolism. For example, Schouten (1991) examined the effect aesthetic plastic surgery had on the self-image of men and women. He discovered that it gave them a sense of completeness and symbolized a new role and a new beginning for them. Wright (1991) examined product usage among adolescents and found they expressed their adulthood through some of the products and services they consumed. Product symbolism in these two instances was intertwined with major life events, and the symbolism inherent in the products consumed acted as surrogate rites of passage. Belk, Wallendorf, and Sherry (1989) discussed how certain forms of ritualistic consumption (such as gift giving) endowed products with sacred status and meaning.

What is suggested here is a phenomenological creation of product symbolism. Consumers don't merely decode symbols, they create meaning that is personal and private. Thus, the oak table in the kitchen is not just a symbol of country living. As the table around which I raised and fed my family, it has sacred, symbolic status (Belk, Wallendorf, and Sherry 1989). The product image is no longer normative but idiographic, no longer cognitive but phenomenological. These two inputs allow for the creation (and recognition/learning) of product symbolism.

In the context of self congruity theory, recognition/learning of product symbolism is the ability to match product images with symbolic meanings.

Proposition 3: Product/self-perceptions are influenced by use/ownership when there is a strong product symbolic recognition.

The Effect of Product/Use Ownership on Product/Self-Perception

A great deal of the early self-concept research focused on establishing that there was indeed a relationship between product image and self-image (see Sirgy 1982 for a literature review). Evans (1968) argued that Birdwell's (1968) study showed product ownership may influence both self-concept and product image, resulting in high self-concept/product-image congruity. Belch and Landon (1977) argued that product ownership influences self-concept measurement. Delozier (1971) and Delozier and Tillman (1972) found that self-concept/product-image congruity increased with the passage of time, which may possibly indicate the influence of product use/ownership on self-concept changes. However, the possibility that the self-image is formed in response to a product image has received little attention in the more recent consumer self-concept literature.

Symbolic product images give meaning to the product by *personifying* it. The product comes to say, "this is the kind of person who would use this product" or "these are the qualities of a person who would use this product." This personification of the product, the product user image, allows for a direct comparison to the self. Hence, the product use and/or ownership can affect product/self-perception. Sirgy (1982) used the following example to illustrate the relationship between product use/ownership and product/self-perceptions. A consumer may attribute his purchase of a pornographic magazine to his strong need for sexual relations. The formation of the self-image 'I need sex' may have been affected by the product user image associated with pornographic magazines. Sirgy explained this relationship using Bem's self-perception theory (1965, 1967). Self-perception theory states that people infer their attitude and dispositions by observing and explaining their behavior.

Proposition 4: The greater the use and/or ownership of a product, the greater the likelihood that the consumer forms self-images that are based on the product user image.

The Moderating Effect of Recognition/Learning of Product Symbolism and Strength of Self Image

Now let us bring back the concept of recognition/learning of product symbolism. How does it fit in the context of the relationship between product use/ownership and product/self-perception? Using self-congruity theory, one can argue that the relationship between product use/ownership and product/self-perception is moderated by the strength of the product image (or what we are calling "recognition/learning of product symbolism"). That is, the extent to which the use and/or ownership of a product influences the formation of self-images is *dependent* on the strength of the product image. More specifically, the relationship between product use/ownership and product/self-perception may be significantly enhanced when the product image is strong. This is because inferences about the self can be made easily when the image of the product user is clear in the consumer's mind. When the consumer feels less certain about the product user image, inferences about the self (as a function of the product user image) becomes difficult.

Furthermore, from the perspective of self-congruity theory, one can argue that the relationship between product use/ownership and product/self-perception is also *moderated* by the strength of the self-image. That is, the extent to which the use and/or ownership of a product influences the formation of self-images is *dependent* on the strength of the self-image. More specifically, the relationship between product use/ownership and product/self-perception is significantly reduced when the self-image is strong. In other words, consumers may be less inclined to use their consumption behaviors as cues about their

identity when their identity is clearly formed. In contrast, consumers whose self-concept is uncertain may be more motivated to use consumption cues to make inferences about their identity.

Solomon (1983) and Wicklund and Gollwitzer (1982) have made similar arguments. Solomon used the term role knowledge to describe the self-related beliefs, expectations, or images one has in a particular social role. Given that the consumer has low role knowledge, s/he is highly receptive to forming self-related beliefs, expectations, or images through product use. The symbolic self-completion theory of Wicklund and Gollwitzer proposes that individuals lacking the indicators of an aspired-to self definition will display other compensating indicators of the same self definition. The self symbolizing occurs when an individual feels "incomplete" in certain areas and compensates by using or displaying other symbols that are socially recognized as representing "completeness." Wicklund and Gollwitzer (1982) successfully predicted that MBA students who lacked certain indicators of business success (e.g., a high GPA, several job offers) would compensate by displaying other indicators of business success, such as expensive suits, watches, or brief cases, or the lack of facial hair. The men and women interviewed by Schouten (1991) overcame their sense of incompleteness through the consumption of aesthetic plastic surgery. For example, one woman completed her sense of womanhood through breast augmentation surgery. These ideas lead to the following proposition.

Proposition 5: Self-perceptions are influenced by product use/ownership when the product has a strong user image and the consumer does not have a well formed self-image.

Belk (1988) suggests that possessions play a much greater role in defining a person's self-concept than previously recognized in consumer research. Following the existential philosophy of Sartre (1943), Belk proposes that possessions play a major role in contributing to and reflecting an individual's identity. According to Belk's interpretation of Sartre's philosophy,

... the only reason we want to have something is to enlarge our sense of self and that the only way we can know who we are is by observing what we have. In other words, having and being are distinct but inseparable. When an object becomes a possession, what were once self and not-self are synthesized and having and being merge.

Thus, according to Sartre, possessions are all important to knowing who we are. People seek, express, confirm, and ascertain a sense of being through what they have (pp. 145-146).

Belk supports this rationale with abundant evidence. He examines the concept of the extended self from several perspectives and demonstrates the importance of several categories of possessions in a person's self-definition. He summarizes his argument by concluding that "we are what we have" and this "may be the most basic and powerful fact of consumer behavior" (p. 160).

Using self-congruity theory, the extended self can be viewed as an outcome of self-concept generalization. Certain self-expectancies are developed, strengthened, and generalized as a function of repeated messages about the self through the use of products (product/self-perceptions).

This expression of the extended self is "dispositional" in that it is stable across products and situations. The "language" of consumption or product symbolism is used only to describe the individual traits of the extended self. Belk speaks of extending the self by *ownership* of products. In like manner we extend the self through symbolically matching the owned product image and some ideal self-image.

Proposition 6: Repeated and frequent product/self-perceptions leads to greater definition of the self in terms of the products used/owned by the individual (the extended self).

The Moderating Effects of Product Constellation and Materialism

It can be argued that extended self-definition depends on the symbolism inherent in the *constellation* of products surrounding the individual and facilitates role playing when the symbolism of the products surrounding the individual parallel the symbolism associated with a given role. A constellation of products is a group of unrelated products that are used by an individual, and contribute to that individual's sense of self. Solomon (1983) introduced the idea of the product constellation, underscored the importance of the proper constellation of products in delivering a satisfactory self-evaluation, and proposed that products with the proper symbolic meaning may be used to facilitate role performance. He later amplified the idea of a product constellation and proposed several categories around which product constellations were formed (Solomon and Assael 1987).

McCracken (1988b) also recognized the importance of a consistent complement of consumer goods in self definition. He used this notion in an empirical study of the North American homes to identify the constellation of products that created "homeyness" and contributed to the homeowner's sense of well being (McCracken 1989). Products contributing to homeyness included gifts, crafts, trophies, mementos, family heirlooms, etc. In another empirical study, Wright (1991) identified another product constellation, including coffee, alcohol, cars, credit cards, newspapers, etc., that symbolized adulthood for middle class adolescents in a small North American town. The idea of a product

constellation is that the more goods with the appropriate symbolic meaning one has, the higher the probability of a satisfactory self-evaluation. Based on these ideas, the following proposition is developed.

Proposition 7: Repeated and frequent product/self-perceptions may lead to greater definition of the self in terms of the products used/owned by the individual *given* that those products are recognized as product constellations.

Although the concept of materialism has been operationalized several different ways (Belk 1984, 1985; Richins and Dawson 1990; Ger and Belk 1990; Richins 1987; Rudmin 1990), it captures the idea that consumer goods and services provide a significant source of satisfaction and dissatisfaction in life. Without the proper constellation of material products, the probability of a satisfactory self-definition through consumption diminishes. Similarly, a materialistic attitude would seem to increase the probability of a successful self-consumption definition, for materialistic individuals may be more likely to use *a priori* product symbolism to define their sense of self. These ideas lead to proposition 8.

Proposition 8: Repeated and frequent product/self-perceptions may lead to greater definition of the self in terms of the products used/owned by the individual *given* that the individual is materialistically-oriented.

CONCLUSION

This paper has integrated concepts and findings in symbolic consumption, product symbolism, and self-concept. The integrated model, based on Sirgy's (1986) self-congruity theory, specifies predictors and determinants of recognition and/or learning of product symbolism, identifies the mediating process in which consumers use product symbolism to define themselves in the context of a specific situation, and posits that outcomes across a constellation of products, across situations, and over time influence the formation and change of the extended self. Future research is needed to test the proposed relationships and further establish and refine reliable/valid measures of the model's constructs.

New Perspectives in Attitude Research

Youjae Yi, University of Michigan

Ken Gray, University of Michigan

ABSTRACT

This paper provides a summary of a special topic session organized to provide new perspectives in attitude research by reformulating old concepts, exploring new aspects, refining the specification of relevant variables, and utilizing more sophisticated methodology. By providing the audience with emerging novel approaches to the study of attitude, this session provides an impetus for making further developments in this important area. The theoretical and practical implications of these approaches are also discussed.

OVERVIEW

Attitude has been an important topic for consumer researchers for several decades. Despite its long history, however, many traditional theories of attitude have remained virtually intact over the years and there is a need for refinements or paradigm shifts (e.g., Bagozzi 1988, 1991; Tesser and Shaffer 1990). In this regard, we can note several conceptual and methodological developments emerging in recent research that challenge past research and provide potentially fruitful ideas for future research. It seems thus useful to have a forum for examining these advances in contemporary research and exploring directions for further development.

The purpose of this special session is to bring together researchers who provide new perspectives in attitude research by reformulating old concepts, exploring new aspects, refining the specification of relevant variables, and utilizing more sophisticated methodology. By providing the audience with perspectives on emerging novel approaches to the study of attitude, this session will provide an impetus for making further developments in this important area.

The four papers in this session reflect a variety of new perspectives on attitude research by challenging, modifying, and extending the traditional research paradigms. The first paper by Bagozzi provides several major challenges to the theory of reasoned action. The theory of reasoned action is modified by addressing the role of enactment processes with particular emphasis placed on cognitive and emotional self-regulatory mechanisms. The modified model is investigated in the context of fast food restaurant patronage and personal weight maintenance. The second paper by Janiszewski challenges the usefulness of the traditional attitude measurement methodology for predicting the potential sales of new products. To refine current methods of assessing consumer attitudes, a non-verbal, non-obtrusive, attention-based method of assessing consumer interest in products is developed with an eye-tracking system.

The next paper by Shavitt and Lowrey examines the interactive role of product type and personality type for attitude functions in advertising

effectiveness. This paper extends the traditional theory of attitude functions by identifying personality and product characteristics associated with particular attitude functions (e.g., DeBono and Packer 1991; Shavitt 1990). It also develops a novel approach to measuring attitude functions. The final paper by Gray and Yi investigates a new way that one can influence consumers' attitudes toward the product. It is claimed that the diagnosticity of product attributes can affect the evaluation of the product by altering the perceived typicality. The diagnosticity of an attribute indicates how useful an attribute is in distinguishing instances from noninstances of the category (e.g., Smith and Gray 1991). It is thus proposed that one can change consumers' attitudes by emphasizing or priming attributes that are highly diagnostic of a product category.

The approach of this session is both theoretical and practical. Each paper provides a thorough discussion of the conceptual framework. Then, practical implications are drawn and tested with data collected for the respective studies. More detailed abstracts of individual papers are attached.

In summary, this session brings together a group of distinguished and emerging scholars with distinct viewpoints, backgrounds, and methodological approaches to studying attitude. The issues are investigated with several moderator variables (e.g., self-efficacy, product type, self-monitoring) in various contexts (e.g., fast food restaurant patronage, advertisements, new product purchase via catalogs, personal weight maintenance). Given substantial importance of this topic to many researchers and practitioners, the issues to be discussed in this session should stimulate interest among a broad range of ACR members. All of the participants have discussed some of the emerging issues in attitude research in a setting designed to spur an active participation from an audience.

ABSTRACTS

Enactment Processes in the Theory of Reasoned Action

Richard P. Bagozzi, University of Michigan

The theory of reasoned action (e.g., Fishbein and Ajzen 1975; Ajzen and Fishbein 1980) has remained remarkably untouched over the long course of its history. Notable developments such as the theory of planned behavior (e.g., Ajzen 1991) have resulted in the addition of variables to the model without altering its core relations among attitudes, subjective norms, and behavior. Consumer researchers have limited enquiry largely to applications of the model and have taken its content and form for granted.

It is argued in this paper that attitudes and subjective norms are not sufficient determinants of intentions, and intentions are not sufficient impetuses for action, as maintained by the theory of reasoned

action. Nevertheless, attitudes, subjective norms, and intentions are essential elements in the explanation of behavior. To deepen the theory of reasoned action, we address the role of enactment processes with particular emphasis placed on cognitive and emotional self-regulatory mechanisms.

The theory of reasoned action says nothing about the conditions under which attitudes affect intentions. After concluding that the relation must be a contingent one to make logical and empirical sense, we discuss three cognitive and two emotional self-regulatory processes which are shown to moderate the relation. The former include self-efficacy, instrumental beliefs, and expectations of success and failure. The latter are conative processes related to wants or desires and emotional responses stemming from outcome-desire appraisals (i.e., outcome-desire conflict, fulfillment, avoidance, or pursuit).

The subjective norm-intention relation, which is also left uninterpreted in the theory of reasoned action, is hypothesized to be governed by cognitive and emotional self-regulatory processes surrounding perspective taking. Following Mead (1934; Joas 1985), we conceive of perspective taking as consisting of the use of symbols and images to bring about in one's own consciousness the expectations and response tendencies of, and emotional relationship to, significant others. Normative influence is then reconceptualized as the integration of one's own and a significant other's perceived expectations and feelings with respect to the shared moral or social meaning of performing a prospective act. When contemplating an action, a decision maker must come to grips with the implications of positive and negative emotions of conforming and not conforming to one's own and significant others' expectations. In a study of fast food restaurant patronage, three different emotions were found to reside in each of four categories formed by the relevant perspective taking cases: deviant other, deviant self, conforming others, and conforming self.

Finally, intentions are shown to be inadequate predictors of behavior, especially for goal-directed behaviors. It is proposed that the intention-behavior relation is predicated on decisions with regard to means, instrumental acts, motivation, and conditions particular to the actor (e.g., abilities, liabilities) or situation (e.g., facilitators, inhibitors). Some of the moderators and mediators are cognitive processes such as judgments of self-efficacy and instrumentalities concerning means, as well as planning, monitoring, and guidance and control activities. Others are emotional or motivational in content such as affect toward means, psychological commitment, and effort. The intention-behavior relation will be addressed from the point of view of a study on personal weight maintenance.

The Eye is Better than an Aye
Chris Janiszewski, University of Florida

Consumer researchers have traditionally used verbal reports to assess the marketplace's attitude toward a product and the likelihood of purchase. These methods have proved to be commercially successful,

especially when researchers have made an effort to achieve correspondence between the measurement instrument and the expected purchase context (Fishbein and Ajzen 1975). Nevertheless, the failure of 9 of 10 product launches suggest the attitude measurement methodologies used to predict the potential sales of new products could use some improvement. The need is particularly salient in industries that continually update a significant percentage of their product lines (e.g., retail apparel, direct mail).

One strategy for improving predictions of the sales potential of new products is to refine current methods of assessing consumer attitudes. For example, Fazio and his colleagues have found that the accessibility of an attitude, measured as reaction time, is a good predictor of the strength of the relationship between the attitude and behavior (Fazio, Powell and Williams 1989). When attitudes are strongly held, consumers make decisions based on information stored in memory and attitude-behavior consistency is high. When attitudes are weakly held, consumers make decisions based on stimulus information, minimizing the influence of stored attitudes. In these situations, stimulus information has a strong influence on behavior, minimizing the relationship between attitude and behavior.

Many new product purchase opportunities are characterized by weakly held attitudes, suggesting measures of stored attitudes may be a poor predictor of the sales potential products. Instead, a measure of the persuasiveness or appeal of the stimulus information is needed. This measure should provide insights into the consumer's interest in the product, as does the stored attitude. In addition, this measure should incorporate a measure of the automaticity of the process, as a parallel to the accessibility measure in standard research.

To accomplish these objectives, a non-verbal, non-obtrusive, attention-based method of assessing consumer interest in products was developed. An eye-tracking system was used to measure attention in a series of products. The primacy, frequency and length of attention to each product on a series of catalog pages was measured to provide indicators of the influence of the stimulus-based information on the consumer's perceptions of the products. When appropriate, these measures were standardized by individual and then each of the measure was correlated with sales data for the products. The correlations between the attention-based measures and sales were significant. In addition, each subject was asked to verbally rate an independent set of comparable products. The correlations between these ratings and sales were significant, but negative.

The findings suggest that when the purchase decision will be based primarily based on stimulus cues, attention-based measures of interest in a product can predict its sales potential. These measures may prove to be useful in industries that continually update a significant percentage of their product lines. The measures may also provide a useful diagnostic for researchers studying decisions that rely on memory-based and stimulus-based cues.

Attitude Functions in Advertising Effectiveness: The Interactive Role of Product Type and Personality Type
 Sharon Shavitt, University of Illinois
 Tina M. Lowrey, University of Illinois

Several studies (e.g., DeBono and Packer 1991; Snyder and DeBono 1985) have shown that individuals who are high versus low in self-monitoring (Snyder 1974) differ in the types of messages they find persuasive: In the product domain, high self-monitors tend to prefer ads that focus on social image concerns, whereas low self-monitors tend to prefer appeals about product quality. These studies suggest that high and low self-monitors differ in the psychological functions their attitudes serve (Katz 1960; Smith, Bruner, and White 1956), such that the product attitudes of low self-monitors tend to serve a *utilitarian* function (maximizing rewards obtained from a product), whereas the product attitudes of high self-monitors tend to serve a *social* function (managing one's public image).

In addition to personality characteristics, research has shown that products differ in the extent to which they are associated with particular attitude functions (Shavitt 1990). For example, products that are intrinsically associated with rewards and punishments (e.g., Aspirin, air conditioners) tend to elicit utilitarian attitudes, whereas product that represent social classifications or reference groups (e.g., wedding rings, flags) tend to elicit social attitudes. Moreover, attitudes toward these different types of products respond to different types of advertisements (i.e., function-relevant appeals).

Based on these findings, we predicted that the effects of self-monitoring on advertising effectiveness should be apparent only for products that can serve different functions for high versus low self-monitors (i.e., products that are associated with both social and utilitarian outcomes). For highly utilitarian products, utilitarian ad appeals should be considered more persuasive by all individuals. However, for "multi-function" products, high self-monitors should prefer social appeals and low self-monitors should prefer utilitarian appeals.

We present two studies that tested this hypothesis with a unique methodology. Past research in this area has measured individual's attitudinal reactions to *completed* messages. In the present studies, individuals were asked to create their own advertisements. The functional content of these ads was subsequently coded by trained judges. Across the studies, our results were consistent. Regardless of their level of self-monitoring, subjects tended to write utilitarian ads for predominantly utilitarian products and social ads for predominantly social products. However, for multi-function products, high and low self-monitors differed as expected in the types of ads they wrote. This pattern became stronger when subjects were explicitly instructed to write ads that they *themselves* would find persuasive (rather than ads designed to appeal to a broad audience). Implications of these findings for the conditions under which personality and product characteristics influence attitude functions and advertising effectiveness are discussed.

The Effects of Attribute Diagnosticity on Attitudes
 Kenneth C. Gray, University of Michigan
 Youjae Yi, University of Michigan

A product can often be perceived as a member of several product categories. For example, a granola bar with chocolate yogurt may be perceived either as a type of candy or as a health food (Loken and Ward 1990). Also, some periodical may be perceived either as a magazine or a newspaper. In such cases, understanding why a product will be perceived as a member of a particular category is important, because different products will be compared in evaluating the given product, depending upon how it is categorized. Prior research suggests that people judge instances of a category to vary in the degree to which they are typical of a category. The typicality of a product will affect how a product is categorized, which will in turn influence evaluations of the product. These suggest that one can influence attitudes toward a product by varying the perceived typicality of the product.

We investigate a particular way that one can influence the perceived typicality of product, and thereby affecting consumers' attitudes toward the product. It is proposed that the diagnosticity of product attributes can affect the evaluation of the product by increasing or decreasing the typicality. The diagnosticity of an attribute indicates how useful an attribute is in distinguishing instances from noninstances of the category (e.g., Smith and Gray 1991). It is thus expected that one can alter consumers' attitudes by emphasizing or priming attributes that are highly diagnostic of a product category.

We present two studies that examine the role of attribute diagnosticity in the context of advertisements. In one study, the diagnosticity of product attributes described in a target ad is manipulated (high versus low). It employs two versions of advertisements emphasizing attributes high or low in diagnosticity on the basis of pretest results. In a second study, subtler, indirect effects of attribute diagnosticity are investigated. Here, the target ad does not contain information about these attributes, but these attributes are primed through seemingly unrelated materials preceding the target ad. The theoretical and practical implications of the findings for understanding the attitude formation process are discussed.

ACKNOWLEDGEMENTS

The session chair thanks Bernd Schmitt of Columbia University for providing valuable comments as discussant.

Attitude Functions in Advertising Effectiveness: The Interactive Role of Product Type and Personality Type

Sharon Shavitt, University of Illinois
Tina M. Lowrey, University of Illinois¹

ABSTRACT

Several studies have shown that high self-monitors tend to prefer ads that focus on social identity concerns, whereas low self-monitors tend to prefer utilitarian appeals. Other studies have shown that products themselves differ in the extent to which they are associated with utilitarian versus social identity functions. Based on these findings, it was hypothesized that differences between high and low self-monitors in their ad preferences would be manifested most strongly for products that can be thought of in terms of both utilitarian and social identity goals. In two studies, high and low self-monitors were asked to create their own advertisements for various products. When advertising multiple function products, high self-monitors preferred to use social identity arguments, whereas low self-monitors preferred to use utilitarian arguments. However, both high and low self-monitors preferred to use utilitarian arguments for advertising utilitarian products, and social identity arguments for social identity products. This pattern became stronger when subjects were explicitly instructed to write ads that they themselves would find persuasive (rather than ads designed to appeal to a general audience). Overall, these results suggest that self-monitoring affects the way in which people perceive certain products, rather than the absolute importance or salience of utilitarian versus social identity features across products.

Several recent studies have shown that individuals who are high versus low in self-monitoring (Snyder, 1974) differ in the types of messages that they find persuasive (DeBono, 1987; DeBono & Harnish, 1988; DeBono & Packer, 1991; Snyder & DeBono, 1985, 1987). In the product domain, low self-monitors tend to be concerned with dimensions related to product quality, such as the taste of a brand of whiskey or the cleaning performance of a shampoo. Thus, advertisements that focus on the inherent qualities and benefits of the product appear to be particularly effective for low self-monitors. High self-monitors, in contrast, tend to be concerned with the self-presentational significance of products, such as the popular or successful image associated with using a certain brand of whiskey, shampoo, etc. Thus, ads that focus on the impressions created by using the product tend to be especially effective for high self-

monitors (DeBono & Packer, 1991; Snyder & DeBono, 1985).

These differences between high and low self-monitors have been obtained repeatedly across a number of products and advertisements (DeBono & Packer, 1991; Snyder & DeBono, 1985, 1987). The impressive consistency in these results suggests that self-monitoring is tapping a fundamental difference in the motives that individuals associate with products. That is, high and low self-monitors may differ in the psychological *functions* that their product attitudes tend to serve (Snyder & DeBono, 1987, 1989).

Functional theories proposed that attitudes serve important psychological functions for individuals, and that attitudes could be classified according to the functions they met (Smith, Bruner, & White, 1956; Katz, 1960; Kelman, 1958, 1961). Various functions have been proposed, but two functional categories in particular seem relevant to the motives that distinguish low versus high self-monitors' product attitudes: *utilitarian* and *social identity* functions. Utilitarian attitudes function to summarize one's positive and negative experiences with objects and to guide behaviors that maximize rewards. Low self-monitors, who tend to be concerned with the qualities and benefits associated with products, seem likely to have product attitudes that serve a utilitarian function. Attitudes can also function to express one's identity and obtain social approval (incorporating the social-adjustment and value-expressive functions that others have proposed). High self-monitors, who tend to be concerned with their public image and social appropriateness, seem likely to have attitudes that serve this social identity function.

In the present studies, we investigated the conditions under which individual differences in self-monitoring would be associated with the sharpest differences in attitude functions. Previous research, involving a number of products and judgment tasks, has consistently demonstrated that high and low self-monitors differ in their focus on utilitarian versus social identity considerations when making their judgments (DeBono & Packer, 1991; Snyder & DeBono, 1985, 1987). One might expect the magnitude of these differences to vary depending on whether a situation or product afforded high and low self-monitors the *opportunity* to focus on different functional goals. When only one goal is salient (e.g., a utilitarian goal of finding an effective headache remedy), systematic differences between high and low self-monitors should not be expected. Both high and low self-monitors would likely focus on the same product dimensions. However, when opportunities to pursue both utilitarian and social identity goals are present, high and low self-monitors should differ in their focus on image versus quality dimensions. In short, we expected the magnitude of the differences as

¹The authors would like to thank Becky Blaker, Sangpil Han, and Michelle Zasi for their assistance in data collection and coding. We are also grateful to the University of Illinois Social Cognition Group for insightful comments and suggestions regarding this research.

a function of self-monitoring to be sensitive to factors that activate the different goals of the high and low self-monitor.

One factor that may determine, or limit, one's opportunities to pursue different goals is the product itself. Products differ in the extent to which they engage particular attitude functions (Shavitt, 1989, 1990). Some products seem to serve *primarily* a single type of goal. For example, an air conditioner serves primarily utilitarian goals of obtaining comfort and relief from heat. Thus, attitudes toward an air conditioner are most likely to serve a utilitarian function, guiding the purchase and use of the product so as to maximize its rewards. In contrast, attitudes toward university banners or decals are most likely to serve *primarily* a social identity function because they are highly expressive of one's identity and can be used to obtain social acceptance. Although there are certainly exceptions and limitations to the links between products and attitude functions (see Shavitt, 1990), it is possible to identify products that are primarily associated with a single attitude function in most contexts.

Importantly, these distinctions between products have implications for the persuasiveness of advertising appeals. For utilitarian products, quality-based appeals tend to be more effective than image-based appeals, whereas the reverse is true for social identity products (Shavitt, 1990).

Of course, many products serve multiple purposes. For example, sunglasses serve both the utilitarian purpose of providing protection from the sun as well as the social identity purpose of self-expression. Thus, sunglasses may elicit attitudes that serve either a utilitarian or a social identity function or both, and effective ads for such products could involve a variety of arguments, including utilitarian and social identity appeals.

The present studies investigate how such product characteristics interact with individual differences in self-monitoring to influence the persuasiveness of image-based versus quality-based ads. We predicted that self-monitoring effects would be manifested more strongly for some product categories than for others. Specifically, to the extent that a product could be thought of in terms of *both* utilitarian and social identity goals (i.e., a multiple function product), high self-monitors should prefer image appeals, whereas low self-monitors should prefer quality appeals. However, when judging the persuasiveness of appeals for products that primarily engage a single function, both high and low self-monitors might prefer appeals that focus on how well the product fulfills that function.

This hypothesis was tested in two separate studies using a unique methodology. Past research in this area has measured individuals' attitudinal reactions to *completed* messages created by the investigators. In the present experiments, subjects were asked to create their own advertisements. We then coded the functional content of these ads. In this manner, subjects were not restricted to considering any particular set of claims. They could present in their

own words whatever arguments they felt would be most persuasive.

STUDY ONE

In the first study, 67 introductory advertising students were asked to write advertisements for three products: The utilitarian product was an air conditioner, the multiple function product was a watch, and the social identity product was a university class ring. Selection of these products was based on previous research, which had established the attitude functions typically associated with these products by our subjects (Shavitt, Han, Kim & Tillman, 1988). Products were presented in counterbalanced order. Subjects were first asked to write a headline and then to write the copy for a fictitious brand of each product.

Instructions emphasized that subjects should not be concerned with the writing style of the ad. Rather, we wanted to know what approach they considered to be the most persuasive. After finishing the first ad, subjects repeated the same procedure for each of the other two products. Subjects found this to be a fairly easy task, taking less than five minutes to write each ad.

Next, for each product, subjects received a printed list of eight product claims from which they were asked to select the *three* they felt would be the most convincing to include in an ad for the product. Each list contained four utilitarian and four social identity claims, as determined by pre-tests. Importantly, each claim was presented in the list for two of the three products. For example, "highest quality workmanship," a utilitarian claim, appeared in the list for both air conditioners and class rings. "Instantly recognizable and always impressive," a social identity claim, appeared in the list for both watches and class rings. Thus, the inherent quality or persuasiveness of the claims was held constant across products.

After selecting the product claims and rating their overall attitudes and degree of interest in each product, subjects filled out the 25-item Self-Monitoring Scale (Snyder, 1974).

Results

Both the headlines and the copy subjects wrote were coded independently by two trained judges into a number of categories, the primary ones being utilitarian and social identity. Utilitarian statements included claims about the product's quality, features, and rewards. Social identity arguments included claims about the product's image, what it symbolizes or communicates to others, and how others feel about the product. In addition, there was a category for headlines or copy that appealed to multiple functions. See Shavitt (1990) for a complete description of the coding categories. Inter-judge agreement was reasonably high (73% agreement on headline classifications and 80% agreement on copy classifications), and disagreements were coded independently by a third judge. The copy was also coded along a 7-point scale indicating the degree to which it focused on utilitarian versus social benefits (1=completely social, 7=completely utilitarian). The

TABLE 1
Study 1: Means for Coding of Copy on Function Scale

	Low S-M (n=22)	High S-M (n=24)	Overall
Air Conditioner:	6.79	6.75	6.77
Watch:	4.75	4.24	4.48
Class Ring:	4.17	3.71	4.02

Note: Judges coded the copy along a 7-pt. scale (1=completely social; 7=completely utilitarian) with a mid-point of 4 (equally social and utilitarian).

average inter-judge correlation for this coding was .70.

In order to be able to detect sensitively the relation between self-monitoring and appeal choice, we chose to do analyses that contrasted the highest and lowest thirds of the self-monitoring distribution. Forty-six subjects were included in these analyses. (Results based on a median-split were similar to comparisons of the more extreme groups, but the significance levels of the self-monitoring effects were typically weaker.)

Many of the headlines could not be confidently coded into any function category because they consisted only of a catchy phrase (e.g., "Time Flies With Avanti") or the brand name (this was true for 67% of high self-monitors' watch headlines). Coding of the copy was more straightforward. Mean copy coding scores along the 7-point function scale are shown in Table 1. (Coding the copy into discrete function categories yielded similar results.) As expected, copy content differed as a function of the product being advertised ($F(2, 70)=52.86; p<.0001$), with air conditioner eliciting the most utilitarian copy. Moreover, both high and low self-monitors wrote utilitarian copy for advertising the air conditioner. In contrast, for watch and class ring, the degree of focus on utilitarian features appeared to differ for high versus low self-monitors. However, the self-monitoring X product interaction was not significant ($F(2, 70)=.89; n.s.$).

For each product, subjects had been asked to select 3 out of a list of 8 product claims (4 utilitarian and 4 social identity) that they would wish to use in their ad (see Table 2). As expected, the types of claims chosen differed as a function of the product being advertised ($F(2, 80)=96.88; p<.0001$). Both high and low self-monitors chose primarily utilitarian claims for advertising the air conditioner and social identity claims for advertising the class ring. More social identity than utilitarian claims were also chosen for advertising the watch (the multiple function product), but self-monitoring appeared to moderate the extent to which this occurred. The self-monitoring X product interaction was not significant ($F(2, 80)=.61; n.s.$), but planned comparisons showed that high self-monitors selected significantly more social identity than utilitarian claims for watches, whereas low self-monitors chose both types of claims equally often.

Additional analyses revealed that high and low self-monitors did not differ in their attitudes or degree of interest in these products.

Discussion

Consistent with previous research (Shavitt, 1990), product type strongly influenced the functional content of subjects' ads. Subjects used mostly quality-based arguments when advertising the utilitarian product, and mostly image-based arguments when advertising the social identity product.

We had also predicted that differences between high and low self-monitors' ads would emerge primarily when advertising a multiple function product (a watch). Indeed, when selecting product claims for use in advertising the watch, high and low self-monitors differed in their focus on quality versus image arguments. High self-monitors preferred image arguments, whereas low self-monitors did not show a clear preference. High and low self-monitors were not found to differ in their liking of these products or in their degree of interest in them. Thus, any differences in the ad arguments that high and low self-monitors selected apparently were not due to differences in their product attitudes.

However, differences as a function of self-monitoring did not emerge reliably for the copy that subjects wrote themselves. Possibly subjects believed they were expected to write ads that would be persuasive for the general population, rather than for themselves personally. In response, they may have written ads that were prototypic of those they had previously seen for these products. If that were the case, one would not necessarily expect differences in self-monitoring to translate into differences in the ads that subjects wrote. In the next study, the instructions were modified to emphasize that subjects should write ads that they themselves would find persuasive. Also, new measures were added to assist in coding the functional meaning of subjects' headlines.

STUDY TWO

A replication was conducted with 62 students from the same advertising class. In order to assess the generalizability of the Study 1 findings, a different set of products was used: The utilitarian product was aspirin, the multiple function product was sunglasses, and the social identity product was a university flag (these are popular items that students attach to their

car or dormitory windows). Selection of these products was based on previous research (Shavitt, et al., 1988; Shavitt, 1990).

The procedure was very similar to that of Study 1, with a few exceptions. Instructions emphasized that subjects should write ads designed to appeal to themselves personally, not to other consumers. After writing all three ads, subjects were asked to write a brief explanation of each headline. This was included to assist in coding the headlines. Subjects in this study were not asked to select product claims to use in ads (as in Study 1). The products in this study differed

from each other too greatly to allow us to generate valid claims that could be shared between products.

Results

Ads were coded in the same manner as in Study 1. When coding the headlines, judges were free to consult subjects' explanations to help interpret them. As a result, the functional meaning of most headlines could readily be coded. (It should be noted that subjects' codings of their headlines yielded a pattern consistent with the judges' coding.) Judges agreed on 79% of their headline classifications and 77% of their

TABLE 4
Study 2: Means for Coding of Copy on Function Scale

	<u>Low S-M</u> (n=20)	<u>High S-M</u> (n=20)	<u>Overall</u>
Aspirin:	6.61	6.60	6.60
Sunglasses*:	4.56	3.78	4.14
School Flag:	3.03	2.18	2.57

NOTE: Judges coded the copy along a 7-pt. scale (1=completely social; 7=completely utilitarian) with a mid-point of 4 (equally social and utilitarian).

* Planned comparison indicated a significant difference between low and high self-monitors for this product ($p < .05$, one-tailed).

copy classifications. On the 7-point functional scale, the average inter-judge correlation was .63.

As in Study 1, analyses were conducted contrasting the lowest and highest thirds of the self-monitoring distribution (N=40 subjects). (Results based on a median-split were very similar.)

As predicted, the functional content of headlines differed strongly for different products (see Table 3). Virtually all of the headlines written by both high and low self-monitors focused on utilitarian features for aspirin and on social identity for the university flag. For the sunglasses (multiple function product), as expected, there was a mixture of headline types, with low self-monitors writing more utilitarian headlines and fewer social identity headlines than high self-monitors. This 2 X 2 pattern, however, was not statistically significant (chi-square=.34, n.s.).

Mean copy coding scores along the 7-point function scale are shown in Table 4. (Coding the copy into discrete functional categories yielded similar results.) As with the headlines, copy content differed as a function of the product being advertised ($F(2, 58)=102.43$; $p < .0001$).

Both high and low self-monitors wrote utilitarian copy for advertising the aspirin and social identity copy for advertising the university flag. In contrast, for the sunglasses, the type of copy written by high versus low self-monitors differed, with high self-monitors writing more social identity copy and low self-monitors writing more utilitarian copy. Although the self-monitoring X product interaction was not significant ($F(2, 58)=1.52$; n.s.), planned comparisons indicated that high and low self-monitors differed significantly in the copy they wrote for sunglasses, but not for the other products (see Table 4).

Additional analyses revealed that high self-monitors rated their attitudes and degree of interest in the products higher than low self-monitors did. This was true for each of the three products.

Discussion

As in Study 1, product type strongly influenced the types of ads that subjects judged to be persuasive. For both headlines and copy, subjects used primarily

quality-based arguments when advertising the utilitarian product, and primarily image-based arguments when advertising the social identity product. Also as predicted, differences between high and low self-monitors' ads emerged most strongly when advertising a multiple function product (sunglasses). For sunglasses, which could be viewed in terms of both utilitarian and social identity goals, high self-monitors tended to write image-based ads, whereas low self-monitors tended to write quality-based ads.

The fact that subjects were explicitly instructed to write ads designed to appeal to themselves increases confidence in our interpretation of these results in terms of the persuasiveness of appeals. That is, subjects' ads apparently reflected differences in what they *personally* would find to be persuasive arguments for purchasing a given product, rather than differences in what they felt would convince others or differences in the ads they had previously seen for the products. Furthermore, our interpretation of subjects' headlines was guided by subjects' own explanations of the functional meaning of what they had written.

In this study, high self-monitors gave more favorable attitude and interest ratings to all of the products. Although it is not clear why high self-monitors would express more favorable views toward aspirin, sunglasses, and university flags than would low self-monitors, it is difficult to see how this could account for the pattern we observed in the types of ads they wrote. Whereas high and low self-monitors' attitude ratings differed for aspirin and university flags, the predominant functional content of high and low self-monitors' ads did not. That is, attitudinal differences did not correspond with functional differences in the persuasiveness of appeals.

GENERAL DISCUSSION

Overall, the present studies suggest that product characteristics interact with individual differences in self-monitoring to influence the persuasiveness of quality-based versus image-based appeals. Across two studies, when designing advertisements for multiple function products, high self-monitors chose to use social identity arguments

to a greater extent and utilitarian arguments to a lesser extent than did low self-monitors. However, high and low self-monitors did not differ in their choice of arguments for advertising other products: Both high and low self-monitors chose to use mostly utilitarian arguments for advertising utilitarian products, and mostly social identity arguments for advertising social identity products.

Our findings are consistent with several previous studies that have shown that high and low self-monitors differ in their focus on utilitarian versus social identity considerations when making product judgments (DeBono & Packer, 1991; Snyder & DeBono, 1985, 1987). However, the results provide some clarification of the role of self-monitoring in the functions served by attitudes toward products. Our findings suggest that high and low self-monitors differ in the way they perceive certain products, rather than in the absolute importance or salience of utilitarian versus social identity features across products. That is, self-monitoring seems to come into play primarily when a product could be thought of in terms of more than one feature or goal, leading people to focus *selectively* on one type of feature versus another.

Thus, when a product offers opportunities to pursue both utilitarian and social identity goals, high self-monitors tend to evaluate the product in image-based terms and low self-monitors tend to evaluate the product in quality-based terms. However, when one function or goal is predominantly salient with respect to a product, high and low self-monitors appear to evaluate the product in similar terms, and judge similar types of arguments to be persuasive for selling the product.

The present findings also provide support for the validity of the product category distinctions we have proposed. Consistent with previous research on the functions that tend to be associated with particular products (Shavitt, 1990), product type strongly influenced the functional content of the ads that subjects wrote. Importantly, we were able to predict *a priori* whether a product would be promoted predominantly based on its value for achieving utilitarian goals, social identity goals, or both. Subjects' responses validated these predictions in most cases. Thus, it appears possible to identify *a priori* those products for which high and low self-monitors' responses should differ the most.

Nine Consumption Lifestyles
Susan Fournier, University of Florida
David Antes, University of Massachusetts
Glenn Beaumier, Westinghouse Savannah River Company

ABSTRACT

This paper presents an empirical application of behavioral segmentation based not upon isolated brand or category purchase habits but on the collective pattern of a household's purchases across different product/service categories over time. Purchase diary records from 1717 households in the 1986 Consumer Expenditure Survey, capturing a full 88% of total discretionary purchases in 122 product/service categories, were organized in terms of the needs and values reflected in each purchase. After controlling for income, the needs-based expenditure categories were cluster analyzed, yielding nine different consumption lifestyle segments. The distinctive purchasing patterns and demographic profiles of the groups are described. The general utility of this lifestyle approach to segmentation is also considered.

INTRODUCTION

In any given culture there exist various "consumption communities," informal groups expressing shared needs, values, or lifestyles through distinctive consumption patterns (Boorstin 1973). That shared needs support common purchase priorities is reflected in many popular marketing segmentation schemes. Users of social class (Coleman 1983) and family life cycle (Wells and Gubar 1966) assume that shared socio-demographic characteristics imply shared needs and goals, and that product choices reflect those goals. Similarly, lifestyle (Wells 1975) and value-based segmentation schemes such as LOV (Kahle 1983) and VALS (Mitchell 1978) assume that those with shared psychological profiles acquire similar assortments of products for the expression of their values. "Consumption constellations" acquired in the service of social roles (Solomon 1988) further demonstrate the linkage between shared needs and collective consumption patterns.

It can be argued that the study of the collective consumption patterns of groups with shared goals and values is far from complete. In fact, a call for research that identifies a typology of "consumption lifestyles" remains unanswered in the literature (Sheth 1980; Upah and Sudman 1979). Ideally, such a typology would be grounded in actual consumption behaviors rather than the abstracted values, attitudes, interests, or demographics believed to support those behaviors. Moreover, it would concern the total assortment of products purchased over time by a group member, and the overall statement about identity that this collectivity implies.

The present study identifies such a typology from an analysis of the value-based and need-driven purchases made by 1717 panel households responding to the 1986 Consumer Expenditure Survey. Before presenting the results of this cluster analysis, literature regarding the segmentation of consumers into consumption lifestyle groups is first reviewed,

and value-based typologies for the organization of product/service expenditures are considered.

**BEHAVIORAL LIFESTYLE
SEGMENTATION**

Consideration of purchasing as an interrelated, patterned phenomenon was first introduced in the lifestyle segmentation literature (Moore 1963). Before association with cognitive constructs such as interests and opinions, the lifestyle term implied a characteristic pattern of behavior that both determines and is determined by consumption (Anderson and Golden 1984). It stressed the fact that each product purchased is part of a meaningful pattern and that through lifestyle analysis, the interrelated and co-dependent behaviors shared by segment members could be isolated and lifestyle groups identified.

Backward segmentation studies were the first to empirically examine the notion of co-occurring, complementary purchases (Alpert and Gatty 1969; Wells 1967). These early cluster analyses of supermarket purchases demonstrated that purchases do fall into meaningful bundles and that groups of consumers with shared consumption patterns also share demographics, tastes and values such that consumption lifestyle groups can be meaningfully identified.

In the sociology and economics literatures, several studies have attempted to identify groups exhibiting shared consumption patterns. Zablocki and Kanter (1976) used ethnographic data to group consumers according to the sources of identity implied in their patterns of consumption. Four broad consumption communities are proposed: (1) those embracing a hedonistic lifestyle, (2) those rejecting evidences of material success and focusing on consumption of ideas and experiences, (3) those seeking cultural identity through ethnic heritage, and (4) those adopting collective behaviors such as fads or socially-sanctioned identities (e.g., the "Yuppie") to define a sense of self.

A fine example of an empirically-based, behaviorally-driven lifestyle segmentation can be found in the work of Uusitalo (1980). Analyzing share of expenditures for each of seven basic categories (i.e., health, transportation, food, furniture, dwelling, clothing, other), she identifies eight Norwegian "consumption lifestyles." In addition to socio-demographics, these groups vary in dollar allocations for necessities versus discretionary choices, spending on mobility and transportation, and relative "consumption modernity" (i.e., the use of modern, "processed" goods and services).

Douglas and Isherwood (1979) also partitioned consumers into lifestyle groups based on actual expenditure patterns. The three-group solution considers both total spending levels and the targets of those expenditures. These include: (1) a small-scale

expenditure group with a high proportion of dollars allocated to food, (2) a medium scale group with disproportionate spending on advanced consumer technology, and (3) a large-scale group with a high proportion of total expenditures on entertainment and information systems.

Each of these behavior-based lifestyle analyses has been limited by a focus on total expenditures without controls for income. As a result, low/medium/high expenditure groups generally dominate the solutions. In addition, little theoretical justification has been offered for the product and service categories chosen. Typically, available functional category codes such as food and housing are used to collapse expenditure information, restricting the types of insights that are offered. It is suggested that a lifestyle scheme that takes advantage of the richness of the values construct and its conceptual link to behaviors, while not losing the advantage of the validity of the behavioral measures themselves, will add such richness and insight. The cluster analysis that follows takes this approach.

A CONSUMPTION LIFESTYLES SEGMENTATION STUDY

Product/Service Categorization Schemes

A call for a needs-based categorization scheme for consumer products and services has been raised in the literature (Sheth 1980). Such a scheme would provide insight into consumer purchase motivations and allow inferences about the values that structure those motivations, thus providing a meaningful framework for analysis of collective consumption patterns. By classifying products/services in terms of the needs and values they imply, and then clustering people on their purchase patterns in relation to those categories, a rich and valid typology of consumption lifestyles emerges.

Several researchers have indirectly attempted product categorization along these lines. Csikszentmihalyi and Rochberg-Halton (1981) studied people's special possessions in terms of the meanings they held for their owners and found that products could be grouped according to the basic values they satisfy. Prentice (1987) had subjects classify favorite possessions into groups reflecting their similarities as sources of value to their owners; based on these data, she developed a four-dimensional solution for favorite possessions, including self-expressive/instrumental, recreational/practical, cultured/everyday, and prestigious/common dimensions. More directly, Settle and Alreck (1989) suggest classifying all consumer products, not just special possessions, according to the needs and values fulfilled through their purchase and usage. The authors propose their own list of fifteen needs categories for this purpose.

The categorization scheme used in the current exercise incorporates the above-mentioned research while building from an existing values framework (White 1951). By categorizing the values evidenced in a wide-variety of written and verbal materials collected over an eight-year period (e.g.,

autobiographies, TAT records, children's stories, ads, psychoanalytic records, speeches), White identified seven basic needs and 14 sub-categories believed to capture "the all-pervasive values that people in our culture talk about when they say they want something" (p.11). The categories include: (1) egoistic needs, including achievement/recognition and dominance/control, (2) need for play, including desires for experience and excitement, beauty, and creativity, (3) need for practicality, (4) need for cognition and knowledge, (5) morality, as reflected in legal and religious codes, (6) physiological needs, including food and health, safety and security, physical comfort, and cleanliness and (7) social needs, including appearance and belonging.

Product/Service Expenditure Categorization Task

Preliminary tests supported the selection of White's scheme over other typologies offered in the literature. Three judges more readily and reliably classified products into White's value categories (83% of products classified with 73% interjudge agreement) than they did using Settle and Alreck's groups (80% classification; 67% agreement) or the categories of Rokeach (65% classification; 65% agreement) and LOV (70% classification; 68% agreement).

Several revisions to White's original scheme were made in order to increase its relevance to the consumption setting. First, pretest diagnostics suggested a split of the practicality need into two categories: functionality and convenience. Segmentation studies in the economics area supported the addition of a separate category for housing expenses. Lastly, other value schemes highlighted two important but missing social needs, namely conformity and nurturance. This resulted in 18 need/value groups for classification and analysis.

One hundred thirty-two product and service expenditure categories were classified into the 18 need/value groups for purposes of this study. The assignment of products/services to the need/value categories was determined by a panel of ten "expert judges," i.e. students and faculty in the marketing and sociology fields familiar with the values literature. First, each of the need/value categories was discussed with the judges as cards summarizing abbreviated definitions were systematically arranged on a table. The judge was then provided with a stack of randomized cards on which the names of the 132 product/service categories were printed. Judges were instructed to "consider the predominant purchase motivation behind consumer acquisition of that particular product or service" and to classify it into one of the need/value categories accordingly. Beyond the 18 categories mentioned above, a "don't know/product ambiguous" category and "multiple needs/no one need dominant" group were also available to improve the reliability and accuracy of classification decisions.

Retained for study were those products for which a dominant need/value group was identified. It was arbitrarily decided that majority (i.e. greater than 50%) interjudge classification agreement would

satisfy the criterion of dominance. Ten products were eliminated because of ambiguity, leaving 122 products classified reliably into 18 needs-values categories for analysis. Percentage agreement between judges for the sorting task was calculated at 72%, a result which compares favorably with other studies in which stimuli have been classified along complex value or need lines (Pollay 1983). A list of the final need/value categories and a sample of consumer products assigned to each is provided in Table 1.

The Data

Data for the empirical portion of this paper are from the 1986 Consumer Expenditure Survey (CES), a public domain data set that contains a rich collection of household expenditure and demographic information. Adhering to strict sampling and data collection guidelines set by the U.S. Census Bureau, the survey is considered representative of U.S. households and is used by the Department of Labor's Bureau of Labor Statistics (BLS) to estimate the consumer price index. BLS estimates that 90-95% of total yearly household expenditures are captured in survey panel member diaries.

The CES expenditure data is in diary format; on a quarterly basis, each household reports the dollar amount of expenditures in each of 528 possible categories. As a data management technique for the present study, several expenditure categories were aggregated into comprehensive, non-redundant variables (e.g., six floor coverings were collapsed to form a "carpet" category). Other variables were excluded in light of their savings or investment nature. This left 132 expenditure categories, capturing 88% of the expenditures reported by CES, for the previously-described product classification task.

To remove the effects of seasonality and to maximize the probability of purchase incidence in low frequency categories, only households with purchase data for a contiguous 12-month period were used in the present analysis. This reduced the sample from 21,466 interviews to 6868 interviews within 1717 households.

In order to remove the effects of income from the analysis, to reduce effects of range variability across categories, and to encourage solutions beyond low/medium/high expenditure groups, two transformations were performed on the data. Each category expense was first expressed in terms of its share of total household expenditures; these percentage allocations were then normalized.

Cluster Methodology

One-hundred seven multivariate outliers, arbitrarily defined as those remaining "ungrouped" after 75% of total agglomerations, were first removed from the analysis in light of their potential biasing effects. The remaining sample of 1610 households was randomly split to allow a reliability assessment of the final cluster solution.

A two-stage approach to clustering was selected (Punj and Stewart 1983). Initial solutions, identified using Ward's hierarchical method with squared Euclidean distance as a measure of similarity, provided

a preliminary indication of the total number of clusters and identified expenditure category variables that did not discriminate effectively among the groups. As a result of the first phase, the nine cluster solution was chosen and three expenditure categories (i.e., conformity, cleanliness and control) were excluded. The final cluster solution was identified using the Quick Cluster K-Means procedure.

FINDINGS

In this section, profiles of the nine consumption lifestyle clusters are presented. Each group has been assigned a label to reflect the central theme governing its unique value-related spending pattern. Despite the fact that the clustering was determined on the basis of normalized proportionate spending patterns, marked discrimination between the groups in terms of socio-demographic characteristics is also evident. Admitting within-group variation on age, income, social class and family life-cycle, the groups do nonetheless display dominant demographic profiles that effectively distinguish them from other groups. These differences are also highlighted in the profiles that follow. Average spending patterns, in terms of both absolute dollars and shares, are presented in Table II; Table III summarizes key socio-demographic characteristics of the clusters.

Functionalists

True to their name, the Functionalists spend most of their money on essentials necessary for practical and efficient operation of the household, allocating a full 39% of their dollars to items such as household appliances, tools, cookware, window blinds, glassware, dishes and linens (versus 15% of dollars on functional needs for the sample as a whole). This "mainstream" group of average educated, average income, largely blue collar workers possesses life-stage characteristics one would expect to be associated with investment in household amenities; the group is mainly comprised of young (33% less than 35 years of age as compared to 23% on average) and middle-aged (37% are 35-54) dual-earning couples (78% married versus 62% for other groups' average; 65% two earners versus 47% on average) in the full nest stage (45% in full nest versus 29% on average; 50% have kids versus 37% on average).

Nurturers

The second group has been labeled the Nurturers. Also predominantly in the Full Nest stage of the FLC (47% versus 29% on average), expenditure patterns in this group are governed by child-rearing concerns and family values. Almost one-in-five dollars (18.3%) are spent on nurturance needs as compared to only 2.9% for the total sample on average. It appears that household start-up expenses have been completed or perhaps postponed, as expenses in the functional category among this group are the second lowest in the sample (8.7% versus 14.8% on average). Nurturers are younger than the Functionalists (52% under 35 years of age versus 33% for Functionalists), perhaps in initial stages of household formation. Nurturer households are largely

TABLE 1
Consumption Need/Value Categories

<u>Category</u>	<u>Description</u>	<u>Examples of Products/Services</u>
Appearance	Concern with looks, face, being "beautiful," physical strength	Clothing, watches and jewelry, wigs, hair care products and services, personal care appliances, health club memberships
Beauty/ Aesthetics	Pleasure in sight; Beauty in physical objects	Artwork, paint and paper, curtains, slipcovers, rugs, china, aesthetic home improvements
Belonging	Being approved, liked, accepted; attaining group unity/identity	Monthly telephone charges; campers trailers, hunting and fishing gear; country/tennis/social clubs; beer, wine, and liquor
Cleanliness/ Orderliness	Concern with the absence of dirt and smells; desire for order/ neatness	Garbage collection fees; cleaning equipment, supplies, and charges; closet and storage organizers; dry cleaning; maid service
Comfort	Bodily pleasures/satisfaction; return of the body to homeostatic state	Bed and other linens; mattresses; air conditioning, heat/ portable heating/cooling systems; cigarettes; jackets and coats; blankets
Conformity	Fitting in, obeying laws	Uniforms; car registration fees, licensing fees, inspection fees
Control/ Power	Management of/or power over people/environment	Power tools; insect and pest control; answering machines
Convenience	Efficient meeting of needs; satisfying needs in less time	Dishwashers, disposals, washers and dryers, microwaves; record and book clubs; calculators; convenience store purchases
Creativity	"Making things," making statements of uniqueness of self	Sewing materials, supplies, sewing machines; landscaping supplies; musical instruments; camera equipment and photo supplies
Fun/ Entertainment	Desire for fun, good times, activity, experience	Cable TV, movie rentals, VCR's, video cameras, stereos, sports equipment, toys/games, tickets to sporting events, dining out
Functionality	Adapting means to ends; something useful, effective, necessary, purposeful	Transportation expenses, general repair/maintenance charges, luggage, dinner and glassware, towels, roofing and gutters,blinds, clocks, lamps, stoves, refrigerators, tools
Housing	Basic housing	Rent, taxes, mortgage
Knowledge	Sources of information, learning aids	Radios, newspapers, magazines, books, tuition, computers
Morality	Reflection of right and wrong	Contributions to church, charity, educational institutions; alimony, child support
Nurturance	To give comfort, support to others	Plants, babysitting services, care for elderly/invalids, children's clothing, pets and pet services
Security	Peace of mind, stability, permanence	Personal, fire, homeowner's, and car insurance; safe deposit boxes; smoke alarms, cemetery plots
Status	Statement of rank, success, prestige, or superiority over others	Vacation homes and related expenses, silver serving pieces, housekeeping/gardening services, new cars, theater, concert, or opera tickets
Survival	Satisfaction of basic physiological needs	Food and beverages; plumbing, heating, and electrical service; water and sewage

College	22	32	41	34	66	26	28	12	11	26

middle class (45% versus 30% on average); the heads of these households are more likely than average to be highly educated persons (32% graduated from college versus 26% on average) with white collar jobs (47% versus 39% for the total sample). Interestingly, the group is characterized by lower-than-average income levels (\$19,569 vs \$25,875 on average), largely reflective of the one-earner status child-rearing duties have commanded for a third of these households.

Aspirers

This group has been labelled in light of its overwhelming status-seeking purchase behaviors. Spending a full 34.6% of their total dollars on status-related goods and services (versus only 3.9% on average), this group claims an average yearly status expense of \$12,823 (versus \$1,451 for total sample). Providing further evidence of "enjoying the high life" through excess consumption, members of this group report comparatively high spending on (status) housing accommodations (\$3,689 versus \$3,064 on average), (privileged) entertainment needs (\$1,876 versus \$1,319 on average), and (expensive gourmet) foods (\$5,292 on survival needs versus \$4,916 on average). While Aspirers have the income to support their habits (\$35,946 before-tax income versus \$25,875 for the total sample), their rank within the sample as only fourth-highest in earnings stands in sharp contrast to their #1 rank in total expenditures.

The Aspirers possess all the stereotypical "Yuppie" characteristics. Beyond the high incomes mentioned above, group members are highly educated (41% versus 26% have graduated from college) and hold the greatest proportion of white collar positions in the sample (63% versus 39%). The majority have attained middle (48%) or upper-middle (33%) social class standing. Many of these consumers are DINKS: married (75%), dual-earner households (65%) with no children (2.8 HH size; 28% from husband/wife pairs with no kids).

Experientials

This group's distinctive spending characteristic is a disproportionate allocation of dollars to entertainment needs (9.2% versus 5.8% on average) and hobbies (.6% versus .3% on average). Experientials also spend disproportionately in the appearance category (3.3% versus 2.5% on average; \$844 versus \$624 on average). These fun-lovers appear to exhibit active, "on-the-go" lifestyles, overspending on convenience-oriented products (3.1% versus 1.7% in total) that perhaps save time for things they hold to be more important i.e., having fun.

The Experiential group is disproportionately comprised of singles (32% versus 25% on average; 43% single-earner HH versus 31% on average). Possessing only average educational credentials, members of the group nevertheless hold white collar jobs (52% versus 39% in total) and earn incomes that are more than capable of supporting their vast entertainment needs (\$32,048 versus \$25,875 on average).

Succeeders

A group of established households, labelled Succeeders, was also identified. Middle-aged members of this cluster (59% are 35-54 compared to 37% for the total sample) possess by far the highest educational credentials in the sample (66% graduated college as compared to 26% for the total, and as compared to 41% and 34%, respectively, for the Aspirers and the Experientials). Their tendency toward dual-earner status (74% versus 47% for total sample, 65% for Aspirers, and 45% for Experientials) in white collar jobs (56%) commands for them the highest household income levels of any group in the sample; on average, Succeeders earn a full \$42,779.

And Succeeders spend their money, claiming the highest absolute dollar expenditures in 12 of the 15 value categories. They also report purchases in 61 of the product categories measured, as compared to only 43 on average. Besides this difference in pure volume, a distinguishing feature of the Succeeder is disproportionate spending on knowledge, education and self-advancement (7.6% of total expenditures versus 1.4% on average). In addition, Succeeders invest in their work-world appearances, overspending on self-enhancement needs (3.8% of total expenditures versus 2.6% on average; over twice the average dollar amount, \$1407 versus \$624 on average).

The Moral Minority

The only distinguishing feature of the Moral Minority is their disproportionate donations to educational organizations, political causes and the church (12.8% of total expenditures versus other groups' average of 1.7%). Moral Minority households contain a disproportionate share of husband/wife pairs in the Empty Nest phase (37% versus 23% on average). Members of this group command the second-highest levels of income in the sample (\$39,558) while maintaining traditional husband/wife roles (42% single earners versus 31% on average, the highest percentage of single earners in the sample).

The Golden Years

Golden Years' spending patterns suggest the establishment of second homes or the long-awaited remodeling of original homes; despite their ages (average age 54; 36% over 65 years of age), group members claim the third highest spending levels for housing (\$3,909 versus \$3,064), report heavy investments in aesthetic improvements to the home (a full 20% of expenses are devoted to this need versus only 2.1% on average), and are investing disproportionately in labor-saving conveniences (2.3% versus 1.7% on average). True to their name, the Golden Years also spend the greatest amount on products that provide physical comforts (\$595 versus \$362) and entertainment value (\$1,895 versus \$1,319). In line with their demographics, they also invest in a variety of insurance policies that yield for them emotional security in facing the uncertainties of old age (6.5% on the security need versus 4.3% for the sample on average).

Income levels are exceedingly high in this group (\$38,129), second only to Succeeders and Moral Minority members. Much of their money appears to be from pension funds and investments, however, as 36% of the households report no-earner status and 40% are retired.

Sustainers

In sharp contrast to the Golden Years is a group of mature consumers (59 years of age on average; 44% over 65; 41% retired) labeled the Sustainers. Members of this group devote a full 45% of their total dollars (versus 27% on average) to basic survival needs such as food, electricity, heat and water. This group also spends a higher than average amount in absolute dollar terms on expenses in this category, perhaps reflecting use of more expensive inner-city outlets and high consumption of convenience foods (i.e., "the poor pay more"). Higher than average allocations are also reported in the belonging category (4.5% versus 3.7% for total sample), largely due to alcohol-related expenses. The Sustainers' fate appears largely constrained by economic circumstance. The group exhibits the lowest education levels (47% did not graduate from high school), the second lowest income levels (\$14,909 on average), and the lowest social class rankings (75% occupy the bottom two classes) in the sample. Forty percent of the households have no earners.

Subsisters

Subsisters report the lowest expenditures of any group across all 18 need categories. The group is best described as being "house poor;" over one-third (36%) of Subsisters' total expenditures is devoted to housing, which compares markedly to a total sample average of 14.8%. Spending patterns in this group are clearly a function of socio-economic factors. Subsisters report the lowest household income levels (\$12,573; 38% with incomes under \$7,000), the second lowest education levels (38% less than high school), and the highest percentage of unemployed (22% versus 11% on average). A large percentage of these households live on welfare (38% have no salaried earners yet report income from other sources). A sizeable minority are single-earner families (31%) and single parents (13%), and a disproportionate number have minority racial status (29% versus 16% for total sample).

VALIDATION

Replicability of the final solution was tested using a holdout sample of 823 households. The solution was replicated in terms of both need/value and demographic profiles. The solution's predictive validity was assessed via regression analysis using FLC, social class and income as additional predictor variables. The cluster solution alone accounts for 29% of the variance in total expenditures and uniquely contributes 7% to the total variance explained when FLC, social class and income are in the model (significant at $p < .001$).

DISCUSSION

The results of this analysis suggest that value-related consumption patterns can be identified and that these patterns reflect more than a simple manifestation of age and income effects. While the transformation of the data into normalized percentage allocations among the value-based categories successfully attenuated income effects in the final solution, it is recognized that income nevertheless exerts some influence through variability in discretionary dollars (e.g., the percent allocated to food decreases when dollars increase). However, the regression results suggest that consumption lifestyles reveal patterns of motivation that are not captured when the focus is on the more income-privileged aspects of choice indicated through social class and income classifications, or on the evolutionary nature of needs reflected in life-cycle schemes. The fact that such strong demographic differences emerge despite controls and in solutions defined not on demographics but on value-related consumption patterns is strong testament to the continued significance of life course, income and social class variables in shaping consumer behavior.

These arguments support the utility of other value-based consumption typologies. In fact, numerous parallels between the consumption lifestyles solution presented here and the VALS typology can be drawn (e.g., Succeeders = Achievers, Aspirers = Emulators). However, several comparative advantages of the present solution can be cited. Importantly, the present scheme has been driven by actual, value-based dollar expenditures rather than abstracted, consumption-irrelevant values (e.g., "Marijuana should be legalized). Additionally, the present scheme represents members from a broad spectrum of ages, capturing each lifestyle adequately, while VALS disproportionately weights older consumer groups in its solution. A test of the predictive validity and explanatory power of a consumption lifestyle scheme such as this versus more traditional value-based schemes such as VALS or LOV could demonstrate the power of behaviorally-based value analyses, perhaps revitalizing interest in value segmentation as a marketing tool.

A final point regarding the coding of products and services into value groups deserves mention. The current procedure used expert judges to classify products and services into 18 theoretically-derived value groups and then applied an arbitrary criterion (50% agreement) to assign codes. This strategy resulted in a strong level of interjudge agreement as compared to previously-reported value classification exercises. Regardless, the procedure does ignore that fact that a given product may address multiple needs by displaying strong secondary value themes or by tapping different values for different consumers, values perhaps overlooked in theoretically-derived coding schemes such as the one used here. To control this source of error, future investigations might consider restricting analysis to products with strong, singular value themes. In addition, having consumers define and derive relevant value categories appears warranted.

Consumption Choice Within the Black Extended Family Network

Judy Cohen, Rider College
Carol Kaufman, Rutgers University

INTRODUCTION

Family decision making has long been recognized as an important component of consumer behavior. The first Association for Consumer Research - Household Consumption Behavior Session (Burns and Gentry 1988) uncovered several topic areas which are needed to further develop knowledge in household theory. One such area is subcultural influence on family consumption choice.

Subcultural influences have also been identified as an intervening variable in family decision making by Buss and Schaninger (1984). Penalzoa and Gilly (1986) have suggested frameworks for studying Hispanic families. O'Guinn, Faber and Imperia (1986) have found that family decision making of Hispanics differs from that of whites.

Another major subcultural group is the black market. In 1990, there were 31 million blacks, comprising over 12 per cent of the U.S. population. In spite of this market presence, few studies in consumer research (Baran 1986; Wilkes 1971) have been done on black family consumption choice processes. Other disciplines, such as sociology and anthropology, have extensively discussed and debated approaches to the study of black families, black family structure and behavior, and black family consumption choice.

This paper offers suggestions to fill this gap in the consumer research literature. This paper: (1) describes the controversy over the structure and behavior of the black family; (2) reviews the interdisciplinary literature on black family structure and black family decision making, to (3) develop propositions concerning black family consumption choice; (4) suggests methodologies to test the propositions; and (5) discusses the contribution of the framework for the black extended family network to family research.

BLACK FAMILIES: THE CONTROVERSY OVER THE MATRIARCHAL MARKET

The structure and behavior of black families, as viewed by practitioners and academicians from a variety of disciplines, is that of a matriarchy. The description of Afro-American society as a matriarchy was first developed by Frazier (1939), who proposed that the U. S. black family evolved as a result of slavery and blacks' subsequent history in the United States. Frazier painted a picture of broken families, ineffectual or absent fathers, and a matriarchal system. This view was reinforced by Moynihan (1965), who felt that the instability of the black family was the cause of problems in the black community. That is, the black family exhibits traits which are dysfunctional and deviant from the norm. The concept of the black matriarchy has been and still is adopted by some marketers (Bauer and Cunningham 1970; Taylor 1982).

In the 1970's, scholars in various fields began to react against Frazier's conceptualization of the black family (Allen 1978a and 1978b; Mathis 1978; Nobles 1978; Willie and Greenblatt 1978). Some scholars (Nobles 1978; Scanzoni 1971; Staples 1976) proposed that black families were victimized by economic and racial discrimination. If given the same economic conditions, black families and white families are equivalent (Liebow 1966; Mack 1971; Rodman 1963; Scanzoni 1971; Willie 1974). Others argued that the unique aspects of black family life must be taken into account (Allen 1978a and 1978b). By focusing on the stereotypical matriarchal figure, the interactions among other family members are ignored. In this paper, we examine the black family as a network of interactions. The key to understanding this network of interactions is the adoption of a cultural variant perspective.

We use Johnson's (1988) criterion of a cultural variant study, i. e. "... white middle class norms are not the primary referent and Black cultural patterns are primarily explained by use of Black values and experiences" (p. 95). The need for a cultural variant perspective stems from the fact that "black and white families exist in different social and cultural environments, and as a result they differ in both structure and way of functioning..." (Allen, 1978a, p. 125-6).

PRINCIPLES UNDERLYING A CULTURAL VARIANT PERSPECTIVE TO THE STUDY OF BLACK FAMILY STRUCTURE

Our cultural variant perspective is based on two guiding principles. These assumptions are (1) the extended family, rather than the nuclear family, is the black family structural norm; and (2) interaction between family members can be best understood in the context of mutual exchange, rather than power and conflict resolution.

Black Family Structure: The Nuclear vs. Extended Family

Approaches to the study of the black family which do not use a cultural variant perspective assume that the structural norm for all families must be the nuclear family. The cultural variant perspective reaches a different conclusion; that the norm for black families derives from African family structure. "[I]n African societies the conjugal unit (the African counterpart to the nuclear family) is subordinate to the consanguineal kinship group" (Foster 1983, p. 214). The family consists of both lineage (relations based on descent) and marriage, forming an extended family. In addition, the extended family network may include "adopted" members. McAdoo (1980) found that 70 per cent of the black mothers surveyed had "fictive kin" as children; 71 per cent of those relationships had continued into adulthood.

Sudakarsa (1980) and Martin and Martin (1978) emphasize that the black extended family is not a collection of nuclear families. "[I]n many cases, single family households are only part of larger family structures" (Sudakarsa 1975). Even in what appears to be a nuclear family, "there is a greater likelihood of black two-parent families to interact with extended family than their white counterparts" (Wilson 1986, p. 254). In addition, what appears to be a "broken home" may only be a component of an extended family.

Only by considering the extended family in its entirety can black family structure be understood. Because black subculture has a broader notion of family than mainstream white culture, the term "family" must include the notion of kin living at different residences, which we designate the "extended family network". In this paper, the term "household" will be used to refer to a group (both relatives and nonrelatives) living in the same residence.

The interactions within black extended family networks are likely to be more complex than those within the household or the nuclear family unit. In addition, we argue that interactions in black extended family networks differ qualitatively from those in mainstream nuclear families. Interactions within the nuclear family unit are often studied in terms of power and conflict, following Wolfe's (1959) seminal work. We propose that a preferable approach to power and conflict resolution is the mutual exchange framework.

Power and Conflict Resolution vs. Mutual Exchange

Power is related to the household decision process whenever a household member recognizes that his or her own need satisfaction depends on an ability to influence the behavior of one or more other household members. Blau (1964) describes power as an influence "where one induces others to accede to his wishes by rewarding them for doing do" (p. 115). Thus the focus is on satisfaction of one's own needs. A wealth of household studies have focused on power, without taking culture into account (e.g., Burns 1976; Burns and Granbois 1977; Filitault and Ritchie 1980; Green and Cunningham 1975; Jenkins 1979; Hempel 1972). Power is related to conflict in family consumer choice because individuals will choose to enter into or prolong conflict if they lack the ability to bring to a satisfying conclusion the discrepancies in wants of different family members (Seymour and Lessne 1984). Discrepancies of wants, resulting in a win-lose situation, is assumed.

This orientation contrasts with that of Corfman and Lehman (1987), who define power as a more benign construct, and view conflict as being resolved cooperatively. In this paper, we agree that cooperation is an important component to research in family consumption choice. However, since the adversarial definition of power best reflects the orientation of studies which examine the matriarchal nature of black families (e.g., King 1969; Mack 1971; Willie and Greenblatt 1978), we will also adopt this definition. In this way, we can discuss the literature on black families in a manner consistent with the

assumptions of those studies, and also discuss the limitations of this orientation. For example, Martin (1980) notes ". . . the power concept does not provide much of an explanation for outcomes which are not in terms of winning and losing . . . Only under special conditions can families survive when zero-sum hedonistic power confrontations are used as strategies for solving conflicts" (p. 130).

A more appropriate perspective to the study of black families uses the concept of mutual exchange. "Exchange involves 'a transfer of something tangible or intangible, actual or symbolic, between two or more social actors,' implying that each party to the exchange both gives and receives value" (Houston and Gassenheimer 1987, p. 4). Blau (1964) differentiates between social and economic exchange. In economic exchange, the terms of the exchange are given before any transfer takes place. For example, in a buyer-seller economic exchange, the price for a specific product is decided before the product is exchanged for money. Social exchange, in contrast, "involves favors that create diffuse future obligations, not precisely specified ones, and the nature of the return cannot be bargained about but must be left to the discretion of the one who makes it" (Blau 1964, p. 94).

When Martin and Martin (1978) and Stack (1974) regularly refer to mutual exchange relationships within the black family, they are describing social exchange. Rather than focusing on who "wins" in situations of power and conflict, these studies examine exchanges in which all parties involved, and thus the family as a whole, benefit through mutual financial, emotional and material support. By examining mutual exchange, we do not mean to imply that conflicts never occur in black families. Rather, power and conflict occur within the context of mutual exchange. Therefore, this paper focuses on mutual exchange as the framework for the structure of and interactions within the black family extended network.

Frenzen and Davis (1990) incorporate the concept of social exchange into their discussion of embedded markets, which are "markets in which social relations alter market relations" (p. 1). More specifically, "horizontal embeddedness occurs when strong relations bind buyers to other buyers . . . on one side of the market interface" (p. 9). When Frenzen and Davis identify "relatives and close friends" as a potential market segment, they indicate that families are a form of embedded horizontal markets. Study of the black extended family creates an opportunity to assess how social exchanges within horizontal embedded markets affects both family structure and family consumption choice.

BLACK FAMILY CONSUMPTION CHOICE

Using the concepts of extended family and mutual exchange, we can examine in greater detail black family consumption choice. It may be tempting to discuss black family consumption choice in comparison with that of other cultures. We argue that until we study and begin to understand black families

themselves, we will not have sufficient bases upon which to make comparisons. Thus, this initial effort will develop propositions which focus solely on black families. Our discussion begins with larger issues of black family structure. We then turn our attention to more specific issues of family member interaction, and individual-level roles in black families.

Overall Family Structure

The first, and perhaps most general, proposition is that consumer behavior takes place in the context of the extended family network. Some researchers have recognized the importance of the black extended family, but have limited their studies to extended families living in a single residence (Angel and Tienda 1982; Nobles 1978; Wilson 1986). In contrast, Taylor (1986) emphasizes the need to study interactions between households.

Proposition 1: Black family consumption choice includes participation both by family members living within the consuming household and family members living in other households.

Proposition 1 leads to methodological imperatives for researchers of black family consumption choice. The household is not the appropriate unit of analysis. In the extended family network, individuals are interconnected across residence boundaries to form a system of information flow and mutual exchange. The nature of the proposed interpersonal interaction suggests that network analysis may be a useful methodology for the study of black families. (See Brown and Reingen 1987; Reingen, Foster, Brown and Seidman 1984; Reingen and Kernan 1986 for reviews of this technique). The individuals who play the key roles in the network can also be identified using network analysis (Martin and Martin 1978).

Although the extended family appears to be the structural norm in black culture, "black families do not constitute a monolithic pattern of familial relationships . . . but vary by social class as do white families" (Willie and Greenblatt 1978, p. 693). One issue that researchers of black families have addressed is whether the black extended family structure stays intact for families in the middle class, i.e., whether black families become more nuclearized as they move up in social classes.

Two theories regarding the effect of social mobility on the black extended family have been proposed (Brown-Collins 1981; McAdoo 1978). One theory states that the nuclear family is more conducive to social mobility than the extended family. This is because the nuclear family is more geographically mobile, more autonomous, and can use their resources solely for the promotion of their own welfare. This theory would predict that middle class black families would tend to be nuclear; extended family ties have weakened. The opposing theory states that the extended family ". . . promotes social mobility by providing economic resources and social support not available in the small family" (Brown-Collins 1981,

p. 36). This theory would predict that the extended family remains intact for middle class black families.

Empirical support for these theories is mixed. McAdoo (1978) studied upwardly mobile black families. She found that both emotional and functional help were received and given. McAdoo found no difference between those born working class, who had moved up to middle class, and those born middle class. Furthermore, those studied ". . . continued their close interaction and help exchange pattern with kin before, during, and after mobility" (p. 775). Thus these families did not "move out to move up"; in fact, some families felt their upward mobility would not have been possible without help from kin. Taylor (1986), in a national study of blacks of varying income levels, found that income was positively correlated with receiving support from the extended family.

These findings appear to contradict those of Martin and Martin (1978), in their study of blacks in small town areas and Kansas City. They found that mutual aid keeps family members out of poverty, but that individuals may find it harder to rise to middle class because they may have to contribute to the family welfare instead of going to school. Martin and Martin also found, however, that middle class family members are expected to help kin. If middle class family members are not willing to share their resources, they become alienated from the family. Alienation can also come involuntarily, as middle class family members change their lifestyles. They may feel distant from family, although they wish to be close.

The different findings of McAdoo (1978) and Taylor (1986) compared with Martin and Martin (1978) may in part be due to different research methodologies. Both McAdoo and Taylor used structured surveys, which focused on exchange relationships which were intact, rather than those which were weakening. Martin and Martin's (1978) unstructured, in-depth approach allowed for more serendipitous findings. It appears that, although the exchange network is present in all social classes, conflicts may arise when some family members move into middle class, while others remain in lower socioeconomic classes.

Proposition 2: The black extended family can be observed in all social classes. However, when different members belong to both middle and lower socioeconomic classes, some middle class households may become alienated.

Functions of the Black Extended Family

Scholars studying the black extended family network have suggested a network of mutual assistance, or exchange, between family members. Martin and Martin (1978) found two major functions of the black extended family: leadership and support. "Relatives depend on one another for emotional, social, and - most important - material support." Mindel (1980) found the black extended family help system included more functional forms of help than that of whites and Hispanics. Functional help

"involved a variety of mutual aid and support" (p. 26), including advice and monetary support. Similarly, McAdoo (1978) found that both financial and emotional help was received from the family. The combination of material support and advice-giving leads us to:

Proposition 3: The functions of the black extended family include a system of mutual social exchange, including financial support, help with consumption choice, and provision of consumer goods.

A few studies have examined whether the functions of black extended families differ by region of the country or by urban vs. rural residence. Regional differences do not appear to be significant. Aschenbrenner (1973), in her study of black extended families in Chicago, noted that "[s]everal of those who had been born in the South described family relationships and activities there which closely resembled those in Chicago" (p. 259). Taylor (1986), in a national study, also found no difference in receiving support from the extended family between regions in the United States. Nor did he find urban/rural differences. Martin and Martin (1978), however, found that urban blacks relied more on government aid and less on family than rural blacks. Because government aid can not be shared with other family members, the extended family network weakened.

Proposition 4: The black extended family network does not differ regionally.

Proposition 5: Extended family networks weaken when poor urban blacks receive government aid which cannot be shared with kin.

Structure of and Interactions within the Black Extended Family

Social exchange functions within the black extended family take place on two levels: group and individual. On the group level, an individual family member may offer support to the family (through family mechanisms described below) or individual family members. In turn, the individual expects to be helped by the family, rather than by the individual who received their support. On the individual exchange level, a family member offering support to another member expects the recipient to be obligated to return something of value at a later date. Unfortunately, research on exchanges within black extended families often ask respondents about giving and receiving from "family members" (McAdoo 1978,1980; Mindel 1980; Taylor 1986). While these studies offer valuable information about some aspects of black extended family structure and behavior, they do not differentiate between exchange with the family vs. exchange between individuals within the family. Other studies do differentiate between individual vs. group exchange.

Exchange between Individuals and the Family.

When an exchange is made between an individual and the family, the individual gives help to the family and expects to receive support in times of need, but not necessarily from the person who received their help. McAdoo (1980) refers to this as the "kin insurance policy". A major provider of support is the dominant family figure.

Dominant Family Figure(s): Martin and Martin (1978) found that at the head of the black extended family was a dominant family figure. This person, who was usually the eldest, was either male or female, or a husband/wife team. Because black women tend to outlive black men, it was often a female. When the dominant family figure(s) die, the role(s) are generally taken over by the family member(s) who seem most competent and appropriate for this role. The dominant family member gives advice and material support. When a husband and wife share the leadership role, one of the major duties of the husband is to "help provide for the family" (Martin and Martin, p. 20); one of the major duties of the wife is to teach family members "how to handle money" (Martin and Martin, p. 20). Martin and Martin (1978) refer to the husband's role as the stabilizer and the wife's role as the organizer. Because of the family leaders' influences on consumption activities of family members, we would expect:

Proposition 6: The family leader(s) is often a "giver" in the exchange network; giving includes consumer goods and advice on financial and consumption choices.

The family leader's home serves as a base household for the extended family. Interactions among family members is frequent. In Martin and Martin's (1978) study, 65 per cent of respondents said they interacted with extended family members at least once a week. In McAdoo's (1980) study, black mothers living within 30 miles of their relatives tended to see relatives at least weekly. However, family members do not have to live in the base household or even be geographically close to be an integral member of the family or to receive support from the family. It is logical to expect that:

Proposition 7: Family members who live closer to the base household interact more frequently in person with other family members, and thus are more likely to receive assistance in the form of small consumer goods and small monetary gifts. For larger monetary gifts, more expensive consumer goods and advice on financial and consumption choices, distance from the base household does not affect the exchange process.

"Momma": As stated above, individuals in the extended family engage in social exchange with the family as a group. The individual who facilitates this exchange process is "Momma". Because "Momma" is often but not necessarily the family leader (Martin and Martin 1978), she will be considered independently of

the leadership role. "Momma" acts as an exchange facilitator for the entire black extended family. She receives money from different family members, who have in turn received help from her or other family members. Donations may be given in small amounts on a regular or irregular basis, and/or in times of special need. "Momma" distributes money to family members, as needed (Martin and Martin 1978). Jack (1978) emphasizes that "Momma" is not a matriarch or power figure, but a figure of respect. "Momma" is the spiritual leader of the group. "Her influence comes from persuasiveness in that what she has to say is right" (Jack 1978).

Proposition 8: "Momma" serves as the focal point for the facilitation of monetary exchange within the family. "Momma" is an active participant in family consumption choice. This is especially true in the consumption choices of those receiving aid. Participation may include offering advice on purchases, or buying and offering the goods themselves.

In return for giving to the family, the giver has the knowledge that he or she will be helped in times of need. In addition, the giver receives status in the family (Martin and Martin 1978).

Besides giving to "Momma", individuals may give to other individuals in the extended family, without obligating the other individual to repay the debt. For example, McAdoo (1980) found that the black mothers in her sample, ". . . felt obligated to help poorer members of the family and in turn would expect to be helped by someone who was substantially better off than they were" (p. 143). McAdoo also found that aid in the form of consumer goods and services was generally not expected to be paid back.

When assistance to an individual does not result in the recipient's obligation to reciprocate, this does not mean that social exchange is absent. Rather, the contribution reinforces the giver's membership in the kin insurance system; the family, through Momma or other individuals, will reciprocate in times of need.

Proposition 9: Exchanges take place between individuals and the family in the sense that contributing to another family member places an obligation on the family as a whole, rather than to the actual recipient, to reciprocate.

Exchanges Between Individuals in the Black Extended Family. The operation of the individual exchange network consists of a system of reciprocal obligations among its members. How these obligations are defined and fulfilled may differ across social classes among blacks. In this section, individual exchanges among very poor blacks will first be discussed, and then compared with exchanges among blacks with higher income levels.

A classic study on mutual exchange was done by Stack (1974), who describes an exchange network among very poor blacks that consists of "swapping" or "trading". In swapping, consumer goods are

exchanged (as well as services such as child care). While the exchange can be simultaneous, more frequently one good is given in return for an obligation to give something in the future to the initiator of the exchange. Members of the extended family (which include both kin and others defined as kin) will directly ask to be given goods which others own. Swapping is heaviest with closest kin. "Haves" are expected to share with "have nots." Those who take without giving are criticized. Family members may encourage others to whom they are heavily obligated to take something, to better balance the exchange relationship. Swapping appears to be an urban adaptation of the rural cooperative economic system which was once common. In this system, different households in the extended family specialized in one or a few farm products. These products were shared within the family (Shimkin, Louie and Frate 1978). Because the urban poor cannot specialize in production as farmers can, mutual exchange consists of whatever possessions are available.

Proposition 10: Among very poor blacks, individual exchanges are of goods and services. This compares with exchanges among blacks of higher socioeconomic classes, which may not be individual and can, in addition to goods and services, include money.

When mutual exchange consists of exchanging goods and services, family consumption choices are often limited to the possessions of family members. Thus, we would expect:

Proposition 11: When swapping occurs, consumption choices resemble impulse purchases; an item is seen and requested by one family member of another member. Problem recognition and final decision occur simultaneously; there is no search for information regarding alternatives.

For middle and working class blacks, individual gifts of goods and services are not expected to be repaid; rather, as described above, giving of goods and services is considered part of the "kin insurance policy" (McAdoo 1980). However, McAdoo also found that financial gifts are more likely to incur an obligation to reciprocate. Martin and Martin (1978) also note "[m]oney sometimes changes hands in the form of a loan without any serious pressure put on the borrower to pay it back" (p. 30), implying that the absence of obligation in monetary loans is not the norm. It appears that monetary loans sometimes incur a direct obligation, but not always.

Proposition 12: For blacks who are not extremely poor, monetary loans are more likely to be considered individual exchanges, incurring obligations to directly reciprocate, than are goods or services.

The prevalence of individual exchange among very poor blacks has important implications for these families' functions and interactions. When Stack (1974) did in-depth ethnographic research in a poor

black community, she did not find the extended family structure (consisting of a dominant family figure and "Momma") which Martin and Martin (1978) describe. While this may have been a result of methodological error, there is also a possibility that the structure does not exist among very poor black families. In order to understand why, we need to consider the necessary requirements for the "kin insurance policy" which exists when an individual engages in exchange with the family. As with any insurance policy, something of value is given with the expectation that sometime, perhaps far in the future, the contributor will be helped in times of need. For middle class blacks, for example, help is received from the family when making large purchases (McAdoo 1980). Martin and Martin (1978), who found a kin insurance policy, studied families which were in economic need, but all family members were not living in extreme poverty. For very poor blacks, it is not possible to buy "insurance" from the family as a credit against future needs; the needs of everyday life are overwhelming. Thus, individuals exchange with each other on a daily basis. And, unlike families who are not so poor, in which one can, for the most part, give without expectations of receiving from the recipient because one will be helped by family members who are better off (McAdoo 1980), in very poor families, no one is better off. As Stack points out, "[t]heir social and economic lives were so entwined that not to repay an exchange meant that someone else's child would not eat" (p. 28).

Proposition 13: Among very poor blacks, there is no kin insurance policy and no exchange facilitator; exchanges are between individuals only.

We have developed the above propositions based on the principles of the black extended family norm and the prevalence of mutual exchange in the black extended family. These principles not only guide what should be studied regarding consumption choice behavior in the black family, but also how studies in black family consumption choice should be designed.

METHODOLOGICAL APPROACHES TO THE STUDY OF BLACK FAMILY CONSUMPTION CHOICE

As mentioned above, research on the black extended family should be through network analysis and not be limited to members of one household. Although potentially time-consuming and costly (Hagestad 1981), this will require the identification of all family members in the network (Brown and Reingen 1987; Reingen, Foster, Brown and Seidman 1984; Reingen and Kernan 1986), including those in special roles (e.g., "Momma"). Data collection would include in-depth interviews with those with major roles in the family (e.g., family leader(s) and "Momma"), and shorter interviews with other family members (McAdoo 1988). An alternative methodology would be through intensive ethnographical observation, as done by Stack (1974).

While observation would certainly be a useful data collection method, the need to be accepted as a member of a family may not be a viable one for most researchers. In either case, small sample sizes (in terms of number of families) would be used, due to the extensive interviewing needed. For more specific issues in research design, see Hill (1970).

Researchers of the black extended family should also identify exchanges between individuals vs. exchanges between the individual and the family. For example, questions must be more specific than asking about aid given to and/or received from "the family". Rather, the research instrument should differentiate between: (1) aid received from the dominant family members; (2) aid given to or received from "Momma"; (3) aid given to individuals as part of the kin insurance policy, which obligates the family, but not the recipient, to reciprocate; and (4) aid given to individual family members which incurs an obligation on the part of the recipient to directly reciprocate. In addition, researchers may want to explore the structure of products/services/monetary gifts with regard to these four categories.

For all research, the focus should be on mutual exchange, rather than power and conflict. This is not to imply that there are no situations of power and conflict in black extended families. Rather, power and conflict are not the driving forces which motivate family structure and interactions among family members. Only when the basic structures and interactions of black extended families are better understood should more specific situations, such as conflict resolution, be explored.

CONTRIBUTIONS OF THE PROPOSED FRAMEWORK TO FAMILY RESEARCH

The framework presented in this paper offers several benefits to consumer researchers who are interested in the effect of subculture on family consumption choice. First, this framework allows better understanding of black family consumption choice. Study of black family consumption choice must be approached from the black cultural perspective, rather than studied through the filters of white family research.

Secondly, this framework can serve as a reminder of the need to relinquish the filters of white family research for all research on family decision making in subcultures. Two principle components of this framework, mutual exchange and extended family, which are important for the understanding of black family consumption choice, may or may not be applicable to other subcultures. Researchers of other subcultures will need to identify the appropriate structure and functions of the family in each subculture.

Finally, the propositions set forth in this paper may be used to approach white family consumption choice in a new light. In addition to subcultural influences, the extended family was an area identified during first Association for Consumer Research - Household Consumption Behavior Session (Burns and Gentry 1988) as one needing research to further develop knowledge in household theory.

Willie and Greenblatt (1978) note "[t]he traditional two-parent nuclear family was never the only viable family unit in Western culture, and in our rapidly changing society, it can no longer be viewed as the ideal arrangement which all families should be encouraged to emulate" (p. 694). The white extended family may operate differently than the black extended family; more research is needed. Equally important, the concept of mutual exchange, rather than power and conflict, should be considered an alternative perspective when approaching the study of white family consumption choice. Perhaps in the post-machismo era, a kinder and gentler approach to family consumption choice is needed.

Psychographic Variation Across United States Geographic Regions

Lynn R. Kahle, University of Oregon

Ruiming Liu, University of Oregon

Harry Watkins, University of Oregon

ABSTRACT

As an extension of previous work on values and geographic segmentation (Kahle 1986), this paper tested the predicted geographic variation of each value from the List of Values, and related psychographic and behavioral measures, across four regions of the United States. The values of self-respect, warm relationships with others, self-fulfillment, sense of accomplishment, being well-respected, and sense of belonging, as well as theoretically-related measures of psychographics and behavioral measures, showed significant differences across regions. In contrast, security and fun and enjoyment in life, as well as their related psychographic and behavioral measures, showed no significant variations across regions. People in the West and East prize respect and sociability less highly than do people in the Midwest and South, with the difference between West and South being especially significant. The marketing implications are discussed.

INTRODUCTION

One of the key concepts and techniques in marketing is segmentation (Dickson and Ginter 1987), which is widely used by managers and researchers for market analysis. Although some popular segmentation strategies divide people based on geographic regions and although geographic segmentation is widely used in marketing consumer products, only a few scholars have considered the cross-frontier effects of relating geographic segmentation to consumer behavior. Kahle (1986) studied the variation of values among the "Nine Nations of North America" and among the different regions of the United States as defined by the U. S. Bureau of Census (BOC). Based on the theory of Garreau (1981, cf. William 1982, Baerwald 1983, Salter 1983, Major 1983), Kahle predicted that, because of the regional differences in political considerations, histories, loyalties, climates, resources, and other factors, the values also would vary across regions. He found significant variation across the four (and nine) regions defined by the BOC, but not across the "Nine Nations" described by Garreau (1981).

Rokeach (1973) states that values guide actions, attitudes, and judgments. Clawson and Vinson (1978) suggest that values perhaps equal or surpass the contribution of other major psychographic constructs including attitudes, product attributes, degrees of deliberation, product classification, and life style in understanding consumption behaviors. Furthermore, in an structural equation study Homer and Kahle (1988) provide evidence consistent with the theoretical flow:

consumer values → attitudes → consumer behaviors.

An expanding body of knowledge corroborates these conclusions as applied to the consumer behavior literature, but few studies demonstrate the function of geographic differences in this sequence.

It would be logical to conclude from the above work that, because values vary among regions and because values are closely related to activities, attitudes, opinions and other dimensions of psychographic profiles, which themselves are often directly related to behavior, these dimensions and behaviors should also vary by geographic region. Thus, one objective of the research reported here is to examine whether the previously-observed variation in values across geographic regions extends to the attitudes and behaviors most closely associated with those values.

Another issue is that Kahle (1986) examined the variation of the most important value of individuals in List of Values (LOV) across regions, but did not examine how individual value ratings vary by region. That is, the nominally-measured values do differ in that the proportion of people in each region who select each value as most important differ, but it is unclear whether similar patterns would emerge with intervally-measured values, considered on a value-by-value basis. This study addresses that issue of regional variation in the means of values.

In sum, this study attempts to test the variation of each individual value from the LOV (Kahle 1983) across the regions, and then it extends the test to other dimensions of consumers' psychographic profiles. Theoretically from the above discussion, the variation of each value across different regions should correspond with the variation of other dimensions of psychographics that are related to that value.

The general theoretical orientation guiding this research can be described in a simplified form by the diagram in Figure 1.

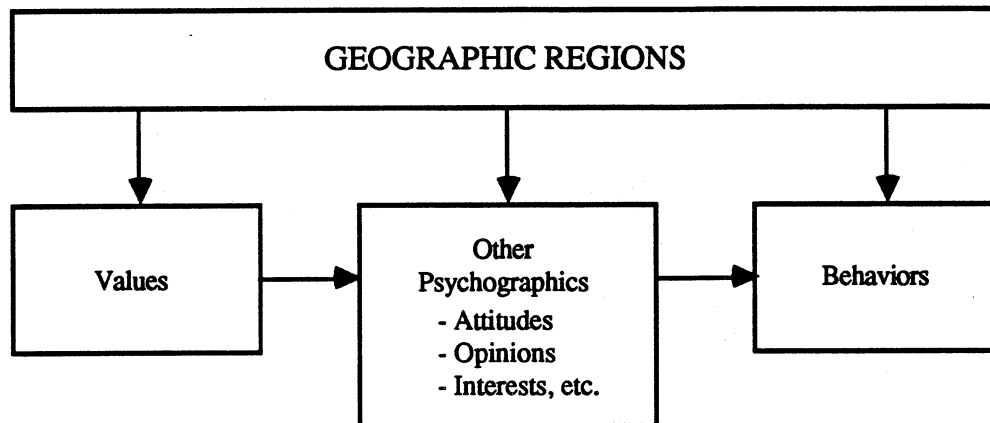

HYPOTHESES

- H1: Each of the individual values of the LOV will vary significantly across the four geographic regions identified by the BOC, as hypothesized by Kahle (1986).
- H2: Other psychographic dimensions, as well as behaviors that are most closely associated with each value, will also vary significantly and in a similar pattern to the value variation across the same four geographic regions.

METHOD

Data for this study came from a consumer mail panel study, which was based on a national quota sample of 640 respondents in the United States,

FIGURE 1
Conceptual Model

designed to represent region, sex, age, income, and education accurately. The overall response rate was 66%, with no significant deviations from BOC proportions among the major demographic subgroups.

Regions were defined by states using the BOC definitions, as follows: East (New England: ME, NH, VT, MA, RI, CT; Mid-Atlantic: NY, PA, NJ, DE), Midwest (East North Central: WI, IL, MI, IN, OH; West North Central: ND, SD, MN, NE, KS, IA, MO), South (South Atlantic: WV, MD, DC, VA, NC, SC, GA, FL; East South Central: KY, TN, MS, AL; West South Central: TX, OK, AR, LA), and West (Mountain: NV, ID, MT, WY, UT, AZ, CO, NM; Pacific: CA, OR, WA, AK, HI). Region was defined by state in which a person was born rather than state in which a person currently resides because cultural transmission is often stronger from birth place than from place of current residence.

The List of Values (LOV) consists of 8 values for respondents to evaluate: self-respect, being well respected, sense of belonging, warm relationships with others, fun and enjoyment in life, self-fulfillment, sense of accomplishment, and security. For each value from the LOV, a Likert-type scale (1 to 7) was used, where "7" means "extremely important to me," and "1" means "not at all important to me." Following social science convention, these scales were assumed to be interval. ANOVA was used to test for value differences across the four regions defined by the BOC. Furthermore, the Tukey test was used to see how responses differ across the regions for each value.

Next, the measured dimensions of psychographics (also measured by 7 point Likert scales anchored by phrases such as "extremely important to me" vs. "not at all important to me," or "describes me extremely well" vs. "doesn't describe me at all,") were sorted into different categories based on the theoretical descriptions of the nine values of the LOV (cf. Kahle 1983; Kahle and Kennedy 1989). For instance, "I often go to a church or synagogue," "I identify strongly with people of my age," and "People should think about the good of society, not just about

whatever makes them happy as individuals," are sorted into the *Sense of belonging* category; on the other hand, "I am polite and well-mannered," and "If everyone would just love one another as brothers and sisters, most of the world's problems would go away" are sorted into the *Warm relationships with others* category. This sorting process was carried out based on a combination of the results of a factor analysis and especially on the theory-driven judgement of three independent experts. The judgment process used the following procedure: (1) A value-related list of psychographic items was generated. (2) Each expert independently sorted the psychographic items into the different value categories based on prior knowledge of the categories. (3) The three experts came together and resolved any discrepancies among the judgments. After sorting, ANOVA was used to test the differences of each event in each category across the different regions.

In a few instances a particular lifestyle item was not viewed as uniquely applicable to only one value. Some values have overlapping spheres. For example, both warm relationships with others and sense of belonging have stronger implications for sociability than the other values; or both self-fulfillment and sense of accomplishment have a strong achievement component. Likewise, identical attitudes may result from different values for very different psychological reasons or very different means-ends ladders (Gutman 1982, Reynolds and Gutman 1988). For example, two people may prefer a wine cooler to a mixed drink because it contains less alcohol. In one case the decrease in alcohol content may be desired in order to be well respected, and in another case the desire may result from seeking to belong to a group in which excessive alcohol consumption is discouraged. The causal chains may differ, and the ideal consequences may differ, even though one point on the chains may be identical. Because we wanted to develop possible consequences of values rather than mutually-exclusive categorizations, we occasionally allowed lifestyle items to reflect more than one value.

TABLE 1
Value Variation by Region

Values	F	Region Order	Comparison	X1	X2	X3	X4
Self respect	4.43*	W,E,M,S	W-S**	6.37	6.55	6.55	6.72

I am beautiful, attractive	3.65*	W,E,M,S	EW-S

* P < .05

** E = East, M = Midwest, S = South, and W = West

Finally, by comparing the results of the experts' sorting with the empirical results, the degree of consistency in the variations of these dimensions of psychographics across the regions with the variations of each corresponding value will be evident.

RESULTS AND DISCUSSION

The results are shown in Tables 1 through 7. In the Tables, *region order* means the ascending order of the means in different regions where E = East, M = Midwest, S = South, and W = West. For example, the order of W, E, M, S implies that the mean in the West is the smallest (i.e., "least important" or "least characteristic") and in the East is the second smallest. *Comparison* means that, given alpha = 0.05, a Tukey multiple pairwise comparison test shows the significantly different pairs of regions. For simplicity, we listed the results in only the four regions case, but not the nine regions case. The conclusions for the nine regions case are essentially the same as for the four regions case.

Table 1 shows the results of the comparisons of the four geographic regions for each of the LOV values. Only the importance ratings for security and

fun and enjoyment in life failed to vary significantly by geographic region. Thus, Hypothesis 1 is generally supported. People in the West and East prize respect (self-respect, being well-respected) and sociability (warm relationships with others, sense of belonging) less highly than do people in the Midwest and South, with the difference between West and South being especially significant. People in the Midwest, West, and East prize achievement (self-fulfillment, sense of accomplishment) less highly than do Southerners, with the difference between the Midwest and the South being especially significant.

Perhaps the most interesting observation from these data is that the Southern region assigned the highest ratings to *all* of these values. This result may be due to any one of several factors. 1) The difference may be a measurement artifact. Perhaps these particular values have more appeal or are more appropriate for the South than for other regions. We have previously argued that the proper list of values may vary geographically by continent (Liu and Kahle 1989); the same argument may apply within a country. 2) The difference may be a regionally-based response style. Although it seems unlikely, perhaps people in the South use rating scales differently than

people in other parts of the United States. 3) The psychological importance of values may be greater in the South than in other regions. Theoretically, this possibility is the most intriguing. Clearly additional research on this topic would be interesting.

Neither the values of security, fun and enjoyment in life, nor their related psychographics

and behaviors, are viewed significantly differently across geographic regions. One explanation for this lack of variation might be the prevalence of these values in nation-wide activities and services, such as communications. For instance, the nationwide equivalent occurrence of security-related phenomena, such as insurance companies, crime, disease, and

** E = East, M = Midwest, S = South, and W = West

death, may lead to equivalent concerns for the value of security. Threats to security, such as military threats, may be more national than regional. For fun and enjoyment in life, the nationwide occurrence of sporting events, television entertainment, magazines, movies, and other factors may lead to equivalent concerns for that value. Likewise, intra-regional variability may create large variances. What people mean by *fun* may vary more between some pairs of Western states (e.g., California vs. Alaska, Nevada vs. Utah) than between the West and Midwest, for example.

The focus of this research is to provide additional support for the notion that both values and related lifestyles vary by geographic region. Hypothesis 2 states that other psychographic dimensions, as well as behaviors that are most closely associated with each value, will also vary significantly and in a similar pattern to the value variation across the same four geographic regions. In

general Tables 2 through 7 show support for this hypothesis. Most of the lifestyle items measured in this study vary significantly across regions, and many (but not all) vary in patterns that reflect their associated value.

Table 2 presents the comparisons by geographic region for the lifestyle items associated with self-respect. Self-respect is accorded the lowest rating by respondents from the West, followed by the East, the Midwest, and the South. This general pattern is reflected by many of the lifestyle items. For example, Southerners are particularly likely to be independent in terms of their buying patterns. This finding would suggest, for example, that retailers may need to offer a wider selection in the South than in the West.

Table 3 presents the comparisons by geographic region for the lifestyle items associated with warm relationships with others. This value is rated similarly by respondents from the East, the

West, and the Midwest, but it is rated significantly higher by respondents from the South. Similarly, Southerners rate the associated lifestyle items more favorably than respondents from other regions. These results might be of interest, for example, to fund raisers targeting different regions.

Table 4 presents the comparisons by geographic region for the lifestyle items associated with self-fulfillment. For example, Midwesterners rate self-fulfillment relatively unfavorably. In this region the value seems to be reflected in lifestyle terms by a high interest in improving health and appearance but not by self-perceived attractiveness. Midwesterners are relatively unlikely to pursue information concerning these interests in fashion magazines. In contrast, Southerners, who rate self-fulfillment favorably, also rate health favorably but already viewed themselves as attractive. They are more likely to read self-improvement books. These data provide mixed support for Hypothesis 2.

Table 5 presents the comparisons by geographic region for the lifestyle items associated with sense of accomplishment. Of the lifestyle items in this table, only the item on mail-order purchasing demonstrates the identical rating pattern across regions as was exhibited by the sense of accomplishment value. Southerners, who rate sense of accomplishment favorably, are relatively concerned about time spent watching television and preparing meals. Easterners and Westerners are less likely to value planning for the future, reexamining goals, and buying high quality products. These results suggest, for example, that advertisements that tie product quality to the value of a personal sense of accomplishment will be more effective in the South than in the East or West.

Table 6 presents the comparisons by geographic region for the lifestyle items associated with being well respected. Westerners are relatively likely to rate this value low. Respondents are concerned about moral values and about personal tidiness. Drinking imported beer is prized less by Midwesterners than by respondents from the East. Again, Hypothesis 2 received mixed support.

Table 7 presents the comparisons by geographic region for the lifestyle items associated with sense of belonging. The items deemed to be associated with this value fall into two categories. One category, which closely follows the regional pattern of the base value, consists of items measuring respondents' relationships and identities with relative abstractions such as God, society, and their race and ethnic group. Westerners placed the least emphasis on these items. The other category of items involved more concrete relationships with employers, parents, and families, as well as feelings of personal loneliness. These items were emphasized by Easterners. Of these items, Southerners placed the most favorable ratings on lifestyle items related to the family.

Overall, the data in Tables 2-7 show parallel patterns to the data in Table 1. For 20 of the 47 items included in the Tables 2-7, the same exact pair of post-hoc comparisons emerged as significant at the .05

level. Given 4 regions, the total number of possible different pairs would be the permutation, $4!/2! = 12$. The probability of any given pair being chosen would be $1/12$. According to binomial probability distribution, the p-value of 20 particular (i.e., significant) pairs being chosen would be:

$$p(x \geq 20) = 1 - \sum_{x=0}^{19} \binom{47}{x} \left(\frac{1}{12}\right)^x \left(\frac{11}{12}\right)^{47-x} < .0001$$

Thus, with any reasonable alpha level we can reject the null hypothesis that the lifestyle pairings resulted from a random process.

IMPLICATIONS

People's activities, interests, opinions, and attitudes, vary approximately as do their related values. This pattern fits the value-attitude-behavior hierarchy hypothesized by Homer and Kahle (1988). Value information can aid in understanding lifestyle and consumer behavior, consistent with the theory presented in the Introduction section and elsewhere (e.g., Kahle 1986). Marketing managers ought to recognize the importance of geographic differences in values and lifestyles. When marketing managers try to meet consumers' needs in terms of self respect, warm relationships with others, being well-respected, and/or sense of belonging, they should consider the differences across the four regions, especially the differences between the West and the South.

Values have the potential to help clarify consumers' motivations and may point to the underlying "rationality" or "psycho-logic" of ostensibly illogical buying decision processes. Marketers can use value-behavior linkages or value chains to help measure and understand consumers' involvement with a product. Similarly, value chains provide the opportunity to develop advertising programs that tie product benefits to consumers' personal meanings at several, increasingly meaningful levels of abstraction. Furthermore, efforts to measure advertising effectiveness may be improved by assessing how successfully the ads tie product meanings back to personal values. Even if value and lifestyle information is not directly utilized, creatives can understand the characteristics of certain regions and target segments if this type of information is available.

Because these value-behavior linkages or chains vary geographically, managers have some potentially useful segmentation opportunities. Consumers could be segmented by value chains, and then the value chain segments could be prioritized by geography for further regionally-focused marketing attention. This prioritizing could be of significant utility to marketers attempting either to develop regional products or to market national products on a regionally-sensitive basis. It may even be possible to decide whether to use values to segment based on these results. For example, Westerners appear to place a less weight on the core values than do Southerners. Thus, an advertising campaign for a product in the South might emphasize value fulfillment more,

whereas a campaign in the West might emphasize benefits and more literal aspects of consumption. For another example, because people view security and fun and enjoyment in life no differently across the nation, marketing managers in nation-wide companies who sell security-oriented products or services might well advertise most effectively on nation-wide TV programs or in nation-wide magazines. The extra effort of geographic segmentation is lost for products and services that tie to these values.

Because these data were collected more than a decade after the data were collected for the Kahle (1986) study and because this study relied on interval rather than nominal data, it implies that geographic differences have a certain robustness. These results suggest that the underlying geographic differences within the United States have a persistent and detectable effect on consumer activities.

CONCLUSION

As an extension of Kahle's work (1986), this paper tests the variations of each value and related psychographic and behavioral measures across four regions of the United States. Self-respect, warm relationships with others, self-fulfillment, sense of accomplishment, being well-respected and sense of belonging, and theoretically-related psychographic and behavioral measures, show significant differences across the regions. In contrast, security, excitement, and fun and enjoyment in life, and related psychographic and behavioral measures show no significant variations across the regions. People in the West and East prize respect and sociability less highly than do people in the Midwest and South, with the difference between West and South being especially significant. We have only just begun to understand all of the marketing implications of these findings.

Effects of Source Likability on Attitude Change Through Message Repetition

Jean-Charles Chebat, University of Quebec at Montreal

Daisy Baddoura, University of Quebec at Montreal
Pierre Filiatrault, University of Quebec at Montreal¹

ABSTRACT

This paper reports on an empirical study of the effects of source likability, message repetition and the memorization of arguments on attitude change. The results indicate that likable sources enhance attitude change only through the mediation of message memorization and repetition. It is suggested that likable sources cannot compensate for inadequate argumentation.

INTRODUCTION

Advertisers pay much attention to the choice of an adequate character who will introduce their product or service in the advertisement. One of the most desired characteristics of the personality is likability. Some studies have shown that likability has positive effect on attitudes toward the message, but these results are somewhat controversial; moreover, few studies have investigated the combined effect of attractiveness and repetition which is related to the following question: Do the positive effects of attractive sources wear out through repetition? If yes, advertising investments in personalities such as Madonna or Michael Jackson should be reconsidered.

This paper first reviews the main effects of likability on message acceptance and the effects of repetition on attitude change. Hypotheses will be presented on the basis of experimental results on the effects of repetition. Results from the empirical study are discussed and some managerial implications are proposed.

Effects of Likable Sources on Attitude Change

In the marketing literature, likability has often been confused with physical attractiveness. However, Kahle and Homer (1985) have suggested that there might not be any correlation between the two: for example, John McEnroe could be both physically attractive and unlikable due to his behavior.

A likable person may be defined as one who says pleasant things (Eagly and Chaiken, 1975). Based on this specific definition, Himmelfarb and Arazi (1974) found that, while an attractive communicator may be more persuasive than an unattractive one when subjects have no choice but to listen to the message, the unattractive communicator may be more effective when subjects have that choice. In a counter attitudinal behavior situation, Eagly and Chaiken (1975) found that, even if attractive communicators were more persuasive than unattractive

ones when given undesirable positions, both were equally persuasive when given desirable positions.

Effects of Repetition on Attitude Change

Repeated exposure to a stimulus positively enhances its assessment (Zajonc, 1968). As shown by Moreland and Zajonc (1979), repeated exposure to a new stimulus brings about a loop reaction between two subjective elements: a feeling of familiarity and a predisposition toward the object of a message. Repetition of a given message makes the memorized elements more accessible to evaluation. Cacioppo and Petty (1979) have suggested that repeated exposure to a message triggers the cognitive elaboration of arguments: the number of counter-arguments declined then increased as the number of exposures increased whereas the number of support arguments followed the opposite pattern.

Krugman (1986) also showed that repetition can have negative effects. A message can be too familiar: when consumers are exposed to repeated messages that they have already memorized, even if they are positively assessed, these messages do not bring anything new and do not deserve their attention. This idea has been supported by a number of researchers. In particular, Berlyne's two-factor theory (1963) shows the existence of an inverted U-curve: increasing the number of exposures to a message from a low to a moderate level is expected to enhance its impact, whereas further exposures are expected to cause its effectiveness to decline. At lower levels of repetition, reduction of uncertainty brings about a rather positive assessment of the message; at higher levels, repetition is associated with boredom and leads to a negative assessment of the message. However there is also a substantial number of studies that show no relation between these two variables (e.g., Belch, 1982; Mitchell and Olson, 1981).

Two opposite effects are at play here: on the one hand, a decreased interest for the message when repeated beyond a given threshold and on the other, a positive relationship between the memorized content and the emotion generated by a likable source. How do these two factors interact? It is suggested that a likable source may soften the negative effects of repetition: when the repeated message is associated with a likable source, the rate of advertising wearout, i.e., the decreasing interest, is lower. Consequently, when the message is associated with a likable source, its repetition may have significantly more effect on attitude change than in the case of a neutral source. Memorization of the arguments in the message can be attributed to the fact that the message has triggered the receiver's attention. What remains to be answered are the following two questions:

¹The authors very gratefully acknowledge the financial support of the Social Sciences and Humanities Research Council of Canada.

- (1) Does memorization enhance the production of counterarguments and create a negative attitude when the message is frequently repeated?
- (2) Does memorization lead to a positive attitude when the message is associated with a likable source that creates a positive emotional bond with the audience?

Hypotheses

a) *Main Effects*

- H₁ A likable source generates more attitude change than a neutral source.
- H₂ Repetition generates attitude change in a curvilinear way (inverted U shaped curve).
- H₃ Attitude change is higher for respondents who have memorized at least one argument than for those who have not.

b) *Two-way Interaction Effects*

- H₄ The effects of repetition on attitude change are stronger in the case of respondents exposed to a likable source than in the case of respondents exposed to a neutral source.
- H₅ The effects of memorized arguments on attitude change are significantly stronger when associated with a likable source than when associated with a neutral source.
- H₆ The effects of repeated arguments on attitude change are significantly stronger when memorized by respondents than when not memorized.

No three-way effect hypothesis is proposed due to the fact that the literature is silent on this relationship.

METHODOLOGY

The hypotheses were tested on the basis of a factorial design experiment. Each dimension of the factorial design was conceived as properly representing a single concept. The essential purpose of the design was to understand the interactive effects of affective variables. The factorial design coupled with the analysis of variance were chosen to combine best the experimental technology and the data analysis.

Dimensions of the Factorial Design

For the purpose of this research, the factorial design was constructed around two major dimensions:

- The level of message *repetition*
- The level of *likability* (or attractiveness) of the source
- The complete design used *six* experimental conditions:
- *Three* levels of repetition: 1, 3 and 5
- *Two* levels of likability: high and neutral

Each of these dimensions is further explained in the following sections.

Repetition

The rationale for varying the level of repetition from 1 to 3 to 5 for the same advertising message was to design an experiment which would as much as possible simulate real-life situations. In a normal television advertising sequence, a given message never appears more than five times; thus, 1, 3 and 5 seemed the appropriate frequencies to use, 1 being the minimum, 5 the maximum, and 3 the intermediate frequency. These are also the levels of frequency used in previous studies on repetition; for instance, Belch (1982) tested the effects of 1-3-5 repetitions on message acceptance. The commonly accepted rationale for three frequencies is that most studies on the effects of repetition show a curvilinear relationship, generally known as "wear-out effects" (Chestnut 1980).

Likability

This construct was operationalized in terms of a dichotomy. The same professional actor was instructed to play two different roles, i.e., a likable individual and a neutral one. The likable source used a soft and pleasant voice and showed a great deal of consideration for the audience, while the neutral source spoke in a natural fashion, with a rhythm in his speech intended to convey neither pleasantness nor aggressiveness. This is in accordance with the definition given by Eagly and Chaiken (1975). The actor was directed by a professional film director.

Experimental Stimuli

All messages were created specifically for the purpose of the research and used a team of professionals (e.g., an actor, a director, cameramen, editors) to produce very realistic television commercials, all being 30 seconds long.

Verbal Messages

The scenario for all the commercials was a financial executive sitting at his desk in a nicely decorated office. He introduced himself as an executive in a given financial institution. Then he gave a message on credit cards which contained five central arguments and he closed with an appeal to apply for the credit card offered by his financial institution.

Context

These commercials were inserted into a real television program dealing with economics and finance. This program lasted 30 minutes and it contained one 150-second commercial pod. Subjects in a given experimental condition were exposed to only one type of commercial (one of the two versions). The program contained one, three or five repetitions of the same commercial inserted into the existing commercial pod at the same position. For all the experimental conditions, the rest of the program was identical, including the other (non-experimental) commercials.

Subjects

Each of the six experimental conditions provided an average of 150 respondents (25 for each level of repetition) for a total of 918 subjects. All were college graduates, 48 percent were male, between the ages of 21 and 42. All were university students attending the same mandatory management course at the same level in their curriculum.

Questionnaire

The subjects were administered a questionnaire whose purpose was to measure attitude change toward credit cards as a result of the experimental stimuli. Before viewing the videotape, subjects were asked a series of questions to measure a number of variables including their attitude toward credit cards (the 'before' measure). The same questions were also asked after viewing the videotape but they were organized in a different order which was randomly determined. After being exposed to the videotape, the subjects were requested to write down all the elements of the message they could recall spontaneously. These elements could be formal (such as the speaker's tie or physical appearance), or substantive, i.e., related to the arguments in the message. In this study, only the number of arguments recalled was used: 19% of the subjects could not recall any argument, and 81% could recall at least one of the five arguments contained in the message.

The five following statements related to the attitudes toward credit cards were provided to the S's before and after they were exposed to the commercials:

- In general I like credit cards;
- I prefer to use credit cards instead of cash;
- To use credit cards is pleasant;
- I like the idea of owning a credit card;
- I prefer using a credit card to writing a check.

Respondents were asked to indicate their degree of agreement with each statement on a 6-point Likert scale. The Cronbach's alpha for these five items is 0.83, which is very good.

The average score of these five items was computed as a 'before' and 'after' attitude measure, and the difference between these two attitude scores was computed for the attitude change measure.

ANALYSIS

Manipulation Checks

First, a manipulation check was performed on the experimental conditions.

Source Likability

The level of likability of the source was manipulated so that respondents were exposed to only one of two levels of source likability: high and neutral (which serves as a control condition). Respondents were asked to indicate to which degree they agreed with the following statement: "The character (named) in the commercial could become a friend of mine." On a 6-point scale the neutral likability group scored 2.82 and the high likability

scored 4.52. This difference is highly significant ($t = 10.2$; $p = 0.00$).

Tests of Hypotheses

An analysis of variance (ANOVA) was performed with attitude change toward credit cards as the dependent variable and with repetition, likability and memorization as the three independent variables.

Results

Table 1 shows the results of the analysis of variance (ANOVA), and the results are summarized next.

Main Effects

- H₁ is rejected: the effects of likability are not significant ($F = 1.03$; $p = 0.31$).
- H₂ is rejected: the effects of repetition are not significant ($F = 1.65$; $p = 0.19$).
- H₃ is supported: the respondents having memorized at least one argument significantly changed their attitude more toward credit cards than those not having memorized any argument ($F = 4.95$; $p = 0.03$).

Two-Way Interaction Effects

- H₄ is supported: the individuals exposed to a likable source more than once showed more positive attitude change than those exposed to a neutral source ($F = 3.76$; $p = 0.02$). Moreover, as shown in Figure 1, for those exposed to the ad three times, the likable source induced significantly more attitude change toward the financial service than the neutral source ($F = 5.59$; $p = 0.02$). For both those exposed to the ad five times ($F = 0.71$; $p = 0.40$) and those exposed only once ($F = 1.31$; $p = 0.25$), no significant difference is shown between the likable and the neutral sources. The relationship between repetition and attitude change is quadratic in the case of the likable source ($F = 4.48$; $p = 0.03$ for the weighted quadratic term), and linear for the neutral source ($F = 5.68$; $p = 0.02$ for the weighted linear term).

- H₅ is supported. While memorization has no significant effect on respondents exposed to the neutral source, it has a significant effect on those exposed to the likable source ($F = 3.65$; $p = 0.06$). More specifically, as shown in Figure 2, in the case of consumers having memorized no argument the effects of likability are remarkably insignificant ($F = 0.00$; $p = 0.99$): the average scores for the two groups are identical ($X = 3.45$). However, for those who have memorized at least one argument, likability has a significant effect on attitude change ($F = 3.45$; $p = 0.07$).

H_6 is rejected ($F = 0.27$; $p = 0.76$).

SUMMARY AND DISCUSSION

Contrary to previous findings (e.g., Himmelfarb and Arazi, 1974), likable sources do not score higher on attitude change than neutral sources; however, our results are in line with what Eagly and Chaiken (1975) found, i.e., if the topic is not controversial, both sources are equally persuasive.

Repetition has no direct significant effect, contrary to previous findings.

Memorization of at least one of the message arguments significantly enhances attitude change. Memorization enhances attitude change in a way which is congruent with the arguments.

Repetition and likability strongly interact: the likable source brings about more attitude change than the neutral source when the message is repeated three times. At both one and five exposures, likability does not bring about significant attitude change. What is most remarkable is that the Berlyne's curvilinear effects (inverted U shape) are found only for the likable source and not for the neutral source. In the latter case, the relation is linear: likability counterbalances the negative effects of repetition. In other words, the tedium effects generated by repetition show up earlier when the source is neutral, as predicted. The results can be interpreted as follows: from 1 to 3 exposures, repetition increases the feeling of familiarity with the message and reinforces the link between the positive affect toward the source and acceptance of the arguments (Moreland and Zajonc, 1979); from 3 to 5 exposures, familiarity turns into boredom: all the formal cues (such as the speaker's physical appearance) serve to confirm that this is the same ad once again. If, as suggested by Hirschman and Holbrook (1982), a commercial is a "psychological reward," its utility decreases after a certain threshold of repetition. Thus, excessive repetition leads to a reduction in the positive effects of likability but not

in the memorization of the arguments, which explains why the 3-way interaction is not significant ($F = 1.09$; $p = 0.33$).

Likability and memorization significantly interact. Memorization enhances attitude change in the case of consumers exposed to a likable source but not in the case of those exposed to a neutral source. One interpretation is that the likable source acts as a node, in the sense used by Bower (1981): pleasant feelings toward the source are associated with the arguments contained in the message. The association, when it exists (i.e., the arguments are memorized and are provided by a likable source), makes the arguments more persuasive since their effect is positive. The relationship gives the arguments the same emotional tone as the source itself. In the case of the attractive source, it could be assumed that the receivers' moods were enhanced by their positive identification with the source which then could have focused their attention on the positive elements of the message. Thus, as suggested by Forgas and Bower (1988), better integration and recall of the arguments would result; the positive emotion may bias the recalled arguments to produce a positive attitude. Memorization alone is not a panacea: it enhances positive attitude only when the message arguments are associated with a likable source.

Memorization and repetition do not interact significantly because repetition enhances memorization ($\chi^2 = 17.82$; $p = 0.00$). Their effects are additive. However, for the groups exposed five times to the same message, the non-memorization group scored significantly higher than the memorization group ($F = 3.95$; $p = 0.05$). It can be surmised that, as suggested by Cacioppo and Petty (1979), repeated arguments which are also memorized are mentally reviewed and criticized: counter-arguments are generated which reduce the level of attitude change. Repetition makes the counter-arguments more

available which were left latent at lower levels of repetition.

CONCLUSION

A likable source enhances attitude change only through the mediation of memorized arguments or repetition of the arguments. It has no direct effects. Likable sources are no substitute for adequate argumentation: advertisers cannot simply invest in likable characters and presume their persuasive strategy to be a probable success. Likable sources can counterbalance the negative effects of repetition but only to a certain extent: beyond three repetitions, the effects of likability appear to be cancelled.

Memorization of the arguments in the message is not a panacea either: repetition may be more likely to generate counterarguments, if some arguments are memorized and more easily available for a critical assessment. When associated with a likable source, memorization appears to lead to a more positive attitude toward the message.

The Effects of Message Valence on Inferential Processes

Lydia J. Price, INSEAD

Although inferential belief formation and inferential belief change processes have frequently been investigated, there remains a gap in our knowledge about the naturally occurring conditions that may lead to their activation. In this paper we explore the effects of message valence on inferencing behavior. Empirical evidence suggests that negative information may be effective in stimulating inferential reasoning. Results concerning the effects of positive information cues were inconclusive.

In recent years a number of researchers have examined inferential processes by which consumers expand upon given product information in order to form new beliefs (Ford and Smith 1987; Gardial and Biehal 1987; Huber and McCann 1982; Johnson and Levin 1985; Simmons and Leonard 1990) or modify existing beliefs (Kaplan 1972; Lutz 1975a, 1975b; Yi 1990a, 1990b) about attributes that are unknown or are unmentioned in a communication. Although there is mounting evidence that inferencing can have a strong effect on consumer judgments, it is clear that inferential processing does not always occur spontaneously (Lim, Olshavsky, and Kim 1988; Simmons and Lynch 1991). Investigators thus have begun to search for environmental factors that may provide an impetus for inferential reasoning. In the research reported here, we examine the effects of message valence on inferential belief change processes. Empirical evidence suggests that negative messages may be effective in stimulating inferential thinking.

WHAT CONDITIONS STIMULATE INFERENTIAL PROCESSING?

In a communications context, inferencing occurs when consumers expand upon the attribute information provided in a message so as to form new beliefs or update their existing beliefs about attributes that are not mentioned in the message. Inferred attribute values are likely to be either probabilistically (i.e., correlational) or evaluatively consistent with the attribute claims made in the communication (Fishbein and Ajzen 1975). Although both probabilistic and evaluative inferencing strategies have been observed empirically, it has been suggested that the former are more common, particularly when attribute correlations are high (Fishbein and Ajzen 1975; Gardial and Biehal 1987).

On the basis of this suggestion, it seems reasonable to expect the likelihood of inferencing behavior to be positively related to the strength of the correlations among mentioned and unmentioned product attributes (Huber and McCann 1982). Empirical tests of this proposition, however, indicate that high correlations are not a sufficient condition for the onset of inferential reasoning. Although the magnitude of inferred attribute values has been found to covary with the strength of attribute correlations when probabilistic inferencing is observed (Ford and

Smith 1987; Yi 1990b), several researchers have failed to find evidence of spontaneous inferencing behavior in a context where attribute correlations were strong (Lim et al. 1988; Simmons and Lynch 1991).

Others have reasoned that environmental factors must lead consumers to think about unmentioned product attributes or about attribute correlations in order to stimulate inferential processing (Hansen and Zinkham 1984; Huber and McCann 1982). In accordance with this view, Yi (1990b) found significant effects of visual advertising cues in prompting inferential belief change. Apparently, visual cues were effective in leading message recipients to think about the unmentioned attributes and to update their beliefs accordingly. Similarly, Kardes and Strahle (1986) found evidence of inferential belief formation when the perceived technicality of product information was moderate, but not when it was high or low. In this case it seems that subjects were motivated to process the given information deeply, thus prompting inferential thinking, when the information offered new insights which subjects felt capable of understanding. When information was uninformative or overly complex, processing motivation was reduced.

On the other hand, there have been studies where proposed environmental factors have failed to elicit inferencing behavior. Simmons and Lynch (1991) found very little incidence of inferencing activity in a study where competitor communications were used to increase the salience of a target brand's unmentioned attributes. Zwick (1988) similarly failed to find systematic effects of information format (brand dominant, attribute dominant, or matrix format) on the way that subjects accessed information items and subsequently used them to guide inferential reasoning. Moreover, a substantial proportion of Zwick's research subjects (14 out of 37 who were not prompted) showed no signs at all of spontaneous inferencing activity.

In light of the mixed evidence regarding specific environmental factors Dick, Chakravarti, and Biehal (1990) have argued that consumers will engage in inferencing activity only when 1) the unmentioned attribute information is noticed and is sufficiently relevant to motivate efforts to impute its value, 2) an inferencing rule and the necessary supporting information are readily accessible in memory, 3) the inferencing rule is perceived to be capable of generating diagnostic inputs for the decision task at hand, and 4) other diagnostic inputs to the decision are not as readily accessible or available from external sources (Feldman and Lynch 1988; Lynch, Marmorstein, and Weigold 1988). Dick et al. support this view with the results of an experiment where inferencing instructions were varied and information accessibility was manipulated. When subjects were not explicitly instructed to infer missing attribute values, inferencing behavior was not uniformly observed. Inferencing effort was greatest, however,

when prior brand evaluations were favorable rather than unfavorable, and attribute information was highly accessible from memory. Unfavorable prior evaluations apparently decreased subjects' interest in a given choice alternative, thus reducing the relevance of an inferencing strategy for subsequent choice deliberations. Low attribute accessibility apparently decreased the perceived diagnosticity of an inferencing rule.

The Dick et al. (1990) framework sheds light on previous failures to stimulate inferencing activity in the laboratory. For example, many subjects in the Simmons and Lynch (1991) study failed to note the absence of target attribute information. Moreover, of those who did notice, some probably lacked access to an inferencing rule linking the predominantly tangible product features used as stimulus attributes. Simmons and Lynch (1991) and Lim et al. (1988) note that inferences pertaining to tangible product features are less common than those pertaining to a price/quality relationship. This is not surprising given that price/quality relationships are observed in many product categories, leading to a highly accessible rule linking the two characteristics. For tangible product features, on the other hand, less frequent observations of attribute associations render inferencing rules less readily accessible. When subjects in the Simmons and Lynch study were induced to repeatedly make similar product evaluation decisions, their awareness of missing information and attribute correlations was likely increased. Consistent with the Dick et al. (1990) framework, inferencing behavior also increased (Experiment 3).

Simmons and Leonard (1990) further point out that, of the inferences made by subjects in the Simmons and Lynch (1991) study, a probabilistic consistency rule tended to apply when attribute correlations were expected to be high. When no attribute correlations were expected, probabilistic inferences were rare. Thus, despite the low overall incidence of inferencing behavior, subjects seemed most willing to use a probabilistic inferencing rule when it was expected to yield diagnostic conclusions.

The Effects Of Information Valence: Following the Dick et al. (1990) framework one would expect that any factor which increases the relevance, the accessibility and/or the diagnosticity of an inferencing rule will increase the likelihood that inferential processing is observed. One such factor might be information valence. The disproportionate influence of negative information on consumer judgment tasks has been documented repeatedly (see Kanouse 1984 for a review of the negativity literature), and there is evidence that inferencing activity may be sensitive to negativity effects. Lutz (1975a), in an early study, found that negative messages stimulated stronger changes than positive messages in an index of total cognitive structure. It appears that inferential belief change may have been stronger in response to the negative stimuli, although it is difficult to verify this conclusion as individual belief changes were not reported in the paper. Mizerski (1982) later found that inferential belief formation was stronger in response to negative rather

than positive information in a context where inferences were prompted explicitly by the researcher. Finally, Wansink (1989) found that negative information about the source of a message led subjects to make negative attributions as to why the source omitted attribute information from its advertisements. These negative attributions had an adverse effect on product evaluations, particularly when the unmentioned attributes were covariant with those actually mentioned in the ad. The significant covariance effect suggests that inferencing behavior might have mediated the source effects on product evaluations.

It is possible that negative information would stimulate inferencing behavior because of the way that it is processed by message recipients. Fiske (1980) has argued that negative information is allocated greater attention and is processed more deeply than is positive information. There are many reasons why this might be so. First, negative information may be more rare or atypical than positive information (Boucher and Osgood 1968; Fiske 1980; Zajonc 1968), or it might be less consistent with prior product beliefs. Alternatively, negative product aspects may interfere with the enjoyment of positive product aspects, or individuals may find it risky to ignore the implications of negative claims (Kanouse and Hanson 1972). Although these conditions are not likely to hold in all situations (e.g., when negative information is consistent with prior beliefs because it refers to an already disliked brand, or when negative information is typical, as might be the case for comparative advertisements), they can reasonably be expected in many consumer communication environments.

Although there are differences among these conditions, each represents a motivating reason for the individual to review his beliefs and knowledge about the object of the communication. In the first set of conditions, a review of prior beliefs might serve to check the veracity of the new information and the prior beliefs. In the second set of conditions, a review of prior beliefs might serve to weigh the implications of those beliefs against that of the new information. In either event, negative information increases the likelihood that message recipients will compare the new product claim to previously learned brand information.

One outcome of such a comparison procedure is likely to be an increase in the accessibility of brand attribute information. A second outcome is likely to be heightened recognition of the extent to which the new information deviates from prior product beliefs. In the event that the negative information is judged to be valid, deviations from prior beliefs would create pressure for the individual to change those prior beliefs. Negative information thus may increase the relevance to message recipients of an inferential belief change strategy for modifying product evaluations.

Given the diagnosticity of a probabilistic inferencing rule for updating attribute beliefs, recipients of negative messages may be encouraged to seek the correlation information which, when combined with accessible brand attribute information,

would enable them to make probabilistic inferences. Following Dick et al. (1990) we would expect such a search for correlation information to lead negative message recipients to perceive stronger correlations among the attributes of the target product category. As positive messages are more likely to be subject to cursory processing effort (Fiske 1980), message recipients may be less likely to note deviations between positive messages and prior beliefs. Consequently, the perceived relevance of an inferential belief change strategy may be lower following positive information exposure, and recipients may be less likely to seek correlation information.

HYPOTHESES

On the basis of the preceding discussion, two research hypotheses were formed. The first follows from the argument that negative information increases the relevance of an inferential belief change strategy for the modification of brand evaluations. Given high perceived diagnosticity of a probabilistic inferencing rule, message recipients are expected to search for correlation information which would facilitate implementation of such a rule.

- H1: Recipients of negative information about a given product attribute will perceive stronger correlations between that attribute and others of the target product category than will recipients of positive attribute information.

As a result of the search for correlation information, the informational inputs to a probabilistic inferencing rule should be highly accessible to the message recipient. The likelihood of observing probabilistic inferencing behavior in this situation is high.

- H2a: Individuals exposed to negative information will be more likely than those exposed to positive information to exhibit inferencing behavior.
- H2b: Inferential processing in response to negative information will conform to a probabilistic consistency rule.

METHOD

Subjects and Procedure

An experiment was conducted to test the above hypotheses in a context where attribute information was provided for previously known brands. The focus of the study was on inferential belief change processes rather than inferential belief formation. Subjects were 56 undergraduate and graduate students at two U.S. universities who were recruited from announcements placed on campus. Each person was paid \$7 for participating in the study, and his/her name was entered into a lottery for a larger cash prize.

The research design was a two-group pretest-posttest in which groups were exposed to stimulus messages differing in valence. Subjects were told that

the purpose of the study was to examine the effects of independent laboratory testing reports on consumer perceptions and opinions. Their first task was to rate a set of 11 adult cereals (one of which was the target brand for the experimental manipulation) on 7-point semantic differential scales labelled "very low/very high in sugar", "very low/very high in calories", "not at all/very nutritious", and "not at all/very pleasant in taste".

After completing a filler task unrelated to the study's purposes, subjects were asked to examine a rating form which, they were told, had appeared in a laboratory testing report. This form, which presented the stimulus message, rated the target brand as being either very low or very high in sugar content. Following their review of the stimulus materials, subjects were asked a series of questions concerning the perceived credibility of the testing laboratory and of the laboratory report. Next, they were asked once again to rate the target brand in terms of sugar content, calories, nutrition, and taste using the 7-point scales described above. Finally, following a format described by Ford and Smith (1987), subjects were asked to indicate (on a 10 point scale) how likely it is that they could predict the level of the other cereal attributes given knowledge of a brand's sugar content. Responses to this question were divided by 10 to serve as post-message measurements of the strength of perceived correlations between sugar and the other cereal attributes.

Stimulus Materials

Pretesting revealed that the target cereal brand was perceived to be moderate in sugar content (3.36 on a 5-point scale). Furthermore, pretest subjects perceived sugar to be strongly correlated with calories, moderately correlated with taste and weakly correlated with nutrition. This pattern of correlations allows for differences in the magnitude of belief change across the three attributes following the application of a probabilistic inferencing rule. In this event, the relative magnitudes of observed belief changes would be expected to correspond to the relative magnitudes of perceived correlations with sugar (Ford and Smith 1987). That is, observed belief changes would be strongest for calories and weakest for nutrition. If inferencing followed an evaluative consistency rule, there would be no differences in the magnitudes of the observed changes across the three attributes. On the basis of this difference in the hypothesized effects of the two inferencing rules, sugar was considered to be an appropriate attribute for testing hypothesis 2b. Accordingly, sugar was selected as the stimulus attribute for experimental messages, and belief changes pertaining to calories, taste, and nutrition were measured as dependent variables.

After rescaling, the target brand was found to be rated 4.5 on a 7-point scale of sugar content. Equal polarity of positive and negative stimulus messages was attained by rating the target brand of cereal either as 2 (very low in sugar) or as 7 (very high in sugar) on a 7-point rating scale. As pretest subjects had indicated that the ideal level of sugar in a cereal was 2.98 on a 7-point scale, a rating of 2 for the target

brand was expected to be seen as a positive message whereas a rating of 7 was expected to be seen as negative.

RESULTS

Manipulation Check

Subjects' perceptions about attribute correlations were checked to be sure that they were similar to those of the pretest sample. Correlations were calculated from subjects' brand by attribute ratings of the 11 adult cereals. The average correlation between sugar and calories was 0.67; that between sugar and taste was 0.24, and that between sugar and nutrition was -0.15. This pattern matches that of the pretest sample, suggesting that perceptions of attribute correlations are reasonably stable for the adult cereal category.

A second check sought to verify that the stimulus messages had changed subjects' beliefs about the sugar content of the target brand. Subjects receiving the negative (high sugar) message significantly increased their sugar ratings of the target brand (average increase 1.21, $t_{54}=4.93$, $p<.001$), indicating a successful belief change manipulation. Subjects receiving the positive (low sugar) message, on the other hand, failed to significantly change their beliefs about the brand's sugar content (average decrease 0.07, $t=-0.23$, $p<.82$).

This unexpected failure of the positive manipulation weakens our planned tests of hypotheses 1 and 2a. The failure suggests either that subjects processed the positive message but subsequently rejected it as inaccurate or untrue, or that they simply failed to process the message very deeply. The first possibility seems unlikely in light of the result that subjects perceived the positive message to be as credible as its negative counterpart (4.63 and 4.45, respectively, on a 7-point scale; $t_{54}=0.45$, $p=0.65$). The second possibility seems more likely. Fiske (1980) has argued that positive information attracts less attention than negative information, and that it is correspondingly subject to more shallow processing mechanisms. In this case, processing of the positive stimulus message may have been especially low. Why this would be so is unclear. It is possible that subjects in this study classified cereal brands into wide categories of sugary/non-sugary, with the result that the target brand was seen as a low sugar brand, despite its moderate sugar ratings. In this situation, any low sugar message might have matched subjects' expectations to such an extent that it would be subject to little attention.

Limited processing of the positive claim would make a subsequent search for correlation information unlikely. This in turn would render inferencing behavior unlikely. The hypothesized effects of a weakly processed positive message thus are no different from those hypothesized for a stronger positive claim, and the planned tests can still be conducted. In this case, however, the tests will be conceptually similar to a one-sided test which compares a negative message to a null situation where no targeted belief change activity is observed. It will

be impossible to draw conclusions about inferencing behavior under conditions of positive change in a targeted attribute belief.

Test of H1

The first hypothesis states that subjects exposed to a negative stimulus message will perceive stronger correlations among the cereal attributes than will those exposed to a positive stimulus message. In contrast to the hypothesis, however, differences in post-message ratings of attribute relationships across the two groups were directionally correct for each attribute, but none of the effects attained statistical significance. Perceived correlations between sugar and calories were 0.81 and 0.77 for the negative and positive groups, respectively ($t_{54}=0.69$, $p<0.50$), those between sugar and taste were 0.72 and 0.69, respectively ($t_{54}=0.49$, $p<0.63$), and those between sugar and nutrition were 0.62 and 0.58, respectively ($t_{54}=0.49$, $p<0.63$). The first hypothesis thus is not supported by these data.

Perceived Correlations. It was observed in the test of the first hypothesis that subjects' stated perceptions about correlations between sugar and nutrition and between sugar and taste were much higher than those calculated from their ratings of the 11 cereal brands. Although this result was unexpected, it makes sense with a bit of reflection. It appears that subjects saw little covariance among the attributes in the sample of adult cereals tested, but they did expect a relationship for cereal brands in general. As questioning did not specify that subjects should think of the adult cereal sub-category, their answers evidently pertain to the cereal category as a whole.

This result is not problematic for testing the first hypothesis unless it is believed that a post-message search for correlation information would be restricted to the adult cereal sub-category. This seems unlikely in light of spreading activation theories of memory processes (e.g., Anderson 1983) which suggest that, even if sub-category perceptions of attribute associations were activated initially, links between perceptions at various product levels would eventually lead to activation of them all. In the experiment reported here, ample time had elapsed between delivery of the stimulus message and measurement of perceived correlations to allow for activation of the broader network of information.

A more interesting question arises with respect to testing the second set of hypotheses. If message recipients have ready access to information about attribute associations at both the category and the sub-category levels, either set of information could be used as an input to an inferencing rule. In the present case, it might be expected that subjects' category-level perceptions of strong associations between sugar and taste and between sugar and nutrition would lead to strong inferential changes in their beliefs about these attributes in response to a strong sugar message. Alternatively, it might be expected that perceptions of weaker relationships at the sub-category level would lead to weaker inferential changes. Although we are unaware of any prior studies that have looked explicitly at this question, it would seem that sub-

TABLE
Observed Changes in Cereal Attribute Beliefs

Attribute	Average Correlation With Sugar (Across 11 Brands)	Observed Belief Change	
		Negative Information (High Sugar) Condition n=29	Positive Information (Low Sugar) Condition n=27
Sugar		1.21 ***	-0.07
Calories	0.67	0.48 **	-0.26
Taste	0.24	0.34 **	0.11
Nutrition	-0.15	0.17	0.00

*** significant at $p < .001$
** significant at $p < .05$

category perceptions would lead to more diagnostic inferences, and thus would be preferred as an input to decision making. In that case, we would expect relatively weak inferencing behavior with respect to the nutrition and taste attributes.

Tests of H2a and H2b

The second hypothesis requires that inferential belief change be observed in the negative, but not the positive, message condition. Subjects exposed to positive messages thus should exhibit no significant changes in their beliefs about the level of calories, taste, or nutrition exhibited by the target brand. Additionally, H2b requires that inferencing behavior in the negative message condition follow a probabilistic consistency rule. The relative magnitudes of the belief changes observed in the negative message condition thus should correspond to the relative magnitudes of the correlations among the respective attributes.

As sugar and calories consistently were perceived to be strongly related it was expected that subjects in the negative message condition would exhibit large, significant changes in their beliefs about the caloric content of the target brand. For the taste and nutrition attributes, predictions were made on the basis of sub-category perceptions of attribute correlations since these were expected to be more diagnostic than those at the category level. It thus was expected that observed belief changes would be moderate for taste and small for nutrition. The weak sugar/nutrition correlation suggests that the magnitude of the change in nutrition beliefs will fail to reach statistical significance. It is more difficult, however, to predict whether belief change will be significant for taste. No specific predictions were

made for this question since greater insight was expected to come from comparing the relative magnitudes of the belief changes rather than their significance levels.

Belief changes were calculated for each attribute by subtracting pre-message ratings of the target brand's attribute levels from their post-message equivalents. The table shows the magnitude of each observed change for both of the experimental groups. As expected, no significant inferencing was detected among subjects in the positive information condition. In contrast, subjects in the negative information condition significantly changed their beliefs about the levels of calories and taste exhibited by the target brand. The results are supportive of the second hypothesis in demonstrating that negative information prompted significant, systematic changes in non-targeted attribute beliefs whereas the positive message prompted no significant effects. Although the failure of the positive manipulation renders the test inconclusive regarding the effects of a positive targeted belief change on inferencing behavior, the lack of significant effects in the positive condition increases our confidence that the inferencing observed in the negative condition was more than a random event.

As seen in the table, the relative magnitudes of the observed belief changes in the negative message condition conform to the relative magnitudes of the perceived correlations among the attributes of the 11 adult cereal brands. These results are strongly supportive of part two of the second hypothesis. If an evaluative consistency rule had been followed, all beliefs would have changed in an unfavorable direction. Further, the magnitude of observed changes would have been similar across the attributes. The

observed differences in magnitude and the more favorable ratings of the target brand's taste make it unlikely that an evaluative inferencing rule was followed.

The observed differences in inferencing magnitude also make it unlikely that category level perceptions of attribute correlations were used as an input to the inferencing process. The use of sub-category correlations is consistent with the Dick et al. (1990) argument that the choice of an inferencing rule will be influenced by considerations of rule diagnosticity. In this case, inferences drawn from the adult cereal sub-category would be more diagnostic than those drawn from the cereal category considered as a whole.

DISCUSSION

The experiment provides evidence that negative information may stimulate inferential processing, although the reasons for the effect remain unclear. Subjects who saw negative brand information did not perceive stronger attribute correlations than those who saw positive brand information. There thus was no evidence that negative message recipients were more likely than positive message recipients to actively seek correlation information. This lack of support for the first hypothesis is especially noteworthy in light of the failure of the positive manipulation. If negative information fails to increase the strength of perceived correlations over the level realized by a weakly processed positive message, it is unlikely to be more effective in relation to a stronger positive message which is subject to heavier processing.

On the other hand, tests of the second hypothesis suggest that perceived correlations were accessible to subjects in the negative message condition. Without access to this information it is unlikely that subjects would have followed the hypothesized probabilistic inferencing strategy. Combined, then, the two hypothesis tests suggest that attribute correlations were accessible to subjects in both information conditions. It is possible that in questioning the positive message recipients about attribute correlations, the experimental procedure led them to seek correlation information. The similarity of responses across the two groups thus may reflect testing effects rather than an error in the logic supporting the first hypothesis. Future research should seek to reexamine this question using less problematic measures of the mechanisms underlying the inferencing process.

An additional question arose during hypothesis testing pertaining to whether inferential reasoning would be based on perceived attribute associations within the entire product category, or on those within a subset of the category to which the target brand belonged. In the present case, the latter appears to have held. The result is consistent with the argument made by Dick et al. (1990) that the inferencing rule which produces the most diagnostic conclusions will be selected. In addition to bolstering support for the Dick et al. framework, our finding should serve as a warning to others who work in this area that the

appropriate category level must be used to make inferencing predictions.

Limitations

The failure of the positive manipulation to change a targeted attribute belief made comparison of the negative and positive message conditions less informative. Conclusions about the effects of message valence on inferencing behavior thus must be made with care. In this research only negative information stimulated inferencing activity. It is possible, however, that the frequency and nature of inferencing behavior would have been the same in the positive information condition if the manipulation had realized greater success.

The study was further limited to product information delivered in the form of a laboratory testing report about a single product category. It may be that negative information from other sources or concerning other product categories would be less effective than that presented here. The laboratory report was judged to be reasonably credible by both groups of research subjects. Other sources clearly would be less credible as providers of both positive and negative information. In such an event, the interaction of source credibility and information valence might yield outcomes that differ from those reported here.

Another question to be explored in future research is that of how inferencing behavior would change if subjects' expectations about message valence were violated. If positive messages were delivered by unlikely sources (such as competitors) or positive information were very extreme, the atypicality of the situation might make positive information a sufficient stimulus for inferencing behavior. Alternatively, if negative information were delivered in a context where it was expected (such as in comparative advertisements), inferencing might not result. These unanswered questions highlight the need for additional research into the mechanisms that underlie inferencing behavior.

Attention, Memory, Attitude, and Conation: A Test of the Advertising Hierarchy

Esther Thorson, University of Wisconsin-Madison
Annie Chi, University of Wisconsin-Madison
Clark Leavitt, Ohio State University

One of the earliest theories of how advertising works was the hierarchy of effects model (Lewis, 1898). This model posits that the processes of *attending* to a commercial, *learning and remembering* its content, developing *attitudes*, and generating *conative* responses occur in a sequential causal chain. Lavidge and Steiner (1961) articulated a relatively recent version of the hierarchy model. They suggested that the steps in responding to advertising included: awareness of the ad, knowing what the brand has to offer, liking the brand, preferring the brand to competitors, conviction about the purchase, and purchase. Although advertising texts (e.g., Bovee & Arens, 1982; Wells, Burnett, & Moriarty, 1989) do not always specify a particular theory when they talk about how advertising works, they too suggest that first the ad must catch and hold attention. Then people must comprehend and remember its contents. Next, there must be attitudinal impact, and finally, conation.

Thus much of the scientific and heuristic literature of advertising theory adheres to the notion that responses to commercials fall into a single causal flow of effects. That is, no matter how complicated or simple, hierarchy models all derive from the central assumption that to be effective, advertising must "move people through a series of processing steps." In addition to positing a series of processing stages, hierarchy models also assume (Preston and Thorson, 1983) that to claim that a commercial has been effective, *each* step in the hierarchy must occur and it must occur in the *specified order*.

But is it true that an ad must propel people through these steps in order to reach conation? Graphic representation of this idea is shown in Figure 1. This model basically suggests that first there is attention to the ad. As a result, a memory for it is created. Based on the content of that memory, attitudinal responses develop, and as a result of these attitudes, conation eventually occurs.

To evaluate the model of Figure 1, we must examine the links between contiguous stages in the hierarchy. There is significant support in the literature that attitudinal and conative responses are correlated with each other. Indeed, a recent highly publicized finding sponsored by Advertising Research Foundation has shown that the best predictor of purchase is liking for ads. (Haley, 1990).

The link between memory and attitudinal responses is problematic. Gibson (1983) criticized the use of recall measures to evaluate ads because of the "common finding" that recall has little or no correlation with consumer choices in the marketplace. However, Stewart (1986) has presented compelling evidence that commercials that are well-recalled and comprehended and which present a message that clearly differentiates the brand, do score higher on persuasion. His findings suggest, in fact, that perhaps

a number of variables that increase the impact of processing may lead to commercial memory being correlated with persuasion.

The relationship of attention to the other steps of the hierarchy is also unclear. MacKenzie (1986) demonstrated that attention to a brand attribute in an ad affected perceived importance of that attribute. His study did not look at the subsequent impact on attitude. Olney, Holbrook, & Batra (1991) showed a close link between attention and attitudinal responses when attention was measured as the amount of viewing time people give the ad when they have the opportunity to zip the ad instead of watching it. This study did not, however, look at memory. Thorson, Zhao, & Friestad (1988) showed strong links between attention and memory when attention was measured as the percent of time people actually watched the TV screen. There were not, however, significant links between attitude toward the ad or brand and the eyes-on-screen measure of attention. The authors suggested that attention affects memory because without watching, input is drastically reduced and there is nothing to remember. However, once people watched a commercial, their attitudes were influenced by the attributes of the ad, eliminating the impact of simply attending to the ad.

Attributes of Ads

Perhaps most importantly in the hierarchical schema, however, are attributes of the ad itself and how well each of these attributes predict the various responses to the ad: attention, memory, attitude and conation. Probably the most studied link in recent studies has been between ad attributes and attitudinal responses. Many studies have looked at the emotional attributes of ads and attitudinal responses (e.g., Stayman and Aaker, 1987; Edell and Burke, 1987; Thorson & Friestad, 1989). Holbrook and Batra (1987) showed that ad content measured as emotional, threatening, mundane, sexy, cerebral, and personal predicted both pleasure and arousal responses to ads and attitude toward the ad and brand. Other attributes of ads examined for their links with attitudinal impact have included informational and transformational appeals (Edell & Burke, 1987), and presence and type of illustrations (Mitchell, 1986).

There have also been studies of ad attributes and memory. One of the earliest attempts to predict recall of TV commercials was by Haller (1972). He used experts' judgments of four commercial dimensions: (1) the extent to which the visual aided the audio in getting the message across; (2) the stopping power of the message, (3) message clarity, and (4) the extent to which the message spoke personally to the viewer. Thorson and Snyder (1984) and Thorson (1983) used predictions from a psycholinguistic model of comprehension (Kintsch & van Dijk, 1979) to predict

FIGURE 1
The Hierarchic Models of Advertising Effects

Figure 1b: The Two-Route Hierarchic Model of Advertising Effects

Figure 1c: Significant Relationships among Components of the Advertising Hierarchy Based on the Whole Sample of Commercials

industry measures of recall for commercials. Measures such as the number and arrangement of idea units in the scripts predicted about 33 percent of the variance in recall scores.

In experimental studies of consumer responses to television commercials, Thorson & Friestad (1989) and Thorson & Page (1990) have shown that commercials that create emotion in viewers are better recalled than commercials neutral in emotional impact.

Other studies have examined the impact of ad attributes on both memory and attitude. Stewart and Furse (1985, 1986) defined 153 variables and used them to predict Research System Corporation's three (ARS) measures of ad effectiveness: recall, key message comprehension, and persuasion. After removing product category effects, Stewart and Furse found variables that accounted for 13 to 26 percent of the variance in recall, 8 percent of the variance in key

message comprehension, and 9 to 11 percent of the variance in persuasion. This aspect of the impact of ad attributes is important. McGuire (1969), another of the hierarchy theorists, pointed out that the different stages in the hierarchy are influenced by different aspects of ad structure. For example, attention may be increased by such ad variables as color, brightness contrast, camera movement, and gender of speakers. But memory may be increased by such variables as repetitiveness in the script, simplicity, and novelty. Although each stage in the hierarchy of effects operates contingently on the stage prior to it, it also is influenced by different ad attributes than the stages preceding and following it.

Indeed, the notion that different attributes of commercials differentially affect success in transiting different stages in the hierarchy has driven many attempts to build lists of attributes of commercials that will lead to "successful" consumer responses at

FIGURE 2
The Two-Route Hierarchic Models of Advertising Effects: Emotional vs. Nonemotional commercials

Figure 2a: The Two-Route Hierarchic Model for Emotional Commercials

Figure 2b: The Two-Route Hierarchic Model for Nonemotional Commercials

various levels of the hierarchy--memory, persuasion, and liking for commercials. The search for a complete specification of all ad attributes relevant to eventual impact is termed "copy testing," and of course this area of advertising research also has a long history.

In the copytesting tradition, but emphasizing the hierarchical nature of responses to ads, Leavitt (1970) presented people watching ads with 52 adjectives that he found most used by consumers in focus groups. Leavitt expected that the dimensions that would emerge from factor analysis of the adjectives would reflect the four stages of the basic hierarchy model: attention, learning or memory, attitude change, and conative impact. Four dimensions did emerge. They included: Stimulation (amusing, energetic, novel, slow, and worn out); Relevance (convincing, credible, relativistic, irritating, and confusing); Gratification (agreeable, attractive, tender, warm); and Familiarity (well-known, new, saw before). In validation studies with the four dimensions, Leavitt found that Stimulation was related to attention. Relevance was related to attitude and conation. However, none of the four dimensions was related to memory.

The four dimensions from Leavitt's study have face validity; that is, they appear to be reasonable responses to commercials. They also find much support in the copy-testing literature (e.g., see Ju, Stout, & Leckenby's review (1990) of copy research). The items also seemed to relate to the critical stages of

the hierarchy model. Thus it was the 52 items that made up Leavitt's original system that were employed in this study.

Models and Research Questions

The main thrust of the study reported here was to test the predictions of the quintessential hierarchy model of advertising effects. This model posits that ad characteristics will drive attention to the ad, which will in turn affect memory for the ad, and then attitude toward the ad and its brand, and finally, conative responses to the ad. Based on the uncertainties about the mediating relationships of these variables reflected the literature reviewed above, a second form of hierarchy was also deemed important to test. Specifically, the impressive literature demonstrating that memory and attitudes are not correlated suggests the model depicted in Figure 2. In this model, there are two routes of responses to ads: (1) the comprehension/learning route and (2) the evaluative route. In the learning route, ad characteristics drive attention, which in turn determines comprehension and memory. In the evaluative route, ad characteristics drive attention, which in turn determines attitude toward the ad, attitude toward the brand, and intention to purchase. Under this model, ads that are remembered are not necessarily those that create desire and intention to purchase.

A second thrust of the study was to ask whether the same form of the model was applicable both to ads

that created emotion and those that did not. When an ad creates emotion in the viewer, the memory engram for the experience is enhanced over non-emotional conditions (Squires, 1986; Mishkin, Malamut, & Bachevalier, 1984). The engram is stronger in that recall likelihood is higher (Thorson & Friestad, 1989), and the engram is richer in the sense that viewers can report more information about the ad. The engram also contains residue from the experience of the emotion itself and thus is affectively charged. This means that the emotion itself can serve as a recall cue (Clark & Teasdale, 1985; Page, Thorson, & Heide, 1990). Given the enhanced salience of the engram created by emotional commercials, it seems likely that the engram would be more likely to affect attitudinal responses. Actually, Stewart's (1986) finding that ads leaving stronger memory traces and having more brand differentiating impact are more likely to produce greater persuasion is consistent with this view of the impact of emotion stemming from a commercial. We therefore expect that there is more likely to be a direct link between memory and attitudes for the emotional commercials, that is, they will show a pattern more like the classical hierarchy. This result is not expected for nonemotional commercials.

Concepts and Measurements

The concepts employed here included all the steps hypothesized in the hierarchy models. A brief theoretical and methodological explication for each concept follows.

Attention

There are many ways to conceptualize people's attention to television and television commercials. Attention can be thought of as how often people look at the screen under natural and free viewing conditions (e.g., Anderson & Lorch, 1983). Attention can be thought of as how much time people voluntarily watch a commercial when they are enabled to avoid it if they prefer (e.g., Olney, Holbrook, & Batra, 1991). Or, in a forced viewing situation, attention can be conceptualized as the intensity with which people experience their viewing (e.g., Reeves & Thorson, 1986). All three of these conceptualizations seem legitimate and important. Methodologically, however, the simplest of these definitions to operationalize is the third one, and for that reason, the self-reported intensity of watching was employed here.

Memory

Memory can also be defined in a number of different ways. Perhaps the most difficult and challenging memory task for viewers of commercials is to free recall ads. In this task, the subject must provide his/her own cues for remembering. This means the recall task is also the most free of the biasing impact of cues such as product category, brand name, information about the commercial execution itself, and so on. The recall method was for that reason adopted here.

Attitudes and Conation

Attitude toward the ad and brand are the most common measures of people's attitudes that develop at least partially in response to viewing ads. Although there may be a number of dimensions of liking for ads, we were here most interested in a global response of liking or not liking rather than to the intricacies of dimensions of liking (Olney, Holbrook, & Batra, 1991) or aspects of the antecedents to the liking. The same rather global conceptualization of attitude toward the brand was also preferred here.

Conation is another concept with a number of reasonable possible definitions. Conation can be the actual selection or purchase activity. More often, however, in studies that attempt to tie conation to specific ads, self-reported intention to purchase is used as the critical measure of behavior toward the brand. That definition is used here.

A Methodological Caveat

To test the accuracy and generalizability of the two alternative models, and to compare their applicability to emotional and nonemotional commercials, one would need to sample extensively from emotional and nonemotional commercials. Given this is so, how many ads compose a large sample, and how does one know when the sample is representative? Without a taxonomy of all possible ads, these are difficult questions. Thus it was necessary to limit the scope of the study reported here. In the study, a sample of on-air ads was collected from prime time programming in 1989. These ads were then tested for emotional impact on viewers. Six commercials producing high positive emotional impact on viewers and six commercials producing little or no positive impact were chosen for the present study.

Analytic Approach

The basic idea of flow through successive stages of the hierarchy model and the alternative model is tested by the procedure suggested by Holbrook and Batra (1987) and Olney, Holbrook, and Batra (1991, p. 441). This procedure:

"tests for mediating effects via the rule that Y mediates the effect of X on Z if and only if (1) X is related to Z, (2) Y is related to Z, and (3) X is related to Y, and (4) when Z is regressed on X and Y is controlled for, the significance of X in explaining Z decreases (partial mediation) or disappears entirely (complete mediation)."

METHOD

Stimulus materials

Twelve commercials were selected from a large pool of those sampled from prime time programming. Extensive pretesting of the commercials in original pool had shown that some ads generated relatively high positive emotional responses, while others showed very little or no emotional response at all. Three seven-point scales were used to index the emotional-neutral dimension. The items included:

 N=59

warm feeling-neutral feeling; emotional-not emotional, and pleasant-unpleasant. The mean emotion rating for the six emotional commercials was 5.8 and for the six neutral commercials, 2.0. The difference between the two groups was significant ($F(1,60) = 14.8, p < .01$). Three random orders of the twelve commercials were dubbed onto 3/4 inch videotape.

Subjects

Fifty-nine students in an elementary marketing course in a large midwestern university were tested in the study. Subjects were given credits toward a classroom exam as the reward for participating in the study.

Dependent Measures

Commercial attributes were measured using the 52 items developed by Leavitt (1970). These items are shown in Table 1.

Attention to each ad was measured with three seven-point items describing "how closely did you attend to this commercial:" no concentration-full concentration, watched intensely-watched vaguely, and paid full attention-paid no attention.

Attitude toward the commercials (Aad) was measured with three seven-point items: good-bad,

unpleasant-pleasant, and like very much-dislike very much. Attitude toward the brand advertised (Abr) was measured with the same three items.

Purchase Intent served as the index of conation, and was measured with three seven-point items: likely to-unlikely to, plan to-don't plan to, and intend to-don't intend to.

Memory for the commercials was measured at the end of the viewing period with an open-ended questionnaire that asked subjects to "list the brand and/or the basic idea of each commercial you remember seeing."

Procedure and viewing conditions

Subjects were tested in a quiet classroom where they could comfortably view a 19-inch television. The students were randomly assigned to one of the three orders of the 12 stimulus ads. After the interviewer indicated interest in people's responses to commercials and consent forms had been signed, subjects viewed each ad once, then responded to the 52-item adjective checklist, then responded to the attention and attitudinal items. After all 12 of the commercials were completed, a five-minute delay task was introduced. Then subjects were asked to free recall any of the 12 commercials they had seen. After the recall procedure, subjects were thanked and excused.

Purchase Intention	.16	.41	.34	.41	.15

N=59

RESULTS

Ad Characteristics. A factor analysis was conducted on the 52 items used to measure attributes of the commercials. Items loading greater than .5 on each factor were used to form five factors. (See Table 1). The five factors accounted for 75.2% of the total variance. Four of the factors, Stimulation, Liking, Personal Relevance and Familiarity were virtually identical to the four factors reported by Leavitt (1970). The five factors were used as the ad message variables.

Discriminant Validity. To assure that the resulting factors capture different dimensions of ad characteristics, the validity of the measures was assessed by examining the correlations between the factors and dependent measures. The criterion against which discriminant validity is determined is that the factors should relate differentially to at least some of the dependent measures (Carmines & Zeller, 1979).

The correlations are displayed in Table 2. Among the five factors, only personal relevance is related to attention ($r = .34$). Liking and personal relevance are related to memory but in differing directions (.20 vs -.17). Personal relevance is the only variable not related to any of the attitude variables. The relations of the other four variables to attitudes differ in strength. Although Stimulation is correlated with attitude toward the ad, it is not related to brand attitude. Finally, all factors are related to purchase intention. The relations differ in strength. This pattern of correlations supports the position that the adjective measures are valid in representing different dimensions of ad characteristics.

Reliabilities of Attention, Aad, Abr, and Purchase Intention. The three attention items were combined to measure the intensity with which subjects attended to the commercial. Reliability assessments were performed for each of the twelve test commercials across subjects. Alpha coefficients ranged from .74 to .96, with an overall reliability of .93.

For attitude toward the ad, the three items regarding subjects' evaluation of the ad were combined. Alpha coefficients for the Aad indices ranged from .88 to .95. The overall scale reliability was .93. Similarly, the Abr index measure was constructed by combining three attitudinal items

toward the advertised brand. The reliability coefficients ranged from .89 to .90, with overall scale reliability of .95. The purchase intention indices showed relatively high reliability across all twelve commercials, from .94 to .99. The overall scale reliability was .99.

Recall. Memory was indexed by the free recall test. Subjects who could correctly recall any information from a test commercial received a score "1" for that commercial. Failure to recall and incorrect recall was scored "0". Although free recall can capture whether subjects remember anything from the commercial, the dichotomous measure reduces memory variation between subjects. This limitation should be kept in mind when evaluating the results reported below. Descriptive statistics for each of the dependent variables are available from the authors.

Tests of the Research Questions

The purpose of the study was to test two competing hierarchic models, the classic hierarchic (one-way flow) model and the two-route hierarchic model (Figure 1). Hence, the analyses involved the following decisions: (1) first, to determine the relation between ad characteristics and purchase intention; (2) second, to find the appropriate model explained by the present data; and (3) to test the mediating effects of the proposed variables on the relationship between ad characteristics and purchase intention.

Several hierarchical regression analyses were performed in the effort to reach the decisions discussed above. Tables 3-6 display the beta coefficients and R^2 s that were produced when various mediation steps in the hierarchy were considered.

Predictive Impact of the Ad Characteristics. In Table 3, the key regression results for purchase intention as the dependent variable and the various independent variables are presented. Column 1 in the table shows that when ad characteristics alone were entered in the regression equation, they accounted for significant variance in purchase intention ($R^2=49.7\%$, $F=8.55$, $p < .01$). Among them, Credibility, Liking, and Personal Relevance had significant positive influences on purchase intention.

b= p < .05
c= p < .01

Once the relationship between ad characteristics and purchase intention is established, the next task is to test the two models proposed here. First, we examine the classic hierarchy model.

Mediation as Predicted by the Classic Hierarchy Model The classic hierarchic model showed in Figure 1a presents a one-way flow of advertising effectiveness from ad characteristics to purchase intention with various interventions of attention, memory, attitude toward ad, and attitude toward brand. Because the mediation involves four intervening variables, several hierarchical regression equations were built to test each intervening variable step by step. The regression results are, then, subject to meeting the required conditions for mediating effects discussed above.

Columns 1 and 7-10 in Table 3 show that some links are missing from the successive stages of the classic hierarchic model. The missing links may occur in attention and memory. When attention and memory were added to the regression equations (Column 7 and 8), the total variance was not improved to a significant level (R²=51.6% to 54.03%, hierarchical F tests= 2.04, 2.06, p > .05). In addition, the two variables did not perform well as predictors of purchase intention (Columns 2 and 3). Thus, the

results do not meet the condition of mediating effects in that attention and memory should be related to purchase intention. The beta coefficients of the ad characteristics did not decrease or disappear when attention and memory were controlled for. Credibility, Liking and Personal Relevance still affected purchase intention strongly and positively.

However, Columns 1, 6, and 10 reveal that the mediation between ad characteristics and purchase intention exists. When all the mediators were controlled for, the effects of ad characteristics decreased substantially but were still significant, with the exception of Personal Relevance. The source of mediation may come from attitude toward ad and/or attitude toward brand (Aad, Abr). When Aad and Abr were entered, respectively, in the regressions, the effects of Credibility and Liking dropped (Columns 9, 10). Aad and Abr by themselves are also strong predictors of purchase intention (Columns 4, 5).

In conclusion, the classic hierarchic model is not supported by the present data. Ad characteristics affect purchase intention significantly. The effects are both direct and partially mediated. However, the mediation does not flow through attention, memory, to attitudinal responses, and finally to conative responses. Rather, the effects of some ad

characteristics, Credibility and Liking, operate via Aad and Abr on purchase intention. Personal relevance, however, has a strong direct effect on purchase intention, which overwhelms the mediation of Aad and Abr.

Mediation as Predicted by the Two-Route Hierarchic Model. Figure 1b presents the two-route hierarchic model of advertising effectiveness. The model proposes a distinction between learning from ads and evaluative responses to ads. Basically, it suggests that the evaluative route of responses to ads is not affected directly by learning. Here, we first examine the distinction by looking at the relationship between memory and Aad, which separates comprehension/learning from evaluation of ads. Equations 5-6 in Table 4 provide the first evidence to support the hypothetical distinction. Attention and memory do not affect Aad ($\beta = .18, .03, p > .05$).

We now first examine the evaluative route, which leads successive responses to purchase intention in reaction to an ad. Given the evidence that attention affects neither purchase intention nor Aad, the hypothesis that the evaluative route to conative responses is driven by attention is not supported. Thus, further tests of the evaluative route will exclude attention from the regression analyses. Moreover, to test the causal order of mediations in the evaluative route, (1) the links between ad characteristics, Aad, and Abr were tested, then (2) the links between ad characteristics, Aad, Abr, and Purchase Intention were tested.

Results from Equations 7-10 in Table 4 show support for the first link, that is, that Aad mediates the effects of ad characteristics. Aad and Abr were highly correlated. This means that in further analyses, the two variables may suppress each other's effects and thus interpretive caution should be kept in mind. Nonetheless, when Aad was controlled for, the effects of ad characteristics on Abr decrease and even disappear for Credibility ($\beta = .32$ to $.01$). For Credibility, Aad manifests complete mediation. In contrast, for Liking and Familiarity, Aad only partially mediates the effects on Abr. Moreover, Equations 11-13 support the second causal link. After both Aad and Abr are controlled for, the effects of Credibility on Purchase Intention decrease from $.40$ and $.29$ to $.28$. The effects of Liking show the same descending pattern. Similarly, Personal Relevance has a strong direct influence on purchase intention, and it is not mediated by attitude toward the ad.

Equations 1-4 in Table 4 provide slight support for the comprehension/learning route. Both Personal Relevance and Familiarity have strong direct effects on attention. However, ad characteristics and attention do not show direct influence on memory. Yet, the effect of attention is improved and approached significance level when ad characteristics were controlled for ($\beta = .27, p = .07$). The possible explanation for this nonsignificant effect is the memory measurement used in the study. Memory was measured by *whether or not* subjects recalled the ad in the study but not *how much* they could remember about the ad. Again, then, the problem with the

dichotomous nature of the memory measure must be kept in mind.

In conclusion, the two-route hierarchic model is supported but with some qualifications. First, the model proposes that the comprehension/learning route and the evaluative route are both driven by attention. However, the results obtained suggest that attention only influence the comprehension/learning route but without having impact on attitude toward ad. Thus, the effects of ad characteristics on purchase intention are operated via attitude toward ad and attitude toward brand without the intervention of attention. Second, the relationship between attention and memory is hypothesized with a caution over the methodological concern. The resultant model is displayed in Figure 1c.

Mediation as Predicted for Effects of Emotional Commercials. Table 5 displays the key regression results for testing the hierarchic model of advertising effectiveness for emotional commercials. Equations 7-15 provide support for the evaluative route to the final conative responses to ads. With Aad controlled for, the effect of Credibility on Aad disappears. The effects of Liking and Familiarity decrease substantially. Aad shows a complete mediation for credibility and partial mediation for liking and familiarity. The effect of Liking on purchase intention is completely mediated via Aad and Abr, but the effect of Credibility is partially mediated. Personal Relevance turns out to have overwhelming direct effect on purchase intention.

Tests of the comprehension/learning route reveal more interesting applications to the two-route hierarchic model. First, the link between ad characteristics and attention disappear for emotional commercials. Equations 1 and 2 show no significant effects of ad characteristics on attention and memory ($R^2 = 10.7\%, 9.7\%$; $F = 1.03, .93, p > .05$). However, influence of learning on the evaluative process of advertising is still found. Results from Equations 4-6 indicate that both attention and memory have direct effects on Aad. Moreover, the effect of attention is partially mediated by memory. The advertising effectiveness model for emotional commercials is illustrated in Figure 2a. One implication from this model is that for emotional commercials the learning route and the evaluative route converge to influence attitude toward brand and purchase intention.

Mediation as Predicted for Effects of Non-emotional Commercials. Similar tests were performed for non-emotional commercials. The results are shown in Table 6. The empirical findings, again, validate the evaluative route of responses to ads (see Equations 6-14). Credibility and liking have effects on attitude toward ad. The effects of Liking and Familiarity on attitude toward the brand are mediated through attitude toward the ad. Credibility and Liking influence purchase intention via attitude toward ad and attitude toward brand. Personal relevance has a strong direct effect on purchase intention without intervention.

The comprehension/learning process of advertising is partially supported in that a direct effect is found between ad characteristics and attention.

However, both ad characteristics and attention indicate a weak connection with memory (Equations 2 and 3). It seems that both personal relevance and familiarity have a positive impact in drawing attention. Nonetheless, the attention paid to the ad does not necessarily produce better memory for it.

DISCUSSION

Given that the present study involved forced viewing of commercials in a lab setting, the consistency of its results with studies using a variety of other methodologies is striking. First, in the overall sample of commercials, the classic hierarchy of effects is not supported. There is a memory branch and an attitudinal/conative branch and the two do not correlate with each other. This is consistent with the large number of studies that have argued that across the great unwashed world of commercials, recall is not a good index of persuasion. Also of considerable interest is the fact that in the two-branched hierarchy, attention influences processing in the memory branch, but not in the attitudinal branch. This is the same result as found by Thorson, Zhao, & Friestad (1988), even though their study was carried out with non-forced viewing, and with the commercials embedded in ordinary TV programming environment. These results provide strong evidence that watching a commercial makes viewers remember it. But once watching has occurred, it has no intrinsic influence on whether viewers like the ad or brand. That impact is presumably carried by the quality and persuasiveness of the commercial itself.

A third, and perhaps most interesting way in which the present results are consistent with previous findings, is that when commercials are subdivided into those that create emotion in viewers and those that do not, the emotional commercials generate a clear linkage between memory and attitudes. Like in Stewart's large scale study of commercials, those ads that are remembered well and have special impact (in his case, successfully differentiated the brand) are also more likely to show high persuasion scores. Again, it is notable that the present results coincide with Stewart's findings when his study involved so many more commercials and when the persuasion score was significantly different from the one used here. Stewart used the ARS measure of brand change to index persuasion, while here the measure was simply of liking the ad and brand and intention to purchase.

Somewhat puzzling was the result that for emotional commercials, ad characteristics did not predict attention. An obvious explanation was that the emotional ads were all watched with high intensity and the resultant lack of variance in attention scores prevented their prediction by the ad characteristics. Unfortunately the mean attention scores for the emotional commercials simply were not high enough or even consistent enough to provide much support for this explanation. In the overall sample, Personal Relevance and Familiarity predicted attention. Another explanation for the lack of relationship between ad characteristics and attention may have been that the impact of Relevance and Familiarity were

eliminated by the impact of the emotional response to the ads. This idea seems plausible when we also consider that Personal Relevance and Familiarity had a very high impact on processing the nonemotional commercials. When emotion is not around to carry the day for a commercial, then it makes sense that how relevant people think the commercial is and how well they already know the brand would affect how closely they watch.

It is also interesting to consider that even when the attention to memory to attitude to conation link is quite strong, as it is for the emotional commercials, the ad characteristics that predict each step by itself differ. None of the five ad characteristics drive attention or memory, Stimulation and Credibility drive Aad, Credibility, Liking, and Familiarity drive Abr, and Credibility and Personal Relevance drive Purchase Intention. This finding helps to elucidate how McGuire's matrix of persuasion model may operate. Ad characteristics do indeed influence different stages of the hierarchy of responses, just as McGuire posited. However, the stages themselves also influence each other. For example, for the emotional commercials, strong recall is associated with more positive Aad, more positive Aad with more positive Abr, and a greater intention to purchase.

Finally, it is interesting to note that the five dimensions of ad characteristics probably reflect the differences in emotional and nonemotional commercials, but the impact of emotional commercials is not captured by these dimensions. That this is so is confirmed by the finding that the structure of the hierarchical flow of effects is itself changed by emotional impact in commercials. This finding is again consistent with a frequent finding in advertising research. Edell & Burke (1987), Stayman & Aaker (1988), and others have found that even when other antecedents of attitude are taken into account, the impact of individual emotional responses to ads often have independent direct effects on attitude.

Limitations

The consistency of the present study with others using different commercials, different viewing conditions, different dependent measures, and different subjects argues for its generalizability. But as with all studies, the extent to which its conclusions apply must come under close scrutiny and some skepticism. The use of Leavitt's scale of ad attributes rather than one of the many other copytesting systems available may have influenced the pattern of the linkage between stimulus characteristics and flow of processing. The self-reported measure of intensity of attention paid may have significantly changed the pattern of influence flow from ad structure to the other stages of the hierarchy. A different and larger sample of commercials and the method of categorization into emotional and nonemotional might also be expected to change the observed pattern of the processing. Measuring memory with a dichotomous free recall index may have reduced the variation in memory sufficiently to lessen the opportunity to observe its true relations with the other stages of the hierarchy.

Testing of adults or the elderly or any other population group might yield different results from those observed in college students. And certainly intention to purchase is a different measure from actual purchase behavior. As always, the narrower-than-desirable scope of this study motivates a call for further research on the question.

Subject to these limitations, however, the results reported here are encouraging. In spite of those who have long decried the value of looking at memory for commercials, there are under certain conditions, clear relationships between memory, attitudes, and conation. In spite of the age of the hierarchy model and the many attacks on its validity (e.g., Preston & Thorson, 1983), with some modifications, the model remains strongly predictive of viewer behavior. And finally, the study suggests that there is a role for both memory and attention to play. In an advertising literature dominated by attitude theory and measurement, these other two processes are often given short shrift. But in a media world burdened with high levels of clutter, attending and remembering some ads rather than others may soon come to be seen as critically important.

Nostalgia: An Exploratory Study of Themes and Emotions in the Nostalgic Experience

Susan L. Holak, Rutgers University
William J. Havlena, Rutgers University

ABSTRACT

A set of 164 experience descriptions provided by 62 individuals is used as the basis for an examination of common themes and subjects for nostalgic reflection. Family and home serve as potent stimuli for nostalgia, but a wide variety of other persons, objects, and events were also mentioned by the respondents. Objects and events (such as birthdays, holidays, and reunions) tend to evoke strong memories of the people associated with them. As has been suggested in previous studies, childhood and adolescence appear to be particularly fertile periods for nostalgic meditation. Memories of sights, smells, and tastes are recalled in the descriptions. Both personal and historical nostalgia were elicited and a range of emotional responses are evident in the descriptions.

Nostalgia—"a painful yearning to return home"—has recently attracted the attention of marketers and consumer researchers. Despite this popularity, relatively little work has been published in the consumer literature on the character of nostalgia and the emotional reactions typical of such experiences. Although attempts have been made to identify nostalgia-proneness (Holbrook 1991) and the use of nostalgia in marketing (Havlena and Holak 1991a), our understanding of nostalgia in a consumer behavior context remains limited. This paper presents some preliminary findings from a study designed to explore recurring themes and emotions in nostalgic experiences.

THE NOSTALGIC CONDITION

The word "nostalgia" is derived from two Greek roots: "nostos" meaning to "return to one's native land" and "algos" referring to "pain, suffering, or grief" (Hofer 1688; Daniels 1985). Beginning with the writings of Johannes Hofer (1688), nostalgia has been associated with a myriad of physiological and psychological symptoms. Nostalgia as an emotion contains both pleasant and unpleasant components. This "bittersweet" quality of the emotion is a distinguishing characteristic of the nostalgic condition. In terms of time, it refers back to an earlier period in an individual's life, possibly ranging from ten to seventy years, and draws on biased or selective recall of past experiences. Nostalgia may evoke memories of peaceful, pleasant times or of times of tension and turmoil. Until recently, most of the findings on nostalgia were based on anecdotal evidence or individual case histories rather than on larger-scale empirical studies. As Nawas and Platt (1965, p. 51) observe, "It is rather curious that a phenomenon as pressing, as ubiquitous, and as little understood as nostalgia has received only passing attention from psychologists; in the last quarter century no more than six empirical studies have

appeared on the subject." Havlena and Holak (1991a) present a brief review of some of the pertinent psychological and medical literature related to nostalgia.

NOSTALGIA AND BEHAVIOR

Most recent discussions of nostalgic emotion no longer limit the concept to simple homesickness. Given the increased mobility of individuals in today's society, they may be less likely to suffer the same feeling of displacement as in the past, when leaving a country, town, or particular house was a less common occurrence. Recent sociological writings on nostalgia focus on the adaptive and societal aspects of nostalgia rather than on its original medical basis. Davis (1979) presents a view of nostalgia as a mechanism that permits people to maintain their identity in the face of major transitions that serve as discontinuities in the life cycle (e.g., the identity change from childhood to pubescence, from adolescence to adulthood, from single to married life, from spouse to parent, etc.). Thus, the tendency to engage in nostalgic feelings varies over the course of the individual's lifetime. "Nostalgia-proneness" has been hypothesized to peak as individuals move into middle age and during the "retirement" years. In addition, some past experiences and eras are more likely than others to evoke nostalgic feelings, with nostalgia being stronger for adolescence and early adulthood than for any other period. According to Davis (1979), nostalgic reflections must draw from one's own personal history rather than from external sources such as books, stories, or other publications. A narrow definition of nostalgia suggests that an individual cannot experience true nostalgia for a period or event through which he or she has not lived. This idea of the relevant past is a controversial one, as some researchers have argued in favor of relaxing the personal experience condition in their definition of nostalgia (Havlena and Holak 1991a; Holbrook 1990). Certainly, in terms of the use of nostalgia-evoking stimuli, advertising and product management professionals take a broad perspective with respect to the time dimension of such stimuli. Empirical studies have only recently begun to address the types of past events or experiences most likely to evoke a nostalgic condition in the present. One purpose of this study is to investigate the themes and subjects associated with nostalgia.

Davis (1979) distinguishes among three orders or levels of nostalgic experience. *First order* or *simple nostalgia* is associated with the simple, unquestioning belief that "things were better in the past." *Second order* or *reflexive nostalgia* involves a critical analysis of the past rather than sentimentalization of it. Finally, in *third order* or *interpreted nostalgia*, the individual analyzes the nostalgic experience itself.

Research in the consumer literature focusing directly on nostalgia has only recently begun to appear. Havlena and Holak (1991a) present a review of some of the pertinent literature and samples of nostalgic appeals and products in the marketplace. Holbrook (1990) describes a Nostalgia Index designed to measure nostalgia-proneness and predict affective reactions to nostalgic stimuli at the individual consumer level. This instrument was tested in the context of a broad range of consumer product categories. Acceptable levels of reliability and predictive validity were achieved. Holbrook and Schindler (1991) describe another application of the Nostalgia Index to predict affective reactions to actors and actresses. In a paper based on a subset of the same experience descriptions used in this paper, Havlena and Holak (1991b) analyze nostalgia-evoking events using a time structure and allocation perspective (Feldman and Hornik 1981). They found that activities in the past that serve as subjects for nostalgic emotions at some later point in time are most often leisure activities, both those that are inherently satisfying and those that are satisfying due to an individual's association with other people while pursuing the activity. The current study represents an attempt to examine the nostalgic experience directly and to develop an understanding of the components of the experience.

METHOD

The data used for this study consist of a set of 164 descriptions of nostalgic experiences collected from a sample of 62 individuals. Data collection was accomplished using a written questionnaire format. After being presented with a brief definition of nostalgia as defined in the *American Heritage Dictionary*, the individuals were asked to provide written descriptions of three different experiences, related to objects, events, and people. Respondents were requested to describe these experiences in as much detail as possible, writing about both (1) their feelings and (2) the object(s), person(s), or event(s) that stirs up these feelings. This method is similar to that used by Havlena and Holbrook (1986) to examine the emotional content of consumption experiences.

Additional parts of the data collection instrument followed the varied ordering of the nostalgia experiences. They included: (1) 18 emotion scales describing how subjects rate their feelings, in general, (2) a twenty-item nostalgia index scale (Holbrook 1991), and eight classification questions dealing with year of birth, year of graduation from high school, year of graduation from college, sex, country of origin, marital status, ethnic background, and religious affiliation.

A snowball convenience sample of respondents was used, with a broad distribution of ages being the primary criterion for the selection of the sample. Geographic diversity, student vs. non-student populations, and general interest in the survey were also considered in selecting sample members. One-hundred and eighteen surveys accompanied by self-addressed, postage-paid return envelopes were mailed to geographically dispersed respondents, with an

additional thirty-two surveys distributed to local respondents affiliated with student, church, and civic organizations. The respondents represent a range of age groups (from subjects in their 20s to those in their 70s), educational levels (from non-high school graduates to individuals with graduate degrees), and cultural and religious backgrounds. No compensation was offered for participation. A total of sixty-two (out of 150) questionnaires were returned for a response rate of 41%. An overview of the respondent population appears in Havlena and Holak (1991b).

RESULTS

In the following discussion, recurrent themes are examined in the context of persons, objects, and events. A number of examples from the experience descriptions are used to illustrate the range of topics and themes present in the narratives. Connections between the categories are noted as they apply in this qualitative assessment of the descriptions.

PEOPLE IN NOSTALGIC EXPERIENCES

The Family

As might be expected, family and friends appear as important elements in many of the experiences reported by the subjects. This is true not only for those experiences directly related to people, but also for experiences that were reported as involving objects or events. For example, one male respondent in his sixties experiences and remembers events in terms of his connection to other members of the family:

Events related to Holidays, Birthdays, Weddings, and other similar events tend to remind me of my childhood and the fun I would have at these events.

It is always a pleasant experience for me to experience these events today because I am the patriarch of my family and I attempt to make these events as pleasant as I possibly can for my wife, children, and grandchildren.

I hope that I can leave all my family members with the same pleasant recollections that I have about these events so that they can, in turn, pass these experiences on to their children.

A wide range of *family members* are mentioned as being integral to nostalgic experiences. Certainly, immediate family members (i.e., parents, siblings, and children) appear throughout. Grandparents, particularly grandmothers, are potent subjects for the respondents. Even more distant relatives, such as aunts, uncles, and cousins are focuses for several of the experiences. As one might expect, several respondents have specific recollection of their deceased relatives, often with the "bittersweet" emotion inherent in nostalgia. The accompanying recognition, typical of first-order nostalgic reflection, that "the good old days" are gone forever and can never be recreated is quite clearly recognized. Explicit mention is made of the fact that these subjects are no

longer alive. Expression of sadness for times and experiences which can no longer be shared or missed opportunities to express devotion and/or respect are apparent in the responses. Such sentiments are evident in the following narrative authored by a female in her sixties:

My thoughts of my mother (who has been dead for five years) have left me with more feelings of nostalgia than anyone I have known. There are times when something occurs or when I see something, I think to myself "wait until I tell Mom" and am saddened and have such an empty feeling knowing that I can't share it with her. She loved life and never took any aspect of it for granted and is probably why -- whether it's a wedding, a new baby, the ocean, a flower, a beautiful day -- my thoughts are always with her and how she would have enjoyed them.

Beyond Family

In addition to relatives, a range of personages in the lives of respondents appear repeatedly in nostalgic experiences. *Classmates and friends* from previous educational phases including college, high school, and even elementary school days are mentioned in the narratives. The following narrative authored by a woman in her mid-forties illustrates this theme:

My friend Martha who now lives in Vermont always stirs feelings of warmth & contentment. We were friends from Junior High School on. We don't see each other very often or even write to each other much because of the busyness of our individual lives. However, when we see each other, the years fall away and we feel as young & carefree as when we first became friends. We remember mutual friends and the places we went, our homes and all the joy of school activities. We are not all fortunate enough to have friends that last a lifetime. I feel truly blessed to have such a person in my life.

Individuals of some responsibility and influence during respondents' school years (e.g., teachers and athletic coaches) are indelible in the nostalgic roles they played as illustrated in the recollections of a male approaching thirty:

This past summer a good friend of mine was married. He currently plays for the New York Yankees and was quite a baseball player in high school. I was really looking forward to the wedding because many of my ex-team mates would be in attendance. But it was my American Legion coaches that I was looking forward to seeing the most. Especially Mr. K____. I talked with him for hours and it was strange because I really think about those days a lot and Mr. K____ always seems to be at the beginning of the thought. To this day when I drive by some of the fields I played on when

Mr. K____ was coaching me it instantly brings back fine memories of my childhood and companionship with people that have made me what I am today.

This reflection back to adolescence is quite common. If, as has been suggested, nostalgia often involves transitional periods, it seems reasonable to expect that individuals that have played a major role in one's development, such as the coach referenced above, would serve as subjects for nostalgia.

Friends who have become part of one's life since schooling, co-workers, ex-boyfriends, ex-girlfriends, and ex-spouses, and even former neighbors are named with varying frequency in the responses generated by the respondents. Even more fleeting acquaintances appear to be subjects for nostalgia. The following narrative authored by a man in his mid-thirties illustrates the range of individuals in nostalgic experiences:

I recently had dinner with the people who made up the staff of a business I was employed by some years ago. Since we were all from the same town we all knew each other well, some of the older women had been my baby-sitters when I was an infant. We were so close we all looked out for each other, it was often said that "one of them would lie and the rest would swear to it." We reminisced and laughed for hours, old gripes about work came back as well as funny experiences. Some of us have moved on to other jobs, some retired and some remain in the same job they had years ago, but for a few hours the same "old gang" was back together.

OBJECTS IN NOSTALGIC EXPERIENCES

As we have attempted to demonstrate, key people are consistently the focus of nostalgic experiences -- from immediate and more distant family members, both living and deceased, to classmates and school chums, friends, co-workers, and romantic partners. Often, specific objects or things serve as the stimulus for nostalgic reminiscences of people. Although the author of the following narrative is less attached to objects than most others, the sentiments about objects as a stimulus to nostalgia are expressed very explicitly. It is important to note the analysis beyond first-order nostalgia in this response; the introspection suggests third-order nostalgia.

This one is really taking some pondering . . . objects? objects? Material, replaceable objects? I am really having a tough time with this one because objects come & go, can be replaced, forgotten, even heirloom jewelry or my wonderful cottage by the lake are only possessions for the moment.

I look at photographs of my paintings with a touch of nostalgia, but if my house burnt down and they with it -- so what. The "objects" are not what is important. What is important are people, and memories which is basically what

objects do is evoke thoughts of people and memories. No one object evokes much nostalgia for me. Several times in my life due to self created circumstances, I gave up all my possessions (objects) to start again. Each time I have accumulated many new objects which represent(ed) my life at that moment. All interchangeable, all replaceable, all objects -- no big deal.

Tangible items such as antiques, clothing, jewelry, toys, books, and cars (particularly one's first car) are consistent themes. The following experience authored by a man approaching forty years of age illustrates this connection:

Piano in my father's home has been passed down from my maternal grandmother. As a child roaming in her house, I often hid under the piano . . . I cannot recall the last time the piano was played. Yet, as I recall, in my childhood it was seldom silent. These thoughts typically spark memories of my grandmother (who died when I was 5) and of her household.

Even more intangible stimuli (e.g., music/songs/recordings and movies) trigger nostalgic thoughts. A male respondent in his mid-forties illustrates the impact of a television series on his nostalgic thoughts in the following passage:

While watching the Civil War PBS series, I was reminded of summer vacations with my father touring the battlefields. My father has been deceased for over 10 years and I don't often think of him. Recalling summer vacations reminded me of his child-like curiosity or inquisitiveness.

A very interesting aspect of nostalgia and its "relevant past" is presented in the following narrative authored by a woman in her forties who, while carefully noting objects shown in a movie, experiences nostalgia for a time period in which she, herself, has not lived:

I often like objects of age. Not all old pieces, but many. A delicate cameo brooch, a piece of furniture of a rich dark hue. A few years back I saw a movie "Ragtime." Throughout this movie I experienced feelings of nostalgia. This feeling had nothing to do with the plot of the film but, rather, was caused by artifacts in the film. The rich mahogany of balustrades on curving staircases, fine lace curtains gently billowing on windows, and the rich warmth of brass light fixtures. These and fine crystals on sideboards swept me up in dreams of the quality that average people enjoyed commonly in those days. It is true that the quality and richness of everyday items were enjoyed not only by the elite. But, realistically one knows that even

then there was great poverty -- so not everyone was surrounded by this "quality." It was, however, a more everyday quality than we have today.

Interestingly enough, while this narrative illustrates mostly first-order nostalgia, there is an element of second-order nostalgia reflected in the mention, in passing, of a more realistic assessment of life in the past.

As one might expect, photographs play an important role in initiating nostalgic experiences. This is eloquently illustrated in the following passage, which contains some third-order nostalgic analysis, authored by a woman in her early twenties:

Pictures in general make me nostalgic, even when they are not related to my life. I always enjoy looking at photographs, whether they are mine, my family's or anybody's. I like to imagine the people in the pictures, their environment, their feelings. When I show other people my pictures, I sometimes get a sad feeling that there is little purpose in doing so because they probably cannot relate to them, cannot see the feelings involved at those moments. In other words, photographs represent, to me at least, a variety of feelings. Some may be fun, happy, others may be soothing, sad . . . but they all carry hidden emotions and they all meant something to the person who took them.

The respondent's description indicates the range of emotions that these photographs elicit from her -- happiness, sadness, peacefulness, elation -- due to the memories they trigger. However, she also notes the sadness they may evoke, independent of the subject matter of the photos, as a result of the personal nature of these memories and emotions and the recognition that they can never really be shared, even with close friends.

Usually in response to the elicitation about "objects" which evoke nostalgia, respondents conveyed another major theme in nostalgic experiences -- that of "home." This theme is certainly commensurate with the classic definition of nostalgia -- "a painful yearning to return home." "Home" in this case has broad boundaries; it might literally represent the house in which one grew up, places one has occupied in the past, "the old neighborhood," or even a city in which one has resided. Once again, memories of home are often linked to the people associated with it. This theme is depicted in the following passage authored by a woman in her early sixties:

The event is "returning to the town where I grew up." Whenever I "go home" I drive around town, remembering my wonderful childhood and friends. I have an elderly neighbor who knew me when I was born. She is one of my links to the past.

In keeping with the familiar holiday tune, "grandmother's house" is a potent nostalgic memory. The reader is urged to note the details about furnishings and food, as well as the object (a book) which sparked the recollection in the following passage authored by a man in his early forties:

I was reading from a book that had belonged to my grandmother and slipped into a reverie about her home and the old neighborhood. I was thinking about walking up the block and going to the old bakery. The book reminded me of sitting in my grandparent's parlor reading. The parlor was light and airy, with a couple of very comfortable chairs. Grandfather would be puttering in his workshop and grandmother would be about the house, either in the kitchen or sitting in the front parlor. There would always be napoleon, hot pastries, or black and white cookies. Mom and my sister would be there and dad would come get us after he finished work.

EVENTS IN NOSTALGIC EXPERIENCES

Not only are objects important stimuli for nostalgic experiences involving people, but objects can trigger the recollection of an *event*. People also serve as stimuli for reminiscences about key events as depicted in the first narrative presented in this paper; these events may be personal (e.g., birthdays, graduations, vacations, military service, weddings, reunions, etc.) or they may be more collective in nature with personal and societal elements (e.g., an historical event, major sports event, etc.). A recurrent theme reflected in the experiences concerns holidays as events.

Holidays

Frequently, reminiscences about family or extended family members arise in the context of *holiday celebrations*, a consistent theme in the responses generated. As one might expect, the celebration of Christmas, including specific memories of family gatherings, greeting cards, and even ornaments, triggers nostalgic sentiments for people. The following narrative authored by a man in his mid-forties is a detailed recollection of Christmas including family, friends, music, and even explicit sensations related to the weather:

In high school I took it upon myself to learn the 5-string banjo and formed a folk group which developed a reputation of some note. In addition to sharing musical interests, the other two members of the trio and I were also very close friends. The Christmas of my junior year, after fulfilling family obligations in the morning, the three of us got together and spent the rest of Christmas day travelling around town to carol friends, each other's families and some of the high school faculty (a cappella due to the temperature of the day). I remember this being a particularly happy time being with

close friends and sharing what I guess would be termed a "special time." The crispness of the day -- bright, cold weather -- crunching snow and an occasional cup of beer from some more liberal/indulging parents helped form an incredible memory of "Christmas Past."

What came as somewhat of a surprise was the extent to which Independence Day evokes a nostalgic response in terms of family gatherings and activities. The following narrative by a woman in her mid-forties is indicative of Fourth of July memories:

Fireworks displays and parades, usually on 4th of July always makes me long for the days as I was growing up & all of my brothers & sisters, their spouses & children were all together for family picnics & attended the parades & fireworks displays. We decorated trikes & bikes, waved flags & sang patriotic songs. We were all so proud of our freedom & heritage which my father encouraged in each of us. I felt so privileged to be a member of such a special family. We still all would like to be together, but the distance & our own families including grandchildren keep us from all gathering for those events as we used to do.

Celebrations of Easter, Thanksgiving, and New Year's Eve were mentioned as well. The following experience authored by a woman in her thirties provides explicit detail about the observance of the Paschal holiday, particularly rituals, both religious and habitual (e.g., the annual photograph and primping), special foods, and even aromas:

The celebration of Easter in my father's hometown was quite an event. It always seemed a little larger than life. There was a mystique of the midnight service that only my older cousins were allowed to attend. I remember, every year, having "coffee" (99% milk & 1% coffee) and poppyseed cake for breakfast as everyone took turns waiting for the one bathroom to vacate. There was always a lot of primping -- a new dress, a new purse, gloves and of course a new hat (which was always a source of numerous fights between my mother & me). We would take the annual picture next to the family homestead and my father always carried the Easter basket brimming with meats, cheeses, special bread and beautifully decorated eggs. After church, when the baskets were blessed outside on the sunny hill, it seemed like the entire town had come out for the occasion. New and bigger hats were everywhere -- what a fashion show. To this day, I remember the colors, sounds, and smells of that annual event.

Personal Events

As mentioned previously, in addition to holidays, personal events are a major theme in the experiences gathered from the respondents. A very

explicit birthday recollection, replete with details of family members, activities, and even a reference to food, is found in the following experience written by a man in his mid-sixties:

It was a tradition in our family that on our tenth birthday, my father would take us on a two-day trip to New York City.

For me it was my first visit to the big City. I stayed in a hotel for the first time -- went up into the Statue of Liberty -- rode the ferry, the subway -- visited Newark airport and saw a new plane that had sleeping accommodations for the new cross-country flights -- saw a movie at Radio City -- ate in an Automat -- many treats as a boy from a small town was exposed to the big city. But most of all, I had my Dad all to myself for those two days without the interference of my older brother or younger sister.

In our data, subjects not only discuss birthday celebrations as subjects of nostalgia, but the event of giving birth was also offered as a nostalgic experience, as in the following narrative by a woman in her mid-twenties:

The birth of my son: Nine months seem like an unbelievably long time. But I knew that he'd be born when he was "ready"! I couldn't wait to see him sleep in his crib, or hear the sounds of a baby's cry. Of course, he was two weeks late, and it seemed like agony. He finally arrived on Aug. 28 after 36 hours of labor. But he was well worth it . . . and I wouldn't trade him for the world!

The following description authored by a woman in her sixties depicts an event and nostalgic sentiments for days gone by including close personal relationships:

A few months ago I went to a reception to celebrate the wedding anniversary of a sorority sister. It brought memories of my college days. They were pleasant memories of times spent in the sorority house with friends.

Class reunions, whether high school or college, are, by design, nostalgia-evoking events. The following experience authored by a male approaching forty depicts many of the classic sociological phenomenon associated with nostalgia -- heightened feelings of nostalgia as one approaches the transition to middle-age, reflection back to adolescence as a subject for nostalgia, and the resulting twenty-year interval between the original experience and the nostalgic consideration of it. The experience is replete with references to music, including the school alma mater (a theme which has come up in other descriptions), and photographs. In addition, the author engages in an analysis of his nostalgic feelings and their origins, representative of third-order nostalgia, in this narrative:

20-year high school reunion -- 50 of the 164 classmates attended in June 1990 . . . Event included rendition of alma mater, reproductions of high school photos, period music . . . Plenty of reminiscing, catching up, etc. . . . Last reunion was 10-year event.

Reunion took place off school premises -- in an auditorium I had never before visited and not affiliated with school.

Interestingly, those classmates not there generated more feelings of nostalgia than those who attended (I had close high-school friends in both groups). For example, plenty of wondering who's where and doing what . . .

Much of this not verbalized at event.

Some possible explanations:

1. 20 years seems to be interesting threshold at which some classmates looked as they were remembered and others looked like total strangers . . . Generated questions of what those remembered but not present look like . . .

Mystery. Those present need not be visualized.

2. Several classmates have passed away, leading to the topic of mortality . . . How are those not here -- healthy?

3. Why aren't they here? Issues of self-image and accomplishments? Didn't care? Or, see most everyone at reunion every week anyway. (Many locals were no-shows).

Major historical events may have both *personal* and *collective elements* according to sociologists (Davis 1979). The following description, which includes references to music and a movie and was authored by a woman approaching forty, illustrates both nostalgic elements:

Now here is one that surely you've not read yet (I write tongue in cheek) Woodstock. How predictable for my generation to look at that single event with nostalgia.

Although I never made it to the concerts, the event is still revered in my thoughts. It evokes emotions of a better time, but of a time when I was just old enough to come of age, to rebel, to feel on my own -- with a hefty parental allowance of course. My feelings are not of yearning to return to that time but of sheer joy for having experienced it. The 60's that is. The drugs, the sex, the rock & roll, hitch hiking the Pacific Coast Hwy., etc. Except for the sex & rock & roll, I would not want to duplicate the experience now but feel so happy and thankful that I *had* the experiences. The feelings are all positive for the opportunity to grow in every way during the Woodstock era. When I hear the music or more recently view ads for the new Stone movie "The Doors", I feel a grin cross my face and I thank God that I am not one year younger for I may have missed a most wondrous, exciting time.

Intergenerational nostalgia (Davis 1979) refers to memories of the past created through personal

interactions with others who have lived through earlier periods and events. These memories are a combination of tales of the unexperienced past and the experiences of hearing these reminiscences. With the advent of motion pictures, television, sound recording, and radio, depictions of past events need no longer rely on verbal descriptions and can be much more vivid, imparting a sense of actual participation in an event or era. This phenomenon is clearly illustrated in the following experience authored by a man in his twenties about the same historical event, Woodstock. Again, music is a key theme in the nostalgic experience, as well as the classic filtering (looking at the past through rose-colored glasses) which occurs when one reminisces:

Woodstock makes me nostalgic although I was barely born when it was happening (I was born in 1964). I've seen videos of it, and a lot of it makes me happy. I *wasn't* there since I'm not really into oppressive crowds, being rained on, being stoned/high, etc., and so on. *But*, when I hear the *music* that came from that time period, it makes me nostalgic for an idealized past (that wasn't really ideal). I think of a time period when people stepped out of the tight social structure, broke some (narrowly conceived) rules, and made history. The music of Jim Hendrix, Eric Clapton, Janis Joplin, Stevie Winwood, Country Joe and the Fish, Arlo Guthrie, and so many others, makes me "nostalgic" for a past which, not so much represents a reality I would have liked had I been there, but which I can experience vicariously by taking the best of what happened *then* and incorporating it into my reality now.

DISCUSSION

The findings presented in this paper relate to common themes and emotions in the set of experiences. Subjects such as holidays, religious observances, family, popular music, and school-related experiences tend to occur repeatedly in the set of experience descriptions. Both personal nostalgia, for events or objects from the author's own past, and historical (or intergenerational) nostalgia, for events or objects outside the realm of the respondent's direct experience, are represented in the descriptions. Tangible objects and intangible presentations (in the form of music or film) are depicted as key nostalgia stimuli. Even food and aromas are given considerable attention within the narratives. Although first-order nostalgia occurs most commonly, second and third-order nostalgic sentiments are represented in several experiences.

Greater understanding of nostalgia, the stimuli which evoke it, nostalgia-proneness on the part of individuals, as well as the emotions encompassed in nostalgic experiences would be beneficial to consumer researchers and practitioners. As noted in Havlena and Holak (1991a), there has recently been increased attention to nostalgic themes in advertising strategies and product management. In some sense, nostalgia

connects individuals, objects, and events across time and place. Themes and emotions noted here are relevant to communication providers or facilitators (e.g., telecommunications, greeting cards) which allow individuals to share life experiences at a particular point in time. In addition, the findings discussed here are of particular relevance to products and industries providing time storage or a sharing across time periods (e.g., photographic products, greeting cards, memorabilia, etc.).

As a continuation of this research stream, a project is underway which will shed light on the specific emotions attached to nostalgic experiences using experience descriptions collected from U.S. respondents. Additional research is underway to investigate the universality of nostalgia through cross-cultural data collection. Another fruitful research stream involves the further exploration of the sensory modalities involved in the nostalgic experience (e.g., touching objects, tasting food, smelling aromas, hearing music, seeing visual stimuli).

Abstract
Nostalgia in Advertising Text: Romancing the Past
Barbara B. Stern, Rutgers, The State University of New Jersey

The perennially childlike quality of romance is marked by its extraordinarily persistent nostalgia, its search for some kind of imaginative golden age in time or space (Frye 1973, p. 186).

Nostalgia in advertising has become a focal point of controversy in the past decade. On the one hand, marketing practitioners and advertising creatives hail nostalgic campaigns as a good way to make the most of the "gift" of brand equity possessed by old products, slogans, and packaging (Winters 1990, p. 16). In this view, Barbie Breakfast Cereal, for example, makes effective use of the pleasurable recollections associated with Barbie dolls to appeal to the children of those who first played house with Barbie and Ken. On the other hand, social commentators damn the nostalgia craze as evidence of the collective bad taste of the American public, aided and abetted by advertising. In this view, the Barbie collection now housed in the Smithsonian is "intended presumably to show somebody from the future what disgusting times we lived in" (Gorman 1990, p. 16).

The heat generated by this controversy has precluded close examination of the phenomenon of nostalgia in marketing communications. The purpose of this paper is to address that issue by focusing critical attention on the analysis of nostalgia as an aspect of marketing text. The analytic mission begins by addressing the definitional issue (Havlena and Holak 1991) of what form or forms nostalgia takes in commercial text. The paper uses literary history and theory to analyze nostalgia as a communication *theme*, on the grounds that advertisements borrow both style and substance from literary antecedents. Even though this paper relies on literary criticism, "text" is interpreted broadly to include pictorial (Steiner 1988) and musical elements (Holbrook and Schindler 1989) as well as verbal ones. The reason is that nostalgia themes in advertising are often multimedia, with words, music, and/or pictures interacting. In addition, marketing communications are also interpreted generously to include not only advertisements, but also mail order catalogues, periodicals, and entrepreneurial ventures whose promotion is nostalgia-driven.

This paper follows Blonsky in identifying nostalgia as a theme (or "tape") in promotions (Whalen 1983), and then distinguishes between two separate but related forms: historical and personal. This division is based on advertising's antecedents in literature -- the historical romance and the sentimental novel (Abrams 1988) -- and their differences in both formal elements and intended reader responses. Textual differences center on treatment of time, space, characters, and values, and potential consumer response effects involve empathy with historical romances vis à vis identification with sentimental ones.

The rationale for turning to literary history to explain why both forms of nostalgia are abundant in contemporary advertising rests on the pervasiveness of the *fin de siècle* ("end of century") phenomenon at this time (Showalter 1990). Nostalgia is a popular theme in art produced during the waning years of an epoch, a time when the century is metaphorically dying. The *fin de siècle* syndrome is heightened at present because of an unprecedented temporal coincidence: the century is ending just as the largest group in the population -- the baby boomers -- also must face its own mortality, signalled by reaching the age of fifty. The text of magazines such as *Memories* and catalogues such as *Wireless: A Gift Catalog for Fans and Friends of Public Radio* illustrates nostalgia themes that reflect the "double whammy" of an aging population confronting a century in its final years.

The paper next analyzes the theme of historical nostalgia, in which the past is defined as *a time before the audience was born*. The literary antecedent is the historical romance, often set in far-away space as well as distant time. In addition to exotic settings, the characters are idealized and larger-than-life "others," symbolic rather than individualized heroes who often attain mythic status (Stern 1990). The values are traditional and conservative, as befits the representation of a past era as a golden age. Nearly any era can be haloed in this fashion if the events and characters are sanitized by filtering out situational evils (war, crime, disease) and by enlarging upon universal virtues (goodness, faith, generosity). The effects of historical nostalgia depend on vivification of an audience's imagination in order to stimulate perceivers to empathize with characters personally unknown to them. The J. Peterman Company catalogue -- *Owner's Manual No. 10* -- as well as the magazine *Victoria* exemplify historical nostalgia in marketing communication.

In contrast to historical nostalgia, the personal theme depicts a *time in one's own past*, generally twenty or thirty years before "now" (Davis 1979; Holbrook and Schindler 1989). The literary antecedent is the sentimental novel, and personal nostalgia prettifies the individual's past by screening out all but pleasant details. The time frame is one's own lifetime, for these texts reference events from a personal past, and the spatial setting is "home," the locus of the past self. Thus, familiarity is the rule in treating time and space, as opposed to the exoticism of historical nostalgia. While both forms idealize characters, the idealization here embroiders a "personal best" portrait of the self. The values are traditional, often reflecting nurturance and love associated with maternal tenderness recollected from childhood. The effects of personal nostalgia rely upon triggering the perceiver's memory in order to stimulate identification with cherished reminders of the one's past. Advertisements such as Good 'n Plenty ("Choo Choo Charlie") and Campbell's Soups (The "Campbell Kids") as well as

periodicals such as *Martha Stewart Living* demonstrate the use of personal nostalgia as a marketing communication strategy.

The paper ends with three suggestions for future research. First, content analysis is proposed to determine where and when historical and personal nostalgia themes appear in advertising text. An ancillary suggestion is to investigate the *fin de siècle* phenomenon over two centuries -- the end of the nineteenth and the end of our own -- by examining the nostalgia content of advertising in both epochs. Second, study of nostalgia effects on consumers in the context of potential gender differences is set forth. Given the appeal of literary antecedents -- notably romances -- primarily to women, the issue of differences in nostalgia stimuli appropriate for men versus women requires further study. Last, the under-researched modalities of smell and taste as nostalgic stimuli deserve more attention than they have heretofore received. Proust's tribute to the "vast structure of recollection" summoned by a single crumb in a teacup serves as a call to pay heed to the power of smell and taste in evoking pleasurable recollections (1928, pp. 65-66):

And once I had recognized the taste of the crumb of madeleine soaked in her decoction of lime-flowers which my aunt used to give me...in that moment all the flowers in our garden and in M. Swann's park, and the water-lilies on the Vivonne and the good folk of the village and their little dwellings and the parish church and the whole of Combray and of its surroundings, taking their proper shapes and growing solid, sprang into being, town and gardens alike, from my cup of tea.

Nostalgia: A Neuropsychiatric Understanding

Alan R. Hirsch, Smell & Taste Treatment and Research Foundation, LTD.

Nostalgia, or the bittersweet yearning for the past has been eloquently analyzed in terms of society and consumerism, but what of its neuropsychiatric substrate and its implication? (Havlena, et al). It is these I shall address today.

Within the psychiatric framework, nostalgia may be considered a yearning to return home to the past -- more than this, it is a yearning for an idealized past -- a longing for a sanitized impression of the past, what in psychoanalysis is referred to as a screen memory -- not a true recreation of the past, but rather a combination of many different memories, all integrated together, and in the process all negative emotions filtered out. For a personal example of screen memory think of your first ever vivid memory. Although to you it seems a realistic recall of an early childhood event, it in fact is a compilation of memories all integrated into one. This can be demonstrated in psychoanalysis: during the analysis of the transference neurosis, the patient's earliest memory undergoes changes and divides into multiple components that are separate, definable childhood memories.

If one defines nostalgia as a yearning for an idealized past, the bittersweet nature of it becomes clearer. One can never return to this past, it never truly existed. And the present reality, no matter how good, can never be as good as an ideal -- which nostalgia has created. Thus the saying "you can't go home again."

Nostalgia, unlike screen memory, does not relate to a specific memory, but rather to an emotional state. This idealized emotional state is framed within a past era, and the yearning for the idealized emotional state manifests as an attempt to recreate that past era by reproducing activities performed then and by using symbolic representations of the past.

Idealized past emotions become displaced onto inanimate objects, sounds, smells and tastes that were experienced concurrently with the emotions. This same mechanism of displacement is utilized in medicine for its negative impact in the treatment of alcoholism. Disulfiram (Antabuse) is used as an aversive conditioning agent to inhibit recurrent use of alcohol in addicts. (Kaplan, et al 1988, p. 227).

The nostalgic urge to recreate the past within the present is, in many ways, a driving force for behavior -- how frequently we marry spouses with characteristics reminiscent of those of our parents. As other examples, we may adopt the political affiliations and prejudices of our forebears, become democrats, republicans, or even racists because our parents were.

Similarly, the nostalgic urge to recreate the past explains why so many abused children marry abusive spouses, and children of alcoholics marry alcoholic spouses -- not because their childhood was happy, but rather because they seek to recreate their idealized sanitized memories of their childhood by

identifying with symbolic manifestations of the past which they find in their alcoholic or abusive spouses.

This same paradigm governs the repetition of failures on the part of "neurotics" who behave as if oblivious to logical rationale. This is seen in persons with recurrent failing relationships (those marrying seven or eight times), those with recurrent failures at business, and even those with recurrent experiences of being victimized.

Through daily behavior, the nostalgic urges may also be partially gratified -- food choices for example (hence the passing down from generation to generation of family recipes) -- with an actual primitive incorporation into the self of the nostalgic object.

Observing holidays precipitates nostalgic desires, while it simultaneously recreates past experiences, hence fulfilling the nostalgic yearning. Emotionally-laden rituals discharge nostalgic energies through the physical activity of the ritual, while forging linkages with the past. Religious practices may be viewed as an immersion in institutionalized nostalgia -- unchanged over the millenia, hence gratifying nostalgic wishes. This explains how the intertwining of religion with the major holidays (Christmas, Thanksgiving, Easter) achieves the greatest impact and relief of nostalgic drives.

Thus, nostalgia may be viewed in psychiatric terms as a driving force for actual behavior -- the attempt to recreate an idealized past in the present. By attempting to recreate this idealized past, one discharges psychic energies to fulfill nostalgic yearnings. Some results of these attempts throughout society may be seen in the production of sequels to movies, TV shows, and in the common practice of naming first-born sons after their fathers.

Nostalgia exists in the pathological, as well as the normal, states. Some severely regressed schizophrenics actually live within the delusional system of their idealized memories.(Hill). In pathological bereavement, obsession with loss of the idealized past causes depression.(Kaplan et al, 1988, p. 299). In senile dementia of the Alzheimer's type, or Wernicke-Korsakoff syndrome, where recent memory is markedly hampered, nostalgic memories are still available, hence substituting the past for the present.(Lishman;Hales et al).

On the other hand, in an antithetical state to nostalgia, those suffering from posttraumatic stress disorder do not yearn for the past but rather desire to eliminate memory for the past.(*Diagnostic and Statistical Manual of Mental Disorders*). However, in both nostalgia and in posttraumatic stress disorder immediate stimuli can precipitate emotionally-laden memories. These stimuli are context specific. For instance, many Viet Nam veterans with posttraumatic stress disorder describe odors of seafood or burning diesel fuel as precipitants for the flashback phenomena.(Kline et al). Flashbacks for those who were Korean veterans with posttraumatic stress

disorder describe odors of beaches and wet canvas as precipitants. And Persian Gulf veterans describe gustatory-evoked recall from drinking ionized water.(Coombs).

Homesickness is not true nostalgia, but rather a geographic nostalgia -- a yearning for a different space rather than a different time -- for return to idealized memories of a location and people left behind.

All the senses may be used to precipitate the nostalgic experience -- hearing music (witness the popularity of "classics" of the '60s, '70s, '80s, etc.), seeing pictures (photo albums in fashion with their recurring trends), and possibly the most significant, smelling odors.

Even as early as 1908, Freud recognized a strong link between odors and the emotions.(Freud). Anatomically, the nose directly connects with the olfactory lobe in the limbic system -- that area of the brain considered the seat of the emotions. The olfactory lobe is actually part and parcel of the limbic system.(MacLean). Therefore, the most powerful impact upon the emotions is through the sense of smell. In a universal phenomena called olfactory-evoked recall, an odor can bring back a memory from the past. Often a vivid visual image is evoked along with an associated positive mood state. A classic example was described by Marcel Proust in the first volume of his novel *A La Recherche Du Temps Perdu* (English translation *Remembrance of Things Past*).(Proust). The aroma of madeleine dipped in tea evoked in the author a flood of memories and feelings of nostalgia.

The understanding that odors evoke more powerful reactions than the other senses do is not particularly new. It is well known that the aroma of freshly baked goods conjures up warm childhood memories. When an odor of baked bread was released in a U.S. supermarket, sales in the bakery section increased threefold. Movie theater managers infuse the air in their lobbies with the aroma of popcorn to entice patrons to buy. The smell of chocolate chip cookies released into the air in front of cookie stands induces the people to salivate and buy cookies. The unique, leathery "new car scent" is an exciting enticement to most customers and a positive inducement to make a purchase. Victoria's Secret, a successful women's underclothing chain, uses a special floral potpourri throughout its stores. Many of the customers say that the aroma lifts their spirits.

Some odors, however, can have a negative impact. Among 1002 people queried in a 1989 Gallop poll throughout the United States, the most disliked odor was the odor of fish.(unpublished study, 1989). We might well expect any store located next to a seafood market to have their sales negatively affected by the odor.

An ordinary person can smell 10,000 odors.(Ackerman). But no two people react in exactly the same way.

In general women are more sensitive to odors than are men.(Doty et al). Ethnicity and geographical background strongly affect odor sensitivity. Japanese perfume may not be a popular sales item in North America. Among sample populations taken across the

U.S., Korean-Americans had a keener ability to identify odors than either black or white Americans. Native Japanese were least able to identify the odors used in the study.

As might be expected, our judgement as to the pleasantness or the unpleasantness of various odors depends too upon who we are and where we live. In one study, sample populations from 20 nations were asked to evaluate 22 different fragrances.(Davis et al). The populations with similar odor preferences could be grouped geographically. One group with similar odor preferences included residents of California, Kansas, Japan, West Germany, Taiwan, Canada, Italians in Brazil, Phillipines and Taiwanese in California. A second group with similar preferences included residents of Australia, Sweden, France, Norway, East Germany, Finland, Mexico, Japanese in Brazil and Africans in Brazil. This clustering of odor preferences implies a similar clustering of preferences with regard to foods and perfumes.

Among the 1002 people mentioned previously, the particular area of the United States from which they came had a decisive influence on their responses to odors (Table 1).(unpublished study, 1989). Although in general, baked goods were the most common precipitant of an olfactory-evoked recall, among persons from the east coast, the smell of flowers prompted an olfactory-evoked recall of their childhoods. Among persons from the south, the smell of fresh air prompted a similar recall - among those from the midwest, the smell of farm animals, and among those from the west coast, the smell of meat cooking or barbecuing. Evoked memories of childhood are usually associated with a positive emotional state which may then be transferred to the place where the evoked memories are experienced -- the store and the items for sale. The makers of certain oriental perfumes already take advantage of this effect by adding the smell of baby powder to their formulas, baby powder being associated in most persons' minds with a safe, clean environment.

In order to further investigate olfactory-evoked recall, in September of 1991, 989 English-speaking individuals selected at random in Water Tower Place shopping mall in Chicago consented to be interviewed in person for this Institutional Review Board approved study. Respondents reported basic demographic data including the decade of their birth and their predominant geographic location during childhood. Psychological data revealed the existence of olfactory evoked recall, the particular smells that precipitated childhood memories and the overall level of happiness with the individual's childhood.

Demographic Profile: 478 were male, 511 were female. Decades of birth ranged from the 1900s to the 1970s as follows: 1900s - 3, 1910s - 16, 1920s - 43, 1930s - 70, 1940s - 118, 1950s 204, 1960s - 338, 1970s - 197 (Table 2). In order to achieve statistical significance, data for people born in the 1900s, 1910s and 1920s were combined into a single grouping. While most were reared in Chicago (325) or its suburbs (176), 45 states were represented and 39 countries as well.

TABLE 1
QUESTION:
"What smells or odors remind you of your childhood?"

Childhood Smells and Odors (n = 1,002) (Three Responses)		
Percent of Response	Who Gave Total	Percent of Those Specific Response
Baking bread, cookies, cakes, etc.	18	23%
Fresh air, rain, outdoors	5	7
Baby powder, powder	4	6
Chicken	4	5
Flowers	4	5
Farm smells	4	5
Meat cooking	4	5
Cut grass	3	5
Burning leaves, wood	3	4
Popcorn	2	3
Apples	2	3
Spaghetti	2	3
General food cooking	2	3
Apple pie	2	2
Cleaning products	2	2
Bacon	2	2
Soup	2	2
Fish, seafood	2	2
Other (1% or less)	50	65
Don't know	20	

Statistics were analyzed using Chi-square test on contingency tables or Z-test for the difference between pairs of proportions.

Results: Overall, 85.2% displayed olfactory evoked recall, a generational effect was demonstrated in this regard (Table 3).

Eighty-six and eight tenths percent of those born after 1930 displayed olfactory-evoked recall, whereas only 61.3% of those born before 1930 displayed it. This implies that the marketing of products through nostalgia with odors would be more efficacious in a target consumer group born after 1930. This is not surprising since olfactory ability decreases with age: one-half of those over 65 and three-quarters of those over 80 years of age have a reduced ability to smell.(Doty et al). In addition, memory worsens with age further explaining our findings in the elderly.(Bartus et al).

As mentioned, women have better olfactory ability than do men. Yet in our study at Water Tower, no statistically significant difference was shown

between the genders in their self-reports of odor-evoked nostalgia (Table 4). Hence, regardless of sex, aroma is an important nostalgia inducer. Based on the Z-test for the difference between two proportions, a statistically significant generational difference was found (Table 5). Those born from the 1930s on were more likely to have nostalgia induced by food odors and less likely to have nostalgia induced by nature odors than those born before the 1930s.

Those born before the 1930s cited smells of nature including pine, hay, horses, sea air and meadows, whereas those born in 1930 to 1979 were reminded of their childhood by such smells as plastic, scented markers, airplane fuel, vaporub, sweet tarts, and playdough. This shift away from natural odors and toward artificial ones may portend future problems for society. If we are concerned about ecology partly out of nostalgia for nature odors, then 50 years from now, how will the environmental movement be of much concern to the people who are nostalgic only for manmade chemicals?

TABLE 2

DECADE OF BIRTH (ALL DECADES)	POSITIVE SMELL PERSONS	NO SMELL PERSONS	TOTAL
1970's	171	26	197
1960's	290	48	338
1950's	186	18	204
1940's	98	20	118
1930's	60	10	70
1920's	28	15	43
1910's	8	8	16
1900's	2	1	3

Nature-related Smells	30.6%	44.7%

TABLE 6

	<u>UNHAPPY CHILDHOOD</u>	<u>HAPPY CHILDHOOD</u>
Foul Smell- Evoked Nostalgia	19.7%	7.8%

Clearly, in targeting a younger consumer group, food smells would be more efficacious than would nature smells, but the opposite would be true in targeting an older group. Odors were divided into foul and nonfoul smells. Foul smells (i.e. garbage, urine, manure) were defined by a panel of olfactory experts. Eight and eight tenths percent of those who reported olfactory-induced nostalgia said that foul smells were the precipitant. Eight and seven tenths percent (or one person in 12) reported an unhappy childhood. This was independent of birth decade or gender. And whether one had a happy childhood influenced which kind of smell evoked a childhood memory. The one person in 12 who reported having an unhappy childhood, was more than twice as likely to describe such foul odors as mothballs, body odor, dog waste, sewer gas, bus fumes, and mother's menstrual cycle (Table 6). This suggests that psychotherapists might well inquire into what odor induces childhood memories as a further method of gaining insight into personality.

Interestingly, happiness in childhood did not correlate with ability for olfactory evoked recall -- suggesting the universal nature of this phenomenon.

About equal numbers, 91% of men and 92% of women, reported a happy childhood.

Implications of our findings for marketers are: 1) approximately 85% of both men and women report smell-induced nostalgia -- suggesting smell is an important tool in marketing, 2) consumers under 60 years old are better targets for marketing nostalgia than older consumers, 3) while a wide range of smells could be utilized to induce nostalgic recall, food smells are a more effective stimulus for the younger consumer while nature smells are more effective for the older consumer, 4) in attempting to sell a product now, odorize it to maximize nostalgia of present-day consumers, 5) the product now odorized may come to be the focus of nostalgia for future consumers, 6) use of nostalgia through activation of the limbic system through the sense of smell will produce the strongest emotional appeal as a means of product marketing.

Through odors, nostalgia may be induced with greatest ease. One may speculate that nostalgic desires will increase in the coming decade since it seems likely that the more dissatisfied we are with the present, the more we idealize the past (a temporal equivalent of "the grass is greener on the other side" or as Richard Llewellyn wrote, "how green was my valley").(Liwellyn). Therefore, in the hard times ahead, it will be easier to sell nostalgia.

The Role of Consumption and Disposition During Classic Rites of Passage: The Journey of Birth, Initiation, and Death

Julie L. Ozanne, Virginia Polytechnic Institute and State University

OVERVIEW OF THE SPECIAL SESSION

Our lives are marked by stages through which we pass. From childhood we pass into adulthood. Many of us become wives and husbands, mothers and fathers, and even grandparents. Death punctuates our life and is our final passage. These journeys are important for they announce that we are different; our lives as before no longer exist (Gennep 1960/orig. 1908).

Rites of passage tell us who we are and how we fit into the fabric of society. While consumer behavior has been studied during role transition (McAlexander 1991; Roberts 1991; Schouten 1991a, 1991b; Wright 1991; Young 1991), the role and meaning of consumption and disposition during the classic rites of passage into adulthood, parenthood, and death are unexplored. The objective of this special session was to examine consumer behavior during these critical life events. The proposed session included four presentations of interpretive empirical work from researchers in the fields of consumer behavior and communications. John Schouten was the discussant.

First, Newell Wright and Jon Shapiro examined the transformation of women and men into parents upon the birth of their first child. This study was based on a series of in-depth interviews with mothers and/or parents before the birth of their first child. For those parents who gave birth to their child, the gestational period is a liminal state between being childless and being a parent. While some of the preparatory activities during this period are functional in nature, other pre-birth consumption activities and rituals help prepare the couple for their new role as parents. Consumption activities also help the parents deal with some of the anticipated stresses and anxieties of being a parent.

Second, Julie Ozanne discusses the rite of passage into adulthood. The child's transition into adulthood in our society generally lacks any formal initiation rite (Hiebert 1976; McCracken 1988). In the absence of initiation rites, consumption habits take on a greater role in distinguishing the pre-adult from the adult (Wright 1991). However, when formal initiation rites exist, consumption behaviors may play a less important role. This study examined young men from the Mormon subculture. It has been suggested that the mission experience acts as a public demarcation for the young men between being a pre-adult and an adult. Analysis of daily journals, graffiti, and in-depth interviews with young men before, during, and after their missionary work suggests that being on a mission is a rite of passage. Furthermore, these men enter a sacred state that is nearly devoid of the material concerns that exist in their former profane state.

Third, Ron Hill's in-depth interviews with troubled young men trying to come of age in a harsh

environment offers a stark contrast to coming of age as a Mormon. Whereas the Mormon young men in the Ozanne study are almost exclusively from intact, secure, middle-class families, Ron investigated the rite of passage into adulthood with young men who are institutionalized for criminal behavior and come from broken and economically impoverished homes. While the passage into adulthood is difficult for most people, the transition into adulthood for these young men exacts a price from society. Criminal behavior, namely acquisition of goods through illicit means, plays an important role in their claims to adulthood. Ron explores the implications of such dysfunctional behavior for society.

Finally, Mara Adelman discusses the different rites of passage that people living with AIDs face, first as they move into institutions and then as they come to grips with their imminent death. After over two years of courageous volunteer work at an AID's residential home and interviews with patients and staff, Mara suggests that possessions help individuals during change to reassemble and disassemble the self. For example, institutionalization forces AIDs patients to dispose of possessions as they break with their past lives. They then use the few possessions that they are allowed to bring to reassemble a new life and self. The disposition of possessions prior to death is another opportunity to disassemble the self. The material legacy offers the people left behind an opportunity to reassemble the person through associated experiences and memories.

MATERIAL CONCERNS WHILE COMING OF AGE IN THE MORMON FAITH: SPIRITUAL WORK IN A SECULAR WORLD

Julie L. Ozanne, Virginia Polytechnic Institute and State University

Initiation rites mark the transition from childhood to adulthood (Gennep 1960/orig. 1908). Generally few formal initiation rites exist in western cultures (Hiebert 1976; McCracken 1988). However, the passage from pre-adult to adult in the Mormon faith occurs for many young men during their missionary work. At this time, young men are separated from their family and friends and almost all aspects of their material world. For two years these men have few possessions and live in a monastic state, forsaking worldly goods and pleasures such as television, newspapers, music, friendships, jobs, school, romantic relationships, and family. Thus, the rite of passage into manhood for the Mormons is defined in part by antimaterialism. It was hoped that greater insight might be gained into materialism by examining individuals who temporarily renounce their possessions.

In-depth interviews were done with six informants at different stages in the mission experience: before, during, and after their missionary work. As well, two daily diaries of missionaries were analyzed over the two year missionary experience. Graffiti found in the Language Training Center (later called the Missionary Training Center) also provided insight into the experience. In the following section on the results, two sets of initial findings from the study are discussed. First, the role of the community in the lives of these men is explored. Second, the missionary experience as a rite of passage is examined.

RESULTS

Community

The informants receive strong support from family and friends. All the young men received partial to full financial help from their parents. Sometimes fathers worked extra jobs to support their children's missionary work. Some families were supporting two missionaries at once, yet these financial difficulties were taken in stride. The families were excited about the prospect of their sons going on a mission and believed that they would be blessed for their efforts. As well, family members showed their support through letters over the two year sojourn. For example, Ben comments on his parent's reaction:

They love it. They're glad I'm out here. I don't think it would matter how tight the money got at home they'd still support me while I was out here. We're a close family.

Because young men are expected to go out when they are 19 years old, many high school friends leave around the same time. Often watching friends leave on their missions is a pivotal event and motivates the young men to decide to go. As Adam remarks: "Then when I got out of high school, when my friends started leaving, it really kind of hit me that I should go on a mission." Friends also stay in contact with each other while on missions.

Church members and family friends provide financial and emotional support. At the missionary farewell, a ritual ceremony in church given to the young men before their departure, family and friends shower the initiates with money, good wishes, and advice. And during the mission experience the local church members act as surrogate fathers and mothers to the missionaries. The missionary companions provided daily support and help. As well, the church and church officials were seen as being supportive and wanting to help the young men succeed. Even potential converts at times are supportive, as David noted, he and his missionary companion were affectionately referred to by the black community as their "preacher boys."

Not all aspects of the social environment were supportive. Girlfriends were seen as trouble to missionaries, since they would be distracted from their missionary work by thoughts of them. There were Mormon myths surrounding girlfriends. Stories abounded of "dear John" letters sent by girlfriends who could not wait for their return. A common theme was that women in general were trouble and should be kept at arms length. Eli recalled a story from his uncle's foreign mission experience:

...there were several occasions where he and his companion literally ran home from a meeting...because they (women) would want to chase them. They were American and its a ticket to the United States.

But the influence of the community extended beyond emotional and financial support. The religious indoctrination was pervasive. Many young men graduated from seminary school during their high school years. For four years classes meet for an hour a day, often before regular high school, to study religious texts. Students also attended their regular Sunday school meetings and midweek youth activities, and families are encouraged to have Monday night family home meetings for religious studies. Couple these influences with personal prayer, religious study, church youth groups, church social activities, church callings, and so forth, and there is a powerful religious training given to these young men.

Thus, the family and friends of the missionaries provide strong and consistent emotional and financial support for their missionaries. However, the spiritual preparation is so pervasive and comprehensive that it

is surprising how any practicing Mormon could choose not to go on a mission. In fact, one interesting group to interview would be practicing Mormons who chose not to go on a mission or Mormon missionaries who left the church.

Rite of Passage

Consistent with Genep's (1960/orig. 1908) three principle phases in rites of passage, the young men are separated from their past life, go through a stage of transition between their past and future lives, and are eventually reincorporated. However, this rite of passage is not the same for each young man and varies from a passage into adulthood to a religious coming of age.

Separation. Before entering the Missionary Training Center, all young men receive short, conservative hair cuts, purchase dark, conservative suits, and are "set apart" by the stake president, a regional church authority, who literally lays his hands upon the initiate, sets them apart as missionaries, and transfers responsibility to them. From this time forward until the man is released two years later by the same stake president, he is a missionary. Next they report to the Missionary Training Center (MTC) where they are physically set apart from their families, community, and past lives before beginning their mission. The young men head off to the MTC carrying all their possessions for the next two years in two suitcases and a briefcase. Often the initiates arrive at the MTC with their parents for an orientation. After the orientation, the parents leave through one door and the missionaries leave through another. For many young men, it is at this point that they realize the magnitude of what they are doing:

Well, the first day of course I was just freaked. They bring you in there and your parents leave. All of a sudden you're just standing there and you are freaking out going you're looking at two years. What am I doing? (Adam)

Life before and after the MTC is clearly different. This MTC experience allows the missionary to break with his old life and prepare him for his new life as a missionary. It is here that he get over being homesick and where he is intensely trained to be a missionary.

Not only is he separated from his past life, he is also severed from his past identity. He gives up one of the most individual of all possessions, his first name. He is no longer "John," he is now "Elder Smith." This new identity is reinforced by a name tag that is always worn, by a new uniform (i.e., dark suit, white shirt, black shoes,...) and by a "missionary hair cut." All Elders are the same in name and dress for all are equal servants of the Lord. Elders are identified not by where they have been (i.e., their home and past) but by where they are going (i.e., their field of labor, whether that be in Paris, Lima, or San Francisco).

Life in the MTC is characterized by asceticism. Few possessions from their past are brought or allowed. What few possessions are brought are related to their work. The primary possessions brought are

clothes: white shirts, conservative ties, slacks, suits, dark shoes,... The new clothes and haircut are put on as the new role is donned. Few of the men had worn these clothes before. If worn at all this uniform was worn to church. One or two other casual outfits were brought for the one day a week that the men had off to do personal tasks like shopping, laundry,... Other possessions that were brought were primarily spiritual in nature: religious books, pictures of Christ, poems,... The only real personal possessions taken were pictures of the family. There were no other possessions or symbols of their past lives.

Life at the MTC is different. One is thrown among new people, schedule, food, surroundings,... Every moment is scheduled, even recreational time is planned. All control and choice is removed from the initiates upon entry into the MTC. The schedules is seen by the missionaries as physically, mentally, and emotionally demanding. (This experience is more demanding for those who learn a language and stay for eight weeks rather than two weeks.) Graffiti discovered at the Language Training Mission, the predecessor to the MTC, refers to this place as the "rock" and "the ball and chain." Surviving this experience is considered to be an accomplishment, yet informants speak of a closeness and comradeship among the missionaries forged by common adversity.

Transition. After the MTC, the missionaries go to their respective fields of labor and begin their work. In Mormon scriptures, missionaries are commanded to go out "two by two," therefore they are assigned a companion with whom they spend every waking moment. Over the next two years they are assigned to different locations about every 4 to 6 months and are assigned new companions every 3 to 4 months on average.

While each mission experience is unique, some common elements exist. Each missionary entered the field confident only to experienced an initial period of adjustment during which he was not very effective.

When you come out you expect to get into every door you knock on cause you're so powerful and everything. You start knocking on doors and they shut them on you. It kind of hurts (Ben).

During this period most missionaries felt their testimony challenged. (Testimony is knowing in your heart that the scriptures are true as opposed to believing that they are true.) Day in and day out these men had to face 16 hour days of religious work that included tracting (door to door proselyting), studying, teaching, counseling, baptizing,... Personal and religious doubts would make this grueling schedule difficult. These adversities strengthened most missionaries' testimony. Similarly, one had to struggle with selfish desires and thoughts of the past in order to live up to the expectations for a missionary. As Caleb put it:

You represent the Church. You are the Church... You're not suppose to speak about other things--you are a missionary full

time...So you take on that pretty seriously...You don't talk about going out doing something else. You talk about scriptures and helping people out. Serving people, that's basically who you are...Your family's still the same and you're kind of different. You're still part of the family and you write and sign you name, you know, your first name, but as far as who you are you're kind of different...being a missionary servant, you always have to be serving you know. You have to kind of give up selfishness, your going to have give up worldly things.

This quote captures the transition that these men face.

A strong theme across the informants was that the mission was a sacred time and task. Their experience of time was different than their life before. In their pre-missionary lives, weekends meant something but here there was a "sameness" of days. The days are full but the months fly by. Being a missionary is like being a priest. These young men are set apart; they must remain celibate and refrain from all worldly concerns and stay focused on the spiritual realm. They feel different. Caleb talks about sitting on the plane looking at all the people around them and thinking "these people are just regular people...we're missionaries." Each man spoke of the physical weight of the responsibility that they felt. Many spoke of the physical sensation of spirituality as "goose bumps all over," "a calm feeling inside," and so forth. Other people treated them differently, "like they know everything." People "put you on a pedestal."

The difference between the mission life and their life after the mission is most dramatic upon their return. Adam describes his brother's return:

The thing he said was the hardest, was one week he was doing something that's the most important thing that someone can ever do--try to teach someone the truth--and how he returned back from God to filling ash trucks.

David said he "felt like bawling" upon his return. The return to the past life is often met with depression.

Reincorporation. While the results in this section are less complete, there were some preliminary findings. The new experiences faced by the young men had changed them: living away from home and family, being in a large town, living in the country, traveling overseas, and meeting new people and new ways of life. Many of the men spoke of a new tolerance for people of differing backgrounds. These men had learned new skills. Caleb talked of learning how to lead people and David spoke of overcoming his shyness.

However, most missionaries felt out of touch with the secular world and experienced some depression. Successful return seemed to depend on getting on with life and using the new skills and insights that they had acquired. Many returned missionaries go back to school or work. Others become involved in the church. Others get married.

CONCLUSIONS

To summarize, the Mormon missionary experience is a rite of passage. These young men are separated from their community and all of their worldly goods. They then struggle with the demands and challenges of missionary life that often lead them to reevaluate different aspects of their life. The time after the missionary experience is characterized by a the need to go on with their life while somehow integrating this experience into their life.

TRANSITION IN TURMOIL: WHEN BECOMING AN ADULT INVOLVES CRIMINAL BEHAVIOR

Ron Hill, Villanova University

The transition from childhood to adulthood is a major rite of passage in all societies, and involves a significant change in status and role behaviors (Wright 1990). However, unlike societies in which adolescents develop new identities by emulating the actions of adults within their communities, American youths "have difficulty finding a preordained place in the social unit" (Lipsitz 1977; p. 5). Instead of supplying a clear path, our culture provides adolescents with a long period of emphasis on self-definition, with expectations of "open choice" and the possibility of social mobility.

While most individuals are able to confront this challenge and re-create the self into a positive, functioning adult member of the community, there are many in our society who fail to move successfully to adult roles and end up engaging in anti-social or criminal behaviors. According to Lipsitz (1977), one possible explanation is that these youths are faced with the additional burden that mobility and opportunity are closed to them because of poverty and lack of education. Thus, violent and illegal acts may become a way of gaining revenge against a society that imprisons them. For example, stealing may be viewed as a substitute for employment at low level service jobs that provide limited opportunities for advancement or higher incomes (National Commission on Youth 1980).

The purpose of this research is to balance the discussion of rites of passage by including a group of individuals who are finding this transition troublesome. To this end, twelve in-depth interviews were conducted with 17 and 18 year old males who were boarders at a residential facility for court adjudicated youth. All of these young men had been convicted of serious crimes including robbery and assault, burglary,

auto theft, and possession and selling of illegal drugs. Our discussion of this experience focuses on the lack of positive role models in their lives as well as the threatening nature of their day-to-day existence. Next, our attention is turned to their resulting desire to "live for today" through the acquisition of money and possessions, typically by unlawful means, and the subsequent value of these items to these youths. Finally, a brief conclusion presents preliminary analysis.

RESULTS

One of the greatest deficits among these young men is the lack of a positive male role model or mentor in their lives. To a person, they had troubled relationships with their fathers, who were distant, strict, reserved, or absent and often viewed negatively. Consider the following description provided by Jim:

See my Dad, he lives in [another state]. Like we don't get along all that good... My dad has always been for him [my brother] and like he's never had no time for me or nothing.

Occasionally, a brother or uncle took on this role, but this substitute usually fell short of providing necessary guidance and interaction. Further, the older men in their communities provided little in the way of additional mentoring, and were also seen as wishing they were young or acting young themselves, almost in competition with their younger counterparts. Thus, these men were often viewed in negative terms:

When I was younger, I would go up and say look at those bums. With their kids, drinkin'. I still say it when I'm walkin' with my friends. We see some, you know, we'll come back from the movies or something and it's real late at night and we'll look over there [and see men in our neighborhood] hangin' over all drunk, disgustin' and me and my, we all say 'I can't wait to get out of this neighborhood!' (Tom)

Further, the world that these young men inhabit is filled with violence and crime, and they feel that they must grow up fast in order to survive. Gangs and street fighting are common, and there is little one can do to avoid contact with the resulting brutality:

What's it like growin' up in [your neighborhood]?
It was tiring, I guess you could say 'Man I want to get out of here!' Like you look around and there was a situation, you figure out who you should be with, you gonna look around now and be like 'Where's so and so? He's dead. What about so and so? He's dead too, he got shot in the head' somethin' like that.' (Dan)

This combination of factors - lack of role models and a hostile environment - leads them to focus their attention on living for now with members of their peer group. Also, opportunities for engaging in criminal behaviors such as stealing cars and selling

drugs exist widely, and are considerably more rewarding than the menial careers that these young men are qualified to enter. Thus, to avoid the frustrations associated with the working world and to enjoy the things that are available within society, they tend to gravitate towards criminality in an almost addictive way:

And like a couple nights straight just, I just stayed up like all night, I don't know, stealing... cars and stuff. I brought, ahh, I had to put a lot of stuff in bags and stuff that I had about, I'd say about 150 dollars in cash like, change, dollars, stuff like that. And then we just caught the bus and went back to my house and dropped, dropped the stuff off and then emptied our pockets and all, put it in the jar and went back out later on and got another car. (Steve)

The resulting money received from such activities provides these youths with status and power in their communities and a sense of freedom that is not possible given the relative poverty in their communities:

My neighborhood's a real material neighborhood like if you don't have something you're shit. If someone's got something, you don't got it, you're shit. (Bill)

You gots to have money to impress, but not to just impress the girls. I got to have money to impress myself. Like I can't walk through a mall you know and be like 'Oh, I want to get that. I get that next week with my paycheck.' or 'I'll get that, you know, when I get the money.' You know I want that, I want to get that right now! I got to get that! (Jim)

CONCLUSION

The results of this study suggest that youths who live in a world of poverty and violence without appropriate role models and legitimate opportunities to raise their standard of living may resort to criminal behaviors in order to "live for today." While Belk (1988, p. 148) concludes that "self-definition through doing things may be preferred to self-definition through having things," their lack of skills and uncertain futures may lead them to search for "achievement through consumption" (Cox, Cox, and Moschis 1990, p. 158). Future research needs to explore this link between self-concept development and possessions more completely, and look for ways to enhance self-esteem through legally sanctioned methods such as skills development.

RITUALS OF ADVERSITY AND REMEMBERING: THE ROLE OF POSSESSIONS FOR PERSONS AND COMMUNITY LIVING WITH AIDS
Mara Adelman, Northwestern University

"The past is hidden...beyond the reach of the intellect -- in some material object." (Marcel Proust)

In his classic work, *The Rites of Passage*, van Gennep (1908) identifies three stages in 'life crisis' -- separation, merger or transition, and reincorporation. During the states of transition, people experience what van Gennep refers to as liminality -- a boundaryless, marginalized experience often accompanied by isolation and suspension of social status. In short, liminal people are 'betwixt and between' two life stages or social roles.

Recently, scholars of consumer behavior have examined the role of disposition of objects during role transitions (Young, 1990; Roberts, 1990; McAlexander, 1990). A central theme in these works is the notion that objects facilitate and reflect identity transformation during various life passages. Furthermore, in some transitions the symbolism and manipulation of possessions is a central feature of the ritualized transformation (e.g., the removal of wedding rings to symbolically mark a divorce).

Yet few passages are as dramatic or adverse as those experienced by persons facing a terminal illness. The purpose of this study is to explore the role that disposition of objects play in a residential community for persons living with AIDS (PLWA). A major premise in this study is that the meanings, forms, and functions of dispossessing are inextricably linked to the liminal nature of the AIDS illness and the community setting.

Liminality and Life-threatening Illness

Works on the social construction of life-threatening illness (LTI) points to the liminality that accompanies the chaos and threat to physical and social identity. Physical identity is severely shaken by the uncertainty of the diagnosis, the ambiguity surrounding complex symptoms, and the loss of control in predicting remissions and ultimately the time of death (Comaroff & Maguire, 1981; Murphy, 1987). For persons living with AIDS, the range of opportunistic infections, the side effects of new

medications, and the unpredictable onset of disabling symptoms heightens a sense of physical liminality.

Social liminality is often experienced by PLWAs as their personal identity is threatened by the stigma of this disease and loss of social ties. Furthermore, the images associated with AIDS are so symbolically powerful, that this illness has emerged as a metaphor for societal paranoia and chaos (Sontag, 1989). Murphy et al. (1988) observed that disability creates liminality, since the disabled are neither well, nor sick, "declassified but are not yet reclassified; they have died in their old status and are not reborn in a new one" (p. 237). For those unfamiliar with the extended prognosis and fearful of AIDS, PLWA's may represent the living-dead, a state which is betwixt and between.

Liminal Settings

Between diagnosis and death, there can be intermediary stages or multiple role transitions in redefining the personal and social self in coping with a LTI. Changes in a living situation often signals a transition for personal identity, particularly for those moving from independent living to assisted living. These physical moves in coping with a LTI can become dramatic demarcation points, especially when the new environment is designed for those who share a similar illness.

In response to the needs for housing, social services, and medical assistance for PLWA, there has been a rapid growth in congregate living facilities specifically designed for PLWA. The variation among these residencies makes it likely that some settings are more liminal or ambiguous than others. For example, a hospice is specifically designated and designed for those in their final stages of dying may be less liminal than other forms of congregate living for those during various stages of the illness, even before the onset of frail health. Regardless of its mission, residential facilities for PLWA openly acknowledges the illness, heightens awareness of personal death (Unruh, 1983), and provides a reference group of comparable others. As Frankel (1989) demonstrates in her study of a therapeutic community, socialization to these environments can produce a dramatic shift in self-concept, altering the attributions for self and others.

Disposition of Possessions

Personal possessions serve numerous identity functions as people move through various life transitions and specifically during death when artifacts become the symbols by which individuals wish to be remembered (Unruh, 1983). But possessions are also vehicles for social communication (Olson, 1985). Herein the symbolic meanings of the object itself and its use in facilitating interaction can serve as rituals for departing, as spiritual companions for those who survive, and as visible markers for reaffirming community purpose.

The goal of the present study was to explore and obtain descriptions of the role of disposition of possessions for PLWA in a residential setting for similar others. More specifically, this study examined the phases of the disposition of possessions and the

significance of personal possessions for the community at large.

METHODOLOGY

This study was conducted in a congregate care facility for PLWAs, herein referred to as "Homelife." Founded in 1988 by a religious order, this facility houses 26 PLWAs and is designed for those who are still ambulatory and self-sufficient in daily activities. The demographic profile of the residents during the past 2 years shows a highly diverse population (i.e., age, race, gender, education, income), with an average stay of approximately 5.8 months. Approximately 80% of the residents remain in the home until their death or final transfer to another facility.

Participant-observation based on 2.5 years of volunteer work, transcriptions from a documentary film on Homelife (Adelman & Shultz, 1991), initial interviews on community life (n=22) and with key informants (n=5), form the corpus of data for the following thematic and interpretive analysis.

RESULTS

Reassembling and Disassembling the Self

The disposition of objects is inextricably linked to the psycho-social orientation of the residents to Homelife. Expectations and attitudes toward this community will be influenced by the ways in which residents discard and use possessions to reconstruct their identities at Homelife. Furthermore, the process of reconstructing social identity does not take place in a closed relationship between the resident and the possession. Rather social attachments with community members plays a critical role in determining the how possessions will be used and to what affect.

As with any relocation, objects are retained and discarded based on expectations for the new setting. For some residents, entering Homelife signals what one informant referred to as "the last stop" -- the final resting place. This acknowledgement of death, coupled with the pragmatic constraints of small private rooms, can initiate a disposition of major assets long before death is inevitable.

For those who viewed Homelife as a temporary place until recovery, there was minimal effort to reassemble the material world. In some cases, minimalist reassembling appeared to reflect a denial of the illness and lack of commitment to community life. One very affluent resident placed all his possessions in storage for a later time when he recovered and could move out. During his eight month stay at Homelife, he sustained a social detachment from community members. Although he remained critically ill, he continually made plans to move-out. With the exception of a fur coat, a few clothes, and a small television, his room remained stark and in perpetual disarray until his death.

However, most residents, even those who were homeless and with few possessions, use their possessions to reconstruct personal living spaces as a permanent home. Although these possessions were the primary form of personalizing their living

quarters, there was also the accumulation and display of others' possessions. Acquisitions from other residents formed a symbiotic materialism with the community, where the resident's collective identity is fostered by his or her attachments to the possessions of others. A long-term resident who entered the home with two bags of clothes, after two years and several close relationships with dying residents, her room is now filled with their possessions. She notes, "I made this room for memories and good feelings."

Studies of possessions reveal their significance in extending the self (Belk, 1988). Even the organization and display of remnants in the form of scrapbooks, provides a portable secular ritual for assembling the self (Katriel & Farrell, 1991). The transition into Homelife serves as both an environmental and psycho-social boundary marker for incoming residents. Forms of environmental schematization (Holahan, 1978) or reconstruction of the material world within this community setting is central to the role of objects in the final transition to death. Findings from this study indicate that possessions play an important role in reassembling and disassembling the self as residents enter the community. As such, the disposition of possessions as a dying ritual is embedded within the initial transition to the community setting and the development of social involvement with fellow residents.

Collective Memory

The personal possessions that residents leave to fellow members or to Homelife have become a way of incorporating the passing member into the community culture. As with individuals, these possessions provide a visible legacy that triggers stories for the community at large of the incidents and personalities of those who have died. In her study of Holocaust survivors, Myerhoff (1982) found that life stories not only functioned to remember the past, but also to "re-member" -- a special type of recollection that calls

"attention to the reaggregation of members, the figures who belong to one's life story, one's own prior selves, as well as significant others who are part of the story. Re-membering, then is purposive, significant unification, quite different from the passive, continuous fragmentary flickering of images and feelings that accompany other activities in the normal flow of consciousness...It becomes a tidy edited tale" (p. 111).

Although the process of re-membering may remain more fragmentary and less intense for residents than that experienced by Holocaust survivors, PLWA are survivors of a catastrophe in which the search for meaning is essential to account for their suffering and to circumvent despair.

The symbolism that surrounds possessions and the stories evoked by their presence offers an opportunity for residents to re-member with those before them and to develop a collective memory for

the community. For re-membering, linkages must be found "between the group's shared, valued beliefs and symbols, and specific historical events" (p. 111), which may evolve to stories and myths. This form of local knowledge becomes evident at Homelife in the socialization of new members, in the references and stories about past members, and in the naming of specific objects that have become household ornaments.

CONCLUSION

Congregate living for those facing a LTI can relieve or create chaos and uncertainty for personal and collective identity. Disposition of possessions can play a critical role in reassembling and disassembling the self from initial entry to the community to the final stages of dying. Because a major threat to any community is the loss of its members (Kanter, 1972), the disposition of possessions can enhance a sense of *communitas* (Turner, 1969) or psychological support among residents by providing a collective memory for those who have died and evidence for those who are living -- that they too shall be remembered.

Consumption and the Crisis of Teen Pregnancy: A Critical Theory Approach

Newell D. Wright, Virginia Polytechnic Institute and State University
Jon Shapiro, Virginia Polytechnic Institute, and State University¹

ABSTRACT

Teen pregnancy is a growing problem in the United States. This paper provides preliminary findings from a critical theory study on how expectant teen mothers prepare materially for childbirth. Three contradictions between the subjective and objective situations surrounding teen births are discussed. The paper concludes by examining possible theoretically grounded programs of action for dealing with the problem of teen pregnancy.

INTRODUCTION

The role of consumption during life transitional periods has received increasing attention in recent years (Schouten 1991a, 1991b; Roberts 1991; McAlexander 1991; Ozanne 1992; Wright 1991; Young 1991). Pregnancy may also be considered a period of transition, a time "betwixt and between" (Turner 1967) the expectant mother's past state as a non-mother and her future state as a mother. Consumption is an important part of this transition into motherhood as the expectant mother prepares materially for the upcoming birth of the child. The purpose of this study was to examine the role of consumption during the transition into motherhood.

As with previous studies of consumption and transition, we used indepth interviews in naturalistic settings to gather our data, and interpretively analyzed the results (McCracken 1988). Our initial informants consisted of first time parents or mothers, and we sampled across various populations for diversity. Specifically, we interviewed a middle class couple in their late 30's who had a home birth attended by a midwife, a couple in their 20's with financial constraints; an orthodox Jewish couple (Hasidic); an unwed hispanic teen mother; an adoptive mother; and an unwed teen Appalachian mother.

The initial results confirmed our expectations that consumption did play an important part during pregnancy, but we serendipitously discovered a potentially more important issue. The parents who needed material help the least received the most help (middle class couples), and those who needed the most material help, received the least help (unwed teen mothers). Hence, the focus of the study shifted from an interpretive study of consumption during pregnancy to a critical examination of the material needs of teen mothers following the critical theory methodology set forth by Murray and Ozanne (1991). Table 1 provides a summary of the critical theory methodology they laid out. This paper describes the preliminary results of the critical theory study.

CRITICAL THEORY

Initial Stage of Critical Theory Research

The concrete and practical problem investigated in this study focused on how teen mothers prepared materially for their children given that they lacked the economic and social support of married, middle-class women.

This problem is both concrete and practical. Teen pregnancy is a growing problem in this country. Between 1960 and 1990 there was more than a five fold increase in teen births, from 91,700 to 500,000 (Dash 1989, p. 24-25; Los Angeles Times 1990). These births cost the federal government over \$21 billion annually in Food Stamps, Aid to Dependent Children, Medicaid, and other social service offerings (Chicago Tribune 1990). One in six children of teenage mothers has a low birth weight and is more likely to experience physical and cognitive problems (Barnett 1987). In addition, teen mothers are half as likely to graduate from high school than the rest of the teen population, and, if they are married, they are 3 times more likely to be divorced or separated than couples who married in their 20's. One study showed that approximately 90% of the inmate population at Attica State Prison was born to teenage mothers (Evans 1986). Hence, the problem of teen pregnancy is both concrete and practical.

The relevant groups involved with this problem includes the teen mothers; the birth fathers (who frequently do not participate in the upbringing of the children); the children; grandparents and other members of the extended family; social service workers; and health care workers. These relevant groups were studied in this research.

Data Collection Stage of Critical Theory Research

Murray and Ozanne (1991) identified five steps in the data collection process. This research is currently at step three.

First Step

In the first step, researchers attempt to gain a subjective understanding of the informants they interview. Our subjective data was collected through participant observation and indepth interviews. Specifically, we have conducted participant observation of a support group for teen mothers who are still in school. Since most teen mothers drop out of school, we are also planning to participate in a teen mother support group for high school drop outs. We also conducted several indepth interviews with teen mothers at the health department of a small county in the southern part of the United States. We are planning to interview birth fathers for their perspective, as well as extended family members. Finally, we interviewed social service workers, and

¹The authors would like to thank Julie L. Ozanne for her comments and help with data collection.

TABLE 1
CRITICAL THEORY METHODOLOGY

Initial Stage of Research

1. Identify a concrete practical problem.
2. Identify all groups involved with the problem.

Data Collection Stage

1. Construct an interpretive understanding of each group.
2. Develop an historical-empirical understanding of relevant social structures.
3. Look for contradictions between the subjective and objective understandings.
4. Discuss alternative ways of viewing the situation with the groups involved.
5. Initiate programs of action to change existing social conditions.

Adapted from Murray and Ozanne (1991)

plan to interview physicians, health care administrators, and other relevant health care workers.

Second Step

The second step involves the examination of the historical development of the relevant social structures or processes. We have examined the legal structure of the health care system in the state in which we are conducting the study, as well as the health care and the social service structures to obtain a more objective understanding of the structures that impact on teen mothers.

Third Step

The third step involves coming to a dialectical understanding of the subjective and the objective data, and looking for contradictions between the intersubjective understanding and the objective social conditions. The remainder of this paper will examine in detail the initial contradictions we uncovered that affect teen mothers.

Breast Feeding. Teen mothers are unlikely to breast feed their babies. They don't feel it is important, they feel uncomfortable with large breasts, and they often rely on others to help tend the children while they work or go to school. Also, since they are sexually active, they feel some role conflict between "sharing" breasts with babies and boy friends.

Since most of the teen mothers are impoverished, they can't pay for the services of a lactician or other medical professionals while in the hospital to teach them how to breast feed or what to expect during the engorgement process. It appears as if the goal of the health care system is to get the teen mothers in and out of the health care system as fast as possible since their stays are usually being paid for by Medicaid, the state supported health care plan for economically disadvantaged residents, and the hospitals are losing money on each teen birth. There is also evidence that since teen births were usually traumatic and painful, health care workers want to spare them the further pain of engorgement and breast feeding.

This contradiction exposes the need to educate teen mothers about the benefits of breast feeding. However, our research showed that it would be better to stress the economic benefits of breast feeding (e.g., money saved) rather than the health benefits, since the

teen mothers we interviewed or observed were largely unaware of the nutritional or health benefits of breast feedings, or these benefits were unimportant to them. As consumer researchers, we can help by producing and educational literature that is meaningful for and targeted directly to teen mothers, instead of using the traditional educational approaches that stress nutritional reasons for breast feeding.

Child Birth Services. The teen mothers we interviewed or observed are almost all terrified of giving birth, yet they are the least likely to seek out social services and child birth classes. Expectant teen mothers at the support group were so terrified of the thoughts of giving birth that they turned white and felt faint during a hospital visit. This topic came up frequently. Teen mothers we observed or interviewed rarely attended any child birth classes offered by the local hospitals or social services organizations.

Our research revealed there were two principle reasons for this. First, the teen mothers, who often did not have a partner with whom to attend these classes, were very intimidated by the older, more financially secure, married (or at least monogamous) couples who attended these classes. And second, since many teen mothers were impoverished and under the legal driving age, many had no way to get to the classes, even if they had the desire to attend.

Our research shows that the teen mothers have unique and pressing problems that are not being addressed by the prepared child birth classes being offered. This finding suggests a production orientation to prepared child birth classes rather than a market orientation may exist. The needs of the teen mothers are simply not being met by the hospitals and social services groups offering these classes. We suggest tailoring classes, following the marketing concept, to the specific needs of the teen mothers. Specifically, social services needs to design prepared child birth classes targeted to teen mothers, and perhaps even taught by a former teen mother. In this way, the participants will not feel out of place by attending classes with older, more financially secure middle class couples. Additionally, these classes should be prepared in conjunction with existing social services programs, since some programs already provide transportation for teen mothers to other social

services offerings. Or perhaps they should be held near to government subsidized housing or other low income areas in which most of the teen mothers reside.

Legal Status of Teen Mothers. Teen mothers are legally required to take care of their children, yet, until they are 18 years of age, they cannot legally sign contracts, such as those necessary to rent a trailer or apartment. On the one hand, they are legally responsible for providing shelter for and taking care of their children, and on the other hand, they are legally prevented from obtaining shelter. Since many teen mothers are estranged from or no longer live with their parents or with the birth fathers, this is a particularly difficult situation for them to be in.

A related problem focuses on health care. On the one hand, the teen mother can authorize medical services for her child, but, on the other hand, she must get parental authorization if she is to receive any medical attention at all.

Teen mothers are treated like children, but they have an adult job to do. These two legal constraints may prevent the teen mother from obtaining the shelter and/or medical services needed to care for herself and her child. As researchers interested in consumption, it was curious for us to discover legal constraints that thwarted consumption in two such crucial areas as shelter and medical care. Action in this area is necessary to change the legal standing of teen mothers, or at least allow them the legal rights to take care of their children.

Fourth and Fifth Steps

The fourth step will involve discussing alternative ways for each of the relevant groups to see the situation of the teen mothers, and the fifth step will involve participating in a theoretically grounded program of action to change the existing social conditions that are oppressing teen mothers. While we have not yet entered the fourth and fifth stages with our research, our potential contributions as consumer researchers may include increasing awareness of the contradictions faced by teen mothers to health care and social services workers, lawmakers, and other relevant parties to allow the teen mothers access to the goods and services they need to meet their legal obligations as parents. Dissemination of the results of this study might include traditional outlets (e.g., journals, conference proceedings) as well as nontraditional outlets (e.g., TV and radio talk shows, health care trade publications, *Reader's Digest*) to raise public consciousness of the unique and pressing consumption needs faced by teen mothers and their children.

CONCLUSION

Teen mothers, who are usually impoverished and need material goods the most to prepare for the upcoming births, often receive the least material help. This paper detailed the preliminary findings of a critical theory study examining the material problems faced by teen mothers. Specifically, three contradictions derived from subjective and objective research were discussed, and potential, theoretically grounded courses of action set forth.

Consumer Inference

John Kim, Oakland University
Frank R. Kardes, University of Cincinnati

ABSTRACT

The importance of inference processing has been noted by many distinguished consumer researchers (e.g., Alba and Hutchinson 1987; Huber and McCann 1982; Johnson and Levin 1985; Kardes 1988; Meyer 1981; Sawyer 1988; Simmons and Lynch 1991; Yi 1990). The urgings of these researchers and the importance of this topic has led to an increase in research activities, and our understanding of the phenomenon. However, our understanding of inference processing is still limited. Thus, this session attempted to further stimulate inference research by focusing on recent empirical research on how consumers "go beyond the information given" to fill gaps in knowledge that inevitably follow from the reliance on incomplete information. Furthermore, the session endeavoured to facilitate the development of an integrative theory of consumer inference that can be useful in understanding consumer response to missing information.

OVERVIEW

Consumers are often required to make judgments and purchase decisions about products on the basis of limited or incomplete information. Because complete information is rarely available to consumers, it is important to understand how consumers respond and adapt to incomplete information.

The four papers presented in the special topics session investigated consumer inference processes using several very different approaches: some have strategically deleted portions of the text of advertisements to examine the persuasive impact of inferred versus explicit claims; some have manipulated the contents of brand-by-attribute matrices presented on an information display board to examine the relationship between information search and decision making; and some have used Bayesian approaches to examine the diagnostic value of inferences. Although very different products, contexts, and methodologies have been applied, a unified theoretical framework is beginning to emerge that may be useful in addressing unresolved issues. Specifically:

1. All four papers emphasize that several different responses to missing information are possible. Consumers often fail to recognize that judgment-relevant information is missing. When omissions are overlooked, inferential activity is unlikely. Even when omissions are detected and when gap-filling inferences are likely to be generated, several different informational bases for inference making are often available and several different mechanisms for producing inferences can be activated.
2. All four papers adopt a contingency perspective. The results of Sawyer's experiment show that the likelihood of inference generation depends on the consumers' level of need for cognition and on the strength of the link between arguments and conclusions. Yi's study shows that attribute information is often open to multiple interpretations and that the accessibility of judgment-relevant information stored in memory influences which interpretation is likely to be inferred. Simmons and Lynch's experiment shows that inferences are likely to be formed only when several conditions are met: (1) the consumer must detect an omission, (2) an appropriate inference rule must be accessible from memory, and (3) the inference must be perceived to be useful for achieving the goals of the consumer. Kardes, Kim, and Lim show that prior knowledge produces multiple effects: knowledgeable consumers are more likely to generate inferences, and if inferences are generated, knowledgeable consumers are more likely to use their inferences to guide subsequent judgments and decisions.
3. The papers suggest consumer inference processes have important managerial implications across a wide variety of settings (advertising, product management, consumer decision making), attesting to the richness of the concept. Sawyer and Yi focus on the development of creative, new, and effective ad executions. Simmons, Lynch, Kardes, Kim, and Lim focus on the perceived diagnosticity of inferences and on the implications of perceived diagnosticity for consumer decision making. The perceived diagnosticity or importance of various attributes and benefits also has important implications for the design of products.

The session, thus, addressed some unresolved issues in consumer inference processing. Issues such as when inference are formed, what inferences are formed, and the effects of of these inferences on judgment and choice were discussed in the papers. The abstracts provided by the authors are presented next.

ABSTRACTS

Determinants of the Persuasiveness of Open-Ended versus Closed-Ended Advertisements

Alan G. Sawyer, University of Florida

Open-ended advertisements do not have an explicit conclusion that tells the audience what it

should infer from the information in the ad. Alternatively, an ad can be closed-ended and specifically tie up loose ends and offer a message conclusion for an audience. There are several reasons why communication researchers predict that open-ended messages might be more persuasive than closed-ended ones (see Sawyer 1988 for a detailed review). Perhaps most importantly, the absence of any obvious conclusion may lead a motivated audience to try to infer one. In order to reach a conclusion, a motivated audience is more likely to process the central message arguments (Petty and Cacioppo 1986) of open-ended messages since they are unable to rely on the message conclusion available in a closed-ended message. An audience motivated to infer a conclusion is more likely to generate its own thoughts and inferences when exposed to an open-ended ad than when exposed to a closed-ended ad (Kruglanski 1980). Attitudes resulting from effortful self-generated inferences should be more accessible (Kardes 1988) and more positive than attitudes resulting from less effortful processing of inferences explicitly provided in a message (Linder and Worchel 1970).

However, this potentially greater persuasiveness of a no conclusion message is accompanied by several risks. First, the audience may not process the central message arguments and, with no explicit conclusion to summarize the intended position of the message, be unable to infer a conclusion. Second, a message recipient might process the information but either draw no inference from that evidence or draw a different inference than intended. Therefore, it would seem important that the audience be sufficiently motivated to process the contents of an open-ended message in order to make a conclusion and that the message be structured so that the audience is able to make the conclusion intended by the message.

Sawyer and Howard (in press) confirmed the above speculation that the audience had to be involved in order for open-ended messages to be more persuasive than closed-ended ones. This result was replicated across several measures (including brand evaluation, purchase intention, and choice), two products, and two experiments and held after a one week delay as well as immediately after ad exposure. Although it is uncertain what exact process(es) account for these results, it seems that inferences play an important role. Kardes (1988) used a brand evaluation response latency procedure and found that involved subjects viewing an open-ended advertisement were more likely to have already formed an inference (consistent with faster responses) compared to involved subjects exposed to a closed-ended ad. However, unlike Sawyer and Howard's results, Kardes did not find that the open-ended ads were more persuasive; although the attitudes were more accessible, they were not significantly more positive.

This presentation will discuss the role of inferences in the persuasive process(es) evoked by open-ended advertisements and then present the results of a new experiment that tests for additional moderating variables. Two variables - one measured and one manipulated - are examined. The first is the

subject variable of *need for cognition*. Subjects high in need for cognition might be more likely to infer a conclusion just as those who are more educated (Cooper and Dinerman 1951). Since the open-ended message requires more extensive and effortful processing, a closed-ended message may leave considerably less room for further elaboration. Need for cognition might interact with the type of message such that open-ended messages are especially effective for an involved, high need for cognition audience, whereas the effectiveness of closed-ended messages might not vary for involved audiences with varying levels of need for cognition.
